THE XXXI INTERNATIONAL SEMINAR ON URBAN FORM (ISUF 2024)

Since its consolidation as a disciplinary field throughout the twentieth century, the study of urban form has established itself as a fundamental domain for understanding cities and their processes of transformation. The XXXI International Seminar on Urban Form (ISUF 2024), titled Future Horizons for Urban Form: Disruption, Continuity, Expansion and Reverberation, was held from September 16 to 20, 2024, at Mackenzie Prebyterian University, in São Paulo, Brazil. When we decided, Denise Antonucci and I, to propose hosting this edition of ISUF, we were immediately confronted with a persistent and often uncritical narrative: the idea of Brazil as the "country of the future," widely disseminated in the popular imagination and reinforced by Brazil, Land of the Future by Stefan Zweig. While it is an evocative and problematic notion, we chose to honor the title and asked ourselves where better than Brazil, and São Paulo in particular, to interrogate the future of urban form, not as projection or promise, but as a condition already unevenly present.

Conceived as a platform for debate, exchange, and dissemination of knowledge, the conference sought to address the future of cities in a context marked by climate change, socio-spatial inequalities, and technological transformations. Its thematic structure, organized around the four tracks of Disruption, Continuity, Expansion, and Reverberation, reflected the need to engage with both emerging and persistent challenges in urban morphology. These included environmental crises such as global warming, urban heat islands and rising sea levels, as well as questions of heritage, conservation, global urbanization processes, and the circulation of knowledge across teaching, research, and professional practice.

The conference was organized by the School of Architecture and Urbanism of Mackenzie Prebyterian University, under the coordination of Heraldo Ferreira Borges and Denise Antonucci, with the support of CAPES and MackPesquisa and the contribution of an international scientific committee. It brought together approximately 200 participants from nearly thirty countries, including Afghanistan, Australia, Brazil, China, England, Germany, Italy, Poland, Portugal, Russia, Scotland, Serbia, South Africa, Spain, Sweden, Turkey, and the United States. A total of 177 papers were selected, involving 466 authors, and presented through oral sessions and posters, organized into 42 parallel sessions. The diversity of participants and the intensity of exchanges throughout the event demonstrated both the global reach of ISUF and the uneven geographies that continue to shape the field, particularly evident in the limited participation from Latin American countries beyond Brazil.

The relevance of the conference lies in its capacity to bring together different traditions, methodologies, and emerging perspectives within urban morphology at a moment of disciplinary transformation. The prominence of early-career researchers, the growing presence of participants from the Global South, and the emergence of new topics such as artificial intelligence and quantitative methods signaled a shift in the field, while also revealing

tensions with more established approaches, including the relative absence of senior scholars associated with classical morphological schools.

The program combined keynote lectures, roundtables, and parallel sessions, fostering a dense and productive environment for discussion. These exchanges were complemented by informal interactions and symbolic moments, including the tribute to Staël de Alvarenga Pereira Costa and social events such as the gala dinner at Edifício Itália and the book launch at the Brazilian Institute of Architects, which strengthened the sense of community among participants. Field visits and excursions across São Paulo further enriched the experience by engaging participants directly with the city's diverse urban landscapes, reinforcing the idea that the future of urban form is not an abstract projection but a condition already embedded in the complexities of contemporary cities.

This volume of proceedings brings together a selection of contributions presented during the conference, reflecting the diversity of approaches, scales, and contexts that characterize urban morphology today. By publishing these proceedings, we acknowledge the contributions of authors, reviewers, organizers, and participants, and reaffirm the importance of fostering international dialogue and collaboration. At a moment marked by profound environmental, social, and technological transformations, urban morphology remains a critical field for understanding and transforming cities, and the discussions initiated in São Paulo point toward new directions for its future development.

THEMATIC AXIS

The XXXI International Seminar on Urban Form consisted of four thematic axes. Each of these was associated with a keynote speaker who offered a brief summary of the findings and highlights of its researchs.

DISRUPTION

Urban form is increasingly shaped by conditions of rupture and instability. This track examines how environmental crises, public health emergencies, and socio-political conflicts disrupt established urban patterns and challenge conventional design responses. Presentations explore how phenomena such as climate change, heat islands, rising sea levels, and forced migrations reshape settlements across scales, while also addressing the role of urban design in fostering resilience, adaptation, and healthier urban environments.

KEYNOTE SPEAKER: HOWARD DAVIS

CONTINUITY

Urban form is equally defined by persistence and transformation over time. This track focuses on the historical dimensions of cities, examining how inherited structures, cultural heritage, and long-term processes inform contemporary urban design. Contributions investigate continuity through comparative and multidisciplinary approaches, addressing conservation and preservation practices while reflecting on how past urban forms condition present and future spatial configurations.

KEYNOTE SPEAKER: TERESA MARAT-MENDES

EXPANSION

Urbanization processes continue to expand in scale, speed, and geographical scope, particularly across the Global South. This track explores emerging forms of urban growth, including megamorphologies, informal settlements, and provisional urbanisms such as tent cities. Presentations address analytical and methodological approaches, including morphometrics, to understand large-scale transformations and the evolving spatial logics of rapidly expanding urban territories.

KEYNOTE SPEAKER: GABRIELA CELANI

REVERBERATION

The disciplinary field of Urban morphology resonates across education, research, and professional practice. This track investigates how knowledge is produced, transmitted, and applied within and beyond academia. Contributions reflect on pedagogical approaches, methodological innovations, and the translation of research into practice, highlighting how urban morphological thinking reverberates through different domains and scales of action.

KEYNOTE SPEAKER: OLGU ÇALISKAN

50th years of SAAL interventions in Portugal revisiting four neighbourhoods

Alexandra Saraiva[1]
[1] Dinâmia'CET, Iscte University Institute of Lisbon, Portugal, alexandra.saraiva@iscte-iul.pt
Universidade Lusíada Porto, Faculdade de Arquitetura e Artes, Portugal, achaves@por.ulusiada.pt

ABSTRACT

The research intends to investigate revisiting 4 SAAL interventions, from a multi and interdisciplinary perspective, such as architecture, history, sociology, anthropology, among others. The objective is to question the impacts of SAAL. The study proposes a new approach to SAAL interventions, analysing 4 neighborhoods in Portugal: 1) In Lisbon, Fonsecas and Calçada, designed by Hestnes Ferreira (1931-2018), starting in October 1974; 2) In Porto, Lapa, designed by Matos Ferreira (1928-2015) starting in November 1974; 3) Also in Porto, Acácio, designed by Soutinho (1930-2013), starting in October 1974; and 4) in Sintra, Pego Longo, designed by Costa Cabral (b.1929), from August 1975. The investigation aims to reflect on the fragility of SAAL, in part this process was shorter than proposed, and to promote a new perspective about these neighborhoods, empowering populations for a more sustainable future, 50 years later. Through a historical, social, and cultural approach, the objective of this research is to analyse and illustrate the evolution of participatory architecture in Portugal and its relationship with critical thinking and international practices. The objective is to remember and celebrate SAAL's interventions, but also to repeat the strategies of this model to promote a more promising future for these inhabitants. What are SAAL interventions today? How will inhabitants organize their lives and activities? What resources will be needed and how will they be used for housing 50 years later? Will it be possible to promote participatory interventions, currently and in the future? Questions explored chronologically considering 3 times: past, present, and future. It is expected that the research results can contribute to increasing knowledge and literacy in 4 fundamental aspects: Citizenship (social relationships); Built Environment (housing and public space); Policies/Practices (participatory actions); Memory.

Keywords: Housing; Local Support Ambulatory Service (SAAL); Portugal.

INTRODUCTION

To celebrate the 50th anniversary of April 25 in Portugal, the Local Support Ambulatory Service (SAAL), created in July 1974, stands as one of the most important and disruptive experiences of the revolutionary period following the Carnation Revolution. It is in this context that architect Nuno Portas (b. 1934), a researcher at the National Laboratory of Civil Engineering (LNEC) and Secretary of State for Housing and Urbanism in the 1st Provisional Government after his appointment on May 16, 1974, emerged as one of the key figures responsible for implementing this program (d'Almeida and Marat-

Mendes, 2022). His understanding of the country's real situation (social, political, and housing) allowed him to immediately emphasize the urgent need to address the housing shortage and the lack of a theoretical/scientific basis for solving this issue. Thus, on July 31, 1974, through a joint order from the Ministry of Social Equipment and Environment and the Ministry of Internal Administration, Portas propelled the SAAL program forward.

Initially, this program envisioned a decentralized service, supported by technical teams working in collaboration with the local population to build new housing and infrastructure, thereby improving existing living conditions. The order (dated July 31, 1974) safeguarded against potential speculative operations, avoiding, whenever possible, relocating residents to more peripheral areas. Several SAAL operations began across the country under the slogan "Yes to houses, no to slums!"

Two years later, on October 27, 1976, a ministerial order transferred the management of SAAL to local municipalities. At the time, 169 operations were active across the country, involving the housing of 41,665 families. Data indicated that 2,259 housing units were under construction, with an additional 5,741 units planned for imminent development. According to Bandeirinha (2007), only 13% of the land required for these interventions was available, either ceded or expropriated.

However, no operation was completed during the period when SAAL operated as a central administration service (from August 1974 to October 1976). An administrative and procedural adaptation became necessary, which in some cases reversed or nullified the initial plans. Consequently, many operations changed their intervention sites, teams, or projects; some continued with the same projects but without the involvement of the original teams, while others simply disappeared.

Fifty years later, it is essential to understand the specific contributions of the architects' prior research experience in developing these neighborhoods projects. What are the SAAL interventions today? How have the residents organized their lives and activities? What resources will be needed, and how will they be used for housing 50 years later? Is it possible to promote participatory interventions today and in the future?

METHOD

Based on the archives of the four architects under analysis, stored at the Marques da Silva Foundation (FIMS), as well as materials archived at LNEC and the Architects' Association, we analyse the trajectory of each architect, evaluating the possible relationship between their career paths and their respective urban planning and housing projects within the scope of SAAL. This article is part of ongoing research titled "Learning from the Past: The Importance of Former Housing Participatory Production for the Coming Years."

RESULTS AND DISCUSSIONS

Housing in Portugal has undergone significant transformations, driven by economic, political, and social factors. The greatest impact was felt after the Carnation Revolution, with profound political changes, including the nationalization of many properties and businesses. This period was especially important for the most disadvantaged classes, with the Portuguese government launching various housing programs aimed at ensuring access to housing and improving living conditions.

Housing research in Portugal reflects a balance between tradition and innovation, always focusing on cultural and identity-specific aspects. Noteworthy are the studies by Portas (1969, 2004, 2007) and the pairs Portas & Silva Dias (1972) and Cabrita & Coelho (2003). These efforts aimed to develop housing solutions that respect and enrich Portuguese cultural identity while adapting to the needs of a constantly changing global society.

However, with Portugal's entry into the European Community and the country's economic growth in the 1980s and 1990s, these social policies were gradually replaced by homeownership, facilitated by the liberalization of the market. Nevertheless, this led to the relocation of the population to the outskirts of major cities, increasing the distance between housing and work. It was also during this period that fiscal incentives and financing programs emerged to promote the restoration of degraded buildings and the revitalization of urban areas.

Housing cooperatives emerged as an alternative to the traditional housing model. These cooperatives allowed groups of people to come together to collectively build and manage their homes with controlled costs. However, since the dissolution of the SAAL programs and the transfer of responsibilities to the Housing Development Fund or local municipalities, these four neighborhoods were left to their own devices. In this ongoing investigation, we can state that despite the proactive approach and the respect shown towards all participants (technicians, residents, political decision-makers), and the efforts to meet the wishes of the local population, were not enough to fully implement the developed proposals, let alone the facilities proposed by the design teams.

International critical thinking and its echoes in Portugal

Participatory social architecture became widely disseminated from the late 1950s onward. Various international architects and theorists, including Giancarlo de Carlo (1919-2005), Colin Ward (1924-2010), John F. C. Turner (b. 1927), and later N. John Habraken (b. 1928), experimented with different types of client-architect relationships to theorize new approaches and interpretations of architecture itself, focusing more on the process and shifting attention away from the results.

The Housing Policy Colloquium, held at the National Laboratory of Civil Engineering (LNEC) from June 30 to July 5, 1969, highlighted the concrete potential of evolutionary housing and urbanism as important alternatives to the models commonly practiced in public housing block developments. The main goal was to "establish a set of measures" and attempt to outline an "integrated strategy for solving the problems" of housing shortages (Bandeirinha, 2011: 70). Thus, the idea of integrated housing emerged at this congress, defined as "a set of goods and facilities that far exceeds the mere function of shelter" (Bandeirinha, 2011: 75). As stated in point 2 of Article 65 of the Constitution of the Portuguese Republic (1976), "It is the State’s duty to: a) Plan and execute a housing policy included in general territorial reorganization plans and supported by urbanization plans that guarantee the existence of an adequate network of transportation and social facilities." In early July 1974, the then Secretary of State for Housing and Urbanism, architect Nuno Portas (b. 1934), signed an order entitled Program of Priority Actions, circulated among the services under the State Secretariat for Housing and Urbanism, particularly the Housing Development Fund (FFH). But after some setbacks, on July 24, architect Nuno Teotónio Pereira (1922-2022) submitted to the FFH a first document that clearly and succinctly defined the objectives, scope of action, and functional organization of the Local Ambulatory Support Service (Teotónio Pereira, July 24, 1974). On October 24 of that same year, José Augusto

Fernandes, Minister of Social Equipment and Environment, presented the programmatic text of urban policy, titled Activity Plan, which was approved the following day by the Council of Ministers. It outlined basic intentions regarding the distribution of equipment, transport networks and infrastructures, and technical and administrative decentralization (Bandeirinha, 2011). At the invitation of Nuno Portas, architect John F. C. Turner presented his housing experience in Peru in Portugal in November 1974, based on the innovative self-construction model of barriadas, which had a great impact on those attending the SAAL Brigades Seminar. The resolution of land status issues, clarification and delimitation of intervention objects, forms of resident self-organization, and modes of construction financing emerged as the main topics of debate.

However, the SAAL program had a very limited impact as a political tool. Focused on urban housing policy programs, it was innovative in the national and international context, where social and urban equity were key goals to be achieved through deep urban reconstruction, with the populations remaining in the areas where slums existed. Nevertheless, due to the context and its short duration (during the revolutionary period, between 1974-1976, and post-revolution, after 1976), it did not achieve full implementation in all its interventions, nor was its distribution equal throughout the national territory. The international political moment, combined with the Portuguese revolutionary context, helped implement and validate the equation: Theory + Planning = Democracy. The Marxist currents of Henri Lefebvre and Manuel Castells legitimized the policy through actions where architecture, urban planning, and technical knowledge were made available to the population, particularly in their struggle to transform social, individual, and collective relations.

The evaluation of the State's role must be understood in two distinct phases. In the first phase, there was the creation of base actions for continued work, implementing a framework of values, legislation, and military support. Later, in a second phase, social dynamics emerged, bringing about bureaucracy, procedural mismatches, unequal local involvement, and the complex and unstable national political process. The contradiction of a State divided between support and abandonment of this unique social movement is evident. The role of the armed forces movement (MFA) should also be remembered as it intervened in conflict arbitration, especially during the occupation of vacant houses, acting as a force of regulation and social balance between classes.

The success of the various SAAL operations, linked to the multidisciplinary competencies of housing and urban planning technical teams (architects, engineers, sociologists, lawyers, geographers, social workers, etc.), was key to strategy definition. At the same time, alliances were established with neighbourhood committees to shape and customize housing without creating economic constraints, prioritizing low-cost technical solutions. The power of the people was undoubtedly a unique feature of the various social participation phenomena. The importance of housing cooperatives is highlighted as they brought together residents of deteriorating neighborhoods, slum areas, and rented buildings. The movement also greatly impacted and changed the social role of women, who took the most significant roles in the public sphere.

The right to housing, and more specifically the right to quality of life, was the driving force behind SAAL operations. Populations, design teams, and political decision-makers went beyond housing issues, focusing on the importance of residential space and essential infrastructure, advocating for urban equipment (sports facilities, schools, daycare facilities, health facilities, among others) and

social spaces (spaces for associations, leisure areas, green spaces, among others), not to mention adequate public transportation, all part of the broader concern for the right to the place/city.

Four SAAL Operations

In these SAAL interventions coordinated by four architects, it is important to emphasize that in all initial planes have not been fully realized, nor is the proposed schedules of the project. In this context, it is essential to highlight the professional and academic backgrounds of these architects.

Hestnes Ferreira's academic and professional path (table 1) included an internship at the Finnish Institute of Technology (Helsinki, 1958-1959), research at Yale University (New Haven, 1962), and a master's degree completed at the University of Pennsylvania (Philadelphia, 1963-1965). His work at the Technical Housing Office (GTH, 1966-1967) was a significant factor in his decisions and choices regarding this housing complex (Saraiva, 2011).

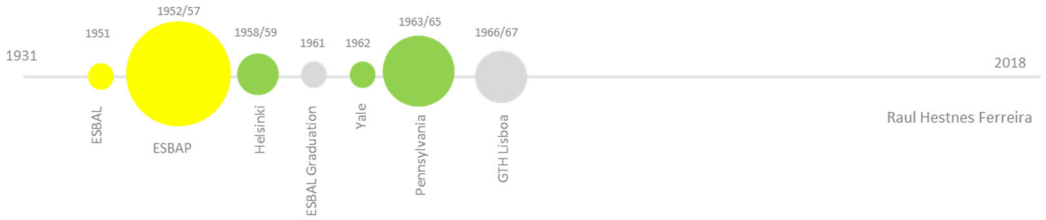

Table 1 – Hestnes Ferreira´s academic and professional path. Source: author

Matos Ferreira (table 2) attended ESBAP from 1948 to 1952 and, during the 1950s, was part of a group of students who shared Room 35 in a building in Praça da Liberdade, downtown Porto (table.2). He was the oldest member of this diverse group, which included Álvaro Siza, Alberto Neves, António Menéres, Joaquim Sampaio, Luís Botelho Dias, and Vasco Macieira Mendes. Távora's involvement in various International Congresses of Modern Architecture (CIAM, 1951-1962) and his role in the "Minho" team for the Survey on Portuguese Regional Architecture (1955-1960) (AAVV, 1961) expanded Ferreira's understanding of housing and territorial issues, deeply influencing him. His personal and professional partnership with Távora (1972-1982) further shaped his approach. Unlike Hestnes Ferreira, Soutinho, and Costa Cabral, Matos Ferreira never studied or interned abroad.

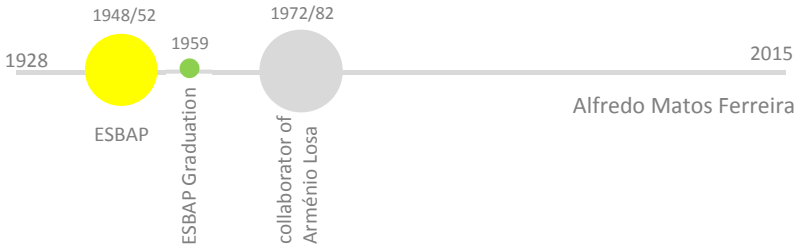

Table 2 – Matos Ferreira´s academic and professional path. Source: author

Alcino Soutinho (1930-2013) earned his architecture diploma from ESBAP in 1959. As a Calouste Gulbenkian Foundation scholar in 1961, he conducted research on museology in Italy, where he was influenced by his Italian peers. Simultaneously, he worked at the Welfare Funds Foundation, designing

numerous social housing projects in northern Portugal until 1971. From early on, he balanced his design practice with teaching (1972-1999). Soutinho was actively engaged in architectural discourse and dissemination through conferences, debates, publications, and articles, as well as holding significant public roles in institutions such as the Portuguese Design Centre (1998-2001), the Árvore Artistic Activities Cooperative (2003-2006), and the Order of Architects (1999-2002). (table 3)

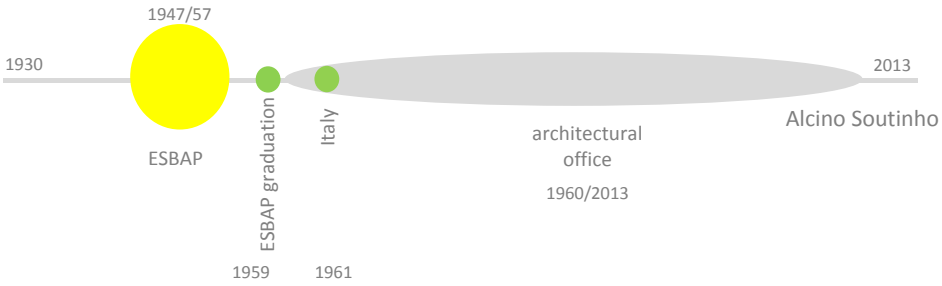

Table 3 – Alcino Soutinho´s academic and professional path. Source: author

Costa Cabral's internships at the Centre Scientifique et Technique du Bâtiment (Paris, 1962), London County Council (London, 1965), and LNEC (Lisbon, 1967) had a significant impact on his approach to research and housing design (d'Almeida et al. 2022). Under the guidance of Nuno Teotónio Pereira (1922-2022), Cabral became involved in Portugal's cooperative movement, working with the Federation of Welfare Funds (FCP) and GTH on the social housing project for Olivais. Two decades later, as part of the SAAL program, he was tasked with developing the Pego Longo neighbourhood (1975-1977) in Sintra (d'Almeida and Marat-Mendes, 2022).

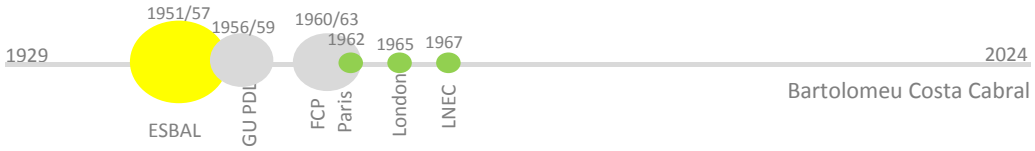

Table 4 – Bartolomeu Costa Cabral´s academic and professional path. Source: author

The professional experience gained by Soutinho and Costa Cabral at the Federation of Welfare Funds, as well as Hestnes Ferreira's experience at the Technical Housing Office of the Lisbon City Council, were decisive in realizing new housing proposals. Matos Ferreira made a significant impact in academia by proposing the graphic documentation and characterization of interior living spaces in his design courses. For this architect (Ferreira, 1995), a building must adhere to three essential principles: formal simplicity, economy, and clarity in spatial organization.

If we analyse the geographical characterization of each intervention, the Hestnes Ferreira coordinated Fonseca and Sidewalk neighbourhood is located on the outskirts of Lisbon, in an expanding area with relatively flat topography at the time. In contrast, the Proposal of Matos Ferreira for the Lapa neighbourhood is in a central area of the Port (zone 3 – central ring area of the 18th and 19th century

expansion ring), which was and is still a highly degraded area with steep topography, restricted further by the rail line (now used by the subway), representing challenges to its implementation.

The neighbourhood of Acacio, later renamed Maceda, is in the eastern part of the city, near its border, in Campanhã (zone 8 – eastern suburban sector). Implementing the project on the ground prioritized the creation of collective spaces and considered the historical, social and cultural significance of urban tissue where the operation occurred.

The neighbourhood of Pego Longo, designed by Costa Cabral, is in a peripheral area of the Sintra, which at the time had little infrastructure and steep topography, influencing the architectural proposal.

SAAL intervention	Architect	Local	Association	Population		Dwellings		Typology	Project	Construction
				families	total	Planned	Built			
Fonsecas and Calçada	Raúl Hestnes Ferreira	Lisboa	Economic Housing Cooperatives (C.H.E) 25 de Abril	310	950	1600	335	T1+(1); T2; T3; T4; T5	1974 - 1976	1976 - 1986
			Calçadas Economic Housing Cooperatives (C.H.E) Unidade do Povo	288	1000					
Lapa	Alfredo Matos Ferreira	Porto	Lapa Residents' Association	482	1700	500 (250 new+ 250 recovered)	74	T1; T2/T3; T3/T4	1975	1976 - 1977
Maceda	Alcino Soutinho	Porto	Maceda Residents' Association	52	186	43	33	T1; T2; T3; T4; T5	1975	1974 - 1977
	Andrea Soutinho						10			2016 - 2020
Pego Longo	Bartolomeu Costa Cabral	Sintra	Pego Longo Residents' Association	143	500	150 (47 new +60 recovered)	81	T1; T2; T3; T4; T5	1975	1977

Table 5. data information- 4 SAAL interventions. Source: author

The table 5 resume all data information about these four interventions, the local, the name of the association involve, the characterization of the population (no. of families and total of population), dwellings (planned and built), the typology, the year of the project and the years of construction.

All the neighborhoods are typologically different: 1) Fonsecas e Calçada is a large development of four-story multifamily buildings, with mostly left/right vertical access, and small access galleries for three housing units at building intersections; 2) Lapa is a medium-sized development of two-story terraced houses with backyards, forming blocks; 3) Maceda is a small development consisting of eight terraced housing units, of which only five were initially built; 4) Pego Longo is a large development of terraced single-story and two-story houses, with front and rear yards, forming blocks.

The rehabilitation interventions in the Fonsecas and Calçada and Pego Longo neighborhoods, promoted by the municipalities of Lisbon and Sintra in 2016 and 2017, respected the participation of the local population and allowed for the redevelopment of public spaces, the improvement of pedestrian and road accessibility, and an overall enhancement of the quality of life for these communities. In 2016, the regularization of the construction situation was finally made possible, with the legalization of all blocks through the issuance of the respective Occupancy Licenses and the creation of Identity Cards for the 355 housing units, resulting from the BIP/ZIP58 process implemented by the Lisbon City Council and endorsed by Hestnes Ferreira. In 2019, the municipality of Sintra invested around 600 million euros in an intervention area of 18,460 square meters to rehabilitate public spaces and improve pedestrian and road accessibility, thereby enhancing the quality of life for the population.

On December 9, 2019, the Porto City Council, through Councilman Pedro Baganha, announced at a council meeting the development of an Urban Study for the Lapa area. It envisioned the creation of new urban fronts, particularly residential areas, a green urban park covering 19,000 square meters (and a second one with 16,000 square meters), the redesign of access to the Lapa metro station, and the completion of the existing road network with the creation of new streets. This project for the Lapa area in Porto considers the reprofiling of Cervantes Street, from its intersection with Alves Redol Street to Antero de Quental Street. This work will have a significant impact on the Lapa neighbourhood, as Cervantes Street is the main access route to this SAAL intervention. Fifty years later, these neighborhoods and their owners, some of them second-generation, finally gained access to the habitation certificate and full ownership of their property.

CONCLUSIONS

These four SAAL interventions did not evolve in the same way, nor do they present the same results. While the intervention for the Lapa neighbourhood was never fully completed, the interventions for the Fonsecas and Calçada neighborhoods, Pego Longo, and Maceda extended over time and space. The active involvement of the architects, particularly with the residents of the latter two neighborhoods, promoted the continuity of their work and spatial ideas among the residents. Alternative approaches, such as collaborative housing and affordable rental models, are gaining ground, offering new solutions to persistent housing problems. In short, the evolution of housing in Portugal since the 1960s reflects a combination of government efforts, community initiatives, and global trends, with a growing emphasis on sustainability and social inclusion.

A comparative study of the forms of mainstream property settlements

ABSTRACT

As an important functional component and spatial type of cities, residential areas dominate the development and evolution of urban morphology to a certain extent. Against the backdrop of the reform of China's commoditized housing system, property developers' voice was increasing and gradually become the mainstay of China's urban construction. The construction process of large-scale residential areas led by mainstream property developers has, to a certain extent, pushed forward the evolution of China's urban morphology. Based on this, this paper uses urban morphology to extract 4 key elements of residential morphology: plot order, road network structure, residential area layout and open space, and 13 relevant morphology indicators, in order to construct a system of elements of property developers' residential morphology, and selects typical samples for comparative analyses. The study finds that the planning logic of the mainstream property developers' residential areas in China since the new century meets the needs of the era of China's incremental development and the policy orientation of local residential construction, and the existing residential construction model presents the characteristics of single land use, inward spatial connection and standardized building layout, which is the basis for the proposal of the morphology of the future residential construction: improve the complexity of the residential land, increase the correlation between the residential area and the external urban space, and enhance the continuity of the macro-morphology. The aim of paper is to guide property developers in improving the environmental quality and social benefits of residential areas and to provide valuable reference for the human residential construction.

Keywords: Chinese residential area, property developer, residential morphology, morphological typology.

INTRODUCTION

Residential area, as the basic spatial type and important functional component of urban, on the one hand, dominates the development and evolution of urban morphology. In the building typology in Italy, Caniggia distinguished all urban buildings into basic and specialized building, and regarded the residential area as “basic building” of urban tissue (Tian *et al*. 2021). Among all the common types of buildings that shape the form of cities, housing is of major importance constituting the bulk of buildings (Polyzoides et al. 1992). As a result, residential area has a high degree of unity in morphology and function, to some extent, it can embody the main characters of urban morphology. (Chen *et al*.

2014). On the other hand, in urban morphology in England, Conzen recognized the residential area as the one of the three important spatial units that make up the urban landscape, as the most important bearing of the residential function in urban, residential area occupies a huge proportion of urban land and play a decisive role in the urban morphology (Conzen and Michael P, 2009). Therefore, residential morphology is related to the quality of the urban environment, and it also dominates the development of overall urban morphology.

At the same time, along with the reform of the land use system and housing policy, in 1998, China's residential area gradually replaced the system of welfare housing allocation with the construction of commercial housing, and market interests became the main driving force in residential planning. In order to meet the real needs of rapid urban development and population expansion, property developers have gradually become the mainstay of urban housing construction, which to a certain extent affects the economic, resource and demand dynamics of residential construction and urban development (Li *et al*. 2016). The evolution of residential morphology is increasingly driven by economic interests (Zhang *et al*. 2013). Specifically, on the one hand, the spatial evolution of residential area is set against the backdrop of housing policy reform, and the characteristics of property developer-dominated residential morphology have a certain relevance to China's national development orientation and government macro-policies at the time. On the other hand, in order to reduce development cost and improve economic efficiency, efficient replication has become the basis for property developers to promote urban expansion and residential construction, and this paradigm premised on standardization has shaped the highly homogenised fabric of contemporary Chinese urban in just a few decades (Dong and Li, 2019). However, Under the influence of this "value-only" philosophy (Yao and Xu, 2020), during the evolution of residential area, new residential problems such as morphological homogeneity, spatial fragmentation, and residential segregation have emerged. This phenomenon has triggered great controversy in the academic world and has become an important issue in the research of contemporary Chinese residential planning.

In recent research, residential morphology focused on the level of residential planning and housing design, mainly concerned with the study of the dynamic and morphology of the spatial evolution of residential area (Zhang et al.2021; Gu et al.2008), the measurement and characterisation of the spatial morphology elements of residential area (Huang et al.2013; Ghosh and Vale, 2009), and the exploration of ideal models of residential area (Huang et al.2017; Braulio-Gonzalo et al.2020). The study covered a wide range of residential types, such as traditional residential area, old residential area, open residential area, mountain residential area, workers' residential area, welfare residential area, informal residential area and specific residential elements, such as boundary spaces, open spaces, and facilities and amenities. In conclusion, in China, a mature methodological system has been developed in the field of residential morphology research, but few studies regarded the residential area of property developers as an independent type. Actually, property developers, as a major participant of China's residential construction, have an increasingly obvious influence on the construction of residential environments and the evolution of urban morphology. Therefore, analysing the characteristics of the residential morphology of mainstream property developers, summarizing the achievements and mistakes and putting forward the corresponding recommendations are of great significance in guiding property developers to pay more attention to the quality of residential area while improving the efficiency of development, responding to the needs of transformation of urban development and upgrading the quality of the human environment.

METHODOLOGY

Research framework

Based on this, this paper adopts the morphological typology to construct a research framework for the residential morphology of mainstream property developers, and examines their morphological characteristics from the following four aspects: ①plot order, the general characteristics of the residential area, intensity, and boundary attributes. ②road network structure, the spatial relationship between road morphology and residential layout. ③Residential layout, the type and morphological characteristics of the layout of residential buildings. ④open space, the relationship between the location and quantity of green spaces, courtyards and other public spaces in the residential area. Based on the above four aspects, a total of 13 elements reflecting the morphological characteristics of the paradigm are set, and the database of the morphological elements of the settlement samples is constructed by collecting official data, and combining with AutoCAD software to calculate and supplement the missing data, which can be used to prove the development trend, dominant value or type of the sample, and then summarize the overall characteristics of the residential morphology of the mainstream property developers in China. Finally, the overall characteristics of residential morphology of mainstream property developers can be summarized.

Table 1.the research framework of residential morphology of mainstream property developers

Morphology Types	Extraction Elements	Influence Mechanism	Description Methods
Plot Order	Plot Area	Reflect the scale of the residential area.	Total area of the plot.
	Plot Boundary	Reflect the functional type of the residential boundary.	The main division is between physical boundaries dominated by green space and fences and functional boundaries dominated by community businesses in residential ground floor.
	Floor Area Ratio (FAR)	Reflect the intensity of the residential construction.	Ratio of gross floor area to the residential plot area.
	Building Coverage Ratio (BCR)	Reflect the compactness of the layout of building entities in residential area.	Ratio of building base area to the residential plot area.
Road Network Structure	Morphology of Road Network	Reflect the spatial correspondence between the road morphology and the building layout.	Include ringlike road, grid road, branchlike road and so on.
	Road Density	Reflect the density of road network.	Ratio of length of road network to the plot area.
Residential Layout	Architectural Layout	Reflect the overall layout of residential building.	Include row layout, courtyard layout, scattered layout, radial layout and so on.
	Average Number of Floor	Reflect the spatial average height of the residential area, focusing on vertical façade morphology.	Ratio of total number of buildings' floor to the total number of building's unit.
	Proportion of Residential Height	Reflect the composition of the residential buildings' height.	Ratio of high-rise buildings, medium-rise buildings or multilayer buildings to the total number of residential buildings.
	Proportion of Residential Unit	Reflect the composition of residential buildings' unit types.	Ratio of panel construction or tower construction to the total number of residential buildings.
Open Space	Greening Rate	Reflect the scale of green space in residential area.	Ratio of green space area to the plot area.

	Concentrated Greening Rate	Reflect the scale of main green space and public activity space in residential area.	Ratio of area of concentrated green space to the plot area.
	Structure of Green Space	Reflect the spatial distribution of the green space in residential area.	Include centralized structure, cluster- model, panel- model, knot- model and so on.

Sample Selection

In order to make the research results become more realistic, the sample selection principles of this paper are as follows: ①typical representation. The samples of residential areas can reflect the typical planning morphology in the context of the corresponding era, as well as the basic logic and planning paradigm of Chinese mainstream property developers' residential construction. In principle, the sample shouldn't include something reflecting the residential needs of minority groups, such as villa areas, and special samples with specific planning orientations, such as sheltered housing and elderly flats; ②comparability. The sample should avoid, as far as possible, the interference of special external factors, such as natural topography, and to carry out comparative analyses of settlements under more universal construction conditions.

Based on the above principles, this paper refers to the typical residential cases selected by architectural academic journals and the “National Comfortable Housing Demonstration Project”, “Shanghai Excellent Residential Community”, “Tien-yow Jeme Civil Engineering Prize” which selected by the government. The collection of these cases can, to a certain extent, serve as a representative of contemporary Chinese residential planning. Sixteen samples of residential areas represented by Chinese mainstream property developers such as Vanke, Longhu, Poly, Greentown, China Resources, Zhonghai, Jindi, and Country Garden are selected according to the construction completion time as the research object for comparative analyses.

Table 2. the residential sample selection of mainstream property developers

Name of Residential Area	Completion Time	Plot Area	FAR	BCR	Greening Rate
Guangzhou Poly Garden	2000	12.09	2.2	29.00%	38.00%
Beijing Country Garden Community	2001	8.94	1.8	16.36%	36.00%
Shanghai Vanke Wonderland Garden	2004	16.65	1.1	28.90%	42.00%

Xiangtan Evergrande Yujing Peninsula Community	2018	24.06	2.8	15.34%	42.00%
Changsha Zhonghai Longyuefu Community	2021	7.06	4.0	19.84%	40.00%

RESULTS AND DISCUSSIONS

Plot Order

The study extracted four data related to plot order from the sample group, including plot area, plot boundary, floor area ratio and building coverage ratio. The analysed sites in residential areas of mainstream property developers were found to show a differentiation in plot area, the evolutionary trend was closely linked to the reform of housing policies, and the management model of residential area was both closed and independent.

Table 3. Statistic of plot order for residential sample

Name of Residential Area	Plot Area	Plot Boundary Type	FAR	BCR
Guangzhou Poly Garden	12.09	physical boundaries	2.2	29.00%
Beijing Country Garden Community	8.94	physical boundaries	1.8	16.36%
Shanghai Vanke Wonderland Garden	16.65	physical boundaries	1.1	28.90%
Greentown Shangyu Osmanthus Garden	9.69	both physical and functional boundaries	1.5	25.20%
Wuhan Vanke City Garden	42.03	physical boundaries	1.2	25.08%
Foshan Country Garden of Fengnan Garden	4.51	functional boundaries	2.3	18.45%
Shenyang Vanke New Mileage Community	5.27	physical boundaries	2.0	21.00%
Zhonghai Jinxiu City Community	8.71	mainly physical boundaries	2.3	26.09%

Changsha Zhonghai Longyuefu Community	7.06	mainly physical boundaries	4.0	19.84%

（1）The average plot area of the residential sample is 14.61hm², with a general construction of two large ends and a small middle (Figure 1), which is closely related to the development process of urbanization and the evolution of housing policies in China. At the beginning of the 21st century, in the context of increasing urban expansion and the need for land finance, large and medium-sized cities have granted land for the construction of large-scale residential areas, and even large-scale residential areas larger than 40 hectares have appeared on the outskirts of many large cities and new development zones, and a considerable portion of them are built as villas or high-grade residences, which are not included in this sample group; On the contrary, most of the new residential areas built on the fringe of urban centres in response to urban expansion are in the form of general commercial residential area, affordable residential area and welfare residential area, the areas of them are moderate. After 2011, the rate of urbanization in China exceeded 50% for the first time, and the concept of “new-type urbanization” was put forward by the government. Since then, China's urban construction and development has begun to transform from incremental expansion to high-quality development, which is reflected in the construction of residential area, with increased emphasis on

the quality of residential area and the promotion of high-rise residential buildings in order to conserve the land. In 2015, as a result of the Chinese government's efforts to promote a new residential mode of “block”, among other things, a significant number of residential plot area in this period were adapted to accommodate the neighbourhood scale of small blocks with dense road networks, and the plot area was more biased towards a smaller area than in the past. After 2017, the 19th China National Congress report proposed that all people should have a comfortable livelihood, and this new regulatory policy has led to a more diversified housing supply system and formed differentiated residential shapes (Bian, 2022).

（2）Different plots and different communities are separated by fences and the modes of management for residentials are mostly closed and independent. The external boundaries of the residential areas are mainly divided into two types: physical boundaries dominated by greenery and fences, and functional boundaries dominated by ground-floor commercial and public service facilities, with physical boundaries accounting for a significantly higher proportion of the total than functional boundaries. However, with the gradual improvement of the demand for supporting facilities in the residential area and the consideration of the convenience of life of the residents, the distribution location of various types of supporting facilities has changed from the centre of the district to the first floor of the building along the city road, and the frequency of the use of functional boundaries has gradually increased, which reflects the practical application of the idea of land use compatibility and functional mixing.

（3）The floor area ratios of the residential samples range from 1.14-4.0, with a mean of 2.41, 50% floor area ratios of residential samples range from 1.51-2.34 and 31.3% floor area ratios of residential samples are more than 3.0(Figure 2), this reflects the fact that the intensity of construction in residential areas of property developers is evenly distributed and moderately intense, and that there is a gradual tendency towards high-rise construction in residential areas of property developers.

（4）The building coverage ratios of the residential samples range from 15.34%-29%, with a mean of 21%, more than 43% building coverage ratios of the residential samples are less than 25.2% and more than 81% are less than 25.2%. According to a relevant study, the building coverage ratio range from 15% to 30% is considered as medium density.(Tang, 2022), this means that the majority of the samples are in the appropriate range of building coverage ratio (Figure 3). At the meantime, with the advancement of the construction era, the overall building coverage ratio of the sample has shown a slow decline, which can reflect the gradual increase in the requirements of property developers' residential areas on the quality of the environment, and they have been reducing the building coverage ratio by increasing the height of the buildings in order to free up more public space and green space.

Road Network Structure

The study extracted 2 data related to the road network structure, including road network morphology and road density. It is found that the road structure of residential areas of mainstream property developers in China, especially in the early period, is deeply influenced by the neighbourhood unit and the Radburn principle, and most of them have a clear road hierarchy with the basic goal of separating pedestrian and vehicle traffic. 87.5% of the sample residential areas have a ring-based internal road network, with the frequency of the inner ring and outer ring being basically equal, and other road network morphologies such as branch and grid are used locally to meet the needs of home flow and fire protection.

At the same time, more than 81% of the sample of residential neighbourhoods had road densities between 0.018 and 0.032, with a mean value of 0.03, which is in the moderate density range, reflecting good accessibility of roads within the residential areas.

Table 4. Statistic of road network structure for residential sample

Name of Residential Area	Road Network Morphology	Road Density(m/㎡)
Guangzhou Poly Garden	ringlike road (inner)	0.035
Beijing Country Garden Community	ringlike road (inner)	0.027
Shanghai Vanke Wonderland Garden	ringlike road (both inner and outer)	0.038
Greentown Shangyu Osmanthus Garden	ringlike road (inner)	0.026
Wuhan Vanke City Garden	ringlike road (both inner and outer)	0.024
Foshan Country Garden of Fengnan Garden	ringlike road (inner)	0.040
Shenyang Vanke New Mileage Community	ringlike road (both inner and outer)	0.020
Zhonghai Jinxiu City Community	ringlike road (inner)	0.020

Nanjing Jindi Mingjing Community	ringlike road (outer)	0.024
Suzhou Zhonghai Haiyue Garden	ringlike road (outer)	0.018
Beijing Vanke Blue Mountain Community	ringlike road (outer)	0.022
Changsha Vanke Charm City Community	grid road	0.025
Xian Poly Xinyu Garden	branchlike road	0.022
Xiangtan Evergrande Yujing Peninsula Community	ringlike road (outer)	0.023
Changsha Zhonghai Longyuefu Community	ringlike road (outer)	0.032

In general, the traffic structure of China's residential areas of mainstream property developers is based on maximising the efficiency of connection for path organization, focusing on the diversion planning of pedestrian and vehicular traffic and the efficiency of vehicular traffic, with a greater emphasis on its own independence and completeness, and seldom considering the connection with the system of urban traffic, nor constituting a morphological counterpart to the residential building layout.

Residential Area Layout

The study extracted data on the architectural layout, the average number of floors, the proportion of residential height, and the proportion of residential unit from both the horizontal and vertical perspectives. It has been analysed that the residential planning mode of mainstream property developers in China tend to be similar, and the architectural layouts have a high degree of homogeneous characteristics to a certain extent.

Table 5. Statistic of residential area layout for residential sample

Name of Residential Area	Architectural Layout	Average Number of Floor	Proportion of Residential Height			Proportion of Residential Unit		
			Multilayer	Medium-rise	High-rise	Panel	Tower	Panel +Tower
Guangzhou Poly Garden	both row and radial layout	10.07	0.035	0.52	0.38	0.10	/	0.10
Beijing Country Garden Community	row layout	11.00	0.027	/	1.00	/	0.86	0.14
Shanghai Vanke Wonderland Garden	row layout	6.00	0.038	1.00	/	/	1.00	/
Greentown Shangyu Osmanthus Garden	both row and point layout	9.23	0.026	0.59	0.26	0.15	1.00	/
Wuhan Vanke City Garden	both row and courtyard layout	5.13	0.024	0.77	0.19	0.05	1.00	/

Foshan Country Garden of Fengnan Garden	courtyard layout	12.36	0.040	0.65	0.18	0.18	0.59	0.41
Shenyang Vanke New Mileage Community	row layout	13.41	0.020	/	/	1	1	/
Zhonghai Jinxiu City Community	row layout	10.72	0.020	/	0.56	0.44	0.91	0.09
Wuhan Jindi Central City Community	row layout	26.57	0.018	/	/	1	/	0.05
Nanjing Jindi Mingjing Community	row layout	11.00	0.024	/	1.00	/	1.00	/
Suzhou Zhonghai Haiyue Garden	row layout	14.39	0.018	/	/	1.00	0.55	/
Beijing Vanke Blue Mountain Community	courtyard layout	27.64	0.022	0.2	/	0.8	1	/
Changsha Vanke Charm City Community	row layout	17.12	0.025	0.07	0.26	0.67	0.69	0.07
Xian Poly Xinyu Garden	row layout	16.26	0.022	0.44	0.07	0.48	0.73	0.01
Xiangtan Evergrande Yujing Peninsula Community	both row and point layout	18.26	0.023	0.33	/	0.67	0.32	/
Changsha Zhonghai Longyuefu Community	row layout	25.00	0.032	/	/	1.00	/	0.09

（1）Considering the orientation of sunlight and the need for standardization, the general layout of buildings in 87.5% of the residential samples is based on the basic principle of row layout, especially the north-south row layout with the front and back rows of buildings aligned, which is the root cause of the high degree of homogeneity of the general residential layout of mainstream property developers in China, especially in the early years. As the overall spatial environment of the residential area has become more and more important, in order to change the monotonous form, some residential areas improve the richness of the architectural layout through the interlacing, enclosure, inclined and other measures.

（2）The number of floor in the residential sample ranges from 5 to 27, with multilayer buildings accounting for 41.5% , medium-rise buildings for 20%, and high-rise buildings for 38.5%, with an average number of 14.63, in accordance with the classification of types of residential heights in "*Code for Residential Design*"[①] (Figure 4). In terms of the distribution of height types, there are residential areas that are made up of a selection of multilayer, medium-rise and high-rise buildings in a single form, as well as those that are mixed in combination with each other. In general, however, with the need for intensification of land use in recently years, high-rise housing has increasingly become the dominant choice of residential height in the current era (Figure 5).

（3）The construction of residential areas in China is dominated by modular housing, including panel construction, tower construction, and construction with both panel and tower. At the beginning of the 21st Century, the main unit organization is panel construction, with a small number of tower construction laid in the core space or on the side of the main road, in order to enrich the spatial form of residential areas (Figure 6). And with the rising demand for residential product differentiation, construction with both panel and tower which offered a wide range of house types is gradually increasing.

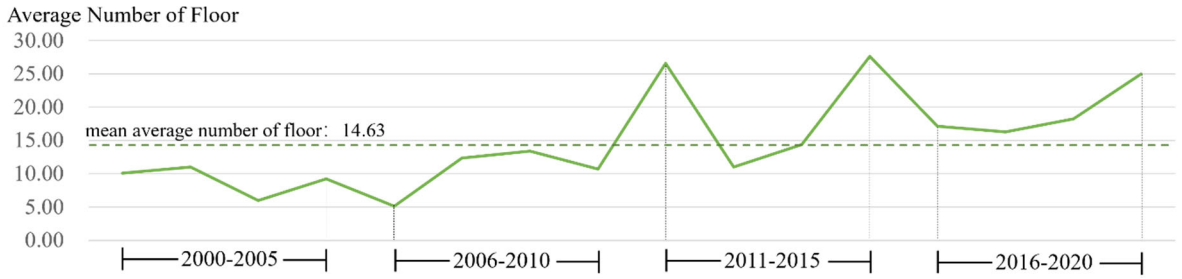

Figure 4. The average number of floors of residential areas, photo credit: author.

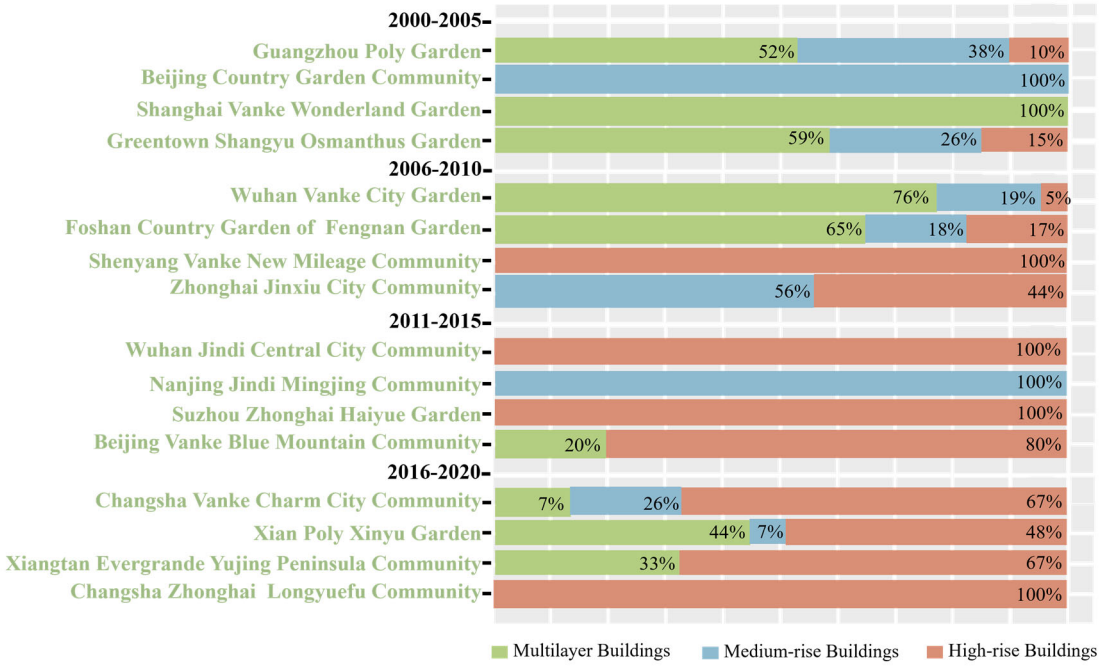

Figure 5. The height distribution of residential areas, photo credit: author.

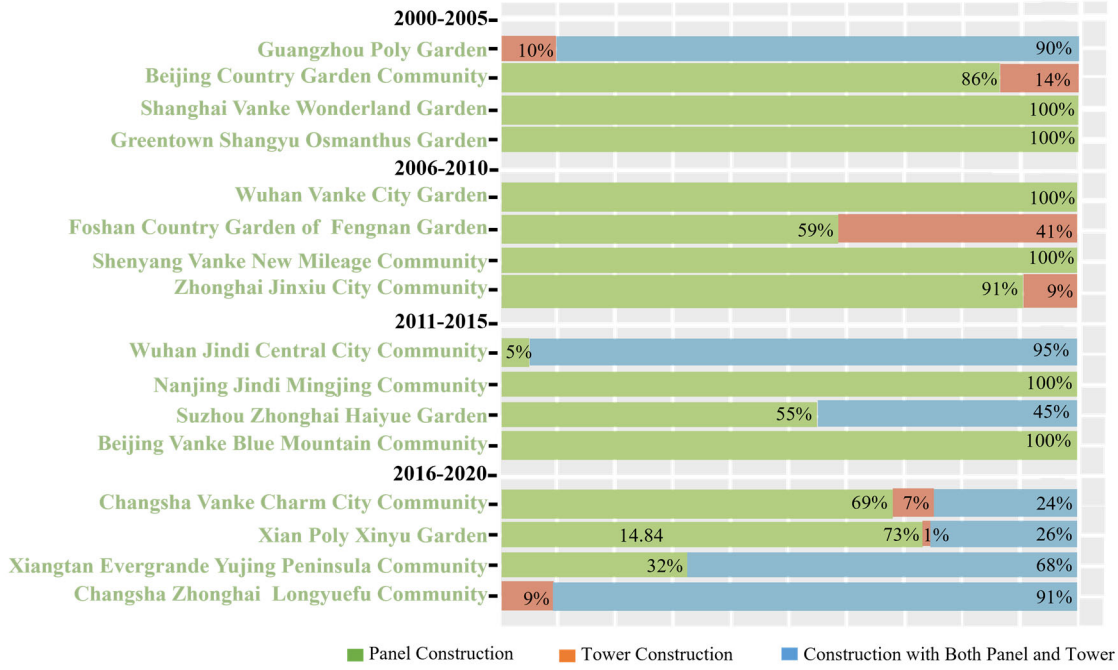

Figure 6. The unit distribution of residential areas, photo credit: author.

Open Space

The study extracted three data on greening rate, centralized greening rate and green space structure for the sample group, in which the average greening rate reached 39%, and the average centralized greening rate, which reflects the scale of open space within the residential area, reached 17.72%, which are far beyond the limit specified in the norms (Figure 7), this suggests that most of the residential samples provide large public spaces in the core space where residents can move around, reflecting that mainstream property developers attached great importance to the quality of residential environment.

In terms of the spatial structure of green space, more than 50% of the sample group is of a centralized structure and more than 30% is of an axial structure, both of which have a significantly higher rate compared to decentralized structures, they can be more effective to utilize the scale effect of green space. Decentralised structures are presented in large neighbourhood, which shape a single homogeneous spatial layout of buildings. At the same time, in the early day, the green space system of mainstream property developers' residential areas had a more obvious hierarchical system, but as property developers pay more attention to the wholeness and evenness of the residential environment, the planning of green space system gradually tends to be holistic, and property developers are increasingly focusing on the green space system. More and more residential areas are beginning to favour a sequential spatial system rather than a strict hierarchical model, with the exception of the central green space as the main public space which still has a more prominent scale, the overall distribution of the green space system is more balanced in order to provide as much as possible a good landscape environment for each resident, and echo with the architectural layout and the surrounding environment, presenting a diversified spatial form.

Table 6. Statistic of open space for residential sample

CONCLUSIONS

Summary of Morphological Features

Based on the above research, the residential morphology of mainstream property developers in China has the following common characteristics: (1)plot order: the plot area in residential area is differentiated by the location of land parcels and housing policies, and at the same time, different residential areas are independent of each other in terms of spatial boundaries and management modes, which creates problems such as the blockage of the urban road system and the loss of vitality of the streets. In addition, with the increased emphasis on land-use intensification, residential areas are gradually moving towards high-rise trends. (2)structure of road network: the road network in residential areas is based on the principle of pedestrian-vehicle circulation and maximum efficiency of internal connections, and often has little relevance to the building rows and external urban space; (3)overall layout of residential building: with the general layout of north-south rows and unit-type building types as the basic principle, as the investment attributes of housing have increased after the commercialization of housing policy reform, property developers have been pursuing replicable modes of standardized designs due to the excessive concern for market efficiency, resulting in the obvious trend of solidification of residential areas in terms of the layout of buildings. (4)open space: gradually, emphasis has been placed on the wholeness and homogeneity of the environment of the settlements, presenting a structural system of centralized green space-group green space-attached

green space, and the structure of the green space and the layout of the buildings in the residential areas always contact with each other.

At the same time, the morphological typology embodied in the sample of residential area of mainstream property developers is closely related to the context of China's urban development and reform of the housing policy. At the beginning of the 21st century, Chinese urban construction in the era of incremental expansion was influenced by the ideas of new urbanism and neighbourhood units, and then large-scale neighbourhoods appeared in the suburbs and new districts of cities. In 2016, following the *"Opinions on Further Strengthening the Management of Urban Planning and Construction"*, a number of "block" have emerged in urban center that are smaller in plot area, with boundary type and road network structure that are more closely linked to the external urban space (Zeng *et al*. 2016). In 2018, the government introduced new planning standard for urban residential areas, which on the one hand adjusted the spatial organization paradigm of China's residential areas, with smaller-scale 'block' as the basic space of residential areas.(Luo *et al*. 2019). On the other hand, by regulating the height of residential buildings and the average number of storeys, it also indirectly controlled the irrational paradigm of residential morphology represented by the "combination of high-rise and low-rise buildings", thus forcing property developers to explore a residential morphology that is more suitable for urban space.

Problem Analysis and Recommendations

However, the characteristics of residential morphology of China's mainstream property developers also reflect the lack of maintenance of the public interest in China's rapid development process: (1) Homogenisation of land use. The lack of consideration of block rezoning in residential areas of property developers and the monolithic approach to land use reduces the efficiency of urban land and, in particular, weakens the spatial mix of the urban public realm. (2) Internalisation of spatial connections. Physical boundaries and enclosed management isolate different residential areas from each other, internalised residential road networks also weaken the outward linkage of residential areas to the urban space. (3) Standardization of building layouts. The standardized form of residential areas caters to the market demand for standardized management, replicated production, and mass sales, but this kind of profit-maximization oriented layout has a homogeneous landscape, which is not in harmony with the urban fabric and is not conducive to the sustainable development of the city.

In the process of transforming the space of China's large cities towards a new stage of development, the constraints imposed by established the mode of residential construction on the development of the urban public realm are becoming more and more pronounced. The following optimisation recommendations are made: (1) Improving the composability of residential land use. Improve the system of supporting facilities based on living circle, encourage the compatibility of land-use and construct mixed-use district, eliminate residential differentiation by promoting equity in the distribution of social resources and providing diverse types of residential buildings. (2) Improving the relevance of residential areas to the external urban space. Promote the integration of the structure of the residential road network into the urban road system and enhance the community character of residential street places by increasing the functional boundaries. (3) Improving the continuity of residential areas in the urban macroscopic morphology. Residential construction should be integrated into the physical character of the site and the ambience of the area, it is important to seek continuity of overall morphology by embedding the residential planning in the existing urban street network and

strengthening the nodes (Goodchild B, 1994), instead of mechanical standardized replication and the models of “profit-oriented layout”②.

Annotation

①Definition of 1.0.3 of the *"Code for Residential Design"*: multilayer buildings have 4-6 floors, medium-rise buildings have 7-9 floors, high-rise buildings have more than 10 floors.

②"Profit-oriented layout" is a unidirectional design approach based on the intention of capital, equating residential planning with a capital business product, seeking a product mix and layout that maximises profit in a short period of time, subject to the constraints of the capitalist. This layout often puts the spatial environment of residential areas on the back burner, and the resulting programmes are often characterised by a single spatial layer and low environmental quality, which is a kind of master plan that ignores the quality of the human environment, deviates from the needs of residents' lives, and focuses on the interests of the capital.

A São Paulo for the future: the production of interstitial infrastructures based on morphological, environmental and social parameters

Eduardo Pimentel Pizarro[1], Joana Carla Soares Gonçalves[2]
[1] Department of Technology, Faculty of Architecture and Urbanism, University of Sao Paulo, Brazil, eduardo.pizarro@usp.br

ABSTRACT

The city of Sao Paulo is planned, designed, built and used from the perspective of "buildings" to the detriment of the urban void and its latent potentialities. It is hypothesized that the city, if produced from interstitial infrastructures based on morphological, environmental and social parameters, results in higher quality urban environments for people. The aim of the article is therefore to evaluate typical urban interstices selected in the existing city and to evolve, analytically, and to apply, prospectively, innovative tools and parameters for urban planning and design, seeking the construction of effective interstitial infrastructures to requalify the city, with a focus on territories with potential for urban transformation. The method is empirical, analytical and speculative in the way that articulates Fieldwork, Analytical Work and Prospective Work, theoretically based. Ultimately, against the prevailing urban regulation and practice, and from the application of the morphological-environmental- social parameters proposed by the thesis, alternative futures are speculated to the city of São Paulo, legitimating and proving the infrastructural role of urban interstices in the requalification of the city.

Keywords: Urban void, Thermal Comfort, Open space, Urban Design, Equivalent Perceived Temperature.

INTRODUCTION

As other cities living in the legacy of Modernist Urbanism, the city of Sao Paulo, in Brazil, is fundamentally planned and built following the logics of self-standing and isolated buildings, regardless to the space in-between them (Rowe and Koetter, 1978). From this panorama, it is launched the hypothesis that when urban planning and design are driven by environmentally, morphologically and socially informed interstitial infrastructures, the resulting urban space acquires higher levels of quality for people (Pizarro, 2019). Therefore, this research pro-design's objective is to analytically develop and prospectively apply simplified and replicable tools and parameters of urban planning and design with the aim of requalifying the existing city through the logics of the urban voids.

The concept of urban void

Based on the concepts of “intervals” (Smithson and Smithson, 2005), “accumulation of voids in largely unmanipulated solid” (Rowe and Koetter, 1978), and “positive spaces” (Alexander, 1977), the term “urban void” or “urban interstice” is understood as a three-dimensional instance that overlaps the term “open space”. It is fundamentally the whole space in-between buildings (Fig. 1) that supports everyday common life, besides environmental dynamics (solar radiation, daylight, wind, sound), regardless to public or private domains.

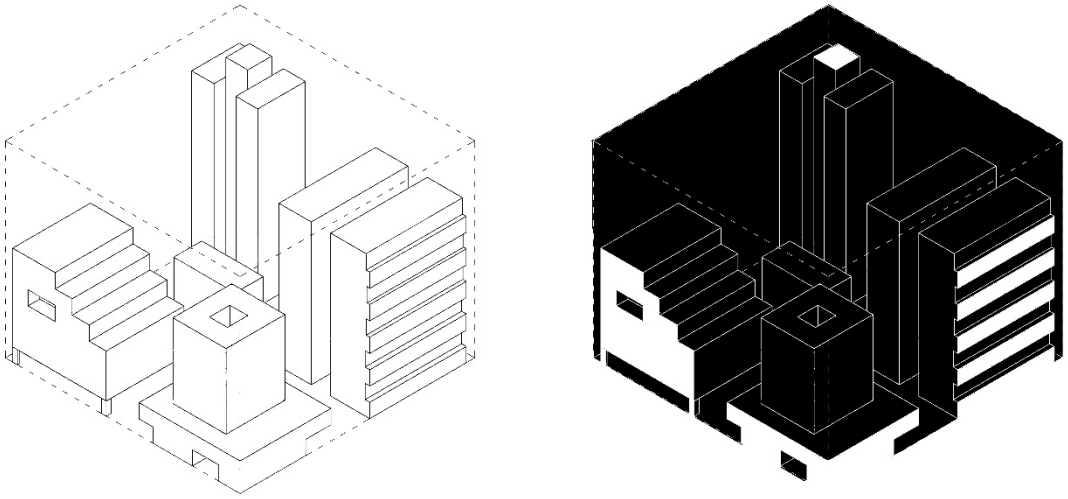

Figure 1. Diagram that illustrates the concept of urban void: self-standing buildings in white (left) and urban void in black (right). Source: Pizarro, 2019.

METHOD

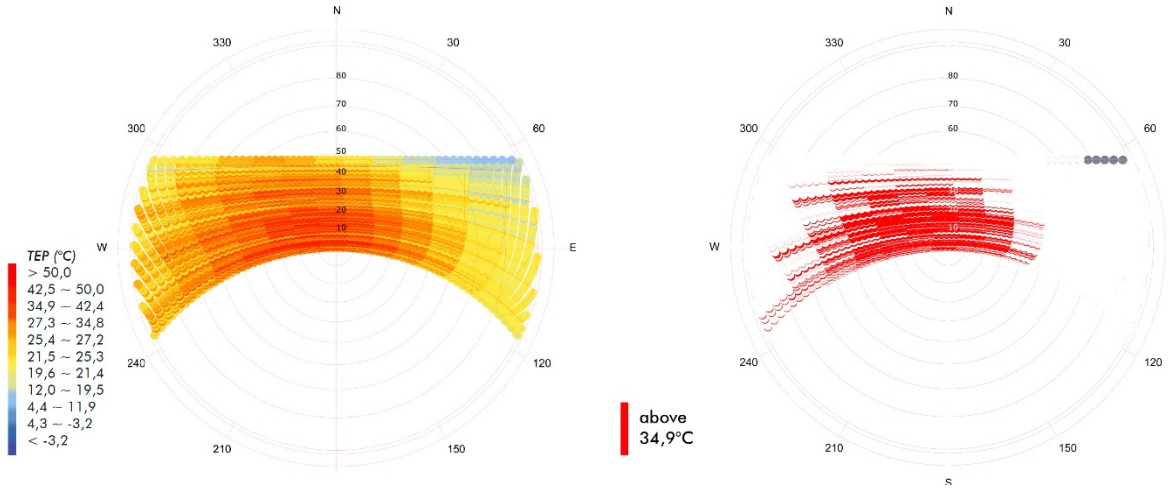
The Method is fundamentally analytical and prospective (Yannas, 2015). The Analytical phase is composed by two parts: first, the development of an innovative and simplified analytical tool that combines the sun path diagram to a thermal comfort index for outdoor spaces; second, the application of this tool to selected typical case studies of urban voids and prospected scenarios in the city of Sao Paulo, from which the assessment leads to the proposition of environmental-morphological parameters. Ultimately, the Prospective phase employs and validates the parameters found in the previous phase that provide outdoors comfort in the various configurations of open spaces through design applicabilities in existing territories under transformation in the city of Sao Paulo. In addition to that, the method is anchored in Theoretical References regarding Outdoor Thermal Comfort (Erell and Pearlmutter, 2010), Urban Morphology (Rossi, 1984) and Social Dynamics of Open Spaces (Gehl, 1980); besides Fieldwork, which is developed in three different territories in the city of Sao Paulo prior to the Analytical phase, in order to check the adopted theoretical concepts and hypothetical assumptions.

RESULTS AND DISCUSSIONS

Tool

The Interstitial Thermal Comfort Chart (ITCC), or “Carta de Desempenho Térmico Intersticial” (CDTI) in Portuguese, is an innovative tool developed with the aim of both assessing and estimating the thermal conditions in existing and proposed urban voids throughout the year for a specific climate

and latitude, in this case referring to the city of Sao Paulo. In essence, the tool is composed by the sun path diagram in which are plotted the calculated values of Equivalent Perceived Temperature (TEP) according to Monteiro's thermal comfort index for outdoor spaces (2018) and to the local climate database. The ITCC (Fig. 2) was constructed using the computer modelling software Rhinoceros 3D, Grasshopper and Ladybug.



Figures 2 and 3. (on the left) Interstitial Thermal Comfort Chart (ITCC) for the city of Sao Paulo (lat. 23°30'S) showing values of Equivalent Perceived Temperature in the scenario: Summer-fall; Global Radiation; and 0% wind. (on the right) Simplified version of ITCC highlighting the TEP range above 34,9°C in the scenario: Summer-fall; Global Radiation; and 0% wind. Tools: Rhino + Grasshopper + Ladybug Source: Rhino + Grasshopper + Ladybug. Source: Pizarro, 2019.

In order to enhance legibility and simplify the application of the ITCC for the case of the city of Sao Paulo (warm temperature, hot summer - Cfa - under the Koppen climate classification, CIBSE) it was produced a further version of it (Fig. 3), highlighting exclusively the TEP range above 34,9°C, which is related to "warm", "super warm" and "extremely warm" sensations according to Monteiro (2018). The value 34,9°C is therefore assumed as threshold for outdoors thermal comfort in this climate. To all intents and purposes, the ITCC tool is composed by an ensemble of eight sun path diagrams encompassing the combination of different scenarios regarding period of the year (summer-fall versus winter-spring), radiation (global versus diffuse), and wind (0% versus 100% of the value registered in the weather file), as shown in the Figure 4. The selection and combination of ITCCs for evaluating and estimating thermal conditions outdoors in a specific given urban void is further described in the next item.

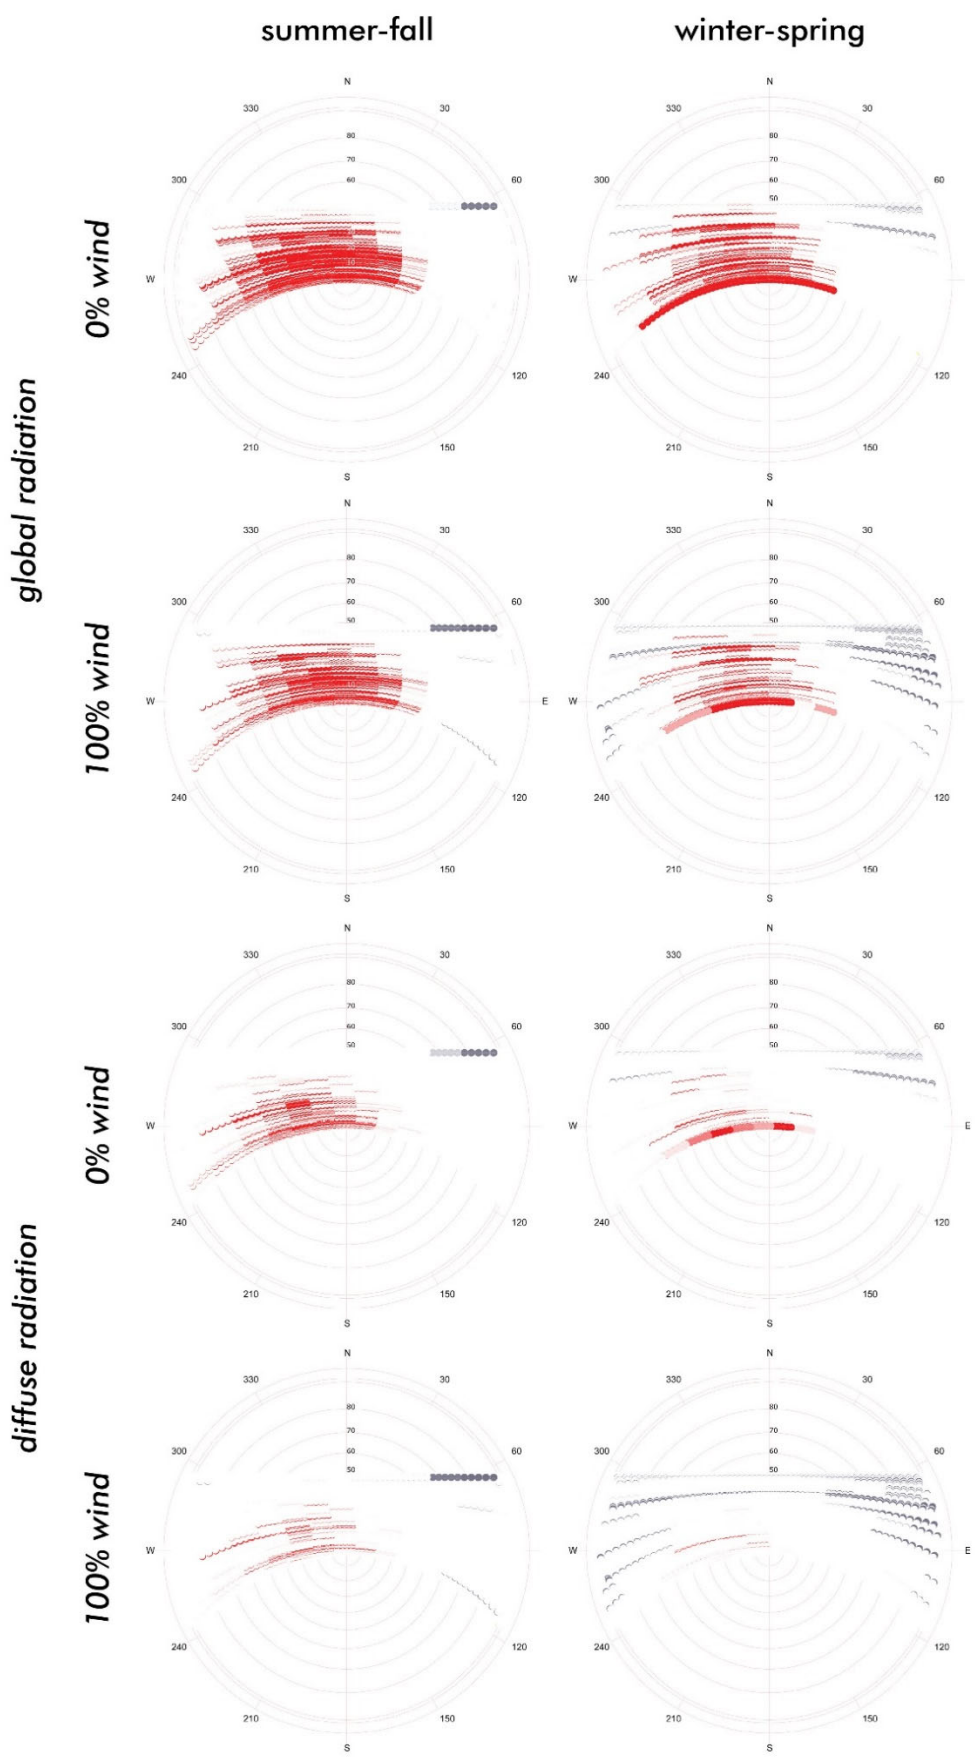


Figure 4. Ensemble of ITCCs for different scenarios regarding period of the year, radiation and wind. Source: Rhino + Grasshopper + Ladybug. Source: Pizarro, 2019.

Tool application

The ITCC tool allows the assessment and prediction of the thermal conditions of a single point (at a time) in an urban void along the day and year once combined with the respective sun mask as shown in Figure 5. It is important to highlight the combination among global and diffuse radiation's ITCCs for exposed and protected zones of the sun mask, respectively.

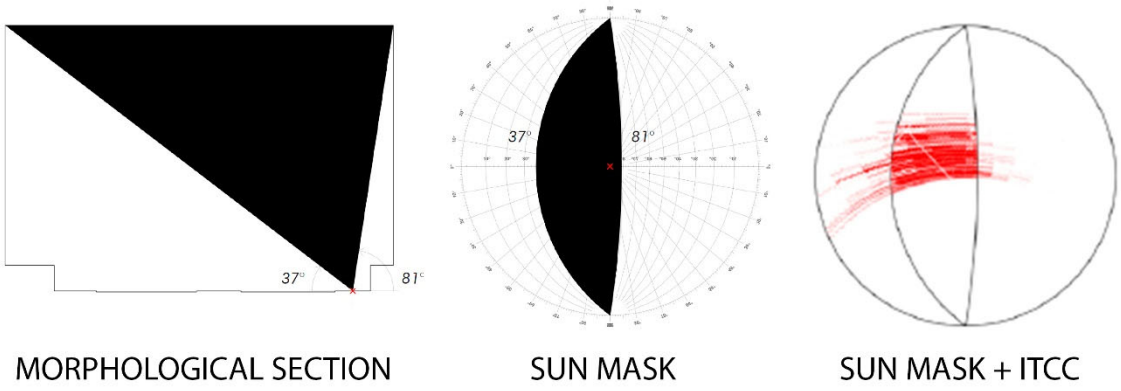

Figure 5. Diagram summarizing the analytical procedure, combining ITCC and sun mask for a single point in the void. Source: Pizarro, 2019.

Since the ITCC and the sun mask are combined, the percentage of hours in thermal discomfort (assumed as TEP above 34,9°C) or comfort is graphically determined through a comparative pixel's counting in the software Photoshop. As part of the Analytical work, the ITCC tool is applied to 87 selected case studies in the city of Sao Paulo (Fig. 6), such as the void on the ground floor the Museum of Modern Art of São Paulo – MASP (Fig. 7), with the aim of analysing the thermal performance of pre-selected existing urban voids. The case studies were selected according to the following criteria: territorial distribution; diversity of morphology, scale and function; environmental, morphological and social singularities or potentialities such as spatial connectivity and liveable edge zones. Depending on the morphology of each case study, the analysis is mainly based on the plan, or section, or both, or in an axonometric perspective.

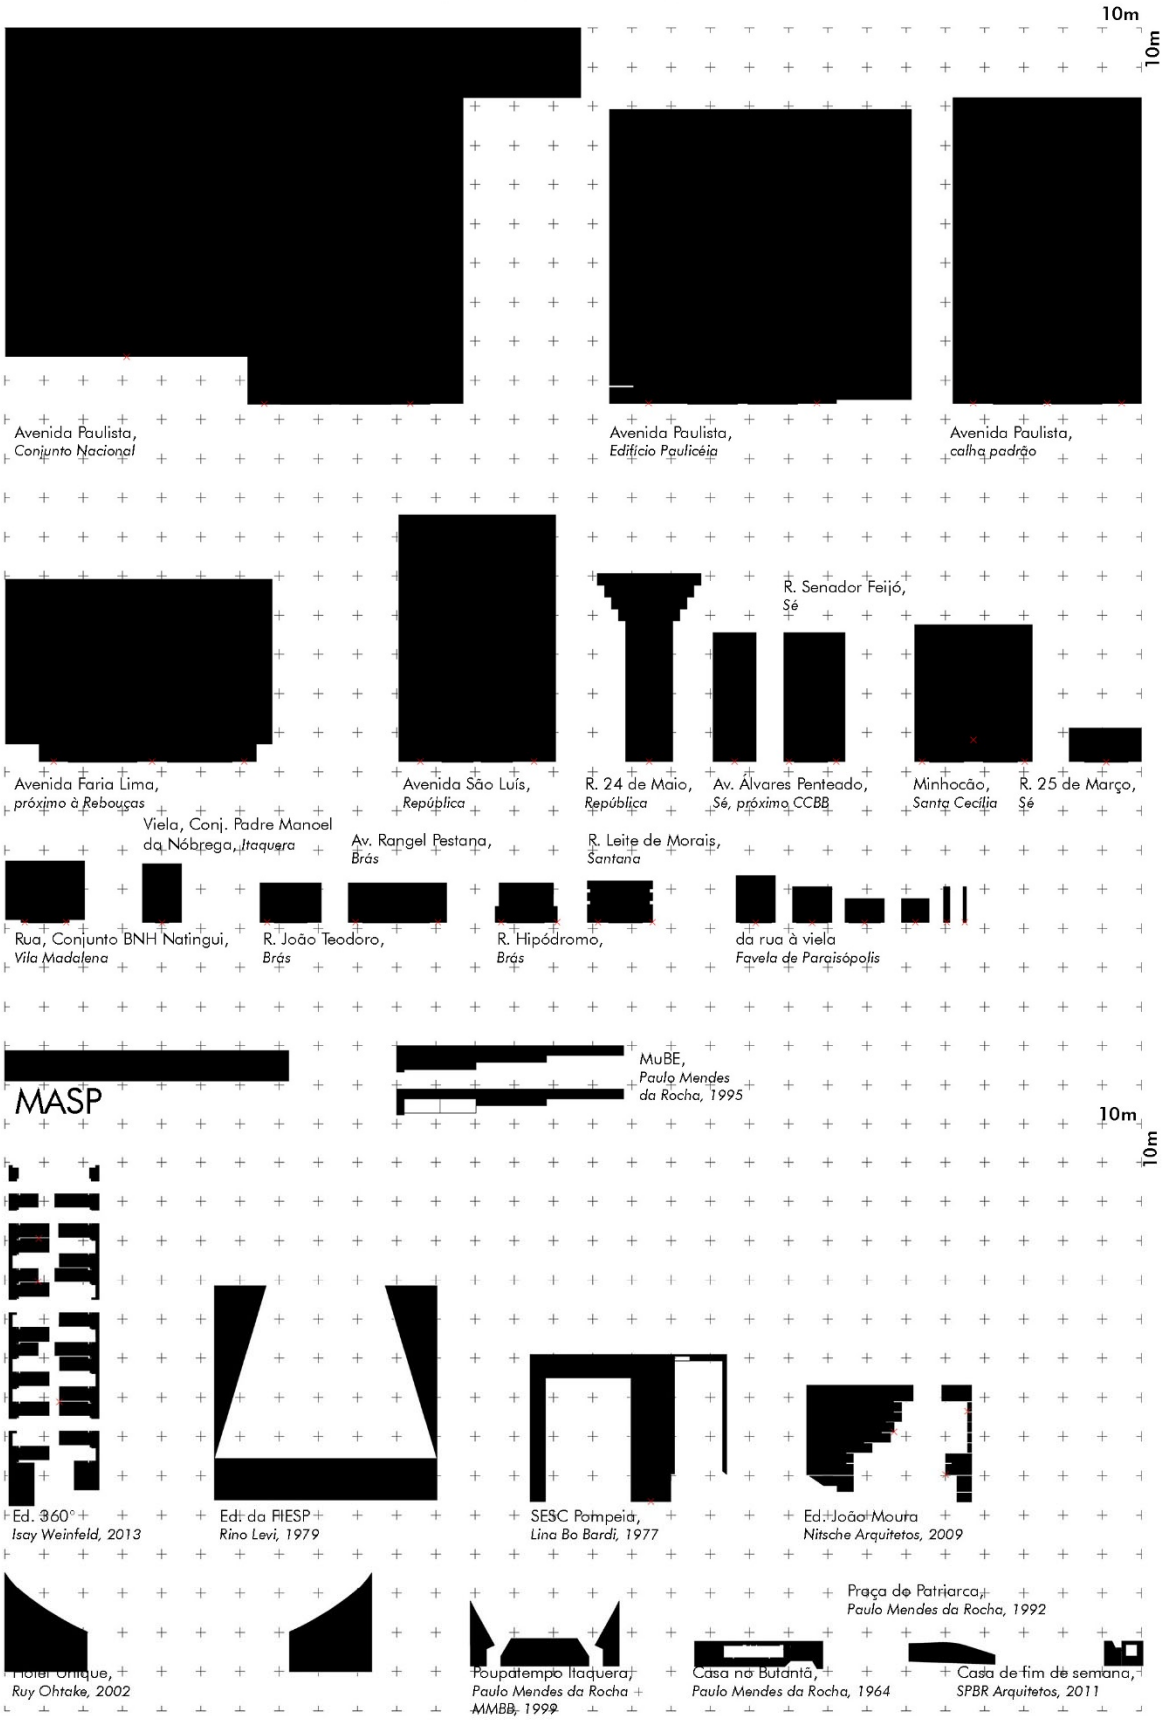

Figure 6. A sample of morphological masks of typical voids taken out of the 87 cases identified in the urban fabric of Sao Paulo, analysed in section. Black refers to urban void. The following figure illustrates one of the morphological masks. Source: Pizarro, 2019.

Figure 7. In reference to previous figure, picture of the void of the Sao Paulo Museum of Art – MASP. Source: AV Monographs, 2015.

The main results of the environmental assessment of the 87 case-studies were: the variation of hours in thermal discomfort along the year, leading to guidelines of adaptable and/or temporary interventions; the positive impact of natural ventilation on mitigating thermal conditions in warmer periods; that East-West oriented urban voids are more critical to thermal comfort; ultimately that typical voids from disparate contexts (for instance formal versus informal settlements) may embody similar thermal and social performances due to equivalent morphological proportions.

Environmental-morphological parameters

Based on the outcome of environmental assessment of the case studies, a correlation between the morphological parameters of height-to-width ratio (H/W) and sky view factor (SVF) with thermal performance. In addition to that, the research speculates other proposed parameters: A/H^2, which compares the area of projection to the void's height; and H/(A/P), which relates the height to the ratio between the area and perimeter of projection. The morphological parameters are rated according to ranges of percentage of hours in thermal comfort or discomfort in different scenarios regarding sun orientation and natural ventilation available (Fig. 8).

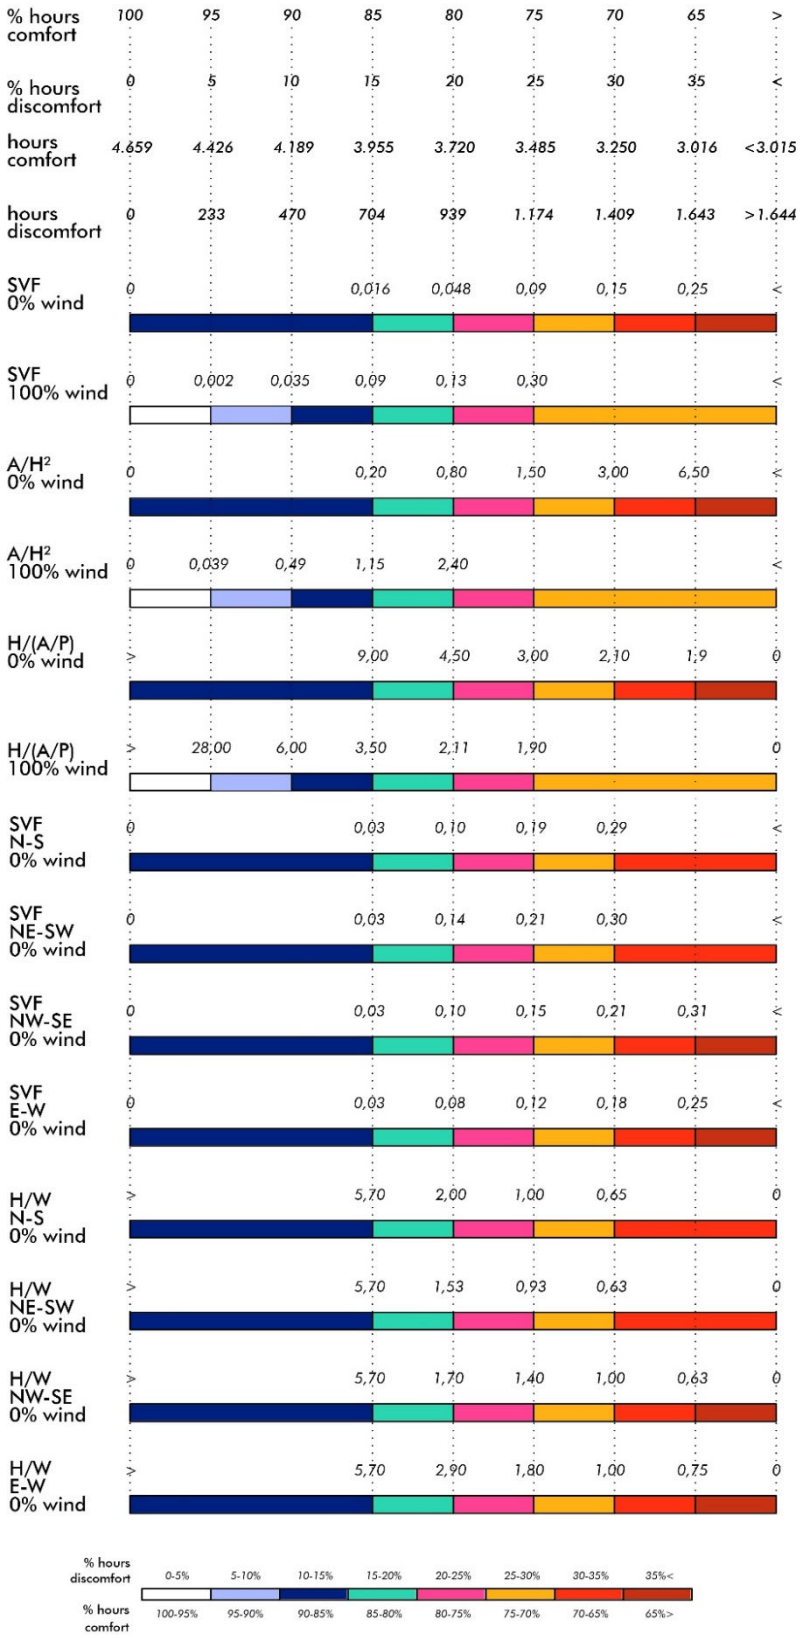

Figure 8. SVF, H/W, A/H² and H/(A/P) parameters related to percentage of hours in thermal comfort or discomfort (referring to TEP = 34,9°C as threshold for thermal comfort) along the year for the city of Sao Paulo. Each line presents a different scenario regarding sun orientation and natural ventilation availability. Source: Pizarro, 2019.

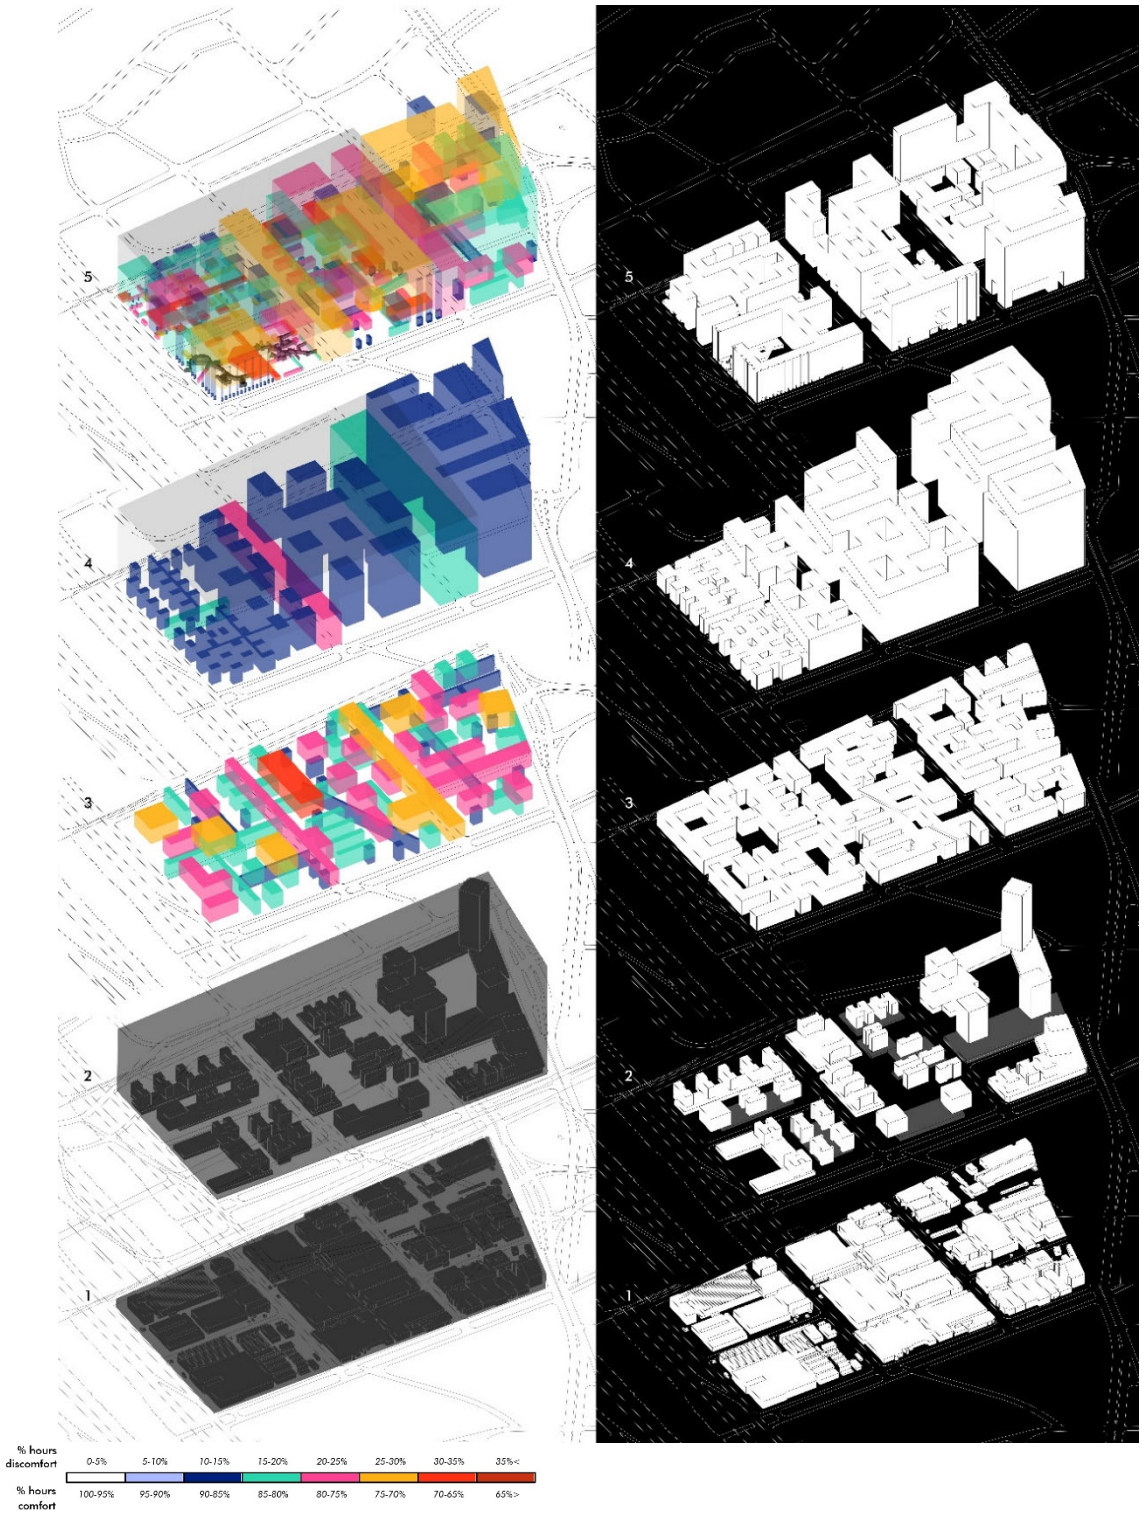
Design Applicability



Figures 9 and 10. Voids on the left and Resulting Buildings on the right. Design applicabilities developed for an ensemble of five existing urban blocks in Lapa's neighborhood. The urban void and resulting buildings are highlighted in different scenarios in Colours: 1. existing factory settlement; 2. proposed scenario according to current urban regulation; 3-5. alternative plans show proposed scenarios based on the application of the proposed performance parameters. Source: Pizarro, 2019.

The proposed parameters are ultimately applied to two different territories in current process of transformation in the city of Sao Paulo with the aim of evaluating their effectiveness and speculating/illustrating possible alternatives to the future of a subtropical city re-structured by environmentally responsive and socially liveable interstitial infrastructures. Each selected territory (five urban blocks in the neighborhood of Lapa and one single urban block along Rebouças Avenue) is re-designed by different interstitial infrastructures (scenarios), through digital and physical models (Figs. 9-15).

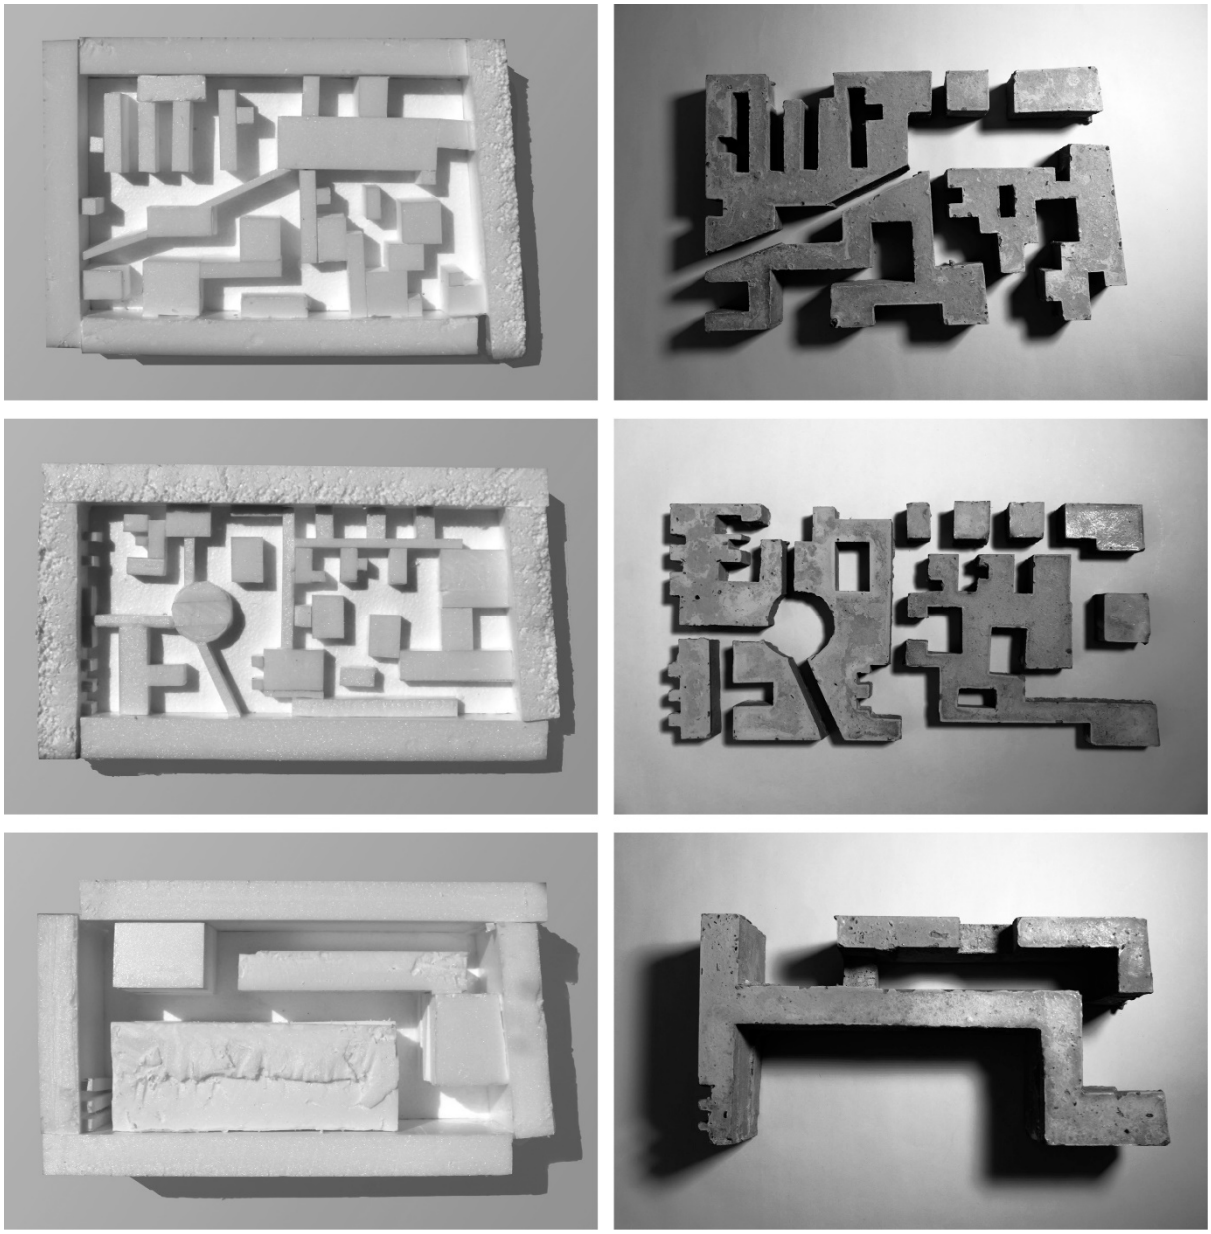


Figure 11. Physical models developed for Lapa's neighborhood: on the left the voids materialized in polystyrene; on the right the resulting buildings in concrete. Source: Pizarro, 2019.

The evaluation of the design applicabilities developed for the territory of Lapa (Figs. 9-11) brings to light important considerations. Firstly, the application of the proposed parameters results in an urban fabric marked by more diverse (regarding shape and scale) and articulated voids than the existing urban layout, emphasizing the "edge zones" as fundamental physical structure for supporting the

social structure (Gehl, 1980). Secondly, the proposal of interstitial infrastructures based on environmental, morphological and social parameters should be developed in articulated layers. In other words, the pre-requisites for urban voids on the ground floor are different to the ones above, but the whole infrastructure's performance relies on their interaction.

This consideration is further investigated in the design applicability for Rebouças Avenue, where the voids are designed in four articulated layers at different heights (Fig. 12-15).

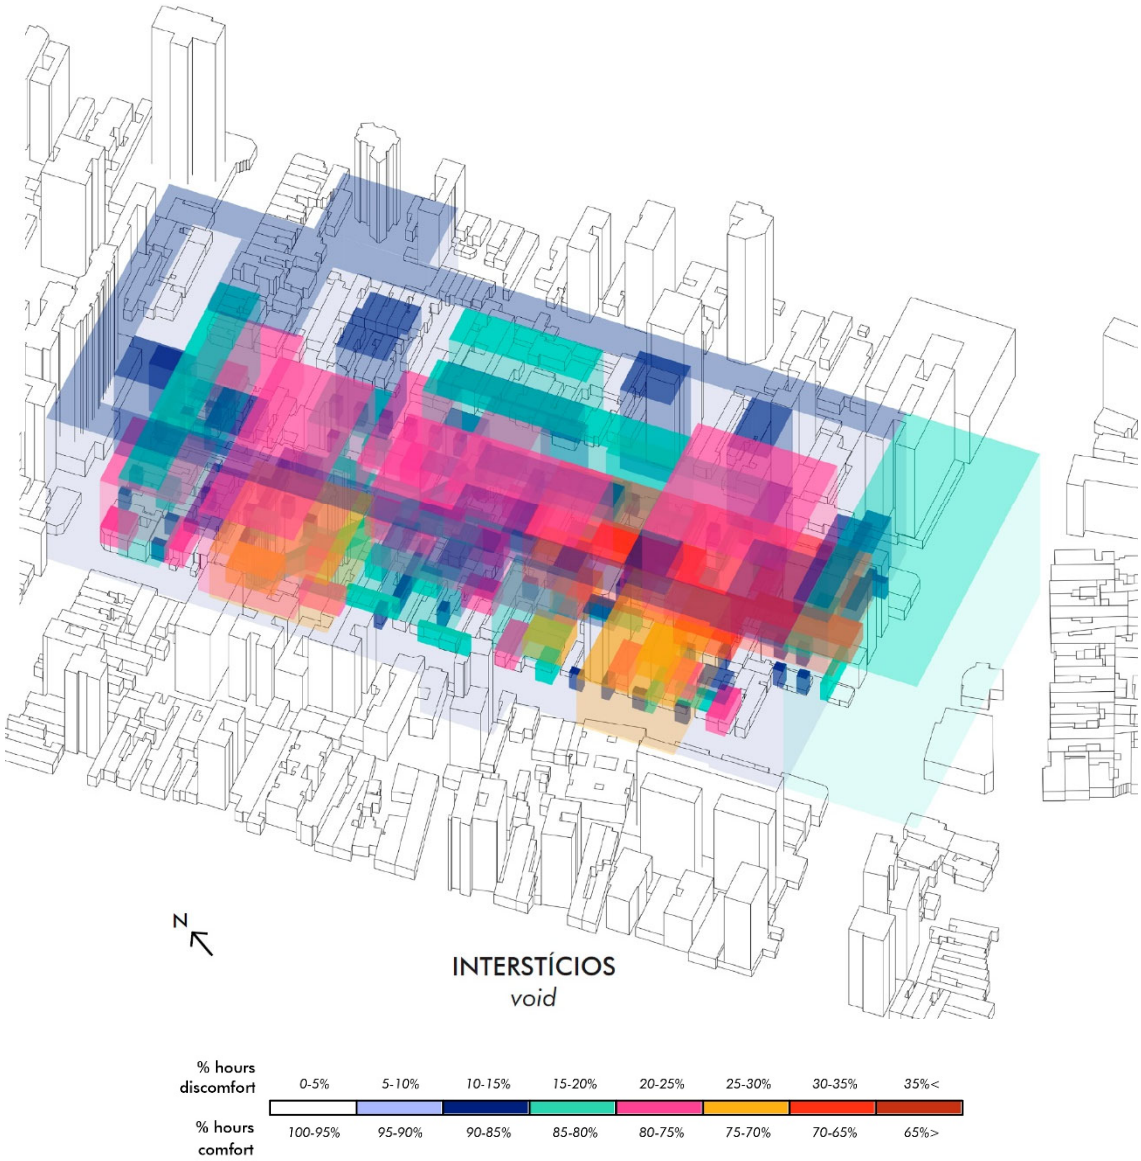

Figure 12: Design applicability in Rebouças' urban block, highlighting the proposed interstitial infrastructure in colors.

Figures 12 to 15 show how different layers address specific requirements: the ground floor layer is designed with the aim of avoiding sun overexposure and stimulating urban life along rougher edge zones; the higher layers should gradually control solar radiation without blocking access to natural light and wind.

Figure 15. Ensemble of diagrammatic sections for Rebouças neighborhood: voids in black; buildings in white. These sections follow "where to build" and "where not to build" logics (Koolhaas, 1995). Source: Pizarro, 2019.

CONCLUSIONS

The analysis of the research's results leads to four possible next steps: firstly, the application of wider ranges of natural ventilation data in the construction of the ITCC tool (instead of simply 0% versus 100%); secondly, the production of the ITCC tool for other latitudes and climates; thirdly, the development of further analysis in order to evaluate the impact of the proposed environmental-morphological parameters in the environmental quality of indoor spaces adjacent to the re-designed urban voids, stressing daylight levels; fourthly, the assessment (mainly based on the user experience) of the proposed parameters through the construction of 1:1 temporary prototypes around the city.

By all means, the investigative process proved the stated hypothesis and led to five key considerations for the environmental quality and potential social success of the urban voids, as follows. Firstly, the importance of basing the research findings in the evaluation of the existing city. Secondly, the articulation of environmental, morphological and social domains in every phase of the research increases the applicability of the proposed tools and parameters. Third, instead of the deterministic implementation of fixed rules, the combined application of quantitative and qualitative parameters leads the city to adaptive spaces and ultimately to a network of "environmental diversity" (Steemers and Steane, 2004). Fourthly, the employment of simplified tools and parameters enhances replicability and scalability levels in urban planning and design, ultimately leading to the improvement of the city's everyday life. Finally, the application of the proposed tools and parameters to the existing city should take the urban block as minimum unit of planning; and besides that, publicly and privately owned open spaces should be planned/designed together as three-dimensional masks assigning "where to build" and "where not to build" (Koolhaas, 1995), ultimately guaranteeing an articulation of scales and, most importantly, the "smallness of big cities" (Jacobs apud Whyte, 1993).

ABSTRACT

With the full development and promotion of China's urbanization, the development of urban centers continues to heat up. Towns located in the urban fringe are facing many development dilemmas, such as hollowing out, weak industrial competitiveness and degradation of human settlements. Many traditional streets are facing decline in morphological structure and characteristic space gradually disappears. In view of the current situation that traditional streets in Sipo Town need to continue their characteristics, this paper introduces the method of morphological typology, divides the elements of street interface into four categories: street space, transition space, street wall system and building texture, and conducts characteristic induction and quantitative analysis from the aspects of morphology, scale and structure. In the implementation, combined with the status quo and design requirements, the prototype of traditional street interface with characteristics of Sipo is refined, the composition logic between various elements is clarified, and the integrated "text-chart-legend" principle is established to guide the update of traditional street interface in Sipo town, and provide new ideas and strategies for the lost traditional streets in the urban fringe, so as to protect the form and texture of the existing streets and lanes, and guide the interface style of newly built streets and lanes.

Keywords: arginal zone; Traditional street interface; Morphological typology; Protection and renewal.

INTRODUCTION

After years of practice in urban construction and exploration of urban renewal, the era of “large-scale demolition and construction” has passed. Urban construction has entered a new stage of improving the quality of existing buildings. A series of renewal activities have injected new vitality into the city. Traditional streets and lanes record history, nurture the lives of the general public, and depict the appearance of the city (Kang and Zhang, 2023). Historical blocks are a concentrated reflection of the city’s spirit and are of great significance for inheriting urban culture and shaping the city’s appearance(Wang *et al*., 2023). Therefore, their cultural and spiritual values are increasingly valued, and traditional historical blocks located in the city center are welcoming new development opportunities. However, compared with the superior geographical location and relatively clear historical development context of traditional blocks in the central city, the urban fringe is an extremely sensitive and unstable space-time complex(Zhou *et al*., 2024). The traditional blocks in the urban fringe often have disadvantages such as unclear development positioning, poor accessibility, scattered distribution, and weak

continuity of street and lane forms. They cannot be effectively protected and developed in the long-term urban and rural construction, and fall into a vicious cycle of population outflow and deterioration of the living environment. The traditional street and lane form structure is facing collapse. This paper focuses on the traditional street interface and attempts to analyze its morphological structure and constituent elements from the perspective of morphological typology. Guided by "morphology" and using "type" as a tool, this paper extracts the "metalanguage" of the traditional street interface, and combines the renewal needs to establish design criteria to control and guide the street interface morphology.

STREET INTERFACE IN URBAN FRINGE AREAS FROM THE PERSPECTIVE OF TYPO-MORPHOLOGICAL APPROACH

Research overview

Since the 1990s, K.S. Kropf and I.Samuels were the first to apply Typo-morphological approach to urban planning and management practices, among which the Mennecy region in France was the most comprehensive(Zhang *et al.*, 2024). In China, scholars Chen F et al. first applied Typo-morphological approach to the renewal of traditional blocks for the purpose of protecting urban context(Kropf, 1996); Li Jinfang et al. applied Typo-morphological approach to the planning practice of historical blocks(Chen, 2010)(Figure 1). Subsequently, more and more scholars have applied it to traditional blocks, historical and cultural ancient towns, villages and other cases, but they are mainly concentrated on the overall planning and design of the city, or the areas in the city center and residential areas where the traditional historical style is well preserved. There are few applied studies focusing on the special urban landscape elements of the urban fringe.

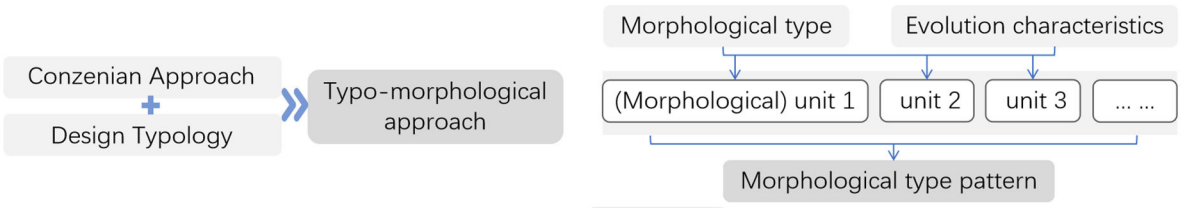

Figure 1.Theoretical development and Practical method. photo credit:Self-painted

In a narrow sense, the street interface refers to the building interface on both sides of the street (Li and Chen, 2021). In a broad sense, it refers to the street itself and the side interface. As the intersection of various components within the block, the street interface has a relatively sensitive characteristic and is the primary reflection point of changes in various elements. The combination of street space and architecture is essentially similar, both are enclosed space environments formed by the interaction of various factors, and the elements have the same constraints; the application of Typo-morphological approach can fully identify and extract the traditional characteristics of street interfaces, and use them as the basis for renewal research. Therefore, the practical method of Typo-morphological approach is relatively applicable to research in specific areas.

Characteristics of street interfaces in urban fringe areas

Sipo Town is located in the northwest of Yibin City, between the edge of the urban construction area and the airport, and faces the Minjiang River to the south(Figure 2). According to legend, the Northern Song Dynasty poet Huang Tingjian was demoted here. Because he missed Su Dongpo, he built a building here and wrote a plaque "Sipo" by hand, waiting for Dongpo to come, hence the name. The town is distributed in a strip along the river. Among them, Dashunchang Block is the street with the

best preserved traditional style in the Sipo Town area. In ancient times, there was a water wharf. It was called "Dukouchang" before the Ming Dynasty and was renamed "Dashunchang" in the late Ming Dynasty(Figure 3). Dashunchang Block has long been the center of Sipo Town's development, but behind the great improvement of the quality of the living environment by modernization, the disadvantages of regional transportation and geographical location have become increasingly prominent: the "historical inherent defects" left by the street width restrict vehicle access, and the street is located on the concave bank of the lower reaches of the Minjiang River and the flat terrain cannot resist flood disasters. In the current context of extreme emphasis on production efficiency, there is undoubtedly great resistance to the development and protection of the street. Driven by transportation and topography as the main factors, Sipo Town gradually expanded to Dongpo Street, which is located on higher ground. The development focus of the urban area also shifted to the northwest block. Traditional buildings were gradually abandoned and replaced by stereotyped modern buildings.

Figure 2. Location map of Sipo Town. Photo credit:Self-painted

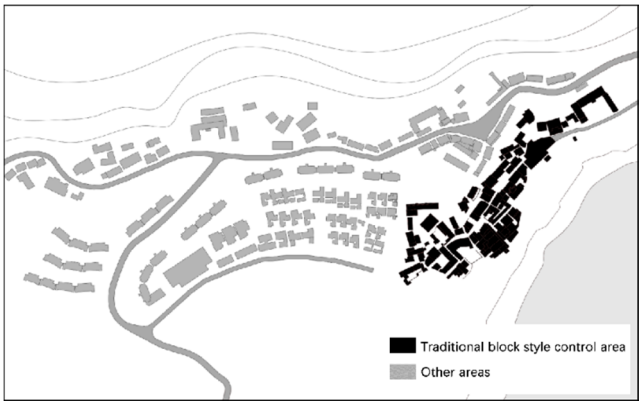

Figure 3. Location map of DaShunChang Block. Photo credit:Self-painted

The so-called Typo-morphological approach is to understand the structure and characteristics of the morphology (physical properties) with the analytical and conceptual cognitive framework of urban morphology, and to examine the logical relationship between the formation and change of these morphologies (human properties) in combination with the evolutionary perspective of typology (Chen et al., 2017). It emphasizes revealing its internal structure and characteristics through the typological study of the urban material space morphology. It focuses on the relationship between different types of buildings, streets and blocks, as well as the evolution of each element in space and time. Its research method is to decompose the entire spatial form into a number of type elements. These type elements should contain a hierarchical system from small to large. The single element should always maintain the relationship with the elements of the same level and the previous level(Li et al., 2023) .

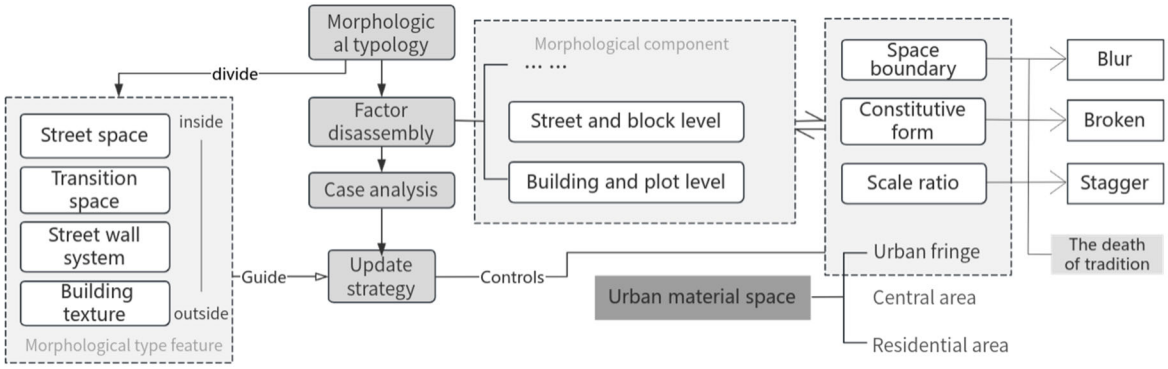

Figure 4.Technical route. photo credit:Self-painted

Typo-morphological approach believes that the morphology of urban material space can be analyzed and recognized at multiple levels, generally divided into four levels: building and plot level, street and block level, city level and regional level; among them, each level influences and restricts each other: high-level elements dominate the macro-morphological characteristics, and low-level elements dominate the meso-micro spatial composition and style. In urban material space, compared with urban central areas and residential areas, urban fringe areas have relatively isolated and highly dynamic development patterns in terms of life, production and ecology, which have accelerated the deconstruction of the traditional characteristics of the various morphological elements and the disconnection between the elements. As a traditional block in the urban fringe, the conflict between the protection of the original buildings and the progress of modern construction in Dongpo Community inevitably has a negative impact on the various element levels themselves, presenting a development dilemma different from ordinary areas, such as the increasingly fragmented rural landscape, the mixture of old and new settlement space, and the particularly prominent management deficit(Wei *et al.,* 2022). The disappearance of tradition has made the boundaries of urban material space increasingly blurred, the constituent forms tend to be fragmented, and the scale proportions are unbalanced(Figure 4).

Fuzzy spatial boundaries

The word “boundary” has different meanings. But generally speaking, boundary means “difference”. It is a mark that distinguishes things and is widely present between things (Li, 2023) . Spatial boundary refers to the boundary between different functional areas in cities, blocks, and even buildings, including natural boundaries and artificial boundaries. It can divide the form of cities or blocks and guide the spatial functional layout. Dashunchang Block is located in a special area where dense urban construction areas transition to open rural areas. Under the influence of the intersection of two different forms of human settlement, urban functions and rural functions penetrate each other, and construction land and agricultural land are intertwined. With the more active urbanization construction activities, the spatial boundary between the two has become dynamically blurred. There is no clear and fixed boundary between urban and rural areas, and traditional blocks are gradually shrinking(Figure 5). Especially in the marginal areas where traditional blocks and modern construction intersect, the functions of block plots are presented in a disordered and complex way. New residential buildings are adjacent to small-scale industrial production areas, and modern high-rise residential areas are adjacent to traditional blocks, which exacerbates the ambiguity of land use nature and

spatial hierarchy fractures between blocks. In addition, there is a contradiction between urban and rural development benefits and standardized management, and the blurred boundaries between public and private property plots have led to many informal reconstructions and expansions in the traditional blocks of Dongpo Community. These reconstructions and expansions have crossed the traditional boundaries, and behaviors such as occupying the road for business and parking have also occurred, and the building boundaries within the blocks have become increasingly blurred.

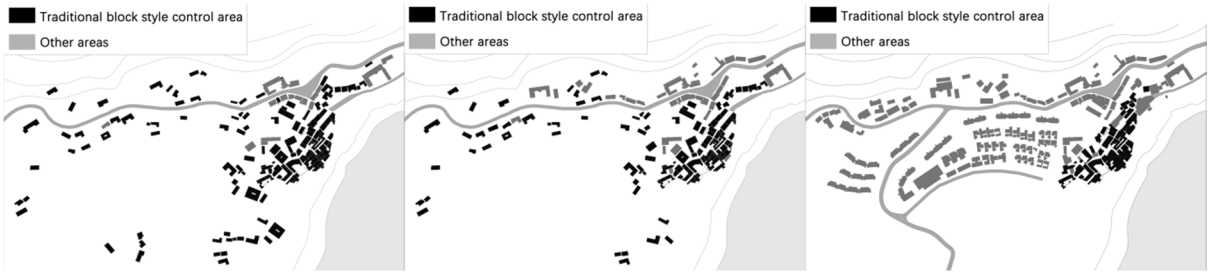

Figure 5.Distribution map of traditional buildings over the years. photo credit:Self-painted

Broken structure

Compositional form refers to the spatial and morphological characteristics of cities, blocks and buildings, including organizational structure and composition elements. As Dashunchang Block gradually expanded northward, it became the core street of the entire community. The limitation of the width of the streets in the traditional blocks resulted in the lack of direct connection between the emerging construction land and the traditional blocks. The continuity of the two was ignored, and the street network became fragmented. Driven by development benefits, some traditional buildings were ignored due to dilapidated structures and locational traffic disadvantages. In the absence of effective human intervention and maintenance, the traditional buildings in Dashunchang Block were mainly interpreted in three different ways. The first is to build new buildings around the original traditional buildings. In this way, the original traditional buildings still bear some of the main functions and can also be better maintained, but the facade style and materials of the new buildings are often incompatible with them. The large-scale use of decorative elements such as glass and tiles weakens the continuity of the traditional street wall system. The second is to extract it from the original main role and place it in auxiliary production, storage and other functions. Although it will still be maintained, due to the trade-off between input and output ratio, the quality is often low, and it can only support the basic space function and temporarily extend the service life of the building. Third, if they are left alone, many buildings with brick and wood as the main load-bearing structure will soon collapse. Under different levels of intervention, the original complete traditional street wall system has more and more fracture points, and the street space interface is presented in a "hodgepodge" style: traditional but modern, modern but dilapidated, various components are gathered in the building facades along the street, and various styles of building facades are gathered in the street wall system.

Unbalanced scale

Any three-dimensional object of any shape must have three dimensions: length, width, and height(Cai, 2016). From the overall block to the level of architectural details, scale ratio always runs through it,

involving the relative size and proportion of architectural details, facades, and street space. Reasonable scale ratio can not only enrich people's spatial experience when walking, promote the overall coordination of the block, but also play a structural role in shaping the block's form. Effective control of scale ratio can also create street spaces with diverse experiences. The traditional streets in Dashunchang Block are small in scale, which restricts vehicle access, but the scale of the family can also accommodate more daily activities, which is crucial to maintaining the traditional characteristics and vitality of the block; in contrast, Dashunchang Block has a large scale of streets and buildings on both sides. Although it strengthens the traffic function, it alienates the street from carrying daily functions to a certain extent. The buildings in Dashunchang Block are mostly one or two stories high. As the traditional buildings are dilapidated, they are replaced by new buildings that are inconsistent with the scale of the blocks. In terms of facade form, most of these buildings are above two stories and have relatively higher floor heights. Therefore, the scale of doors and windows and the scale of materials presented on the facade are different from those of traditional buildings.

ANALYSIS OF INTERFACE ELEMENTS OF TRADITIONAL STREETS IN SIPO TOWN

As part of the urban fabric, traditional streets and lanes carry rich historical memories and cultural accumulation. The continuation of street and lane space is also a guarantee for the continuation of the original social network and life network (Hu and Zhang, 2003). As the forefront and leading area of urban development, the urban fringe area needs to be effectively protected and renewed without delay. There are many traditional buildings preserved in the Dashunchang Block of Sipo Town. Most of them were built in the 1970s and 1980s, and a few are even older, dating back to the Qing Dynasty. The block is now mainly residential, with a small number of commercial and industrial functions scattered around. There are few public service facilities, and only one open cross-street market. The overall layout of the block buildings is the "fishbone" form commonly seen in traditional blocks, with compact streets and lanes and few public spaces. Buildings along the streets are mostly organized in an "introverted" arrangement, that is, the buildings are close to the streets along the street, and there are courtyards inside to form living and production spaces .

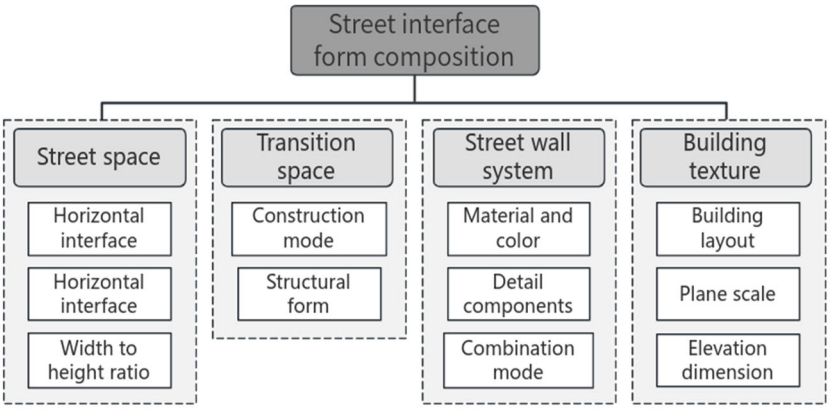

Figure 6.street interface form composition. photo credit:Self-painted

The buildings in the Dashunchang Block are very old. Under the influence of many extensive construction and informal reconstruction activities in the process of urbanization, traditional buildings and places have been destroyed. New buildings have not continued the regional style and

characteristics. The style of the entire block has become increasingly chaotic, and the street interface has been destroyed. Therefore, based on morphological theory, it is particularly important to understand the overall characteristics of the traditional street interface of Sipo Town from the perspective of the special urban landscape component of the urban fringe. On this basis, the street interface is disassembled from the inside to the outside into four major components: street space, transition space, street wall system, and building texture (Figure 6). The traditional characteristics of the street interface are deeply analyzed from the meso-block level and the micro-architectural and spatial levels using the typological operation method, providing a prototype that can highlight the regional characteristics for block renewal and promoting the continuation and modern translation of traditional architectural language.

Street space

Street space is the core component of the traditional street interface, which consists of horizontal and vertical interfaces. The vertical interface of the street is a side interface formed by the surrounding buildings or plants, and the horizontal interface is the street bottom interface. The two together affect the spatial scale and morphological characteristics of the street. The street bottom interface of Dashunchang Block has a rich morphology. According to the street direction and the side interface morphology, it can be roughly divided into four types: straight-through, expansion, turning and crossing. By selecting samples to calculate the aspect ratio (D/H) of the street, that is, the ratio of the street width to the height of the buildings on both sides, the spatial scale of the street is comprehensively measured. The straight-through street is the most common type, and the aspect ratio is usually small, 0.4~0.5. This small aspect ratio can bring people a closer sense of space: low buildings and narrow streets together form a street space with a strong sense of wrapping, allowing pedestrians to participate more in commercial activities in the street. The expansion street is a special form of straight-through street with a width-to-height ratio of 1.25-2. In this state, it can ensure sufficient use space without alienating people from the side interface of the street. As the intersection of two or more streets, it has more complex functions, carries more activities, and acts as a node for local buffering. The turning street has more significant spatial changes. Generally, there are transition sections of two streets of different scales. The height-to-width ratio often shows a uniform increase and decrease, avoiding the appearance of mutation points to ensure a continuous and homogeneous spatial experience. The crossing street is a street that passes through the interior of a building or under an open top. It is generally used as a market space. Compared with other types of streets, the top interface of the crossing street is closed, and the height-to-width ratio of the street is larger, but it still has a relatively close spatial feeling. There is no standardized planning and construction in the Dashunchang Block, but due to the differences in the main business functions carried by its side interface, under the guidance of spontaneous construction and transformation, the spatial comfort of traditional streets can also be just right(Table 1).

Table 1. Spatial form Scale. credit:Self-painted

type	Straight through	Expansion	Breakover	Traversal

Spatial form				Scale （mm）	 D=(2100-3200) H=(4200-5400) D/H=0.4~0.5	 D=(8000-10000) H= (4000-6400) D/H=1.25~2	 D=(2800-6100) H= (3000-5400) D/H=0.5~2	 D=(3600-5100) H= (3600-4500) D/H=1~1.6

Transition space

Transition space refers to the buffer zone between buildings and street space, usually including corridors, porches, courtyards, steps, etc. The transition space of the traditional block of Dashunchang is mainly porches and corridor spaces, which can be divided into three types according to the spatial form: extended type, indented type and additional type. They not only separate and connect the public and private domains, but also provide a rich variety of semi-public activity venues.

The extended type is the most common and original type of transition space. It is usually formed by the structure of the main building directly extending outward or diagonally extending outward to form a porch under the eaves. Due to structural limitations, the width is relatively small, generally ranging from 600-1200mm, and it mainly serves to provide shade and shelter from the rain. In order to relieve some functions to the street surface without interfering with the function of the street itself, the indented corridor space appeared, that is, the street wall of the building is retracted inward by one to three spans of purlins, and the through-beam structure is exposed. The width is usually between 1800-3000mm. It can not only serve as the outdoor area of the store, but also serve as a passage, making the interior of the building more naturally connected with the street. However, due to the wide retraction distance, it will affect the natural lighting of the building along the street. The attached type refers to the corridor space that is separated from the main structure of the building and built independently. Its width is usually more than 2000mm. Its function is similar to the indented type, but because the attached type only needs to meet the normal passage and activity functions, the height is not affected by the main structure and is generally lower than the building. Therefore, the position can be staggered to set window holes to ensure natural lighting indoors. These eaves and porch spaces are often gray spaces for residents to communicate and rest on a daily basis and for shops to carry out commercial activities. This transitional space not only enhances the social function of the street, but also enriches the layering of the street interface(Table 2).

Table 2. Spatial form Scale. credit:Self-painted

type	extension type	indent type	additional type
Spatial form			Scale （mm）	h=3200-4500 l=600-1200	h=4200-5400 l=1800-3000	h=2800-3600 l=2000-2800

Street wall system

The street wall system refers to the continuous facades of buildings on both sides of the street. It is the vertical boundary of the street space, including the building facades, door and window components, material use and decorative details. These elements together constitute the street wall system, affecting the spatial perception and historical style of the streets. In Dashunchang Block, the street wall system is usually composed of one to two story residential and commercial building facades. It is simple and rich in regional characteristics. Local materials are mostly used, mainly bamboo, wood, brick, stone and soil. The wall decoration is simple, emphasizing functionality and practicality. According to the difference in the main materials used in the facade, it can be divided into three types: wood-based, brick-wood mixed and brick-based. The three types of facades have their own characteristics due to different material properties. The wood-based facade type is the most primitive and widely distributed. It is characterized by the exposed gable wall with a through-beam wooden frame, the enclosure structure is a lightweight rammed earth wall with bamboo strips as the skeleton, and the exterior is plastered with lime. In order to cope with the relatively humid local climate, the column pier is generally a natural stone in the shape of a truncated cone, which can avoid direct contact between the wooden structure and the ground and increase the durability of the structure. With the popularity of bricks, a mixed brick-wood facade type began to appear. Bricks are usually used as structural columns and first-floor walls, but the supporting structure of the roof is still wood. Another important reason is that the Dashunchang Block prospered because of the dock. Now that this advantage has faded, the block is built along the river, which makes it vulnerable to floods. The use of water-resistant materials on the first floor can minimize losses. There are relatively few facade types dominated by bricks, but they also retain a more complete traditional style. Although there are differences in the use of materials, the building width is two to three bays, and the bay size is not much different, which is also determined by the characteristics of the wooden roof frame(Table 3).

Table 3. Typical elevation form. credit:Self-painted

type	wood-based	Brick-wood mixture	brick-based

Typical elevation form	

Building texture

Architectural texture refers to the overall characteristics of the layout and spatial organization of buildings in streets and alleys, which affects the direction of streets and the form of street side interfaces. The layout of building monomers in Dashunchang Block mainly includes four basic types: rectangular, "L"-shaped, "U"-shaped and "I"-shaped. The building groups are mainly organized in a straight line along the street. When the population of a single household increases, the function and scale of the residential space will be expanded, and the courtyard layout will be derived from the basic type. There are mainly three types: courtyard type, single group type and composite group type. The courtyard type has a strong integrity. The various parts are generally built at the same time. The interior is relatively closed, and the middle courtyard is small and narrow, which is called a patio. The single group type is a courtyard surrounded by monomer buildings of the same basic type. Usually, the integrity is weak, but the spatial permeability is strong, the shape is relatively regular, and the spatial organization is compact. The composite group type is a courtyard surrounded by monomer buildings of different basic types. Usually there are two basic types, the spatial organization is relatively scattered, and the internal openness is strong(Table 4).

UPDATE STRATEGY

Reset space boundary

In the context of urban and rural interweaving, the functional positioning within the block tends to be vague, making it difficult to achieve the best effect in the allocation of public resources. This ambiguity of spatial boundaries has led to the mutual penetration of urban and rural functions in the block, resulting in a chaotic land use pattern, which in turn affects the overall development efficiency of the block and causes the inactivation of some sections of the block. Clearly dividing the functions of the block not only helps to optimize the allocation of public resources, but also lays the foundation for the continuation of the traditional characteristics of the block. By sorting out the development context of the block, and on the premise of following the existing distribution rules of commercial and production spaces, the block is divided into four functional types, namely, characteristic industries, cultural leisure, catering services, and farmers' market sections (Figure 7). Although the transitional space enhances the spatial continuity between the street and the building, the use of the transitional space in the block does not completely follow the spatial boundary. The behaviors of occupying the road for business and spontaneous construction occur from time to time, which are often regarded as a gray area between the public and private domains. According to the construction logic and type of the transitional space, the public and private domains can be effectively distinguished, so as to determine the type and use of the transitional space (Figure 8).

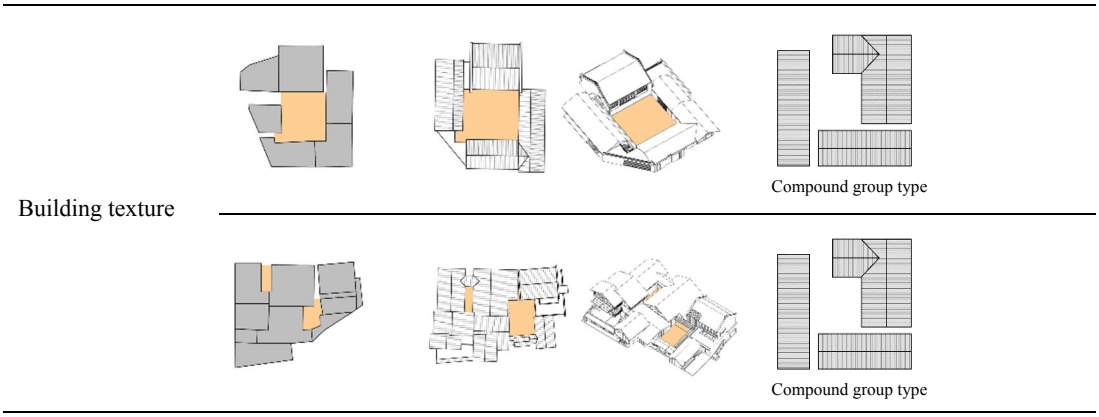
	Current Situation	**simplify**	**prototype**
Elevation composition			



The simplification of the compositional form is mainly reflected in the street wall system and street texture level. In the street wall system, the control of the building facade is an important means to continue the overall style of the block. The street wall system in traditional streets and lanes usually has a clear interface relationship and rich detailed structure, and is the main defining element of the street space. In the renewal process, the facade forms of different types of buildings should be classified and controlled. For existing buildings, the original facade type should be identified and its composition and material characteristics should be inherited. For new buildings, the facade type should be selected in the legend according to different bays and storey heights. By unifying the facade order and applying facade types of different materials, the new and old buildings can visually echo each other, rather than just a stereotyped copy of the facade(Table 5). In addition, for multi-story modern buildings that violate the traditional street facade composition form, eaves can be added on the first or second floor to eliminate the single compositional form in the form of an extended transitional space. The street texture level is mainly aimed at the renovation of existing buildings, that is, to extract characteristics from the original texture of traditional streets and lanes, and to retain and strengthen these characteristics during the renewal process. By reorganizing the combination logic of the original plane, using basic types of architectural texture to regularize the building layout, strengthen the enclosure of the courtyard space, and appropriately adjust the volume and density of the building, the street texture and the overall block form are more coordinated and unified(Table 6).

Restricted scale

In the renewal of traditional streets and lanes, the key to maintaining the spatial order and style consistency of the block is to reasonably control the height-to-width ratio of the street space and the proportion of the street wall system and its components. Through the analysis of the proportion scale of traditional buildings, the renewal of block buildings should maintain a proportional relationship consistent with traditional buildings in terms of facade height, bay width, door and window size, etc., so as to maintain the historical style and spatial order of the block as a whole. Under the condition of ignoring the impact of new buildings in traditional blocks, by analyzing the types of existing street spaces and horizontal and vertical scales, it can be found that the width-to-height ratio of streets and lanes within the Dashunchang Block is between 0.4 and 2, and it shows a relatively homogeneous change with the change of street space type. In the process of block renewal, the original street space form should be maintained and the original height-to-width ratio should be continued(Figure 9). In addition, the proportion of the street wall system and its components should also be strictly controlled during the renewal process. The bay width and floor height of the building should be selected according to the type of street wall structure, and the top floor height should not be higher than other

floors. The components are mainly doors and windows and transition space support structures, and their universal proportion scales are as follows(Table 7).

Figure 9. Street space scale control. photo credit:Self-painted

Table 7. Door, window and component size control. credit:Self-painted

Door and window components						Mullion window	Lattice window	Casement window	Plank door	Grille door
Scale （mm）	a1=800-1200 b1=1000-1400 a1<b1	a2=1200-1800 b2=1200-1800 a2>b2	a3=1500-2100 b3=1200-1800 a3>b3	a4=2000-2400 b4=1200-1600	A5=2400-2800 B5=1400-1800
Transitional spatial structure					Scale (l:Transition space width)	l/h1=2:1	l/h1=2:1 l/h2=1:1	l/h1=2:1	l/h1=2:1-3:1	l/h1=3:1

CONCLUSION

As an important part of the urban material space, the traditional streets and lanes interface of Dashunchang carries rich historical and cultural values and unique spatial characteristics. Through the

method of morphological typology, an in-depth analysis of the elements of the street and lane interface can reveal its spatial characteristics and historical evolution laws, and provide a scientific basis for the protection and renewal of the streets and lanes. Measures such as resetting spatial boundaries, streamlining composition forms, and limiting scale can effectively restore and continue the historical features of traditional streets and lanes, and enhance the cultural value and spatial quality of the blocks. In future urban development, attention should be paid to the protection and utilization of traditional streets and lanes, and explore renewal methods that adapt to modern needs to achieve an organic combination of history and modernity. Renewal that conforms to regional characteristics can not only preserve the historical context of the city, but also create a more pleasant living environment for residents, and provide strong support for the sustainable development of traditional blocks.

Archetypes and archetypal models. The territory between form and cultural heritage

Thomas Pepino [1]]
[1] Department of Architecture and Design (DAD), Politecnico di Torino, Italy, thomas.pepino@polito.it

ABSTRACT

This article describes the relationships between the product of human civilisation and geographical facts, investigating the form through the greenhouses of Sanremo, the "City of Flowers". The territory is here considered as a scientific propositional machine for the architectural project and, in this perspective, the greenhouses are re-signified as les machines du soleil, i.e. the analytical devices that allow to interpret the territorialisation process. This reading considers the urban form as the result of a decoding of geographical archetypes, revealing through cartography, painting and literature the territorial character of the site.

Geography becomes the paradigm for understanding the archetypal patterns of human forms, transcending the distinctions between rural and urban. The text explores how geography is structurally organised into archetypes, from which the archetypal models of the machines du soleil descend, and how these are able to explain the settlement logic of the city.

The aim is to recognise territorial characters as formal tools of an arché from which it is possible to orientate a reasoning aimed at identifying a formativity of the cultural heritage, identity and memory of a place, using urban and territorial facts as construction material to respond to global challenges.

The classification of anthropic forms, generated through the case-studies of the greenhouses, develops two tabelloni (boards) of the machines du soleil capable of rereading through form an order of generalisability of urban and territorial facts of promontory and hillside. The study illustrates how urban and territorial transformations at the time of Man are the outcome of a formal relationship between architecture and geography. The analysis of the greenhouses of Sanremo as machines du soleil thematises the territorialisation and geometrialisation of the earth's crust through archetypes and archetypal models and constitutes the detonating element to re-signify the greenhouses and imagine a territorial regeneration starting from the case-studies of the tabellone.

Keywords: Geography, morphology, territory, archetype, cultural heritage.

ΜΟΡΦΉ AND ΛΌΓΟΣ. LEXICAL-LOGICAL ISSUES

"The greatest danger is that not only things, but history itself, may largely be reduced to mere petrified objectivity, to an accumulation of data and objects unmediated by consciousness and unenlightened by the deciphering and contextualization of their meaning".[1]

(Bodei, 2011: 55).

Studies on form, by generalizing their scope of action, aim to theorize the relationships that exist between things (Muratori, 1960; Rossi, 1966; McHarg, 1969; Caniggia, 1976; Cataldi, 1977; Motta and Pizzigoni, 1991; Krier, 2009; Ravagnati, 2018). The extensive power of the morphological gaze on things, understood here as the relationship established between anthropic figures of different orders and scales – type, urban/rural/architectural form, etc. – in relation to geographic/territorial characters, constitutes a series of investigations that, while diverse, share a common substrate to some extent. Some of these investigations unfold through a sequential perspective (Muratori, 1960), others through a generative grammar process, a language of patterns (Alexander *et al*., 1977), or through the generation of discourse on form that explores the "processual typology" of anthropic figures (Caniggia and Maffei, 1979).

These conditions of analysis are foundational for the construction of theoretical thought and crucial in defining the meanings and formal solutions related to urban and territorial phenomena. They involve investigation through the combination of the terms "μορφή" (morphè) and "λόγος" (logos), which, in ancient Greek, mean "form" e "word, study, or discourse". The union of these terms forms the *corpus* of reasoning on the subjects to which the research on the terrestrial forms of Sanremo is directed, becoming more precise as the word rationally describes the external appearance of things.

"Morphology", as such, belongs to the sense that Deleuze and Guattari attribute to writing, by virtue of the fact that, similarly to morphology understood as the formal writing of things over time, "*n'a rien à voir avec signifier* [signifying is nonetheless a consequence, a meaningful trajectory of discourse]*, mais avec arpenter, cartographier, même des contrées à venir*" (Deleuze and Guattari, 1980: 11).

In this sense, the study conducted here aims, through the lexemes that structure its content – morphology in the strict sense analyzes the structure of things – to identify a territorial syntax aimed at examining the possibility of an interdisciplinary theoretical construction through the textual parts that contribute to the explanation of forms, partly anchored to that logical sense with which the term "morphology" reveals itself to the world in the *Versuch die Metamorphose der Pflanzen zu erklären* (1790), from which the concept of the "primordial or original leaf" (*Urblatt*) originates. This concept corresponds to the search for an archetype in which all parts – Goethe refers to the biological form of things – are variations of a single fundamental structure, the terrestrial substrate from which things are interconnected parts. This image of "morphology" as a form interconnected with space and time does not escape the laws of physics developed a year earlier by Lavoisier (1789), as the arché-type is neither created nor destroyed; rather, it is trans-formed – de-composed and re-composed.

The research tries to understand how the possibility of breaking the linearity of time introduces us to the mechanisms of an operative reading of the interconnection between past, present, and future, in

[1] The English quotations from Italian sources – see bibliography – have been translated by the author.

which the greenhouses constitute the fragments for the decoding of the archetype, since "*the past takes place in the sign but not in every sign*" (Sini, 1985: 45), connecting the forms before and after Man's time.

Territorial Memory and Geographical Condition

The form of the city is studied here through the logical interconnections that can be established over time with its material and immaterial heritage, with the identity and historical memory of the site, both of which constitute the territorial memory. Considering the crisis we are facing – industrial, economic, food, energy, social, etc. – as a point of insurgence, the opportunity emerges for the architectural project to connect the spirit of forms, finding, within the framework of urban analysis sciences, a possibility. The proposal is to reverse the perspective that formalized the idea of an expanding city, where this notion subordinated the form of the territory to the city (Samonà, 1976), reversing the perspective towards the territorialization of the city. Since "*it is not possible to fully describe or understand things... because the figures through which they can be described are already embedded in a movement of references... an unstoppable drift in which the objects of representation are carried away, in an equally unstoppable oscillation*" (Motta and Pizzigoni, 1999: 24) and it is precisely for this reason that "*the city can be described through the mountain, but the mountain, in turn, can only be described by looking at the city*" (Motta and Pizzigoni, 1999: 24).

The possibility of reading the indissoluble relationship between architecture and geography, deriving from a "fundamental" structure – a substratum that cancels and quantifies time as a propositional tool for the architectural project, readable through the forms at the time of Man, the greenhouses – opens up an interpretation focused on geo-morpho-logical characters (Figure 1). These are necessary tools for grafting possible development scenarios for architectural design, urban and territorial regeneration, and landscape, imagining possible worlds starting from the forms of time – in this context, the greenhouses of Sanremo.

With this perspective, it is possible to retrace and rediscover in form what Bergson explains in the ability to see the freezing of the becoming of things, since, in fact "*la forme n'est qu'un instantané pris sur une transition*" (Bergson, 2008: 302). This activity of transition allows for the imagination that in the treatment of the transitoriness of form – architectural, urban, rural, territorial – there exists a principle of arché of the geographical thing, and that, in anthropic transformation, when transitioning from one architectural figure to another, this potentiality of the geographical arché remains and equates to what Martí Arís (2007) refers to as the activity of the intellect that transits in architectural memory from one body to another – a passage that occurs in analogy between the forms before the time of Man and those in the time of Man.

The notes and annotations developed to imagine a possible Plan idea for the Municipality of Sanremo perform this operation: they unite apparently distant strips of time, in which territorial memory and heritage – both material and immaterial – become analysis tools for the architectural project.

In this context, the research for a possible territorial regeneration – through the system of greenhouses – which acts through the reading of geomorphological characters to formulate notes and ideas of a possible image of the city, reflects on the structural and philosophical condition of space in small-medium sized cities in relation to their geographical status.

The study of the terrestrial forms of Sanremo addresses all those fragile territories that struggle to engage constructively with territorial memory, where urban and rural factors have, over the course of time, constituted the interconnection between the characters and cultural specificities of that part of the world.

The Illatency of Form

The research focuses on the study of the micro-decommissioning of San Remo's greenhouses, explaining, through the classification of case-studies, the settlement logic of the ancient city.

Classification, as a method of analysis and theorisation (Soavi *et al*., 2013), recognises archetypes and archetypal patterns between form and cultural heritage in the geographic condition, constructing reasoning to address new global challenges. The greenhouse system, consisting of syntactic relationships – artifacts, agricultural paths, anthropic structures, forms in the time of man, etc. – represents "*the human thing... an immense repository of labours.... testimony of values, are permanence and memory*" (Rossi, 1966: 28).

The recognition of the product of human activity as cultural heritage takes place through the logical construction of the classifier and, as Brandi specifies regarding the work of art, "*it takes place in consciousness: it has to be done each time by a single individual. The human product... is there, before our eyes, but it can be classified generically among the products of human activity, until the recognition that consciousness makes of it as a work of art, exempts it definitively from the commonality of other products*" (Brandi, 1963: 32).

The human product – the greenhouses – preserve and derive from human labour, as "*memory truly seems to be about something, to be as such connected to things*" (Cacciari, 1990: 251).

The greenhouses embody ἔργον – *érgon*, meaning "work, work or action" – and are the physical object whose form, in relation to the spatial scale, does not betray but unveils the purpose and connection to the image of an arché, "*it enchants because it brings to presence, in its saying* [the arché-typical saying of the arché], *that unforgettable being, which time does not devour – because it speaks the truth, Aletheia*" (Cacciari, 1990: 236).

The greenhouses, which constitute the last morpho-logical gesture made by man on the territorial scale, where the lemma *Aletheia* (ἀλήθεια) means "truth or revelation", unveil the geographical nature embodied in the body of architecture – the greenhouses explain themselves and the city (Figure 2). In their constructive simplicity and essentiality of form, they stand in contrast to "lēthē" (oblivion), clinging to the particle "a", turning their gaze to non-forgetfulness, as they not only manifest the memory of forms before Man's time, but also correspond to the manifestation of the essence of things, effectively breaking the linearity of time.

The greenhouse system constitutes the research tool of the archetypes and uses the greenhouse device insofar as "*memory reveals all the power of its timé when it is Memory of the beginning... yes, it addresses the illatence of the beginning... but precisely because Beginning and not beginning-of... already belongs to the series to which it begins, this arché does not exclude anything from itself*" (Cacciari, 1990: 235-36).

In this research, the geographical condition is a detonating condition. Through the logical procedure by which the city is investigated – cartographies, travellers' descriptions, representations, etc. – different ways of seeing and describing the forms of the city of Sanremo intertwine.

In continuity with the studies of Motta-Pizzigoni and Ravagnati, a dual reading is established on which it was possible to construct a Plan idea for the Foce Valley from the analytical image of the form of invisible cities, in which "*the two cities that emerge... are co-present cities, not always and not necessarily collaborating, but certainly not in conflict with each other. ... the most hidden city... is not yet aware of its architectural and settlement vocation. It is the city in which the energy of work accumulated over the centuries has remained there, still, waiting to develop positively. It is the city whose structure can be grasped by looking at it in reverse. ... a city that has disappeared... that never was or, more simply, still is not. To see this city it is necessary to look where architecture seems to be absent or denied*" (Ravagnati, 2018: 41-43).

Micro-decommissioning represents a widespread phenomenon in all those small and medium-sized European municipalities and, together with the theme of territorial regeneration, is the subject of this study. The progressive abandonment of these areas leads to the oblivion of heritage – cultural, landscape, etc. – and leads to loss of identity, economic opportunities, resources, knowledge, degradation and destruction of heritage, as well as a lack of historical and cultural awareness.

The questions this research raises are: is it possible to define a paradigm of regeneration – urban and territorial – capable of counteracting the oblivion to which these places are destined? How can we educate, i.e. "nurture" (from the Latin *educĕre*, composed of *e-* [out] and *ducĕre* [to lead, guide]), the architectural project with the aim of "bringing out" the intrinsic capacities of the territory, developing a model that looks to the substance and geomorphological potential to guide society to grasp the bare potential of these places?

The vertigo of this theme is articulated on two substantial points: a) "The *tabellone*. A Question of Method: Classify, theorize, Signify", in which classification as a theoretical and cognitive paradigm of forms – cultural, historical, landscape, literary, etc. – becomes a tool for the construction and unveiling of urban and territorial facts, which in its formal construction projects interdisciplinary bridges in/for research, demonstrating the strength of language as a stratified process of signification and interpretation of things; b) "Results and Discussion: The case-study of the Foce Valley": defining/recognising problems to generate a plausible response to the new global challenges, orienting the project towards a horizon capable of spatialising between disciplines, interconnecting the regeneration model with the need to plan the future of the territory, with the demands of social, economic and environmental development to ensure the survival and well-being of present and future generations.

The *tabellone*. A Question of Method: Classify, Theorize, Signify

The *tabellone* is an ordering geometric grid that allows for the classification of elements belonging to and/or deriving from the underlying geographical structure. The grid functions as a regulatory system, organizing the samples of the typical fabrics of Sanremo.

This method is employed to address the relationships between terrestrial forms, allowing for an understanding, through study and redesign, of the fragments that characterize the history of urban and territorial transformations, by hierarchizing their logical structure and recognizing their syntax.

The classificatory process required to construct the grid triggers modalities that allow the territory to be read through the formal relationships that the elements present establish with the geographical status of the places and their parts, highlighting characters of generalisability and specificity.

The grid aims to reveal the typical relationships of the preaching concepts of territorial syntax in their complexity and origin.

The arrangement of figures within the *tabellone* generates interpolations between objects, identifying matrices and possible connections between the parts. The *tabellone* is a tool applied by Saverio Muratori to investigate and understand the nature of places, the characters and history of the territory, allowing the study from criteria based on the aspects of the figures present.

The first phase of this study was to articulate the literature on the history of greenhouses, urban and territorial transformations of the Sanremo Gulf theatre, focusing on the partly descriptive textual forms necessary for the construction of the city's image, i.e. the discourse around the forms to which the greenhouses, henceforth referred to as *les machines du soleil* when they operate as analytical devices, anchor the signification of transformations.

This classificatory machine allows for understanding how the form of anthropic structures is related to the characters of the territory. The latter are the result of a slow process of erosion of the orographic structure, in which the water system collaborates in the formal definition of promontory and hillside figures before the time of Man. The hydrographic resources that characterize the valley structure of Sanremo are composed of 14 main watercourses, plus an additional 6 minor courses. The hydrographic network of the valleys of Sanremo, incising the earth's crust, contributes, together with the promontory orographic structure, to define the triangular shape of the theater of the Gulf of Sanremo, whose vertices correspond to the monumental figure of Monte Bignone to the north, Capo Nero to the west, and Capo Verde to the east. The orographic structure, together with the watercourses, constitutes the underlying system of forms in the time of Man.

The analytical relationship that is established between geographical and anthropic forms is enriched by the combination of literary sources, offering a fundamental perspective for the construction of meanings and interdisciplinary correlations. These meanings and correlations derive from the intertwining of descriptions by travellers who, starting from the 17th century, relate to the image of the city and its geographical character. These descriptions, together with the climatic conditions of Sanremo, constituted a highly appreciated attraction for aristocrats and tourists – French, English, German, and Russian – who, in the 19th century, decided to settle during the winter months – the so-called *hivernantes*.

The literary apparatus intertwined with the construction of the cartographic *corpus* – 436 representations from approximately the 16th century onward – chronologically reading the urban and territorial transformations. Together, these documents make it possible to generate the cognitive value of the formative nature of the syntactic relationships between anthropic structures, landforms and textual forms, before and after the time of Man. The chronological arrangement of historical thresholds in the cartographies enables the reading of the cultural significance of what *les machines du soleil* represent, producing knowledge of urban and territorial facts, showing on one side the

geographical character of the site and on the other the political/administrative aspect of a territory in continuous transformation.

The grid of the *tabellone* is composed of cells that organize the systemic reading of the typical samples of the territorial structure. The cells are defined by the intersection of columns (ordinates) and rows (abscissas). The number of columns is determined by the number of case-studies, which establish the extent of the *tabellone*, while the rows are three, each analyzing the territory according to three founding principles of Sanremo's settlement logic: acclivity, exposure, and terrestrial paths. The adjacent arrangement of the cells belonging to the same row constitutes the series of case-studies of the same type, while the reading of a single column analyzes the same case-study according to three different themes.

This scientific machine renders the geographical figures legible, allowing for the construction of reasoning on the relationships of meaning that cultural heritage has instilled between the territorial type and the advent of the city. These syntactic and semantic relationships articulate and determine the settlement logic through two main morphological aspects: the promontory system and the hillside system, necessitating the construction of two *tabelloni* (Figures 3-4).

The first row of each *tabellone* is a "bookmark" row, or the archetype column, and constitutes the matrix of the ancient city, operating an analytical interconnection with *les machines du soleil*. The promontory matrix/archetype is represented by La Pigna, while the hillside archetype is identified with the Rocca district, located on the southwest hillside of La Pigna.

La Pigna, located on a promontory between two valleys, not only preserves in the toponym etymological issues that clarify the indissoluble geomorphological relationship between architecture and geography (Ferrari, 1963; Petracco Sicardi, 1962), but also highlights, through *les machines du soleil*, the interconnections of continuity with the territorial characters derived from the relationships with the monumental figure of the promontory.

The urban and territorial architectural structure of the *machines du soleil* conquers the territory by following a logic that repeats the form of the archetypes over time, giving back a reading that, through the greenhouses, unveils the formativity of the city of ancient foundation. This process manifests the functioning of an orographic and topological model that shows the relationship between city and territory, starting with the phenomenon of the greenhouses.

Les machiens du solieil explain the formativity of the archetypes and vice versa, they become archetypal models in a dual relationship that contributes both to defining the archetype and unveiling the arché of territorial facts.

Acclivity. Going into the merits of the three themes of the *tabellone*, acclivity explains the morphological aspect of the territory and the intelligibility of the forms resulting from the relationship between the slope of the land and the topological condition of the greenhouses. The topographical surface of the greenhouses is illustrated by the technical device of the "plate", which investigates the slope of the terrain and analyses the organisation and distribution of the relationships between the forms of the greenhouses and the geomorphological characters of the site. Acclivity highlights the orographic and plano-altimetric arrangement of the *machines du soleil* concerning the geographical figures of promontory and hillside (Figure 5).

The acclivity series highlights, through the device of the plate, the total adherence to the orographic structure of the territory, analytically producing the leap in time and logically linking the archaeological fragments of the *vicos et castella*. *Les machines du soleil* relate the settlement form of La Pigna with the pre-Roman castellars and in continuity with the work of the terracing extended by the Benedictine monks, where the greenhouses constitute the architectural gesture that exalts and crystallises the geometry of the geographical theatre of Sanremo.

The visible operation, which in the castellari was a strategic issue, operates as “paving”. Paving is the repetitive operation of the plates through the use of the greenhouse bodies. This architectural action shows the geographic characters of the place and becomes the instrumental means for the realisation and/or intensification of the infrastructural system, making the terraced structure and the edges of the transit system intelligible.

The image of the city is, in fact, the result of a paving operation, where the greenhouse plates replace the stone slabs used to pave a street. This repetitive operation levels the orographic structure and positions the greenhouses. Paving defines the relationship with the ground and the size of the slabs – plates – according to the body of the greenhouses, taking on different geometries and measurements. Paving produces a new image of the city, the “Crystal Hill,” which is formalized through the succession of rectangular figures that are the most recurrent form and, depending on the topological conditions, deforms and specifies whether we are in the presence of the promontory or the hillside. The physical operation of paving makes the image of the “Crystal Hill” visible through two founding operations of Sanremo’s architecture: a) the hillside paving is an operation that occurs through the use of narrow and long geometric figures, parallel to the contour lines, and that, from the valley floor to the ridge, shows a fragmented system of stairways; b) the promontory paving follows the orography and covers the “Crystal Hill” with concentric rings towards the summit.

Exposure. Exposure is a determining factor for the specific characters of architecture and its arrangement, as it, together with acclivity and terrestrial paths, establishes the proximity relationships between the anthropic structures of the Sanremo territory and the forms of the geographical system. To study exposure, a specific analytical tool is necessary: the “wall.” The wall, like the plate for acclivity, becomes the analytical object that reveals and measures the architectures and their parts, positioned to optimize their relationship to the sun (Figure 6). This principle explains the strategic placement of the first hotels and how the process of real estate speculation, highlighted by Calvino (Calvino, 1963), follows this constructional aspect. The same criterion is adopted by the greenhouses, which, in the transition from a culture of cut flowers *en plein air* to the floriculture industry, are positioned according to this logic to optimize profits. The selection of these differences has highlighted, in the *tabelloni*, only the external surfaces of the walls of the greenhouses and the buildings subject to irradiation, revealing the logical principle by which the greenhouses – and even earlier, the archetype – relate to the geomorphological characters of the site, defining the most privileged positions for realization – becoming crystal, an icon of the forms of the earth.

Through the analysis of the *machines du soleil* by studying the walls of the greenhouses, we can identify and reveal the geo-architectural works necessary to explain the functioning of the geomorphological characters of an overall design of the greenhouses. This analysis allows us to formulate the importance of the exposure factor and understand how the wall can: a) determine the

choice of location for settlement; b) identify the tectonic structure of the "Crystal Hill"; c) define the height of the plate; d) select the most exposed areas of the territory; e) contribute to the prevention of hydrogeological instability; f) configure the geometry and capturing surface of the greenhouses.

Terrestrial Paths. Terrestrial paths are generated by the persistent and incessant walking of man. The study of walkways reveals the logic of connections between geographical structure and geoarchitectural figures. These paths delineate man's passage from one place to another and decipher the human-territory relationship over time.

The pathways constitute the infrastructure of the geographical figures, materializing human transit and the need to connect the architecture of the Earth through a topological and topographic space, with the goal of linking the greenhouses and the city via roads. In the terrestrial paths of the greenhouses, the layout of the routes reflects the close relationship between anthropic spatialization and the geographical characteristics of the Gulf of Sanremo (Figure 7).

The relationships with the territorial organism develop through three key stages: a) the terrestrial paths of the promontory case-studies originate from the terrestrial figures of the ridge system; b) the terrestrial paths of promontory and hillside follow the logic of counter-ridge paths; c) the terrestrial paths of the hillside derive from the territorial syntax of half-cost paths.

These paths constitute a link with the past, an infrastructure that, during the phases of formation of the territorial syntax, has stratified and deposited in the paths the relations between land use and the geomorphological characters of the Gulf of Sanremo.

Finally, the *tabellone* method becomes, through the grid, a cognitive tool of cultural heritage that, by classifying, theorizing, and signifying the terrestrial figures of the Sanremo territory, allows the decoding of the "City of Flowers," recognizing a posteriori, in the context of the micro-decommissioning crisis, a new image of the city characterized by the system of the *machines du soleil*: the "Crystal Hill."

RESULTS AND DISCUSSION: THE CASE-STUDY OF THE FOCE VALLEY

The results of this study serve to formulate a critical reflection on the interconnected relationships established between forms before and after the time of Man. In describing the fragments of the territory, *les machines du soleil* operate as "*membrane cérébrale où s'affrontent immédiatement, directement, le passé et le futur, l'intérieur et l'extérieur, sans distance assignable, indépendamment de tout point fixe*" as the operating image of *les machines du soleil* "*n'a plus pour caractères premiers l'espace et le mouvement, mais la topologie et le temps*" (Deleuze, 1985: 164).

The *tabellone* produces the possibility of staging, all on the same plane, the thresholds of time and their interconnections, making these abandoned, non-productive and disused figures accessible. They become the logical statement for architectural design, territorial regeneration and landscape restoration in the widest possible sense.

Les machines du soleil operate in continuity with the logic of settlement in the past, in the present and for the future. The result is to rediscover the relations between the formativity of the facts of Man, through the identification and recognition of cultural heritage, in which the geographical condition aims to establish a connection with the image of the arché, spatialising the geomorphological relations

through the process of classification, theorisation and signification, with the aim of structuring the reasoning of the city's emergence through the word.

This passage is fundamental in order to understand how architectural design can intervene at the scale of the territory, staging the ancient relationship with the land and time, understood as a reinterpretation of a memory of things that "*n'est certes plus la faculté d'avoir des souvenirs: elle est la membrane qui, sur les modes les plus divers (continuité, mais aussi discontinuité, enveloppement, etc.), fait correspondre les nappes de passé et les couches de réalité, les unes émanant d'un dedans toujours déjà là, les autres advenant d'un dehors toujours à venir, toutes deux rongeant le présent qui n'est plus que leur rencontre*" (Deleuze, 1985: 269-270).

The notes for a Plan idea for the Foce Valley start from these assumptions. The discussion revolves around how it is possible to establish a model of territorial regeneration applicable to small and medium-sized cities, which rescues the places of micro-decommissioning from oblivion, where cultural heritage allows us to imagine and formulate responses to global challenges through architectural project. The case-study of the Foce Valley is interpreted through the experience of the *tabellone*, in which the analytical devices of *les machines du soleil* become the chosen places for formulating responses that operate in line with the logic of settlement concerning three themes: acclivity, exposure, and terrestrial paths (Figure 8).

The construction of the *tabellone* served to capture the cognitive aspect inherent in the devices, highlighting the permanence of the territorial characters already described in the travellers' accounts, generating further knowledge and awareness of the facts of Man and the territory.

The analysis investigates terrestrial forms through the *tabellone*, elaborating *les machines du soleil* as mnemonic devices that activate modes by which the territorial system and its formative processes can formalize responses to current, concrete, and contemporary problems. The definition of the notes for an idea of a Plan for the Foce Valley is rooted in the thematisation of the display *tabellone* and traces the forms in a path of signification between cartographic *corpus* and site descriptions, in which the places of the micro-decommissioning within the valley become intelligible, making it possible to imagine a regeneration project on a territorial scale in continuity with the becoming of the city.

The Foce Valley, originating from the confluence of the Massei and Gozzo streams, defines the Fallita coast upstream. The rio Massei, located in the upper west valley, originates at 650 m a.s.l. near the Poggi spring, while the rio Gozzo, located to the east of the valley, originates from Mount Carparo (910 m a.s.l.) and joins the rio Massei, giving rise to the Foce river. This conformation recalls the founding theme of the Pigna, reproducing the analogy with the figure of the archetype that lies between two valley systems, where the Pigna constitutes the confrontation with the figure that projects the arché of territorial facts. The Fallita coast ridge, between the Solaro and San Bartolomeo coasts, shows the typical characters of buildings in the hillside areas, exposed to the south-west and characterised by the presence of greenhouses. In the Foce Valley, the greenhouses present similar solutions to those found in the geomorphological relations of the hillside archetype, the ancient Rocca region, facing south-west of Pigna, known as the Borgo.

From the case-study of the Foce Valley, it is possible to deduce an operative retrospective that re-reads the site's transformations over time through its fragmentation, from the ancient "*Lemon Valley*"

described by Hassall in the 19th century (Hassall, 1883: 270), to the continuous fragmentation that is configured over time through the *hortus*, the garden, the house and the greenhouse. This scenario brings us back to the first aspect of the analysis of this study, in which the valley enunciates the founding role of an architecture that begins with the interplay between the orography and the architecture of water, bringing us back to the theme of "paving", the geometry of the earth's crust and, consequently, the terracing system.

This passage occurs through those territorialising and deterritorialising factors of which the territory has always been the geographical theatre. The figures – geographical and anthropic – present in the cartographies activate the outflow of territorial characters through *les machines du solieil*, bringing a new content and semantic impulse, where fragments of time – past, present and future – persist and insist in the architectural body of the greenhouses.

The construction of the three themes makes it possible to analyse the Foce Valley from a new perspective: the gaze rests on the greenhouses, aware of a new reading, where the construction of the grid starts from the phenomenon/epilogue of the crisis of the flower industry, enriched by the analysis matured on the ancient city.

When the architecture of Man collides with or lays on the architecture of the Earth, what Deleuze and Guattari call the process of *"déterritorialisation et de reterritorialisation"* (1980: 70), that is, the genomic passage in which fragments of archetypes – the type of promontory and the type of hillside, predating Man's time, prior to a signification that constitutes them as archetypes in Man's time, the segments of the wasp-orchid-wasp (Deleuze and Guattari, 1983) – re-emerge for parts in habitation, in greenhouses, in artefacts.

The results of this double reading produce an image with a strong semantic content, capable of further specifying the city through *les machines du soleil*. The figure of the promontory is signified through its relationship with the site – reinterpreting the relations of continuity with the first settlements – and becomes the *locus*. Thus, the process of deterritorialisation initiated by the greenhouse phenomenon re-establishes the encounter between the geographical machine and the reinvention of a critical reading of the territorial type – the promontory type – from which Man extracts and abstracts those segments/fragments, the latency of the archetype, in line with the Deleuzian relationship.

This relationship makes it possible to rediscover, in the case-study of the Foce Valley, the type of hillside as well as that of promontory, as autonomous and complementary elements that structure, exercise and show the continuous and unceasing relationship between geographical form and water system.

CONCLUSIONS

The conclusions of this text, like the research itself, are becoming, they do not conclude; the end represents the plausible beginning of something else. They are intended to image the possibility of seeing in the geographical form a timeless myth through which new scenarios can be unveiled/formulated (Figure 9).

The work described here has the opportunity to further formalise and specify the multiplicity of interconnected fields of investigation. The case-study of the Foce Velly shows, through the system of

greenhouses, how anthropic structures are located within a geographical grammar that is a structuring part – formal and cultural – of becoming a city.

From the textual and formal analysis emerges a reflection on the relations between territory, urban form and cultural heritage, in which the interpreting system of the territorial syntax is given by the analytical reading of the phenomenon of the micro-decommissions of Sanremo, or *les machines du soleil*.

The central concept of this argument is the reading of geography as semantic transfer from one body to another. The arché becomes transeunte – in the time of Man – in the sense that, in *transire*, it becomes the subject of becoming. Its destiny is realised in the incarnation of the architectural body, in the proposition -*trans*, which goes beyond, passes through and, as passing through, releases and crystallises, remaining part of the principle of things in the act of settlement/construction. This occurs in the illatency of those fragments derived from Man's interpretation of them when he has to relate to the archetypes of promontory and hillside.

Through the classification of landforms, two *tabelloni* of *machines du soleil* are established, representing a general order of the interconnections between urban and territorial facts. This method of analysis makes it possible to rethink urban and territorial transformations as the result of a formal relationship between architecture and geography, arranging these places – the Foce Valley and, in the future, the entire Sanremo district – as propositions for the architectural project.

This gaze is articulated and defined through the analysis of expositional, pedological, panoramic, connecting, controlling, etc. conditions, the nodes of the interconnection between things, between being and being, in that ancient sense of the discourse on becoming, in which "*from nothing comes nothing...* [and as such] *the generation of something is but transformation or, according to others, composition and separation*" (Aristoteles and Severino 1995: 40-41).

The process of urbanisation is, in this case, seen as the decoding of pre-existing geographical and geomorphological elements. *Les machines du soleil* become hinges between urban and rural; the greenhouses represent the places of the periphery, the critical, neuralgic, unresolved situations that are located in the *transurban* and reinterpret the face of the Earth as a new opportunity.

Through the study of the transformations that led to the formalisation of the culture of cut flowers, it is possible to investigate an economic and social model that, over time, has reinvented itself through the constant transformation of land use.

The notes and drafts for the idea of the Foce Valley Plan are oriented towards building paradigms of sustainable development to counter and mitigate climate change. Through the re-signification of the image of the "Crystal Hill" and the analytical devices of the *machines du soleil*, places are identified to shape a strategy of territorial, energetic, social and economic regeneration: a model of a sustainable valley that starts from the study of the shape of heritage.

Greenhouses, representing the last stage of a continuous reinvention and interpretation of the Earth's forms, hold the cyclical memory of this exaggerated use of the soil and constitute the manifesto of Man's fatigue. From the unsustainable profitability of olive groves and vineyards to their progressive uprooting, part of the Mediterranean beauty has been wiped out to make room for the more

convenient production of flowers and plants, fragmenting and geometrizing the soil and giving rise to a new image.

In line with the objectives of the Green Deal, the COP28 scenarios and the Net-Zero Emissions 2050 (NZE) scenario, the Foce Valley case-study aims to unite agriculture with the production of energy from renewable sources, imagining a model not only for the renewable energy sector, but also capable of creating jobs and new opportunities.

It is possible to start from the founding values of cultural heritage to imagine future transformations. In this perspective, advanced agri-voltaics would become part of a system of design actions aimed at combating climate change, giving rise to interventions involving the environmental resources (soil, water, biodiversity, ecosystem services) and cultural heritage (material and immaterial) of rural and peri-urban areas. These rural areas, if not properly governed, studied and designed according to ambitious European regulations and strategies (Perpiña Castillo et al., 2024; OECD, 2012; OECD, 2006; IRENA, 2024; IEA, 2024), risk damaging the economic, human, social, physical and natural capital specific to these territories.

Liguria is the last region in terms of investment in and consumption of renewables (Italy for Climate, 2022: 16). It has the lowest national motorisation rate (Italy for Climate, 2022: 14). The risk status of ecosystems is classified as vulnerable, with highly endangered areas (ISPRA, 2023: 73). In addition, the region shows a national trend of increasing soil consumption (Munafò, 2023; SNPA, 2023: 78-79), occupying the penultimate place nationwide for agricultural areas with organic production methods (SNPA, 2023: 72-73). Agronomic practices should ensure levels of environmental quality and biodiversity, as well as the wholesomeness of food and the welfare of farm animals, in line with the structural objectives of the *Farm to Fork Strategy* (European Commission, 2020), a central initiative of the Green Deal.

In this scenario, the study transforms the analytical devices into design tools: the ‘wall’ -the exposure- becomes the investigative tool to understand where and how to install renewable energy production plants; the earth paths provide the syntax for the design of the energy management and distribution system, while the system of ‘plates’ enshrines the topological space intended for the project - monitoring, storage, etc. These elements are the material for analysis to unite agricultural and food production in parallel with energy production, monitoring and counteracting the loss of biodiversity, improving soil water retention, orienting these places towards new possible futures.

The new image of the sustainable valley, the “Silicon Valley”, can through advanced agri-voltaics establish a scientific and holistic reading of the territorial system, helping citizens of rural and peri-urban areas to build an equitable society, based on a clean and accessible energy system, consistent with settlement logic and heritage.

Between the plateau and the plain: the phenomenology of the system Anchieta-Imigrantes

Peter Ribon Monteiro[1]
[1] Architecture and Urbanism Course, Mauá Institute of Technology, Brazil, peter.monteiro@maua.br

ABSTRACT

The route between the Planalto Paulistano (plateau at 700 to 800 metres high) and the Baixada Santista (plain at the level sea), composed by two motorways (Via Anchieta, the 'old' one, and Rodovia dos Imigrantes, the 'new' one) constitutes the link between the largest urban concentration (Metropolitan Region of São Paulo) and the main port region in Latin America (Santos), and can be seen as an outstanding element in the history of global urbanization. In addition to this, it also stands out for sitting on a natural landscape – a section of the Serra do Mar– endowed with significant Brazilian physical-geographical references. In this sense, this system (both paths) lies at the heart of decisive processes for architecture and urbanism in the country: original peoples tracks, Portuguese colonization on the seafront, urban sanitation plans, the emergence of the industrial park, the constitution of the metropolis, the formation of the financial centre, rail and road transport connections, irregular occupation and the preservation of natural reserves. Delving into this understanding, we move on to two specific analyses of our object of study, understood as a sign full of meanings that expand, from the high to the low and vice-versa, to these two urban territories. The first analysis focuses on the description of the territory on which it was built (physical-geographical character) and the main movements of its own construction (historical-urban character); while the second is composed by the perception, from a phenomenological point of view, of this constructed scenario. Based on a semiotic structure of understanding, in its syntactic, semantic and pragmatic character, we then identify values, absences and presences that reverberate in the current double path (Anchieta and Imigrantes) since before the formation of the current urban centres, fundamental to appreciation of the still preserved natural landscape and its importance for the cultural landscape of Brazil.

Keywords: Environmental perception, Via Anchieta, Rodovia dos Imigrantes, semiotics, phenomenology.

INTRODUCTION

The system of roads between the Planalto Paulistano (Paulistano Plateau) and the Baixada Santista (Santista Lowlands)[2] is the link between the largest urban concentration and the main port region in Latin America, two relevant areas of the world urbanization. Besides that, is located on a stretch of the Serra do Mar (Sea Mountain Range) - a significant Brazilian natural landscape.

[2] The most important names are kept as original in Portuguese and translated at first time they appear in the text. Paulistano is related to someone or something from São Paulo city, while Santista from Santos city. In the case of Baixada Santista, it is related not only to Santos but all metropolitan area where this city is the main one.

Composed by the Via Anchieta (Anchieta Road) and the Rodovia dos Imigrantes (Immigrants Road) the Anchieta-Imigrantes System is at the heart of decisive processes for architecture and urbanism in Brazil since the beginning to now, such as Portuguese colonization by the sea, urban sanitation plans, the emergence of the industrial park, the establishment of the metropolis, the formation of the financial centre, rail and road transport connections, irregular occupation and the preservation of nature reserves. Since this route is a production of these processes, could we also understand and conceptualize it as an architectural-urbanistic object?

In 'The Aesthetics of Architecture', Roger Scruton[3] (Scruton, 1979) identifies *function* as the first distinctive feature of architecture. In this context, there is no greater utility than the plateau-plain route, which, from the 16th century to the present day and under various designs, indispensably connects the country's largest metropolitan region and the Santos lowlands, its presence being directly linked to the founding of the city of São Paulo, one of the biggest cities of the world.

As another distinctive feature, the author emphasizes the quality of *place* and the intrinsic relationship between the object and the environment in which it is inserted - which presupposes primary concepts such as nature versus culture and tradition versus modernity. The influence of a sui generis geography such as the Serra do Mar on the design of the connections between Santos and São Paulo, including the current System, is undoubted.

A third trait pointed out by Scruton is the presence of *technique*, the 'extension of human competence', and nothing is more representative of this than the evolution of the paths, and the power of the engineering, to permit one to reach the highlands across the huge mountain covered by the Atlantic Forest.

The author also points to the *public character* of the architectural object, responsible for its imposition on the built landscape and its consequent exposure, clearly differentiating it from other arts. Allied to this, he highlights its political nature and human and social representation, which no one can avoid experiencing in some way. Considering this specific scenario, who would be indifferent to what is imposed between the sea level and the almost 800 meters of altitude of the plateau?

METHOD

By considering the hypothesis that the Santos-São Paulo plateau-plain route system can be included in the field of architecture and urbanism as a very significant sign, two specific analyses are defined for this study: while the first one focuses on the description of the territory on which it was built (physical-geographical character) and the main movements of its own construction (historical-urban character); the second is composed by the perception, from a phenomenological point of view, of this constructed scenario. This double analyse is related to a methodological path already indicated in my master and doctorate degree, completed in 2002 and 2010, respectively, at the Faculty of Architecture and Urbanism of the University of São Paulo (FAUUSP). Both research considerer environmental perception theories to understand important elements of the urban form of Vitória (Espírito Santo) and São Paulo[4]. Based on a semiotic structure of understanding, in its syntactic, semantic and pragmatic character, this study aims to identify values, absences and presences that reverberate in

[3] Scruton, 1979.
[4] Monteiro, 2008 and Monteiro, 2010.

the Anchieta-Imigrantes System, fundamental to appreciation of the still preserved natural landscape and its importance for the cultural landscape of Brazil.

These studies culminated in the following key representation, which understands the architectural object (and also the city) as Gestalt[5], but extends the concept beyond the figure-ground relationship only on a special level: {[(figure/ground) x subject] x verb}

Besides that, it considers the understanding of the sign in its simplest character (the compositional structure itself) to the most complex (the use of space), recognizing the value of form as a signifier through the historical apprehension of use.use → meaning → form ← meaning ← use

The Anchieta-Imigrantes system, then, is understood as a sign, to be observed in two stages:

- History (on Geography): understanding the historical construction of the sign, in its most relevant characteristics.

- Geography (on History): understanding the current configuration of the sign - at the three levels of the semiotic approach - taking into account the values assigned historically.

RESULTS AND DISCUSSIONS

The natural territory

The Serra do Mar, a transitional territory between the Metropolitan Region of São Paulo and the Metropolitan Region of Baixada Santista, is a territory classified as a plateau in an orogenic belt, whose formation refers to intense folding followed by erosion processes. It is a mountain range linked to the so-called Atlantic belt, and to the set of plateaus of the eastern Atlantic, the most complex in the country. In general, it consists of a crystalline bedrock with heights of between 800 and 2,000m (highest points), forming an imposing barrier, with a predominant direction almost parallel to the sea coast, on which it sometimes leans. It stretches for more than 1,000km from the north of Santa Catarina to the north of Rio de Janeiro State[6].

Below the Serra do Mar is the Baixada Santista, a typical Brazilian plain, whose design is basically characterized by a flat relief generated by the deposition of recent sediments of marine, lacustrine or fluvial origin. It was in this lowland that the first Brazilian town - São Vicente - was officially founded in 1532, next to the island of the same name. Thirteen years later, the town of Santos was founded, nearby, and afterwards became more important. By including Santos as its economic centre, the Baixada Santista urban agglomeration includes nowadays the cities of Bertioga, Cubatão, Guarujá, Itanhaém. Mongaguá, Peruíbe, Praia Grande and São Vicente, set over islands, rocky outcrops and mangroves, representative elements of the southeast Atlantic coast

Above, as a backdrop to this flat region, the Planalto Paulistano is located, at an average height of 800 meters, forming a veritable natural wall drawn by escarpments on which various connecting paths were drawn between one territory and another. By using original peoples routes as a reference, the new European inhabitants were able to overcome the steep slopes of the Serra do Mar as early as the 16th century, which led to the foundation of a number of towns on the plateau, including São Paulo. Founded in 1555 on a plateau between the Anhangabaú stream and the Tamanduateí river, the city became the most advanced boca-de-sertão at the beginning of Brazilian colonization. From its urban nucleus, known as the Triângulo - an interfluvial plateau situated between 700 and 800 meters above sea level, already detached from the Paulistano Plateau complex - it was possible to access the interior of São Paulo state via the Tietê River, the main route into the region.

The former tracks and the Calçada de Lorena (1792)

There are indications that the original peoples who lived on the Planalto Paulistano, at certain times of the year, went up and down the Serra do Mar, between the plateau and the plain, to fish in rivers and in the ocean, bringing sun-dried fish back to their villages. To do this, they used narrow trails that started and ended at various points. One of these trails was the old Guaianases trail (Piaçaguera Road), which was used by Martim Afonso de Souza and João Ramalho on their first ascent to the Piratininga fields in 1532. The route, on the plain, went from São Vicente to the so-called port of Piaçaguera de Cima on the Cubatão river, by canoe. From there, the Ururaí river valley was crossed overland to the plateau.

A new route - considered safer - was opened by the Portuguese. One version suggests that the opening of this was ordered by Governor-General Mem de Sá in 1553, in order to avoid harassment by the original peoples. Because it was supervised by José de Anchieta, this road was known as the Caminho do Padre José (Padre José Way). During its activity, important events in the Brazilian colonial period were linked to this road, such as the foundation of Santo André (1532) and the foundation of São Paulo (1553).

In the middle of the 17th century, the governor of the Captaincy[7] of São Vicente ordered the construction of a new road, which several bridges over watercourses along the way to allow better passage for carts and carriages. The route reduced considerably the steep stretch along one of the

[7] Division of regions at Colonial time (1500-1822).

hillsides, although required a considerable zigzag design on the slope. Used for a century, this road was then restored by Governor Bernardo José de Lorena and it became the Calçada do Lorena (Lorena´s Sidewalk). The renovation, designed by Portuguese military engineers, included work on the entire sidewalk, the installation of parapets in the most dangerous places and a monument on the peak of the mountain. The paving of this road with stone slabs became a landmark and consolidated the connection between the highlands and the lowlands by assigning a defined place. By the government decision, the territory then demarcated became the official route connecting the sea and the hinterland and allowed the permanent transit of mules[8].

By bringing Santos closer to São Paulo, the Calçada do Lorena became a symbol of a new dynamic in the state, consolidating the link between the internal world (the Brazilian hinterland) and the external world (the Portuguese metropolis). Although "smaller" compared to the Royal Road, the plain-to-plain link was part of a larger network of roads (river and land) that had been gradually developing in the captaincy of São Paulo, geared towards an economy of internal markets, based on commercial activity. While Santos developed as an export centre, São Paulo took on its role as the "radiating centre of roads" and was no longer isolated from the rest of the country.

At the same time as the royal roads connecting the ports of Rio de Janeiro to the captaincy of Minas Gerais, Brazil's gold region, began to decline, the Calçada do Lorena became the "most notable" road in colonial Brazil, consolidating the sugar cycle in São Paulo and commercial interests.

The Estrada da Maioridade (1841) / Caminho do Mar (1922)

In 1841, a new route is created, reinforcing the junction between the plateau and the plain. With a width ranging from four to seven meters, the road was inaugurated by Emperor Dom Pedro II in 1844. In his tribute, it was named the Estrada da Maioridade (Majority Road). The road is filled with curves, laid out alongside one of the slopes of the Serra do Mar, from the current Henry Borden Valve House to the base near the Presidente Bernardes refinery. At times, it crosses the Calçada do Lorena, whose use is then practically abandoned. Some years later, after improvements, the road changed the name to Estrada do Vergueiro (Vergueiro Road). The construction of the railway from Santos to Jundiaí (1867) gradually led to the decline of road usage during the late 19th century. With the emerging automotive era, the first car journey took place in 1908, when the road already showed visible signs of deterioration.

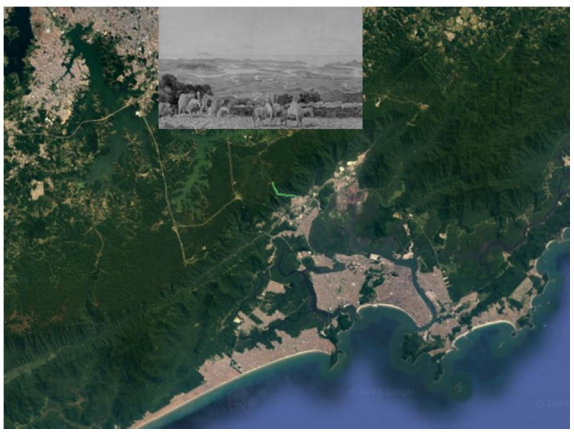
After a period of neglect, a new action by the state government, initiated in 1912, brings the road back to life with new improvements and slight changes to its layout. The road, then called the Caminho do Mar (Sea Way), is paved with macadam, a new drainage system is implemented, retaining walls and supports against landslides are built, as well as a new bridge over the Cubatão River. It becomes the first concrete-paved road in Brazil.

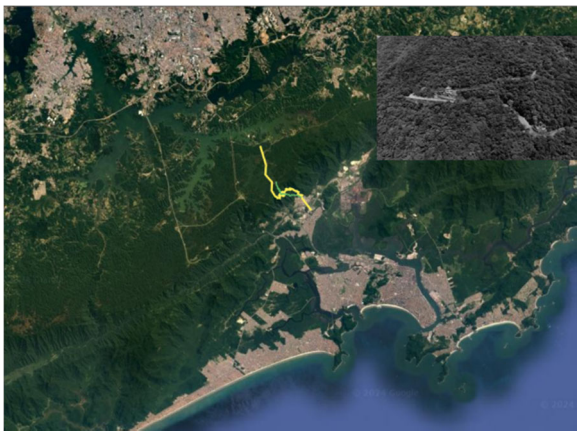
A quite significant moment occurs in 1922, when a series of monuments is inaugurated along the road. To celebrate the 100th anniversary of the country's independence, the governor of the State, Washington Luís, invites the architect Victor Dubugras[9] to design a series of works along the path,

[8] Mendes, 1994.

[9] The architect Victor Dubugras (1868-1933) was born in France but raised in Argentina and based in Brazil, where achieved prestige for designing works such as the redevelopment of Ladeira da Memória in 1921, in São Paulo, and the inss and monuments of the Caminho do Mar (1921/1922), in neocolonial style.

harmoniously aligned with the geography of the place. Such monuments, designed in Neocolonial style, stand out not only for their historical value but also for the way they rest upon the landscape, marking specific places within this setting. The road, monuments and landscape come together in a unique way[10].





Figures 2,3 and 4, 5. Calçada do Lorena (in green) and Caminho do Mar (in yellow). Map credit: Google Earth (edited by the author). Painting credit: Oscar Pereira da Silv. Photo credit: www.turismodenatureza.com

Beyond the integration with the physical geography of the area, the group holds great historical value, constituting an important architectural and landscape heritage. In its Neocolonial architecture, the use of granite with the Portuguese paving technique stands out, along with tile cladding highlighting architectural elements (pediments, friezes, murals, and bases), the use of clay tiles in exposed roofs, and the presence of balconies and porches. The drawings of the artist Wasth Rodrigues[11] reinforce the artistic value of the works, which aim to recover a genuinely Brazilian aesthetic, even though it is connected to the baroque of Portuguese origin. The strategic location along the route creates a harmonious relationship with the surrounding landscape, by allowing impressive views.

At the highest point of the Serra, the Pouso de Paranapiacaba (Paranapiacaba Inn) is located, still in São Bernardo do Campo city. From the balconies, it is possible to have an exceptional view of the landscape and the sea. The program includes a central hall, sheltered, with a fireplace, and balconies, arcades, and external landings. Next, along the path to the plains, you will find the Belvedere Circular, which, in addition to offering another privileged view of the landscape, stands out as the first intersection of the Calçada do Lorena – the previous route – and the Caminho do Mar. From this point, it is possible to enter the sidewalk and then exit at the next intersection further down. Following the road, the next monument is the Rancho da Maioridade (Majority Ranch), which was also built to serve as a resting place for tourists, and was named in honour of the road's name before it became the Caminho do Mar. In the unique implementation, the architectural elements are presented: a semicircular balcony along the curve with tiles that evoke the Portuguese baroque. Right after that, there is the Padrão de Lorena (Lorena´s Standard), which marks the third and final meeting between the sidewalk and the road. It is named in honour of the man who ordered the construction of the Calçada do Lorena. At the plain, there are two monuments: the Raiz da Serra Bridge - which was built

[10] Toledo, 1966.
[11] José Wasth Rodrigues (1891-1957) was a Brazilian painter, draughtsman, illustrator, ceramist, teacher and historian.

to mark the end of the asphalt paving on the road – completed in 1926- and the 16th-century Cross, which stands out for marking the intersection between this path and the Caminho do Padre José.

Despite the advantages, the rapid increase in vehicle traffic soon makes the road inadequate for the growing flow of vehicles and the constant landslides during the rainy season. In 1947, after the inauguration of the Via Anchieta, the Caminho do Mar became a secondary route and was renamed Estrada Velha (Old Road). In 1985, the road was decommissioned. Between 1992 and 2004, it was renovated and became an ecotourism hub. Nowadays, the road is open to visitors on foot or by bicycle, maintenance vehicles, or minibuses from the São Paulo Historical Energy Heritage Foundation, which manages the Ecotourism Hub Caminhos do Mar. Part of the Calçada do Lorena is also reached inside the park.

The parallel paths: Estradas-de-Ferro Santos-Jundiaí (1867) and Mairinque-Santos (1937)

Still at the mid of the 19th century, a new road connects the plateau to the plain, but without replacing the Estrada da Maioridade motorway. The expansion of coffee culture in the interior of São Paulo state necessitaded a more effective route for transporting the product to the port of Santos for export. The Estrada-de-Ferro Santos-Jundiaí (Santos-Jundiaí Railway) is then designed and built.

The railway was inaugurated in 1867, along with urban centres in the plateau, crossing São Paulo at Luz Station and starting the descending from the Alto da Serra station, in the new village of Paranapiacaba. On one side of the track, the English designed and built a very complex funicular system just after the village, an entire neighborhood called Vila Martin Smith, to house engineers and staff in wooden residences with slate roofs. Important buildings stand out in the ensemble, such as the Castelinho (residence of the chief engineer), the Lira Paulistano club, etc. The station, in turn, drew attention for its English-origin design, a clock tower, and the machinery system. The development stands out for the quality of its buildings and streets, turning this area into a historical heritage site[12].

For many years, passengers and goods traveled down the Serra do Mar by train. In 1946, with the end of the São Paulo Railway concession, the process of decline for the village and the railway system begins. In 1970, the funicular system was partially deactivated to make way for a new transportation system, the rack-and-pinion. The Valongo Station in Santos, the last one in the system on the plain, remained active until 1995, when passenger use was discontinued.

Running parallel to the two existing routes - the Caminho do Mar and the Santos-Jundiaí railroad - the Estrada-de-Ferro Mairinque-Santos (Mairinque-Santos Railway)[13] was also planned in the 19th century but inaugurated only in 1937. With a length of 155 km, it was designed to break the monopoly of the São Paulo Railway (“the English”) on the descent from the mountains to the port of Santos, constituting a branch of the Sorocabana railroad, built by the American Brazil Railway Company, which already connected São Paulo (Júlio Prestes Station) to Sorocaba and the western part of São Paulo state. This railroad was built with a maximum gradient of 2%, which allows for a maximum speed of 64 km/h. The descent of the Serra do Mar begins at an altitude of 740 meters at the Evangelista de Souza Station, in São Paulo, and ends near sea level at the railway yard of Paraitinga, in São Vicente.

This rugged stretch of mountain features 27 tunnels, already built with dimensions to accommodate the future duplication of the railway line.

Figures 6,7 and 8, 9. Estrada-de-Ferro Santos-Jundiaí (in light blue) and Estrada-de-Ferro Mairinque-Santos (in dark blue). Map credit: Google Earth (edited by the author). Photos credit: RFFSA; www.ampfmairinque.org

In 1957, the Evangelista de Souza station, in the highlands, became the junction point for the Jurubatuba branch, directly connecting the city centre of São Paulo to Mairinque-Santos. After the creation of FEPASA in 1971, the branch became part of the Araguari-Santos Export Corridor, undergoing several improvements. However, while cargo transport was encouraged, passenger traffic was decreasing, first limited to the Embu-Guaçu to Santos stretch in 1975, until it completely ceased to exist in 1997, when the branch was granted to the private sector.

Nowadays, this stretch is managed by Rumo Logística, which fully doubled the route in 2015 as part of the works for the main export corridor of Brazilian agribusiness. In the same year, the Santos-Paratinga stretch (Praia Grande) began to be used as the track for the VLT for intermunicipal passenger transport in the Baixada Santista.

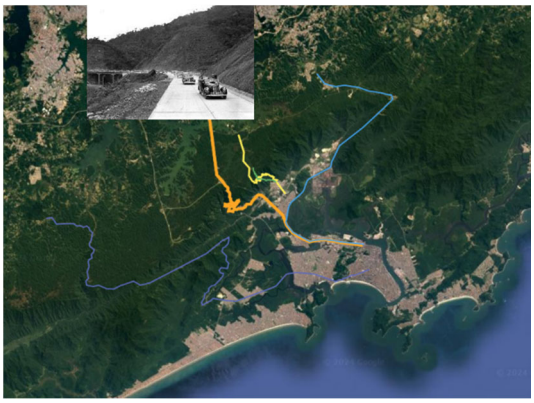
The Anchieta-Imigrantes System (1947, 1976)

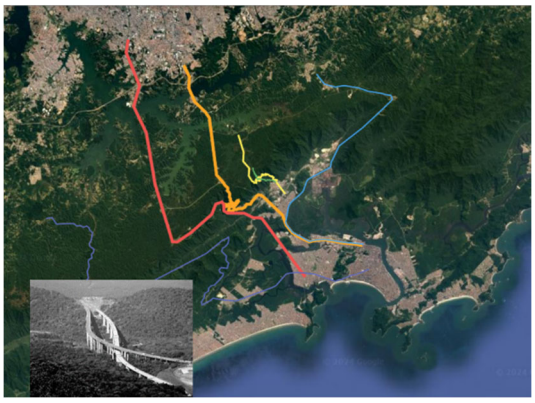
Despite the effectiveness of railways, with rapid urban growth and increased use of motor vehicles, the Sea Road soon becomes limited. A new road is then built, going to be used parallel to the two railways and the (now) Old Road of Santos. For several decades, connections between Santos and São Paulo could be made in various ways.

Father Anchieta, a prominent figure in the colonial history of São Paulo and, indeed, of Brazil, is once again honoured in the 20th century with the new motorway connecting the plain and the plateau, introduced in 1929 as part of the Prestes Maia Avenue Plan. The Via Anchieta, as it is known, employs more advanced techniques than those used on the Caminho do Mar, which soon becomes underutilized and starts to be referred to as the Old Road of Santos. The inauguration of the north runway takes place in 1947, while the south runway is established in 1953, both with two lanes each.

The new road starts, at its highest point, in the city of São Paulo, in the Sacomã neighborhood, passing through São Bernardo, Cubatão, and Santos, providing access to the other cities (São Caetano, Santo André, and Diadema) as well as to the old Caminho do Mar. Like this, it features in its design – over its 72 kilometers – many curves, on a route that often follows the very outline of the mountain range, whose proximity is still very evident. On the other hand, it is innovative in presenting some tunnels

and overpasses that either discreetly penetrate the massif or subtly leap over small valleys. Its use has been explored since 1969 by Dersa, a state-owned company. In 1972, tolls were installed. In 1998, the highway was then privatized, and a consortium of private companies was granted concession until 2018 for the operation and maintenance of the entire Anchieta-Imigrantes system.





Figures 10,11 and 12, 13. Via Anchieta (in orange) and Rodovida dos Imigrantes (in red). Map credit: Google Earth (edited by the author) / Photo credit: www.saobernardodocampo.info; public domain.

Thirty years after the inauguration of the Via Anchieta, a new and more moder road was created to connect plateau and plain. The Immigrant Highway, or SP 160, was planned and built with the aim of serving as a broad export corridor between the largest industrial complex and the largest port in Latin America, carried out by the Department of Highways of São Paulo (DER-SP), with about 100 engineers and 13,000 workers. At that time, it was considered the largest road engineering project in Latin America and one of the five largest roads ever built in the world. Nowadays, it is the main access route from the city of São Paulo to the Baixada Santista and the southern coast of São Paulo.

It was built in two phases, with the first phase starting in 1974 and inaugurated in 1976. The North Track was initially designed for ascending traffic only, and then it was reversed according to the flow of vehicles. Started in 1998, the South Track was inaugurated in 2002. The work was carried out by Ecovias, which was granted the concession for the highway for 20 years. Unlike the North Track, it featured more modern overpasses, as well as longer tunnels - totaling 8,200 meters in length across four sections. The first one, at 3.2 km, was considered at the time the largest road tunnel in Brazil. It is also noteworthy in the construction of this track the use of new technologies for maintenance, such as ventilation jets, sensors for noise reduction, heat detection and wind measurement, and smart accident cameras. Extensive tunnels and viaducts were necessary to ensure that the environmental impact on the Serra do Mar was minimal during the construction of the South Track[14].

The Rodovia dos Imigrantes has an incline of about 6%, which prevents buses and trucks from traveling safely on its lanes. The main users of these highways are, therefore, private cars. Despite the generous number of lanes, for years the Anchieta-Imigrantes System has been unable to handle the enormous flow of vehicles using the motorways to reach the beaches of Baixada Santista and the South Coast, especially on festive dates, especially in summer. A prominent engineering work on the national scene, these two tracks consist of impressive viaducts, bridges, and tunnels, by reducing considerably the time to cross the range.

[14] Ecovias, 2024.

Nowadays, the connection between the plateau and the plain is primarily made through the Anchieta-Imigrantes System, via motor transport, since the Caminho do Mar has become a tourist park while the railways only transport goods. Meanwhile, we understand all the former paths still reverberate on this one, historical and geographically.

The syntax

From a syntactic point of view, it is possible to see that, as time goes by, the route between the plateau and the plain becomes longer - from Calçada do Lorena to Rodovia dos Imigrantes - but also increasingly direct. At the same time as it grows, on the uphill stretch, the route becomes increasingly distant from the territory, aided by artificial elements that fly over (bridges) or penetrate (tunnels) the natural landscape. The zigzags and sharp curves of the Calçada do Lorena and the Caminho do Mar give way to the straights and open curves of the railroads, and within the system itself, the Rodovia dos Imigrantes increasingly expands to speed up the route in relation to the Via Anchieta. New means of transportation allow for greater speed and São Paulo and Santos, with the passage of time, become closer and closer. Nowadays, on a normal traffic, it's possible to go from the city centre of São Paulo to the city centre of Santos in one hour, something impossible to imagine at the colonial time. Time after time, the plain and the plateau get closer. At the same time, direct contact with the territory, solidified by the stones of the Calçada de Lorena and, later, by the concrete of the Caminho do Mar, will increasingly demand devices to traverse over (bridges) and under (tunnels) nature. These elements - already necessary for the railroads - are then emphasized in the Anchieta-Imigrantes System.

Figures 14 to 21. The sintax of the System: then and today. Photo credits (black & white): public domain / Theodor Presing / MSR / public domain // Photo credits (color): Ecovias / Jornal da Orla / Ecovias / Ecovias

From the outset, the challenge of overcoming the 800-meter height in its irregular shape required a great deal of effort and economic and political resources to make significant engineering works possible. The stones of the Calçada do Lorena, the concrete of the Caminho do Mar, the special structures of the bridges and tunnels of the railroads and their improvement in the Anchieta-Imigrantes system, bring to light the gradual technical strength in the historical path of the design of roads between plateau and plain. Increasingly, São Paulo - the radiating hub to the interior of the country - and Santos - the radiating hub to the exterior - have come closer together, in a process of increasingly faster, albeit longer, design. To this end, it is made up of a system recognized as one of the most important engineering works in the world, just as the Caminho do Mar, the railways and even the Calçada do Lorena were at the time. the best engineering works of their time: motorways, railroads and roads.

Technique is present not only in the construction of the design but also in the evolution of means of transportation, from mules to trains, cars, buses and trucks. It is also responsible for the elements that will allow greater protection against natural accidents and "equalize" the route, making its irregularity less and less noticeable. Bridges cross rivers and valleys while tunnels pierce mountains.

The semantics

Because it crosses such a special area, there are many meanings present in the Anchieta-Imigrantes system. Starting with the names: Anchieta in honour of the founding priest of São Paulo, recovering the name of one of the primitive roads; and Imigrantes in honour of those who helped the region's economic growth. Just as the Caminho do Mar was named after its main investor, Vergueiro, and the Barão de Lorena gave his name to the Calçada. Inland and coastal areas are also named after the railways (from Santos to Jundiaí and from Mairinque to Santos). History is present in the naming of the roads, although the original peoples - responsible for the first trails - have been forgotten.

Figures 22 to 29. The semanthics of the System: then and today. Photo credits (black & white): CATV / public domain / Ricardo Koracsony / Anderson Bianchi // Photo credits (color): Ecovias / Urbana / Ecovias / Eduardo Knapp

In the history of the meanings of its design, one can also see how economic periods are reflected in the roads. At the same time that the paving of the Calçada do Lorena symbolizes the commercial function between the plateau and the plain linked to the sugar economy, and the Santos-Jundiaí railway symbolizes the function related to the coffee economy, the Way of the Sea demonstrates the supremacy of the road system, then framed by monuments that honour one hundred years of Brazil's independence, seeking a new aesthetic in its colonial past.

In addition to the route itself, other architectural objects also demonstrate public significance, such as the train stations built below and above the Serra do Mar. With the end of passenger transportation, many were abandoned, such as Marsilac Station, in the south of the São Paulo capital, and Valongo Station, the most important in Santos which, thanks to its aesthetic and historical value, was later restored and today houses a museum. Others ended up adapting to other railway systems, on an inter-city scale - whether on the plains or the plateau - as is the case with Luz Station in São Paulo.

The Anchieta-Imigrantes system speaks to us about the pride of São Paulo's labor, names the Catholic catechization and the immigration of the workforce, all those responsible for the progress of the richest city in the country. In this gradual eloquence, it distances itself from the paths of original peoples, from the colonial stone road, from nationalist monuments, and from imported railways. At

the same time, it owes its existence to all the other paths. Acting on the great wall of mountains, it interferes and modifies.

The pragmatics

In terms of use, it is undoubtedly possible to identify the importance of the Caminho do Mar for the sense of place. Here, the road was not only considered a connection, but also an opportunity to access spaces for viewing the landscape. The inns and stops were spaces to value history and contemplate the Serra do Mar and the Baixada Santista. This character is strengthened by the set of works of inestimable aesthetic value created by Dubugras. Although it is more heavily trafficked than Calçada do Lorena, the highway takes advantage of the rugged topography, featuring a design full of curves. Embracing this harmonious relationship with nature, the Path of the Sea incorporates architectural elements that will serve as moments for resting and appreciating the landscape. Allied to an aesthetic that seeks a national reference – even if it is rooted in the Portuguese colonial past – reinforces the idea of place. Once again, a landscape scenario "in between" is drawn - neither a plain nor a plateau, the Caminho do Mar enhances the identity of São Paulo and becomes a national heritage. Unused for a long time, it became in 2004 not just a park, but an open-air museum, where it is possible to identify a harmonious relationship between architectural objects and the territory. Like in the old colonial cities of Brazil – where the interrelation between built objects and elements of the natural landscape is visibly present – it constructs an identified cultural landscape.

Figures 30 to 37. The pragmatics of the System: then and today. Photo credits (black & white): Google Earth / Caminhos do Mar Park / ATP Cultural / Pulsar Imagens // Photo credits (color): Google Earth / Cobrape / Google Earth / Eduardo Knapp

On the Anchieta-Imigrantes system, there are no terraces to contemplate the landscape, no buildings or monuments that pay tribute to the history of the country and its geography. On the long and fast Imigrantes journey, there is no time to appreciate the landscape. There is no place to rest or to contemplate the delicate (and monumental) poetry of the connection between plain and plateau. Delays only occur on foggy days, when visibility is lost, or in undesirable traffic jams. Despite the complementary views (flying and diving), the Anchieta-Imigrantes complex is still just a passageway. There are only a few glimpses (stops for safety, maintenance and eventual accidents), whose main purpose is not to rest and admire the scenery.

Meanwhile, as contact with nature is lost in the new routes, poor neighbourhoods have sprung up in the environmental protection area, revealing the social differences that are still present in the country. Without proper planning, neighbourhoods occupy the plain and climb the slopes, in precarious constructions. They reveal the social inequality of the country and the precarious life in delicate

natural areas. For some of these places, even direct access from the Anchieta-Imigrantes system is not permitted.

CONCLUSIONS

A territory of large dimensions, Brazil offers considerable diversity in its relief, that, combined with other common natural factors - climate, hydrographic system, vegetation – shape significant specific areas within the context of the Brazilian landscape, such as the numerous mountains and valleys amidst the Atlantic Forest of the Southeast, where the Planalto Paulistano and the Baixada Santista are located. In the appreciation of Brazil's physical and natural landscape, the coastline stands out not only for its geographical formation but also for the fundamental role it has always played in the social structuring of Brazil; its analysis, therefore, raises numerous questions related to the understanding of both Brazilian geography and history.

In this context, the connection between Santos and São Paulo, which required a significant effort of transposition since the 16th century, became a key point in the structuring of the largest economic centre in the country. While the Northeast and, later, Rio de Janeiro and Minas Gerais profited from the first major economic cycles linked to colonial Brazil (sugar and gold), São Paulo region was preparing for rapid development starting in the 19th century, reinforcing its role as a gateway to the hinterlands and a radiating centre. In fact, the building of the connections between the plateau and the plain contributed significantly to make São Paulo the richest city of Brazil. In this sense, it can be said that the Anchieta-Imigrantes complex is an expressive visual communication system, a truly integrated visual message[15], full of meanings constructed by its design: interrelated natural and artificial landscapes.

From the analysis carried out, it can be seen that Anchieta and Imigrantes, in their geographical and historical context, in fact reveal the characteristics pointed out by Scruton to be understood as architecture - or urban form - but with different weights. In the syntactic approach, the presence of *technique* is strong, both in the current design - huge tunnels and viaducts - and in the historical route - the Calçada do Lorena as one of the best roads in colonial Brazil, for example. Without adequate technological resources, it would have been unthinkable to cross the mountains. The semantic approach to *function* and *public character*, on the other hand, is ambiguous, since, while notable works were built on the previous routes - such as the railway stations - the use of the roads is currently prioritized only as a place to pass through. In turn, the sense of *place*, visibly represented in the Camino do Mar and its ensemble of architectural elements, is obscured in the current system. Millions of vehicles travel the Anchieta-imigrantes[16] system every year, going from the highlands to the lowlands and vice-versa, viewing the natural landscape - without, however, ever stopping to feel it phenomenologically. In addition, the precarious neighborhoods in naturally preserved territories on the banks of the Anchieta and Imigrantes motorways are still a big challenge.

In addition to the question *Can we understand the Anchieta-Imigrantes System as architecture?,* one has also to ask: *For whom is this architecture intend?* As an urban form, the Anchieta-Imigrantes System visibly connects the plains and the plateau, at a time not even imagined when the first road

[15] Monzeglio, 1993.
[16] Nowadays Santos and São Paulo house 22 million people, concentrating almost 10% of the population of Brazil.

was consolidated. As a rapid passage, it transports not only goods, but mainly people, for the most diverse reasons. It brings the sea closer to the highlands and vice-versa. It connects lives.

This rapid connection, however, reduces not only time, but also the space between, also formed by a complex natural system of life. As one of the largest natural biodiversity landscapes on the planet, the Atlantic forest between the plateau and the plain remains preserved, despite historical interference: the planned paths and the unforeseen neighborhoods.

For the native peoples - who have always respected this place, while at the same time experiencing it - its name is Nhe'ẽry, the basis of their life experience and resistance[17], the place where the spririts bathe. The place that we have to feel as the same phenomenon. Because to take care of it is to take care of oourselves.

Between tiles and concrete: a dialogue among tradition and modernism in São Luís

ABSTRACT

São Luís is a city renowned for its colonial Portuguese architectural and urban influences. With its tiled mansions and primitive colonial layout dating back to 1612, still preserved, the area was recognized as a UNESCO World Cultural Heritage Site in 1977. However, like elsewhere, São Luís has also been influenced by modern thought, resulting in city expansion and the pursuit of new ways of living and developing, making the analysis of this coexistence intriguing. This study aims to examine the possible continuities or discontinuities generated by modernism in the urban structure of São Luís' historic center. The objective is to discuss how modernist ideas relate to the city's historical urban landscape, evaluating whether there is integration or conflict between modernist elements and traditional architecture. A literature review will be conducted on the impact of modernism on historical heritage, with a specific focus on cases where São Luís' Historic Center resists and coexists with modernist ideals that often promoted the "abandonment" of the old. In light of this, it is noted that modernism, as an artistic, architectural, and cultural movement, was often associated with the valorization of the new, innovation, and the breaking of old traditions. This may have resulted in architectural and urban interventions that neglected the preservation of historical heritage in the name of progress and modernity. Faced with these nuances and dualities within the movement itself, one observes the reasons behind the choices of preservation or transformation of historical heritage in São Luís and how these decisions were influenced by political, economic, and social factors. Ultimately, a critical and comprehensive approach could offer valuable insights into the complex interactions between modernism and historical heritage in São Luís and other historic cities worldwide.

Keywords: Modernism; historical heritage; urban integration.

INTRODUCTION

São Luís is a city recognized for its Portuguese colonial architectural and urban influences. With its tiled mansions and colonial layout dating back to 1612 still preserved, the area was designated a UNESCO World Cultural Heritage site in 1997. Like other historic cities, São Luís has undergone urban transformations in pursuit of modernization, resulting in an interesting coexistence between the old and the new. Separated by the Anil River, on one side lies the old city, the city of Portuguese heritage,

with its mansions, belvederes, and tiles; on the other side, the modern city with its concrete towers and gated communities.

Although modernism, as an architectural and urban movement, is often associated with the appreciation of the new and a break from the past, in São Luís, this condition of two cities facing each other seems to affirm a dialogue, a harmonious coexistence between the construction of the new and the appreciation of the past. This article aims to examine the continuities and discontinuities generated by modernism and the modernization process in the urban structure of São Luís. More specifically, it discusses how modernist conceptions and the modernizing impulse influenced the preservation of heritage and urban development.

Ultimately, it seeks to critically discuss whether this relationship between the old and the modern in São Luís was one of integration or a symbolic and physical separation, and what the implications of these decisions were for the city.

Considering the modernization movement that shaped the concrete city on the other side of the Anil River in the 1970s, it is possible to state that, in the same movement, within the same plan that guided modernizing urbanization, were the guidelines for the conservation of historical heritage, with the old city being treated as a historic city.

SÃO LUÍS: FROM CITY TO HISTORIC CENTER

To address the complex interactions between modernism and the preservation of São Luís' historical heritage, a qualitative approach was adopted, focusing on a critical analysis of the processes that shaped the city's urban configuration. In this context, different methodological strategies were articulated to account for the complexity of the topic investigated. On one hand, there was a focus on the analysis of urban plans, projects, and conservation policies for ancient structures; on the other hand, the observation and recording of the current dynamics of the historic center were emphasized. Portuguese colonial consolidation and the beginning of an urban design in São Luís occurred around 1615, after the definitive conquest by the Portuguese metropolis.

The initial plan was attributed to chief engineer Francisco Frias da Mesquita and can be identified in the city's map drawn by the Dutch during their occupation between 1641 and 1644. This layout revealed orthogonal streets with right angles, making São Luís the first Brazilian city to follow an organized urban plan, oriented by the cardinal points (ANDRÉS, 2016).

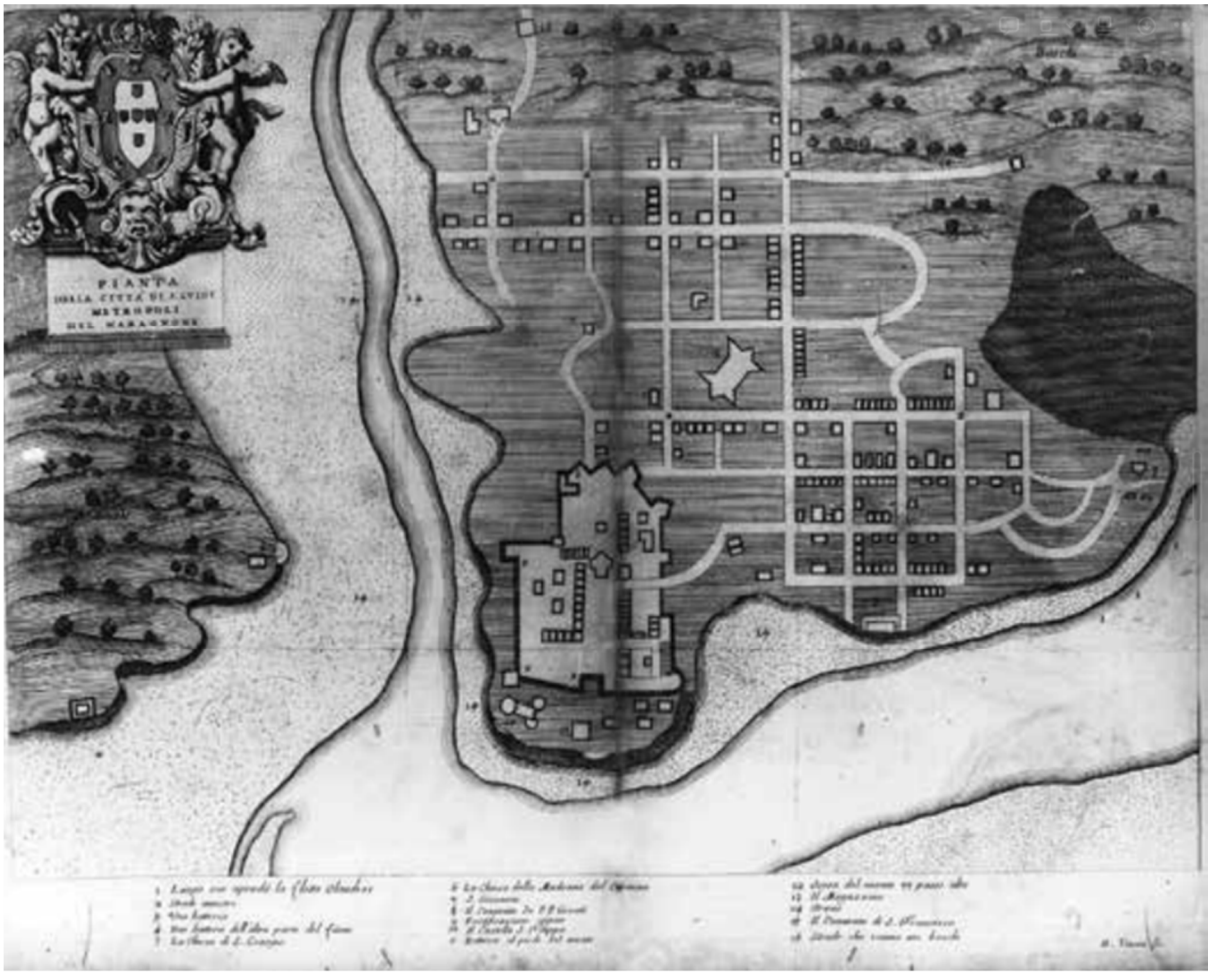

Figure 1. View of the city of São Luís, photo credit: National Library, RJ, 1698.

This urban design endured for centuries, shaping the city's development from this region and leading to São Luís being included on the UNESCO list.

For the purpose of this study, the urban analysis in this region will begin around the 1930s, when a major economic crisis emerged in Maranhão. The decline in agricultural exports resulted in population displacements and impacted urban occupation. However, the changes were guided by the axis defined by the original urban layout, moving towards the interior of the island, following the so-called Caminho Grande, already present on the aforementioned Dutch map. The attempt at recovery through industrialization, with textile factories, brought some prosperity and hope for recovery, until even the factories could not withstand the pressure, entering a state of bankruptcy in the second half of the 20th century. In the old city, the Praia Grande area, near the port and home to a concentration of mansions that had housed the wealthy trade for some time, felt the weight of the bankruptcy and faced a process of abandonment of the factories that existed there. The region remained vibrant due to the presence of residents from Desterro, a popular neighborhood near Praia Grande, along with the Mercado das Tulhas and a distinctive, popular trade.

Near Praia Grande, after Largo do Carmo, Rua Grande concentrated on elite commerce, resisting the crisis. The residences of this elite surrounding Rua Grande in the center coexisted with colonial

mansions, eclectic houses, and even some modern incursions built in the 1960s, following modernist principles in the form of three ten-story buildings, two of which housed public institutions and a third designated for commerce and services. A fourth building, also ten stories high, constituted an initial attempt at modernizing housing: the Caiçara building, a residential structure with four apartments per floor, symbolizing a new way of living.

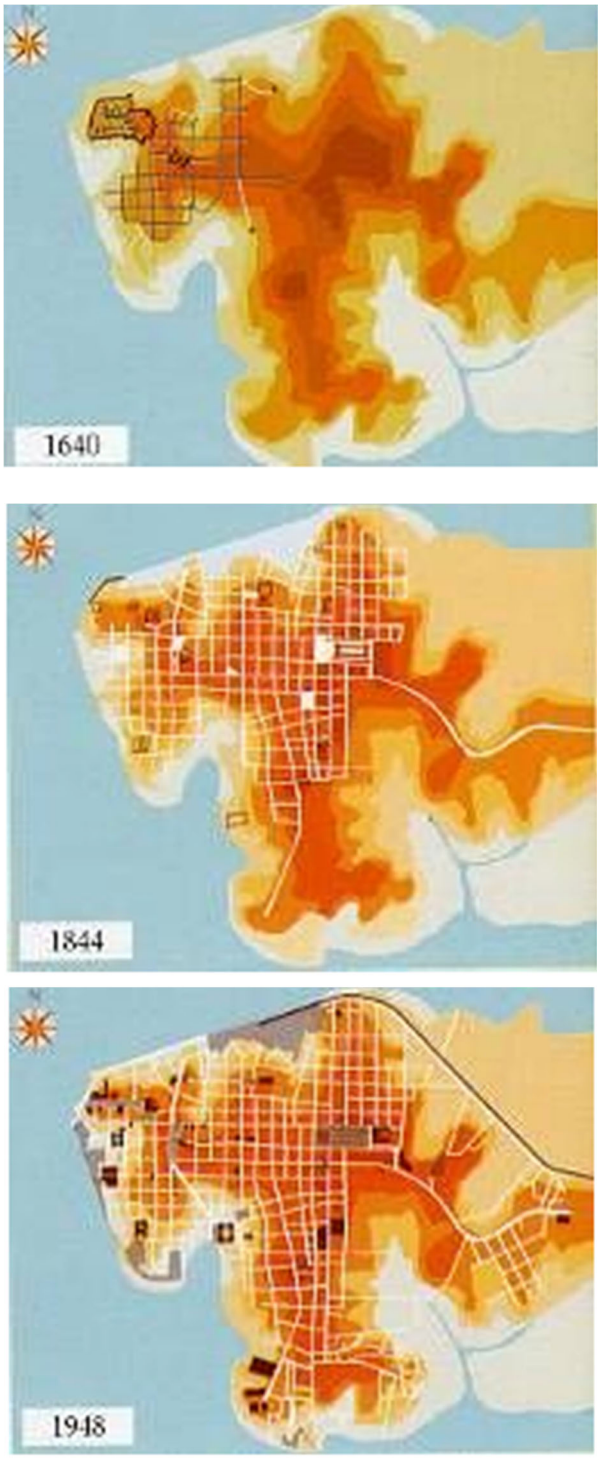

Figure 2. Maps with relief and urban evolution of São Luís. São Luís, photo credit: Andres, 2006

> A hope emerges. The dream of an industrial São Luís would once again be nurtured. A new wave of population growth. São Luís was blatantly swollen, now with five-star hotels, department stores, ALUMAR, Vale do Rio Doce Company, the Port of Itaqui, the enhancement of the coastal area, and the erection of buildings with modern lines in fine contrast to the old, tiled mansions, now decaying, that helped it earn the title of the fourth most important city in Brazil at the beginning of the century (Ribeiro Júnior ,P.26, 1999).

This is a vision of modern São Luís, which was being constructed and transformed through the modernizing expansion guided by the Master Plan (1975), developed under the direction of Wit Olaf Prochinik[18]. A plan that followed the paradigm of modernist urbanism and functionalist urban planning: zoning by function with the consequent creation of homogeneous zones, prioritizing the movement of individual motor vehicles, materialized in the construction of many roads and high-speed thoroughfares, created to meet the needs of modern life: new high-speed avenues, bridges over both rivers, connected, that would quickly integrate the new areas with the old ones (WALL, 201). And, above all, the occupation of the entire territory of the municipality, even if this meant, in practice, the creation of new residential zones in areas that had not yet been urbanized.

It can be stated that starting from the 1960s, several factors would drive the construction of the modern city. First, the developmentalist impetus of the authoritarian government that took power in the country in 1964 favored the construction of a new port that would replace, with many advantages, the old one in Praia Grande, as the construction of the Port was treated as a special project, the Grande Carajás Project, in the National Development Plan (PND), which included the National Urban Development Policy (PNDU) and contemplated medium-sized cities as decentralization poles of development, with São Luís included in this plan. In fact, the construction of the Port of Itaqui, envisioned for decades, finally materialized, and the export of iron ore extracted from the Serra dos Carajás in Pará began to fuel hopes for economic recovery through the industrialization that would follow this export, which was expected to provoke enormous economic growth.

Secondly, the city, founded in 1612, maintained its original 17th-century layout of regular blocks in a reticulated grid, a pattern that created a compact and continuous urban fabric. This logic prevailed until the urbanization process in the 1970s, which made the city spread across unurbanized lands, creating large areas of residential production as well as a port and industrial area. Since then, the logic of producing new urban space has been guided and dominated by a modern network of high-speed avenues, with the new residential areas dispersed along this extensive road network. From this moment on, urban expansion adopted the pattern of a dispersed city.

[18] Development Plan (PND), which included the National Urban Development Policy (PNDU) in the Brazilian context. São Luís was aligned with the proposal to create new development poles in the country, especially in the North and Northeast, aiming to decentralize the population and economic activities by creating new jobs and seeking to reduce income disparities. It was characterized as an area promoting urbanization and as one of the cities that would receive development and industrialization poles led by the establishment of the Port of Itaqui. Wit-Olaf Prochinik's office was responsible for expansion plans for several of these cities, particularly in the Northeast, which were to receive special projects such as the Grande Carajás Project.

To accommodate the expected growth, around 12,500 housing units were built from 1967 to 1980, just to illustrate the strength of this housing policy, financed by the National Housing Bank, accompanied by the construction of developments or subdivisions for the middle class of São Luís, all very well guided by the 1974 Master Plan, following a logic of socio-spatial segregation characteristic of the modern urban planning paradigm.

Although reality did not exactly match these hopes, the city transformed. The displaced growth axis resulted in a fragmented city, with residential areas isolated from one another, connected by large high-speed avenues, and many empty spaces between them.

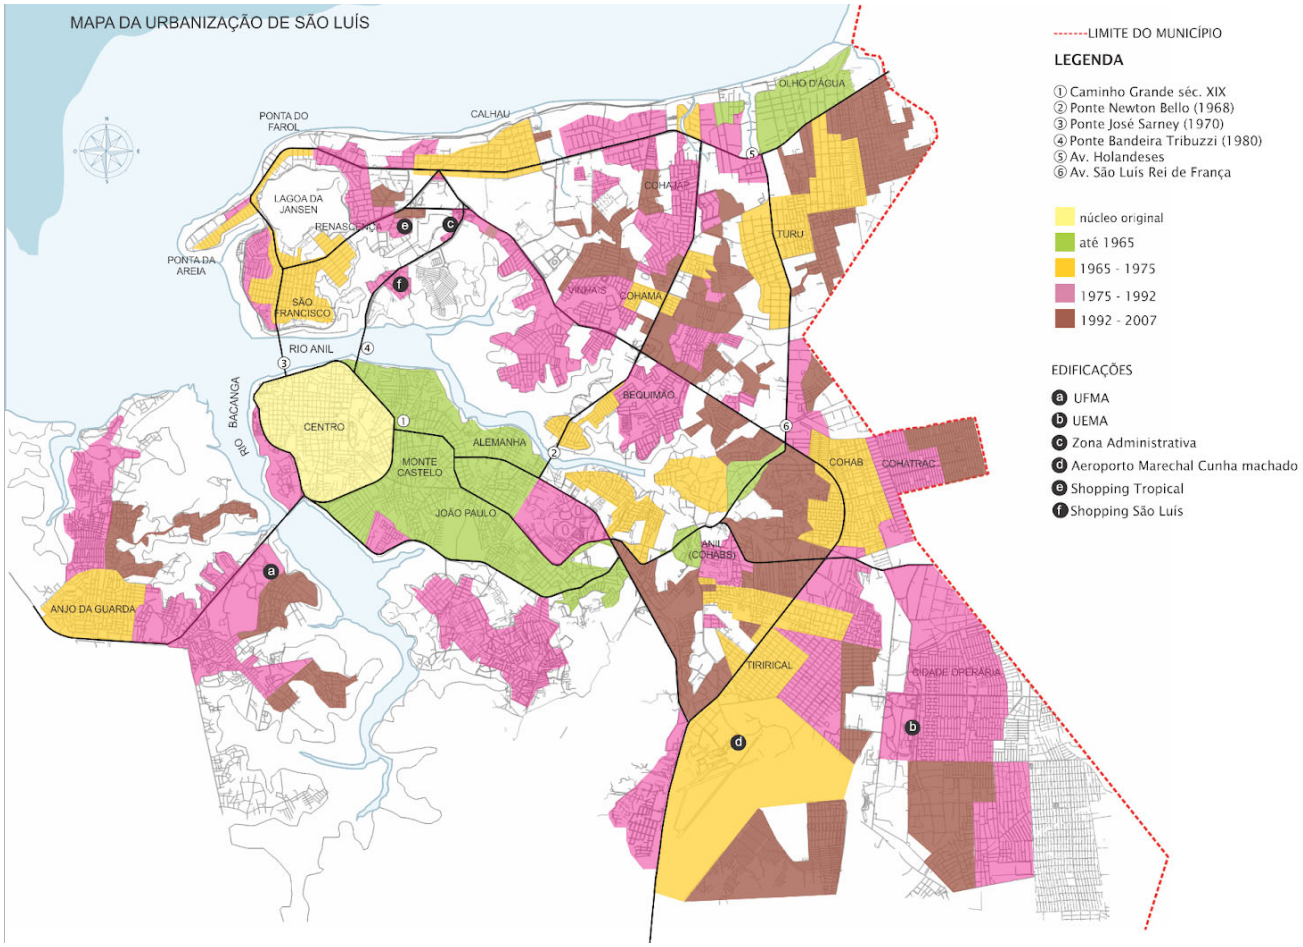

Figure 3. Map of the dispersion of São Luís, photo credit: Wall, 2011

In this context, the proposal to reconcile the existing city with the modern city, the city of tiles with the city of concrete and asphalt, materializes through the enhancement of historical heritage, preserving the colonial urban environment. From that moment on, the colonial city, which was where people lived, became the administrative, institutional, and civic center, also aligning with modernist urbanism's functional zoning, a CBD (Central Business District). The proposal to value the existing historical and cultural heritage included the primary objective of developing art tourism, seeking to integrate this highly valued heritage into the proposed urban and economic development process at that time.

This seemed to be a conciliatory, or even natural, solution capable of pleasing all sectors. A modern city was being constructed while the old one was preserved. Indeed, it is impossible to imagine the center as it remains today, or even the inclusion of this center in the UNESCO World Heritage List, without this process of modernizing expansion that, while embarking on the conquest of new territories, proposed the conservation of the old city. The modernization that had begun in the center, which even included verticalization, was halted. The modern city moved to the other side of the rivers surrounding the original nucleus. To a large extent, this situation preserved the architectural ensemble.

The Center, which once represented the entire city, began to take on new contours around 1970. Now carrying the title of "historical city," it started to be experienced differently by the rest of the city. As Wall (2011) clarifies, urban dynamics transformed the relationship between the center and the other neighborhoods, all of which were distant from the old city.

However, before delving deeper into this aspect, it is important to note that one of the valued areas in the new regions was precisely the waterfront, the beaches. Previously distant from the existing city and difficult to access, the modernization process ensured, if not proximity, at least greater ease of access, with the construction of new high-speed avenues.

In seeking this proximity to the beaches or the possibility of purchasing their own homes as a new way of living, the relationship with the existing city, now transformed into a center, changed.

> For some, the distance was welcome because it kept the turbulence, noise, and pollution of concentration at bay (living modes in coastal neighborhoods); for others, the distance was a necessary evil (residential complexes for the middle classes) to be able to live in their own homes in a more individualized manner; or it was a terrible burden to be endured to get to work (more distant residential complexes and marginalized periphery) (Wall, p. 246, 2011).

The conservation of the old city benefited from the collaboration of UNESCO technicians. In the 1960s, through the French architect Michel Parent, and later with the visit and subsequent preparation of a technical report by architect Alfredo Viana de Lima, who conducted a detailed photographic and cartographic survey of the historic center. This work underpinned the diagnosis and recovery plan for the area, which was even materialized in a chapter of the 1974 Master Plan, and served as a reference for future studies.

It is worth noting that the study conducted by the Portuguese architect not only embraced the idea of modernity but also outlined guidelines for urban expansion aligned with the nationalistic optimism of the "economic miracle," as Lopes and Viana (2018) point out. However, this diagnosis brought an important distinction: based on the Venice Charter, Viana de Lima emphasized the value of built cultural heritage and the importance of its management, in accordance with Article 16 of the Charter:

> Conservation, restoration, and excavation work should always be accompanied by the preparation of precise documentation, in the form of analytical and critical reports, illustrated with drawings and photographs [...] this documentation will be

> deposited in the archives of a public body and made available to researchers; its publication is recommended (BRASIL, 2004, p. 95).

The reverence for the urban ensemble is expressed when the architect emphasizes the importance of adapting the city's expansion process:

> If Brasília is a landmark in contemporary urbanism, the city of São Luís do Maranhão plays an important role in the study of the formation of cities in Colonial Brazil. It must be preserved, cherished, and correctly integrated into the planned expansion (VIANA DE LIMA, 1973, p. 39).

Prior to Viana de Lima's diagnosis, Michel Parent—also a consultant for UNESCO—produced a report entitled "Protection et mise en valeur du patrimoine culturel brésilien dans le cadre du développement touristique et économique" (Protection and Valuation of Brazilian Cultural Heritage within the Scope of Tourist and Economic Development) (Leal, 2008). The central ensemble of São Luís held value and was particularly seen as an opportunity for tourism, specifically art tourism.

Both reports highlighted the liveliness of the existing city, and while proposing the use of its structures for art tourism, they warned of the need to integrate the space, now elevated to historic city status, with the development of the modern city. They suggested the establishment of a university, the Federal University, which was being developed at the same time, and cautioned about which uses could be more detrimental to conservation.

In the ongoing dialectic between expansion and conservation, and with the clear need to preserve monuments, sites, and historic centers, various approaches emerged regarding how to achieve this preservation. Some advocated treating these locations as museum pieces, primarily serving an educational function, while others viewed them as works of art, valued as commodities within the cultural tourism industry. The necessity for innovation, the dialectic of destruction, and the replacement of the old with the new were also discussed.

In this context, the field of conservation gained a chapter, already mentioned, in the 1974 Master Plan, which closely followed the guidance of Viana de Lima and was under the charge of technical teams from conservation agencies (at both federal and state levels, the newly created Department of Historical, Artistic, and Landscape Heritage, DPHAP—established in 1973). They determined a Historic Protection Zone and a Support Zone for historic protection.

Simultaneously, the Government of the State of Maranhão embraced the idea of conservation and supported the implementation of recovery plans for Praia Grande, still in the 1970s. From then on, considering the extent of the existing city, an area was designated as the Historic Center, roughly corresponding to the original nucleus, following Frias de Mesquita's design.

In the 1980s, the largest and most comprehensive program aimed at attracting attention to the area and consolidating its tourist potential was created. Cultural venues such as the Odylo Costa Filho Creativity Center, Morada das Artes, and the Domingos Vieira Filho Popular Culture Center demonstrated this commitment to culture. Furthermore, cultural groups and manifestations found in these revitalized spaces and the accompanying discussions an opportunity to express themselves and strengthen their identities. The phenomenon of appropriation of this space by popular culture

intensified over the years, driven by the construction and consolidation of a vibrant cultural scene in the city center.

On the other hand, the representation of modern living, the perspective of modern ways of living in the new areas, played a decisive role in the devaluation of the old space, of the historic center as a place to live. The modern city developed in a segregated space, presenting closed residential enclaves. The new neighborhoods attracted commerce and services. Following the typology of gated communities came the typology of closed commercial and leisure spaces, such as shopping centers.

Meanwhile, in the historic center, contrary to this representation and against conservation policies that did not demonstrate concern for creating programs to incentivize residents to stay in the center, residential niches remained, and popular culture persisted, challenging desires for the gentrification of the heritage space.

FROM CENTER TO COMMODITY?

In experiencing and witnessing the local scenario, the commitment to culture is sometimes only safeguarded in discourse. The region has been promoted as a large open-air museum, aimed at attracting tourists, many of whom come to the city to visit the Lençóis Maranhenses but take the opportunity to enjoy São Luís's rich cultural heritage, including popular manifestations, traditional games, and the unique local cuisine, which has also had its moment of appreciation, suggesting that the focus on cultural tourism has also been incorporated.

The state government is restoring buildings for the State University to house Law, International Relations, and Music courses, while simultaneously moving out of the city center to other areas, a trend that has been intensifying for some time. In the same process, it abandons important cultural centers, such as the Odylo Costa Filho Creativity Center and the Popular Culture Center, along with other spaces that once hosted special tourism delegations, all undergoing significant degradation and becoming easy targets for theft and vandalism.

The moment is paradoxical: on one side, many new programs and intervention projects are being actively developed, promoted by federal, state, and municipal public authorities. With significant funding, including from international organizations, large cultural projects, economic development, and cultural tourism promotion are underway. On the other hand, there is neglect.

Various actions have been and are being carried out over the years that provide the urban experience described by Mogin (2009), emphasizing encounter and diversity. Weekly events, such as the Feirinha (Little Fair), organized by the Municipal Secretariat of Agriculture, Fisheries, and Supply (SEMAPA) on R. do Giz, promote not only leisure but also the economy through local entrepreneurs and artists.

However, there are also visible signs of promoting rehabilitation aimed at private initiative and the predatory exploitation of cultural resources, including the devaluation of local and popular culture during festive times, such as the June festivities, and the major symbolic act: the dismantling of the Casa do Maranhão. This mansion, which in the 19th century housed the old State Treasury and functioned for decades as the State Department of Finance, served as a reference center for

Maranhão's popular culture, including Black and Indigenous culture, local handicrafts, and was used for cultural group presentations and lectures.

The replacement of the Casa do Maranhão, a center for promoting this culture, supporting local handicrafts, and promoting cultural activities, with a luxury hotel, for example, may aim to attract more tourists who appreciate (undeniably) good accommodations. Still, it risks bringing them in without being able to offer exactly what is currently available in the historic center of São Luís: local culture, handicraft products, and the works of local artists. Similarly, heritage needs to be lived. Wouldn't it be time to allow culture to appropriate and take care of this heritage as it always has?

By implementing incentives for the use and permanence of cultural activities and manifestations in the Historic Center, we would not only be revitalizing the spaces but also the heart of the city. After all, a living heritage is one that pulses, breathes, and transforms alongside the community that inhabits it.

CONCLUSIONS

The historic center of São Luís, as a space of living culture, faces a crucial challenge: how to reconcile tourism, heritage preservation, and the daily life of the community? On one hand, it is evident that government programs have sought to encourage urban rehabilitation, promoting São Luís as a culturally significant tourist destination. However, at the same time, contradictory actions, such as the abandonment of essential public spaces and the replacement of centers for popular culture with private enterprises, point to a devaluation of local culture. Culture, which has always been the soul of the historic center, risks being sidelined in favor of a development model that prioritizes immediate profit.

The transformation of the Casa do Maranhão into a luxury hotel is a symbolic example of this dilemma. By replacing a space dedicated to promoting popular culture with a venture focused on luxury tourism, there is a risk of disconnecting the historic center from its cultural identity. Local culture, expressed in June festivals, traditional games, handicrafts, and community spaces, needs to remain the guiding thread of urban revitalization. A historic heritage cannot be treated as a static object; it is a living organism that breathes and evolves with the community.

For the revitalization of the historic center of São Luís, it would be important to place the permanence of cultural manifestations and residential niches, of current residents, at the heart of rehabilitation policies. Incentives for the continuation of these activities, for the appreciation of handicrafts and local cultural expressions, are essential to ensure that the heritage continues to pulse with the life of the community that inhabits it.

The true success of any intervention in the historic center depends, above all, on authentic and continuous cultural appropriation and an understanding of the place as a space for living, as this experience keeps the heart of the city vibrant and relevant.

The sustainability of the historic center of São Luís, therefore, depends on an approach that values local culture and the traditions that define it. Revitalization policies must go beyond mere restoration of buildings, incorporating strategies that promote social inclusion and the strengthening of cultural

identity. Community participation in decision-making processes is fundamental to ensure that interventions respect the history and experiences of the residents. Only through open and collaborative dialogue will it be possible to build a future that celebrates the cultural diversity and historical heritage of the city.

Moreover, it is imperative that revitalization actions are accompanied by urban planning that prioritizes the well-being of local inhabitants. This involves creating accessible public spaces that encourage interaction and the exchange of experiences among diverse social groups. Strengthening initiatives that promote popular culture, such as craft fairs and cultural events, can contribute to the recovery of the identity of the historic center, attracting not only tourists but also the local population, who should feel part of the process of valuing their heritage.

Finally, the revitalization of the historic center of São Luís should be seen as a long-term project that requires ongoing commitment and investment. Public policies must be supported by partnerships with civil society organizations, the private sector, and universities, aiming for the implementation of integrated and effective actions. The future of the historic center is closely linked to the ability to transform challenges into opportunities, allowing local culture to flourish and ensuring that the city maintains its vibrant essence, in tune with the needs and aspirations of its population.

Acknowledgements

I would like to thank the State University of Maranhão, which has become a home for me and opened doors I never imagined possible. It is a privilege to be part of an institution that values research and knowledge, providing an enriching environment for academic development. My special thanks go to the institutions that support research, especially the Institutional Volunteer Program for Scientific Initiation (PIVIC) at UEMA, which was essential for carrying out the research that led to this article. I also thank Isuf for providing a space for the exchange of ideas and experiences that contributed to my personal and professional growth. These supports were crucial for me to complete this work with dedication and commitment. Each of these moments of learning and exchange was valuable and directly impacted the quality of what I present in this article.

ABSTRACT

To promote the development of Sustainable Cities and Communities, as recommended by one of the United Nations Sustainable Development Goals, this paper addresses design strategies with the potential to promote socio-environmental sustainability in urban spaces from a neighbourhood scale. Co-housing, functioning as a sustainable housing typology, emerges as an intermediary between utopian ideals, experimentation, and social transformation. This paper examines the morphological patterns of Co-housing design, highlighting humanizing attributes to promote socio-environmental sustainability in urban spaces. To achieve this, the study examines the case of the Beddington Zero Energy Development (BedZED) project in the United Kingdom, a pioneering example of experimental urban sustainable housing design. The method adopted uses a design reading of morphological patterns identified in architectural and urban spatial forms incorporating a humanizing approach. Design patterns are identified based on Christopher Alexander's patterns at the neighbourhood and building scales, and analysed graphically in architectural design, and photographs recorded on-site during a technical visit. The outcomes of this analysis contribute to the discussion of existing design strategies in Co-housing typology, fostering socio-environmental sustainability in urban spaces.

Keywords: Co-housing, socio-environmental sustainability, humanization, patterns.

INTRODUCTION

According to the World Cities Report (UN-Habitat, 2022), the global urban population is projected to increase by approximately 2.2 billion people by 2050, rising from 56% in 2021 to 68% of the total population. This rapid growth poses the risk of exacerbating unsustainable urban expansion patterns. In response to this challenge, it is crucial to rethink urbanization through alternative housing and community design approaches that align with sustainable urban development. Both the New Urban

Agenda (UN, 2017) and the Sustainable Development Goals (SDGs) highlight this need, with a particular emphasis on promoting Sustainable Cities and Communities (UN, n.d.).

Within this framework, the focus of this paper is on the seventh target of SDG 11, which aims to ensure the creation of safe, inclusive, accessible, and sustainable public spaces by 2030. To contribute to this objective, the paper proposes a morphological analysis of Co-housing design strategies, exploring their potential to promote socio-environmental sustainability in urban spaces from neighbourhood scales. In this context, socio-environmental sustainability is understood as a strategy for achieving SDG 11, integrating sustainability's social and environmental dimensions. The social dimension addresses human well-being, focusing on equitable access to essential services and fostering social cohesion. In contrast, the environmental dimension addresses the responsible management of ecosystems, encouraging pro-environmental human actions and behaviors (Robert, Parris, and Leiserowitz, 2005; Demantova and Rutkowski, 2007). By balancing these two dimensions, urban spaces can better support sustainable development.

Co-housing, as explored in this study, offers a housing typology that aligns with these sustainability objectives. Widely discussed in the literature, Co-housing is positioned between utopian ideals of social experimentation and practical responses to living in neoliberal contexts, particularly in culturally diverse societies with increasingly limited state support (Sargisson, 2012; Tummers, 2015; Droste, 2015; Boyer, 2018). According to Beck (2020), Co-housing consists of clusters of independent single-family homes with access to communal facilities, integrating open areas and shared spaces within the neighborhood. Since its origins in Denmark, the Co-housing typology has evolved significantly. As Rolando (2022) notes, it now represents an alternative to the traditional model of predefined-function housing, offering more flexible spatial configurations. These configurations challenge conventional privacy boundaries and encourage new forms of social interaction, particularly at the neighborhood scale, making Co-housing a compelling approach to sustainable urban design.

The term "Co-housing" was translated by Vedel-Petersen, Jantzen, and Ranten (1988) from the Danish term Bofællesskab. This concept emerged in Denmark during the 1960s and 1970s as an alternative to conventional single-family suburban residences, aiming to restore a sense of community in modern society. The literature also includes the term "Cohousing," coined by American architects Charles Durrett and Kathryn McCamant, who regarded Danish Bofællesskab experiences as foundational to this housing typology. According to McCamant and Durrett (1988), Cohousing communities are defined by participatory design processes. These strategies promote community living, extensive common facilities, resident-managed spaces, non-hierarchical structures, and independent income sources.

Although there is no consensus in the literature regarding the distinct use of "Co-housing" and "Cohousing," with both terms often used as English translations of Bofællesskab, Babos et al. (2020) suggest that "Co-housing" be understood as a broader concept of collaborative housing. The prefix "co-" encompasses various forms of collective living arrangements, such as cooperative, community, and communal housing, each with different levels of social interaction and distinct spatial configurations. Therefore, examples of the Co-housing typology include Bofællesskab, Cohousing communities, ecovillages, communes, housing cooperatives, co-living, collective self-help housing, community-led housing, and other formats that prioritize collective and collaborative living. While

these arrangements differ in social dynamics and spatial structures, they share a common goal of fostering integrated and socially engaged living environments.

This paper proposes an analysis of Co-housing design strategies through a morphological analysis of patterns, using the Beddington Zero Energy Development (BedZED) as a case study. BedZED, widely recognized as a pioneering experimental sustainable community, was developed in the United Kingdom by the British sustainability charity Bioregional and architect Bill Dunster in the 1990s, in collaboration with the Peabody Trust housing association, which served as the project developer. The central vision behind BedZED was the creation of a community that operates without relying on fossil fuels. To realize this vision, an available site was identified in Beddington Farmlands, a suburban area of London (Figure 1) that had previously served as a sludge disposal site. In 1998, the London Borough of Sutton, which owned the site and acted as the local planning authority, endorsed the project by selling the land to Peabody at a below-market rate. Construction of the project began in 2000 and was completed in 2002. BedZED's residential units range from studios to four-bedroom flats, with 25% allocated for subsidized rental, 25% for affordable private ownership, and 50% for market sale. In addition to residential spaces, the project includes offices, a nursery school, and communal facilities designed to function as extensions of the private living spaces (Bioregional, 2016).

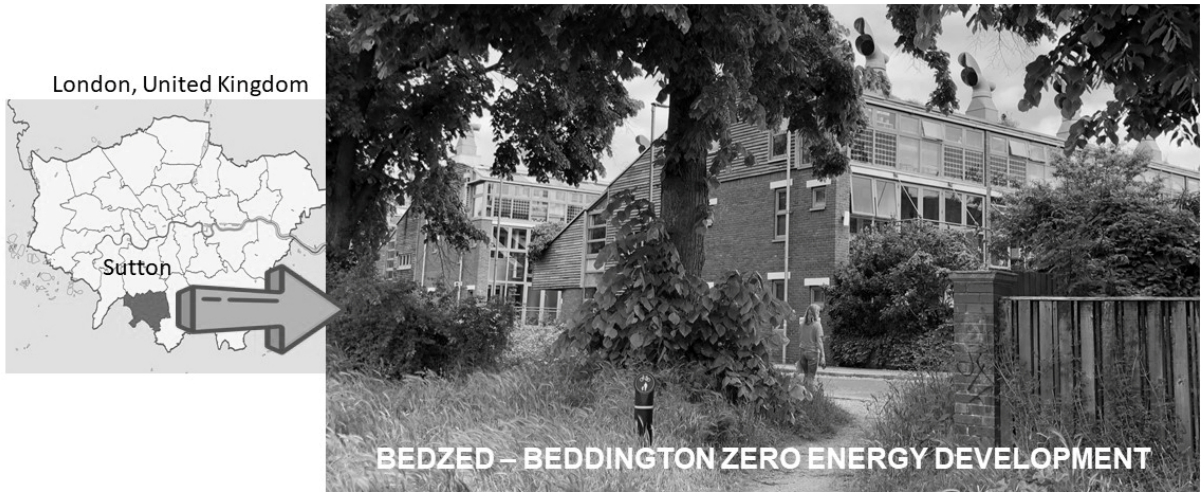

Figure 1. BedZED project location. Source: Authors.

The choice of BedZED as a case study is justified by its status as a consolidated experimental sustainable community, aligning with the objectives of Goal 11 of the SDGs: Sustainable Cities and Communities. While most literature on BedZED focuses on its technical strategies to reduce carbon dioxide emissions, such as the use of renewable energy sources like photovoltaic and wind energy, passive thermal comfort technologies, solar orientation for heating, water-saving systems, and recycled materials (Smith & Butler, 2008; Chance, 2009; Puma et al., 2024), there is limited analysis of its design strategies from an urban morphology perspective. For instance, Sdei (2005) conducted a comparative analysis of the morphological impact of passive solar systems in domestic architecture using BedZED as a case study to identify its energy performance. Another study by Deakin, Reid, and Campbell (2014) does not specifically analyze BedZED but examines its neighborhood through a morphological lens, highlighting issues of energy performance and carbon emission reductions aimed at mitigating climate change. In this context, there is limited exploration of these strategies through a

humanizing design approach and within the framework of Co-housing typology, which functions as an umbrella concept for collective and collaborative contemporary housing arrangements.

In response, this research aims to address that gap by examining how the design strategies adopted in BedZED, as a Co-housing typology with humanizing morphological attributes, can potentially contribute to socio-environmental sustainability in urban spaces. These humanizing attributes are framed through Christopher Alexander's concept of patterns, which encapsulate sensory and affective dimensions into design parameters. While these dimensions are difficult to quantify, they address essential human aspirations and needs in the built environment, such as enhancing social interaction in urban spaces and strengthening human connection with nature (Alexander et al., 1977; Alexander, 1979).

The paper is organized into five sections, starting with this introduction. The following section explores humanization as a design approach, focusing on Christopher Alexander's theory and methodology, particularly his concept of patterns. The third section outlines the design analysis method, explaining the steps of the protocol that applies Alexander et al.'s (1977) patterns as the key parameters. In the fourth section, the results of the BedZED analysis are presented, covering the selection, examination, and articulation of patterns, culminating in the highlighting of humanizing attributes. Finally, the fifth section provides the conclusions drawn from the analysis of the identified morphological patterns and their potential to promote socio-environmental sustainability in urban spaces.

Humanization design approach through patterns

In the field of Architecture and Urban Design, the concept of humanization has evolved, incorporating knowledge from various disciplines to fill stylistic and theoretical gaps (Kowaltowski, 1980). Originally, this evolution stemmed in the history of humanity from movements aimed at preventing physical cruelty against humans and animals and became popular during the 1970s with the countercultural, ecological and human potential-valuing movements, mostly in the USA. This study considers the development of humanization as a design approach, particularly through the research activities and publications of the Design Methods Movement between the 1960s and 1970s, especially by members of the second and third generations. According to Van Der Voordt and Van Wegen (2005), during this period, design methods emerged that focused on addressing human aspirations and needs in the built environment, emphasizing user participation and the validation of interdisciplinary knowledge from fields such as environmental psychology and sociology. Among the main figures of this movement, Christopher Alexander stands out, whose theoretical and methodological work, especially in A Pattern Language and The Timeless Way of Building, introduced the principles of humanization into the design field. The first volume (Alexander et al., 1977) is related to the participatory design method approach with patterns as its major tools, functioning as design parameters in the design process and construction of buildings and towns. The second (Alexander, 1979) is the design philosophy Alexander aimed to propose as a basis for a new paradigm for the design discipline.

Alexander (1979) developed the concept of patterns translating the patterns of human interactions with spaces into design parameters with humanizing attributes that add "life" to the environmental and social dimensions of places, which he associated with "the quality without a name". In this study, these attributes are understood as sensory and affective aspects, difficult to measure, but accepted by the common human sense – such as human needs for social interaction and connection with nature – that are associated with the quality of the built environment and consequently with human health

and well-being. The idea of humanizing attributes is linked to many theories in Architecture and Urban Design fields nowadays – but not necessarily using this designation – indicating that certain spatial arrangements may be beneficial to the built environment as well as to human well-being socially and psychologically (Hillier and Hanson, 1984; Kaplan, Kaplan and Ryan, 1998; Nasar, 1998; Helleur, 2001; Thwaites, Helleur and Simkins, 2005).

Despite being a product of the 1970s, Barros and Kowaltowski (2013) acknowledge Alexander's attempt to translate the patterns of human interactions with environments as design parameters value a more sensitive human connection with place, people's well-being and socio-environmental diversity; since Alexander anticipates concerns about the socio-environmental impact of construction and urban design, as well as issues related to the sustainable use of materials and the creation of healthy environments from a holistic perspective. For Salingaros (2005), the knowledge produced by Alexander et al. (1977) derived from observations and subjective experiences within specific physical and social environments, requires interdisciplinary knowledge to understand them. Thus, understanding Alexander's patterns demands a dialogue between different disciplines and a mental effort to establish their connections.

In A Pattern Language (Alexander et al., 1977), Alexander introduces the concept of pattern as design parameters that translate the patterns of human interactions with places, in a participatory design approach focused on the users' aspirations and needs in the built environment. Organized into a language structure, the patterns replace words with design parameters that combine to essentially support the process design. To facilitate use by participants in the design process, each pattern is presented in a chapter following a consistent structure (Figure 2) for all the 253 patterns identified at scales ranging from cities and communities, progressing to medium themes like buildings, and moving to more specific details such as construction and landscaping: 1) A figure representing the archetypal nature of the pattern. 2) An introductory paragraph discussing the pattern's context and its relationship with larger-scale patterns. 3) A set of three diamonds (⋄⋄⋄) marking the beginning of the problem addressed by the pattern. 4) A bold paragraph summarizing the design problem in one or two sentences. 5) A descriptive text, accompanied by figures or graphs, that provides empirical evidence of the pattern's validity and its various manifestations. 6) Bold text offering the solution to the problem, highlighting the necessary physical and social relationships in the design. 7) Diagrams or drawings illustrating the design strategies proposed. 8) A set of three diamonds (⋄⋄⋄) marking the conclusion of the main design strategy proposed. 9) A final paragraph linking the pattern to smaller, more specific patterns that complete the language structure.

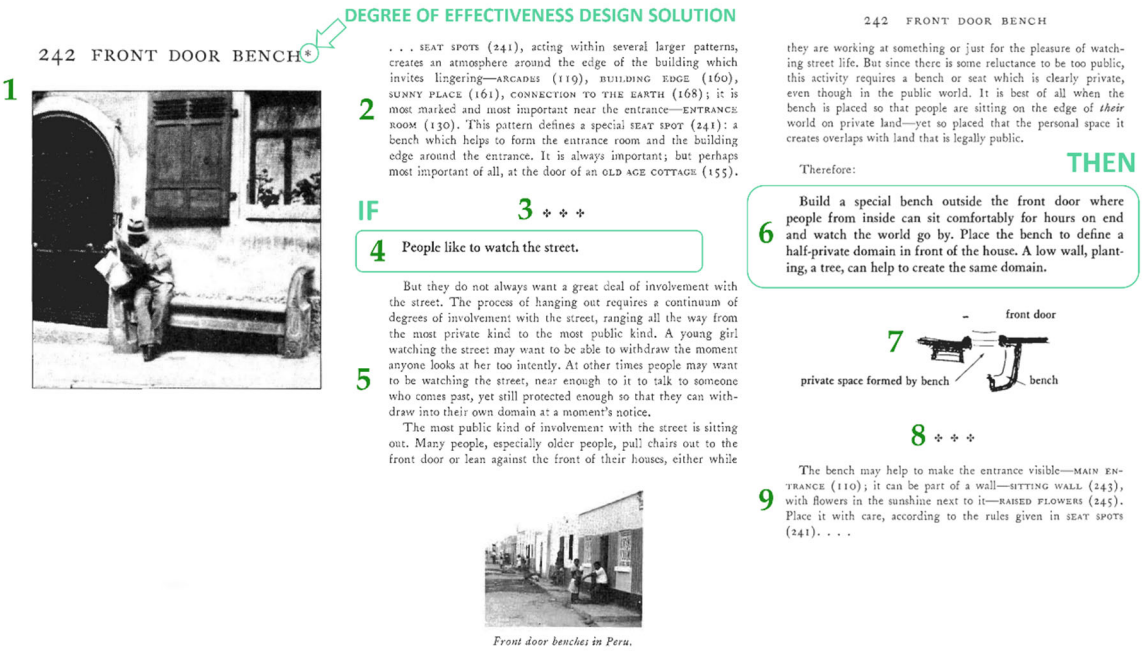

Figure 2. The standard structure presentation of all patterns. Source: Adapted from Alexander et al. (1977).

According to Kowaltowski (1980), this structure reflects a cause-and-effect mindset, characterized by "if... then..." statements rooted in architectural determinism. Authors such as Dovey (1990), Dawes and Ostwald (2017), and Kowaltowski, Gonçalves, and Cleveland (2024) point out that the absence of scientific validation in some hypotheses presented in the patterns reduces the credibility of Alexander's theory. However, this criticism is acknowledged by Alexander et al. (1977), who caution about the lack of guarantees regarding the degree of effectiveness design solutions listed. To address this uncertainty, the titles of the patterns are marked with asterisks to indicate different levels of confidence. Two asterisks (**) signal patterns with design solutions are considered invariant by the authors. One asterisk (*) indicates patterns whose effectiveness is uncertain, suggesting that users approach these solutions with scepticism and explore alternatives. Patterns without asterisks indicate that the authors were unable to identify a plausible solution, admitting that other approaches may be more appropriate.

This study suggests that adopting a probabilistic approach, now commonly used in Urban Design, is more suitable for applying Alexander's design theory. The earlier notion of environmental determinism, once prevalent in Environmental Psychology, is no longer accepted as it neglects human agency by assuming a unidirectional interaction between the environment and people. In reality, the person-environment relationship is bidirectional. As Carmona et al. (2003) state, people are not passive; they actively shape and modify the built environment, which, in turn, influences and alters them. While some of Alexander's pattern design strategies lack scientific rigor, suggesting that certain environmental and social structures may better address human aspirations and needs in the built environment, recent neuroscience studies might confirm these propositions. According to Zeisel (2006), this emerging research niche is classified as Environment/Behavior/Neuroscience.

This study adopts a distinct approach to Alexander's patterns by applying morphological analysis to Co-housing design strategies, focusing on the relationship between the environment and human behavior within the visual dimension of Urban Design. This approach explores the patterns' potential to foster socio-environmental sustainability in urban spaces, mostly from neighbourhood scales.

METHOD

This study analyzes the design of BedZED, focusing on identifying morphological patterns. According to Yin (2009), the case study method requires understanding the complex dynamics that both shape and are shaped by the case. BedZED is examined to explore Co-housing design strategies with humanizing attributes that promote socio-environmental sustainability in urban spaces. The analysis uses Alexander's patterns to identify design strategies, incorporating sensory and affective dimensions into design parameters. The materials include publicly available architectural drawings and photographs taken during a guided site visit on May 25, 2023. The analysis follows a four-stage protocol outlined below.

1st Stage. Patterns' Selection: In this phase, a probabilistic sample of patterns from Alexander et al. (1977) is selected to be identified in the Co-housing design strategy. This selection follows the author's guidelines, considering the hypothesis of developing a design similar to the case study. In this scenario, the goal is to choose patterns whose design strategies are most coherent with the BedZED.

2nd Stage. Pattern Scanning: Here, the patterns from Alexander et al. (1977) are identified as the main evidence in the design analysis. The scanning design analysis strategy involves mapping morphological patterns present in the case study and comparing them with Alexander's patterns. To facilitate identification, the architectural design is hand-redrawn, highlighting the contour of built and open spaces. Subsequently, markings are made on the morphological patterns' locations, and numbering them according to Alexander's patterns using AutoCAD software as a tool. This process is applied to both the drawings and the photographs taken on-site.

3rd Stage. Design Reading Based on Pattern Articulation: Parallel to the scanning, this stage involves a design reading based on the patterns identified and their articulations. The relationships between the patterns help interpret the design strategies adopted, according to their numerical sequence.

4th Stage. Patterns' Humanizing Attributes: In this stage, the humanizing attributes of each identified pattern are summarized in a framework which highlights the humanizing attributes in patterns with the potential to promote socio-environmental sustainability in urban spaces. These attributes are transcribed based on the content from the chapters in Alexander et al. (1977).

RESULTS AND DISCUSSIONS

The results and discussions are organized according to the protocol stages described above. These stages are 1) Patterns' Selection, 2) 3) Pattern Scanning with Design Reading Based on Pattern Articulation, and 4) Patterns' Humanizing Attributes.

Patterns' Selection

Initially, 21 patterns from Alexander et al. (1977) were selected as a sample, described as follows: 15 (neighborhood boundary); 21 (four-story limit); 37 (house cluster); 38 (row houses); 39 (housing hill); 48 (housing in between); 51 (green streets); 52 (network of paths and cars); 53 (main gateways); 59 (quiet backs); 60 (accessible green); 61 (small public square); 67 (common land); 100 (pedestrian street); 103 (small parking lots); 112 (entrance transition); 118 (roof garden); 140 (private terrace on the street); 158 (open stairs); 164 (street windows); and 177 (vegetable garden). From this selection,

the analysis involved scanning architectural drawings and photographs to identify patterns applied as Co-housing design strategies. The goal was to select patterns whose design strategies align most coherently with BedZED.

Pattern Scanning with Design Reading Based on Pattern Articulation

Figure 3 identifies eleven patterns on the BedZED site plan, illustrating how they are articulated as design strategies.

Figure 3. Pattern scans – BedZED schematic site plan. Source: Redesign by the Authors.

Pattern 15 (neighborhood boundary) defines the limits of the housing complex in relation to the surrounding neighborhood. Pattern 37 (house cluster) organizes the overall buildings on site, grouping housing units around circulation realms and interacting with pattern 38 (row houses), which structures the houses in row. Pattern 52 (network of paths and cars) connects circulation routes, forming a network between open spaces and previous patterns. Pattern 59 (quiet backs) establishes a calm environment behind the buildings' spaces, enhancing integration with nature, complemented by pattern 60 (accessible green), which provides accessible green spaces for leisure and food cultivation, further supported by pattern 177 (vegetable garden). Pattern 61 (small public square) creates spaces for social interaction, functioning as a small public square, while pattern 67 (common land) integrates the broader social system neighborhood. Pattern 100 (pedestrian street) connects communal spaces, serving as circulation, uses and appropriations of people, directly interacting with the other patterns. Lastly, pattern 103 (small parking lots) is positioned on the housing complex periphery, reinforcing its boundaries and protecting neighborhood spaces in conjunction with pattern 15. The articulation of these patterns shapes BedZED's design morphology, which challenges the conventional urban

subdivision typically seen in residential neighborhoods. This approach to Urban Design aligns with several New Urbanism design principles, emphasizing sustainable, pedestrian-oriented spaces, energy-efficient design, and environmentally sensitive planning. According to Carmona et al. (2003), these principles prioritize the integration of architectural forms with public places, reflecting a broader commitment to creating functional, human-centered, and ecologically responsible urban spaces.

In Figure 4, four additional patterns from Alexander et al. (1977) are identified in the section of the BedZED housing units.

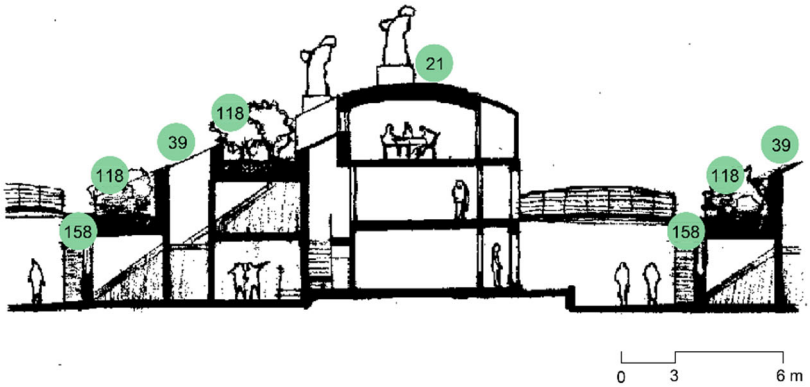

Figure 4. Pattern scans – BedZED schematic section. Source: Redesign by the Authors.

Pattern 21 (four-story limit) limits the building's height to three floors, maintaining a scale compatible with human dimensions. Pattern 39 (housing hill) proposes an alternative flats' layout, breaking with the traditional configuration and creating spatial variations vertically, such as outdoor balconies with different views. Pattern 118 (roof garden) integrates green spaces on the roofs, adding functional and visual value to the building, in addition to strengthening the connection with nature. Finally, pattern 158 (open stairs) suggests open stairs as vertical circulation realms that also act as extensions of community spaces, facilitating integration between buildings and neighborhood spaces. Compared to conventional housing in vertical buildings, BedZED creates more vibrant neighborhood spaces. The integration of green spaces on terraces and the hill-like arrangement of housing units fosters a sense of community and liveliness. According to Day (2002), this design strategy generates an ambiance that communicates: "People are truly living here", enhancing the connection between residents and their surroundings.

As for the facades, the photographs taken on site reveal the presence of three patterns, illustrated in Figure 5, which are articulated with other patterns identified in the BedZED common spaces. To access the pedestrian-only streets, pedestrians pass through a portal corresponding to pattern 53 (main gateways) (Photo 1), which delimits the entrance to the interior of the complex. Within this complex, there are platforms aligned with pattern 140 (private terrace on the street) (Photo 2), which connect the pattern 100 (pedestrian street) to the terraces and bridges for private use, linked to other flats on higher levels, facilitating both social interaction and connection with nature. On the upper levels, pattern 118 (roof garden) (Photo 3) performs a function similar to that of the terraces, offering more privacy and a wider view of the public spaces. These design strategies help to creating a safer atmosphere in neighborhood spaces, particularly for children and youth, as the building facades provide numerous visual contact zones over public spaces, enabling informal surveillance. Jacobs

(1961) described this phenomenon as vital to urban spaces, coining the expression “eyes on the street” to emphasize the role of informal surveillance in enhancing the quality of public places.

Figure 5. Pattern scans - photographs taken on site. Source: Authors.

In Figure 6, additional patterns are identified through photographs of the BedZED housing complex, offering a more comprehensive spatial understanding of its design strategies.

Figure 6. Pattern scans - photographs taken on site. Source: Authors.

Pattern 158 (open stairs) (Photo 4) illustrates a design strategy that fosters spontaneous encounters by connecting different levels of the building. This pattern is complemented by pattern 160 (building edge) and pattern 164 (street windows) (Photo 5), which enhance the social function of the space. Together, these patterns transform an ordinary corner into a social hub, encouraging people to linger while facilitating visual and physical integration between private interiors and neighborhood spaces. In Photo 6, patterns 59 (quiet backs) and 60 (accessible green) are visible, promoting human interaction with nature. Additionally, pattern 177 (vegetable garden) supports the planting and consumption of organic food. The integration of these patterns underscores the significance of an ecological approach to urban planning. This design approach seems vital for advancing the SDGs,

particularly the goal of promoting Sustainable Cities and Communities, by creating urban spaces that are both environmentally sustainable and conducive to social cohesion.

Patterns' Humanizing Attributes

Based on the identification and analysis of the articulations between Alexander's patterns (Alexander et al., 1977) in the BedZED Co-housing design strategies, the framework (Figure 7) highlights the humanizing attributes presented in each pattern, organized into seven thematic subsets of design strategies with similar and complementary contents. These humanizing attributes in Co-housing design typology demonstrate the potential to improve the quality of the built environment, positively impacting human health and wellbeing. However, these proposed attributes need further testing to validate their effectiveness regarding their potential to promote socio-environmental sustainability in urban spaces.

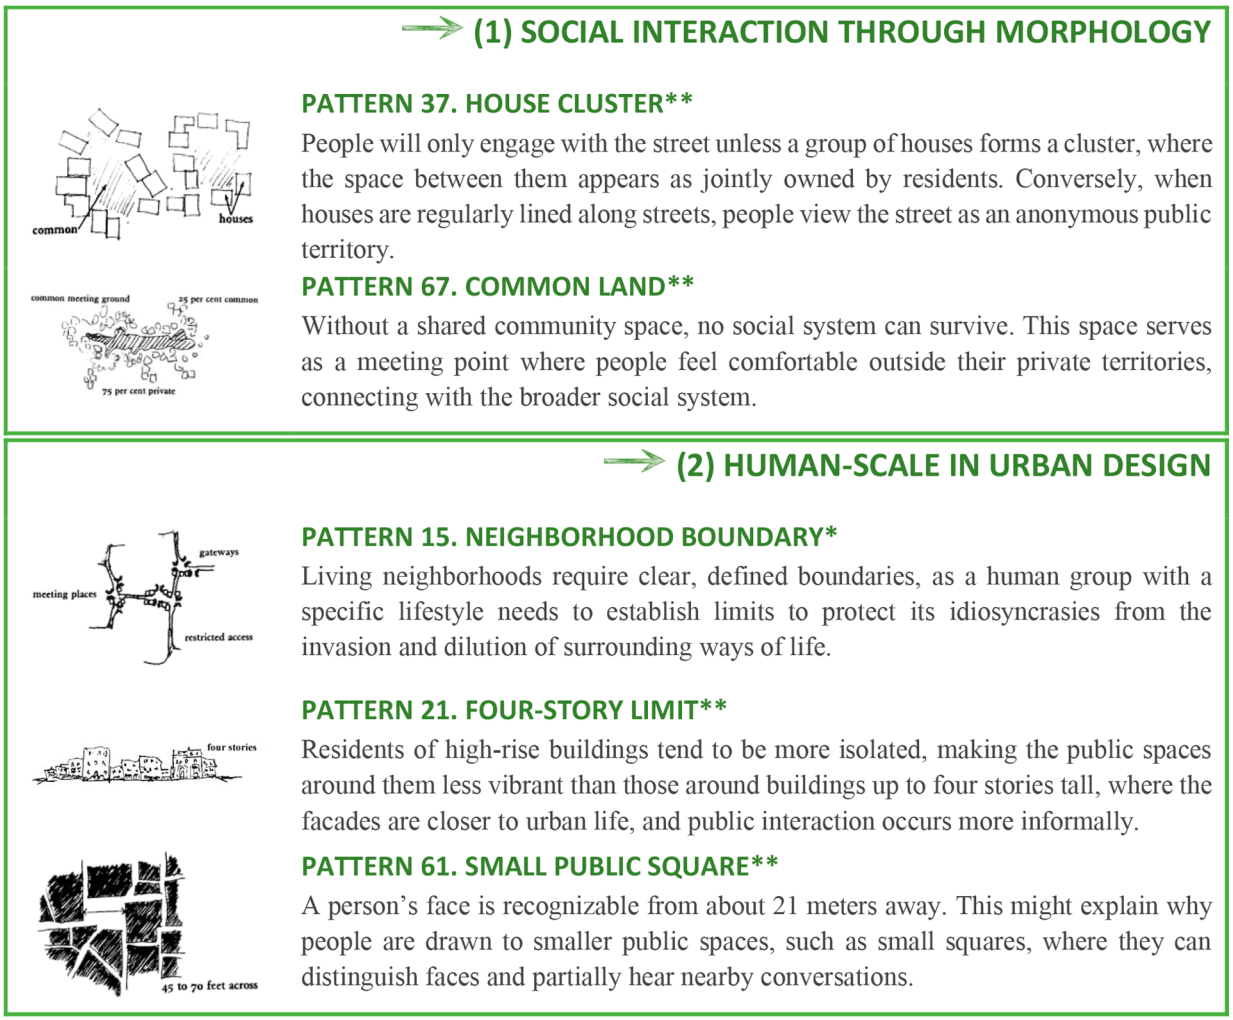

Figure 7. Thematic subsets of Patterns' Humanizing Attributes. Source: Adapted from Alexander et al. (1977).

Figure 7. Thematic subsets of Patterns' Humanizing Attributes. Source: Adapted from Alexander et al. (1977).

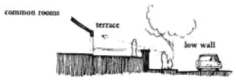
→ (6) BUILDINGS LINKING PEOPLE AND LANDSCAPE

PATTERN 39. HOUSING HILL

Homes built on hills allow upper-floor residents to cultivate outdoor spaces like gardens or yards, meeting the human need for contact with nature and neighbors while creating territoriality in housing unit spaces.

PATTERN 118. ROOF GARDEN*

Buildings with green rooftops allow people to enjoy more sunlight and fresh air, maintaining closer contact with nature. These rooftops meet psychological needs, offering pleasant views and enhancing the quality of urban life.



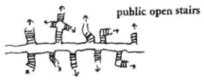
PATTERN 140. PRIVATE TERRACE ON THE STREET**

The relationship between domestic spaces and the street is often ambiguous: people need privacy in their private spaces but also wish to participate in public life. Human nature includes both communal and individual inclinations.

→ (7) PEDESTRIAN-ONLY WALKWAYS

PATTERN 100. PEDESTRIAN STREET**

Pedestrian streets serve as circulation routes leading people from cars, buses, or trains to their destinations while also being places of social interaction and permanence. The social interactions occurring in these spaces are one of the essential "social glue" elements in society.



PATTERN 158. OPEN STAIRS*

Open stairs function as social structures that provide freedom of movement, allowing people to move without the feeling of being under authority. They serve as extensions of public space, facilitating free and unrestricted flow.

Figure 7. Thematic subsets of Patterns' Humanizing Attributes. Source: Adapted from Alexander et al. (1977).

CONCLUSIONS

Examining how Co-housing design strategies can foster socio-environmental sustainability through morphological patterns, using the BedZED project as a case study, provided valuable insights into how design strategies in Architecture and Urban Design can improve urban space quality and contribute to human health and well-being. This approach, grounded in the environment behavior methods for design, involved a scanning design analysis strategy to map morphological patterns. Alexander's patterns were applied as key design parameters to identify and highlight Co-housing strategies with potential humanizing attributes. In this study, the focus shifted away from the traditional emphasis on the aesthetic values of Alexander's patterns, directing attention instead to their sensory and affective morphological values. Though difficult to measure, these aspects address fundamental human aspirations and needs in the built environment, such as social contact and connection with nature, which are universally recognized. This methodological approach requires further graphical and visual refinement in its protocol to be fully operational in future studies to create a more objective design analysis framework. Such a framework could then be used to identify morphological patterns within architectural and urban designs as well as photographs of built environments.

The BedZED project, with its innovative architectural features, is particularly relevant to this study, offering a novel application of Alexander's patterns in urban morphology. BedZED challenges the traditional association of Alexander's patterns with traditional construction methods, demonstrating their relevance in contemporary housing design. The framework of humanizing attributes, organized into seven thematic design strategy subsets, requires further testing to validate its effectiveness. The Co-housing strategies identified through these patterns show potential for promoting socio-environmental sustainability, especially when adopting a bidirectional, probabilistic approach to the person-environment relationship. This involves fostering social interaction, a connection with nature, pro-environmental behavior, and a sense of community, which could be key strategies in developing Sustainable Cities and Communities.

ABSTRACT

The pandemic caused by the new coronavirus responsible for COVID-19 has had a profound impact on urban environments' daily life and the way people interact with their surroundings. Different countries have responded differently to this challenge resulting in a plethora of outcomes, some even changing the way we experience urban spaces. This study compares the situations in both Brazil and South Korea, which have had significantly different paths and policies during the pandemic but arrived at a similar number of confirmed cases. The research shows that the virus outbreaks in the countries were very different, and that proactive governance and unified efforts were crucial in mitigating the pandemic's impact. South Korea's approach, which included comprehensive health measures, mass testing, contact tracing, and strict quarantine protocols, resulted in lower mortality rates and effective control of the virus, all of those aspects were also supported by the culture of vigilance and monitoring that was used to enforce sanitary policies. However, Brazil faced challenges due to a delayed and disjointed response, leading to devastating consequences, especially in its unequal urban landscape, at the same time that privacy was a concerning matter in the country, having many refuse to be tracked for monitoring the pandemic. The study highlights the importance of unified leadership in a complex socio-political context, establishing policies, and having public trust in navigating pandemics. Additionally, the research explores the dynamics of urban spaces during quarantine and the difference they experienced as Korea never had a lockdown, emphasizing the need for resilient urban planning strategies to address socio-spatial inequalities. Overall, this research provides insights into pandemic preparedness and urban resilience and strategies, emphasizing the lessons learned from different national approaches.

Keywords: Urban Planning; South Korea; Brazilian Perspective; Spatial Policies; Regional Development.

INTRODUCTION

The COVID-19 pandemic, caused by the novel coronavirus SARS-CoV-2, has profoundly disrupted urban environments worldwide, reshaping urban planning and public health systems. The rapid spread of the virus, first identified in Wuhan, China, led the World Health Organization (WHO) to declare it a pandemic within 100 days of its discovery (Spiteri et al., 2020). This unprecedented global

health crisis has highlighted the critical role of urban governance and planning in managing public health emergencies. Urban spaces have been reconfigured to accommodate social distancing, and public health strategies have evolved to address the challenges posed by high-density living and the need for accessible healthcare (Zhang et al., 2021).

Brazil and South Korea present compelling case studies for examining diverse responses to the COVID-19 pandemic. Despite both countries experiencing rapid urbanization and facing similar public health challenges, their approaches to managing the pandemic diverged significantly. South Korea's response was characterized by proactive governance, comprehensive health measures, and the use of technology for mass testing and contact tracing, which effectively controlled the virus's spread and resulted in lower mortality rates (Yang et al., 2021b). The country's success was underpinned by its extensive infrastructure of healthcare units, supported by a competitive and subsidized national healthcare security plan that ensured healthcare accessibility across urban areas.

In contrast, Brazil faced challenges with a delayed and fragmented response, exacerbated by a lacking healthcare infrastructure with uneven distribution across its vast territory. During the pandemic, Brazil had to rapidly create new healthcare units to meet the high demand, particularly in its socio-economically diverse urban areas, highlighting the challenges of managing public health in a federal system with significant regional disparities (Santos, 2021).

Figure 1. Left Image: Baseball fans cheer their teams during a popular match during COVID-19 pandemic in Seoul, South Korea, November of 2021 (Source: Yonhap). Right image: Brazil buries COVID-19 victims and reaches over 1 million deaths from the disease, October of 2021 (Source: Brasil de Fato).

This study aims to analyze the urban dynamics, governance strategies, and socio-spatial inequalities that shaped the pandemic responses in Brazil and South Korea. By comparing these two nations, the research seeks to uncover the factors contributing to effective pandemic management and the lessons that can be drawn for future public health crises. The study emphasizes the importance of unified leadership, public trust, and resilient urban planning in mitigating the impacts of pandemics. Furthermore, it contributes to the broader discourse on urban resilience and preparedness, offering insights into how emerging economies can adapt global best practices to their specific contexts, thereby enhancing their capacity to address future health emergencies (Romanillos et al., 2021; Akatsuka & Toyoda, 2023).

COVID-19 and its relation to urban dynamics

The COVID-19 pandemic has significantly altered urban dynamics worldwide, reshaping how cities function and how people interact within them. Urban areas, characterized by high population densities and extensive public transportation networks, were initially perceived as potential hotspots for virus transmission due to the ease of movement and close human interactions (Akatsuka & Toyoda, 2023). The pandemic prompted unprecedented public health measures, including lockdowns and

social distancing, which transformed urban spaces from bustling centers of activity to quieter, more isolated environments. This shift highlighted existing socio-economic disparities, as access to resources and healthcare varied widely across different urban populations (Romanillos et al., 2021). The pandemic also accelerated the adoption of digital technologies, as remote work and education and online services became essential, further emphasizing the digital divide between different socio-economic groups (Santos, 2021). In response to these challenges, cities have had to rethink urban planning and public space usage, emphasizing the need for resilient and adaptable urban environments that can withstand future public health crises (Semantics Scholar, 2023). The experience of cities during COVID-19 underscores the importance of integrating health considerations into urban planning and the need for policies that address socio-spatial inequalities to ensure equitable access to urban benefits for all residents.

Socio Economics or Politics, what determines the impact of the pandemic?

The impact of the COVID-19 pandemic has been profoundly shaped by both socio-economic and political factors, which have influenced the effectiveness of responses and the severity of outcomes across different countries. In Brazil, socio-economic disparities played a significant role in the pandemic's trajectory, as highlighted by the uneven distribution of COVID-19-related deaths across municipalities. Studies have shown that lower socio-economic status, limited access to healthcare, and inadequate infrastructure exacerbated the spread and mortality rates of COVID-19, particularly in vulnerable communities (Coelho et al., 2020). The Brazilian government's response was further complicated by political factors, including a lack of cohesive leadership and mixed messages from federal authorities, which undermined public health measures and contributed to widespread misinformation (Ventura, 2021).

In contrast, South Korea's response was characterized by strong state capacity and effective governance, which mitigated the impact of socio-economic disparities. The country's experience with previous outbreaks, such as MERS, informed a rapid and coordinated response that included widespread testing, contact tracing, and public compliance with health measures (Yang et al., 2021b). Despite initial successes, South Korea faced challenges related to vaccine procurement and public fatigue with ongoing restrictions, which highlighted the complex interplay between socio-economic factors and political decision-making (Hong & Lim, 2023).

The comparison between Brazil and South Korea underscores the critical role of political leadership and state capacity in managing the pandemic. While socio-economic factors undeniably influenced the spread and impact of COVID-19, the effectiveness of governmental responses was pivotal in shaping outcomes. In Brazil, political fragmentation and populist leadership weakened state capacity, leading to a disjointed response that exacerbated socio-economic inequalities.

Conversely, South Korea's cohesive governance and high state capacity facilitated a more effective management of the crisis, despite socio-economic challenges. This analysis highlights the need for integrated approaches that address both socio-economic vulnerabilities and political dynamics to enhance resilience against future pandemics.

South Korea’s starting success in dealing with the virus

South Korea was recognized world-wide for its effective response to the starting phases of the COVID-19 and through the first years of the pandemic. They employed many policies and strategies for testing and quarantines responsible for controlling access and spread of the virus considering also the very strong adoption of sanitary measures from the population as a whole.

The foundation of South Korea's success lay in its preparedness and robust governance framework. The country had already established a comprehensive legal and institutional framework for pandemic response due to the previous MERS outbreak, including the Infectious Disease Control and Prevention Act, which empowered the Korea Centers for Disease Control and Prevention (KCDC) with the authority and resources necessary to manage outbreaks effectively (Lee, 2020). This framework facilitated the rapid deployment of the Three T's strategy (Testing[19], Tracking[20] and Treatment[21]) supported by the healthcare infrastructure installed in the country and technological answers and integration of systems (Choi, 2020); A key factor in South Korea's initial success was the high level of public cooperation and trust in government measures. The government maintained transparent and consistent communication with the public, providing daily updates on the pandemic's status and guidelines for safety measures. This transparency helped build public trust and encouraged compliance with health directives (Noh et al., 2020).

Despite its early achievements, South Korea faced challenges in maintaining the effectiveness of its response as the pandemic evolved. The initial success led to complacency among the public, and the government struggled to adapt its strategies to the changing dynamics of the pandemic. A rise in daily cases highlighted the need for continuous adaptation and engagement with the public to address emerging challenges and sustain public trust (Hong and Lim, 2023).South Korea's experience underscores the importance of preparedness, robust governance, and public cooperation in managing pandemics. It also highlights the need for adaptive strategies that evolve with the crisis and the importance of balancing public health measures with individual rights. As the world moves toward normalcy, the lessons from South Korea's response emphasize the need for international cooperation and the sharing of best practices to effectively tackle future global health crises.

METHOD

This study employs a comparative analysis to examine the COVID-19 pandemic responses of Brazil and South Korea, focusing on governance, public health strategies, and socio-political contexts. The research covers the period from January 2020 to October 2023, providing a comprehensive overview of the pandemic's progression in both countries. Data were collected from a variety of sources,

[19] South Korea prioritized widespread and rapid testing from the onset of the pandemic. The government collaborated with private companies to develop and mass-produce RT-PCR test kits, enabling the country to conduct tens of thousands of tests daily by March 2020. This extensive testing capacity allowed for the early detection and isolation of cases, preventing widespread transmission (Kim, 2020).

[20] The use of advanced information and communication technologies (ICT) played a crucial role in South Korea's contact tracing efforts. The government implemented a robust system that utilized GPS data, credit card transactions, and CCTV footage to trace the movements of confirmed cases. This approach, while raising privacy concerns, was instrumental in quickly identifying and notifying individuals who had been exposed to the virus (Lee et al., 2021).

[21] South Korea's healthcare system, characterized by universal health coverage, ensured that all COVID-19 patients received necessary medical care without financial barriers. The government designated specific hospitals for COVID-19 treatment, effectively managing healthcare resources and preventing system overload (Ministry of Health of the Republic of Korea, 2020).

including official government reports, publications from health agencies such as the World Health Organization (WHO) and the Korea Disease Control and Prevention Agency (KDCA), as well as academic studies and media reports. These sources provided detailed information on public health measures, vaccination rates, and socio-political factors influencing each country's response.

The analysis focuses on several key variables, including the number of confirmed COVID-19 cases, mortality rates, testing and vaccination efforts, and the implementation of public health measures. The study also examines the socio-political context, exploring how governance and public compliance influenced pandemic management. This includes an analysis of leadership decisions, communication strategies, and the impact of misinformation on public perception and behavior.

A comparative analytical framework was employed to assess the pandemic trajectories in Brazil and South Korea. This framework considers governance models, health system capacity, and public health strategies, providing insights into the effectiveness of each country's response. Additionally, the Complex Adaptive Systems (CAS) framework was applied to understand the dynamic interactions between government policies, public behaviour, and health outcomes, highlighting the adaptability and resilience of each country's response to the evolving pandemic context (Hong & Lim, 2023).

The study acknowledges limitations related to data availability and reporting discrepancies between sources. Efforts were made to cross-verify data from multiple sources to ensure accuracy and reliability. Despite these challenges, the research provides valuable insights into the pandemic responses of Brazil and South Korea, offering lessons for future public health preparedness and crisis management.

RESULTS AND DISCUSSIONS

Two countries and two different scenarios

The COVID-19 pandemic has highlighted the diverse responses and impacts experienced by different countries, as illustrated by the cases of South Korea and Brazil.

Table 1. Comparative Overview of Socioeconomic and COVID-19 Indicators: South Korea vs. Brazil

	South Korea	Brazil
Location	Leste da Ásia	América do Sul
Total area	100.378 km² (2010)	8.510.417.771 km² (2022)
Population	51.692.272 (2022)	203.062.512 (2022)
Population Density	Densidade Demográfica 514.6 p/km²	Densidade Demográfica 23.86 p/km²
GDP (PIB)	USD$ 1.67 trilhões (2022)	US$ 1.92 trilhões (2022)
GDP per capita	US$ 32.254.6 (2022)	US$ 8.917.7 (2022)
Average income ($USD)	USD$ 1.542,64[22] (2023)	USD$ 286,32[23] (2023)
Cases of COVID-19	34.571.873[24] (até Setembro, 2023)	38.130.675[25] (até Dezembro, 2023)
Deaths by COVID-19	35.934	708.237

[25] https://covid.saude.gov.br/

	(até Setembro, 2023)	(até Dezembro, 2023)

The substantial difference in GDP per capita between South Korea (US$ 32,254.6 in 2022) and Brazil (US$ 8,917.7 in 2022) reveals a stark divergence in economic development and standards of living. While South Korea's robust economy supports a strong social safety net, evidenced by its adjusted minimum wage and comprehensive welfare state, Brazil grapples with prevalent sub-employment and low wages, indicating deeper structural inequalities. This discrepancy underscores the interplay between economic strength and social well-being, with implications for pandemic resilience and recovery (WORLD BANK, 2022).

The table 1 provides a comparative overview of key socioeconomic and COVID-19 indicators for both nations, revealing stark contrasts in population density, GDP per capita, and pandemic outcomes. South Korea, with its high population density and robust healthcare infrastructure, managed to maintain relatively low COVID-19 mortality rates. In contrast, Brazil faced significant challenges, including a higher number of cases and deaths, exacerbated by socio-economic disparities and governance issues. This comparison underscores the critical role of effective governance, healthcare accessibility, and socio-political context in shaping pandemic responses and outcomes.

The underreporting of COVID-19 cases in Brazil was a significant challenge during the pandemic, particularly in remote and underserved areas where access to testing and healthcare was limited (Coelho et al., 2020). This resulted in many infections going undetected, obscuring the true scale of the pandemic's impact. At the same time, the lack of a centralized data collection system further exacerbated this issue, leading to inconsistencies and delays in reporting and underreporting, that not only hampered effective public health interventions but also fueled misinformation and complacency, undermining efforts to control the virus's spread. In stark contrast, South Korea implemented a robust testing and reporting system that facilitated early detection and containment of COVID-19 (Shin, 2020). The country's well-developed healthcare infrastructure and widespread access to testing enabled rapid identification and isolation of infected individuals. The government's proactive approach to testing and contact tracing, supported by advanced technology and public cooperation, ensured that a high proportion of cases were identified and reported.

This transparency fostered public trust and facilitated targeted interventions. South Korea's urban landscape, with its high population density and well-connected transportation networks, further facilitated access to testing facilities.

Another important factor was the concentration of healthcare resources in urban centers and the efficient public transportation system enabled individuals to readily access testing sites. The government's strategic placement of testing centers in easily accessible locations further enhanced this accessibility (Kim et al., 2020). Also, the COVID-19 pandemic also prompted notable shifts in transportation patterns.

Specially in South Korea, many cities saw a significant increase in bicycle use, driven by concerns about virus transmission on public transport and a desire for outdoor exercise during lockdowns. In response, several cities expanded their cycling infrastructure. This shift towards cycling not only helped reduce strain on public transport but also contributed to improved air quality and public health. Conversely, in Brazil, the pandemic led to a marked decrease in public transport use,

particularly in densely populated areas. Fear of infection in crowded buses and trains prompted many to seek alternative modes of transport, such as motorcycles and used cars. This shift exacerbated traffic congestion and air pollution, highlighting the challenges of maintaining sustainable urban mobility during a public health crisis. The decline in ridership also had economic implications for transport operators, further complicating recovery efforts.

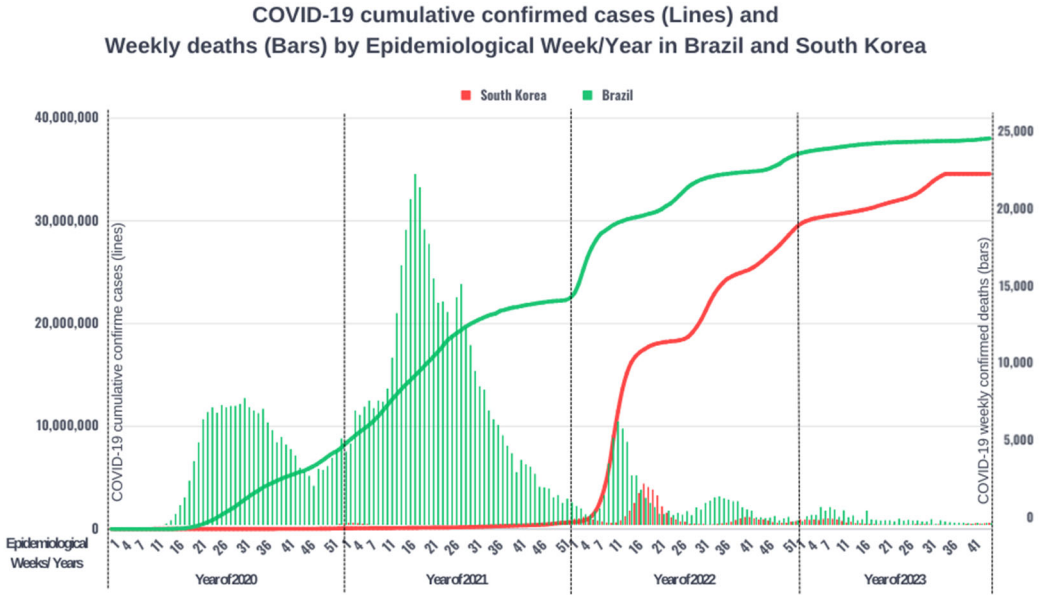

Figure 2. Cumulative Confirmed COVID-19 Cases by Epidemiological Week/Year in Brazil and South Korea from 2020 to the 43rd Epidemiological Week of 2023 (in September). Source: Prepared by the authors, data from official government communication channels for COVID-19 cases.

The graph (figure 1) depicts COVID-19 cumulative confirmed cases and weekly deaths from 2020 to 2024 illustrates the distinct trajectories of Brazil and South Korea during the pandemic. South Korea's early implementation of the "Three Ts" strategy—Testing, Tracking, and Treatment—helped maintain a relatively flat curve initially, reflecting effective containment measures. However, the emergence of new variants like Delta and Omicron led to subsequent increases, highlighting the ongoing challenges of pandemic management. In contrast, Brazil experienced significant spikes in both cases and deaths, particularly during the early stages, due to delayed public health responses and socio-political challenges. The graph underscores the importance of robust healthcare systems and timely interventions in mitigating the pandemic's impact. These insights lead into a detailed examination of South Korea's response strategies and developments over the course of the pandemic.

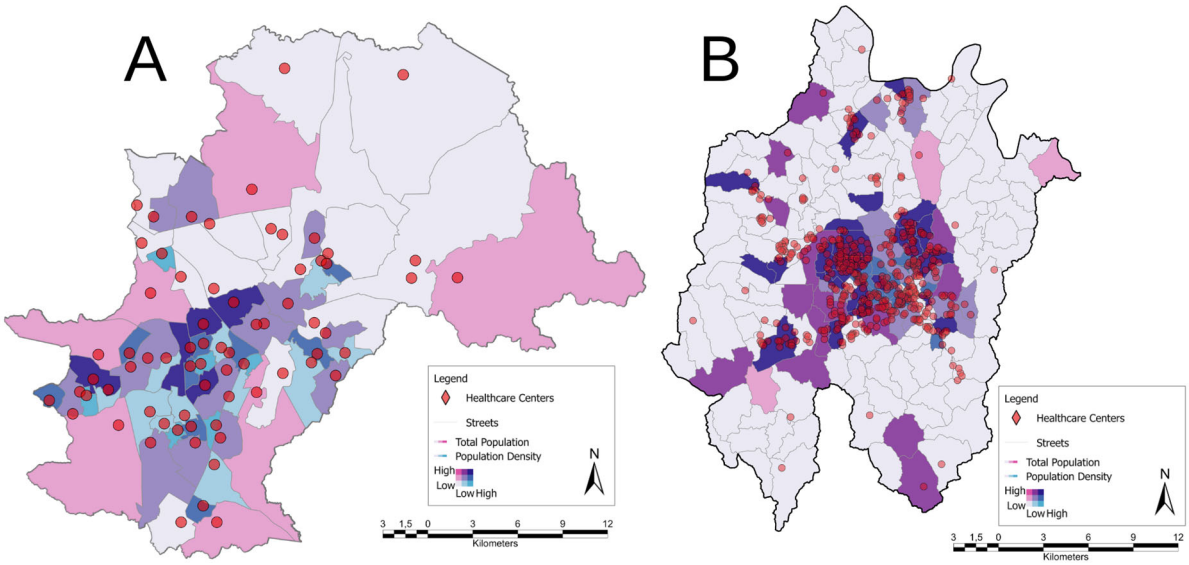

Figure 3. Comparative Spatial Distribution of Healthcare Centers, Population, and Population Density in A - City of Campinas (Brazil) and B - City of Daejeon (South Korea)

The map provides a comparative spatial analysis of healthcare accessibility, population density, and total population in two distinct urban environments: Campinas, Brazil (A) and Daejeon, South Korea (B). Both maps utilize a bivariate choropleth scale to represent population and population density, with darker shades indicating higher values. Healthcare centers are represented by distinct point symbols. This visual comparison serves to highlight potential disparities in healthcare access and resource distribution in relation to population dynamics, particularly relevant in the context of understanding the varied impacts of the COVID-19 pandemic on different urban areas.

Different approaches for political and sanitary measures and their outcomes for each country

South Korea's COVID-19 response and developments

Early Response and Initial Success (2020-2021)

South Korea's initial response to the COVID-19 pandemic was characterized by rapid and effective measures that set a global example in pandemic management. The country was among the first to be affected due to its proximity to China, with the first confirmed case reported on January 20, 2020 (Cha, 2020). Drawing from its experience with the MERS outbreak in 2015, South Korea swiftly implemented a comprehensive strategy known as the "Three Ts": Testing, Tracking, and Treatment. This approach was supported by robust healthcare infrastructure and extensive use of information and communication technologies (ICT) for contact tracing (Choi, 2020; Lee et al., 2021). The government established a special task force under the Korea Centers for Disease Control and Prevention (KCDC) to coordinate the national response, which included real-time public information dissemination and strict quarantine measures for travelers (Yoo et al., 2021).

Challenges and Adaptations (2021-2022)

Despite the initial success, South Korea faced significant challenges as the pandemic progressed. By the end of 2020, the global rollout of vaccines marked a new phase in the pandemic response. However, South Korea experienced delays in securing vaccine supplies, which led to public dissatisfaction and a decrease in trust in government measures (Hong & Lim, 2023). The government accelerated the approval and distribution of vaccines, with the Oxford-AstraZeneca and Pfizer-

BioNTech vaccines becoming available in early 2021 (Nham et al., 2022). Despite these efforts, the emergence of the highly transmissible Omicron variant in late 2021 posed new challenges, leading to a surge in cases and necessitating adjustments in public health strategies (Kwon & Yang, 2022).

Vaccination and Variants (2022-2023)

By early 2022, South Korea had achieved high vaccination coverage, with 85% of the population receiving two doses and booster campaigns underway. However, the Omicron variant led to a significant increase in cases, highlighting the need for ongoing vigilance and adaptation of public health measures (Park et al., 2021). The government responded by implementing winter vaccination programs targeting vulnerable populations and adjusting social distancing measures to balance public health needs with economic and social pressures (Ministry of Health and Welfare, 2022). Despite the challenges, South Korea maintained relatively low fatality rates compared to global averages, demonstrating the effectiveness of its healthcare system and public health policies (Our World in Data, 2023).

Transition back to normal (2023-2024)

In 2023, as global health authorities, including the World Health Organization, began to declare the end of the COVID-19 pandemic as a public health emergency, South Korea started transitioning towards normalcy. The government gradually eased restrictions, including lifting mask mandates in outdoor settings, while continuing to monitor infection rates and adjust policies as needed (MOHW, 2022). By mid-2023, the country had reported over 31 million cases and maintained a low fatality rate of 0.11%, underscoring the success of its comprehensive response strategy (KDCA, 2024). The experience of South Korea during the pandemic highlights the importance of preparedness, adaptability, and effective communication in managing public health crises, providing valuable lessons for future global health challenges.

Brazil’s COVID-19 desperate situation and struggles

Initial Response and Challenges (2020-2021)

In early 2020, Brazil, like the rest of the world, faced an unprecedented public health crisis with the onset of the COVID-19 pandemic. The country had a history of dealing with infectious diseases, but the discontinuation of its Severe Acute Respiratory Syndrome (SARS) surveillance system in 2019 left it somewhat unprepared for the rapid spread of COVID-19. The first confirmed case was reported in February 2020, before the World Health Organization declared COVID-19 a global pandemic on March 11, 2020 (The Lancet, 2020). Despite the establishment of Law No. 13,979/2020 to address the pandemic, the federal government's response, led by President Jair Bolsonaro, was marked by skepticism and downplaying of the virus's severity. This stance influenced public behaviour, leading to widespread disregard for health measures and contributing to the rapid spread of the virus across the country (G1, 2023).

Escalation and Media Intervention (2020)

By March 2020, all Brazilian states had issued alerts due to the presence of COVID-19 cases, and the situation quickly escalated. By June, Brazil had become the second country with the highest number of confirmed cases globally, following the United States. The federal government's attempts to withhold and delay crucial COVID-19 data prompted the formation of the "Consortium of Press Vehicles," a collaboration among major Brazilian media outlets to ensure the public received accurate

and timely information. This initiative was crucial in maintaining transparency and public awareness during a period of significant uncertainty and misinformation (G1, 2023).

Healthcare System Strain and Socioeconomic Impact (2020-2021)

The Brazilian healthcare system faced immense pressure as hospitals reached capacity and healthcare workers experienced significant stress. In response, the government distributed rapid tests and expanded the "More Doctors" program to bolster healthcare services. Public awareness campaigns emphasized the importance of social distancing, mask-wearing, and hand hygiene. The pandemic also had profound economic and social impacts, disproportionately affecting vulnerable populations. The federal government introduced emergency financial aid to support millions of Brazilians facing economic hardships (Ministério da Saúde, 2020).

Vaccination Efforts and Political Challenges (2021-2022)

In 2021, Brazil launched a massive vaccination campaign, marking a significant milestone in its COVID-19 response. The emergency approval of CoronaVac[26] and AstraZeneca vaccines by the National Health Surveillance Agency (Anvisa) in January were pivotal. Despite logistical challenges and political disputes, the campaign achieved notable progress, with over 80% of the population receiving at least one vaccine dose by the end of the year. However, the emergence of new variants like P.1 in Manaus and the oxygen crisis in hospitals underscored the ongoing challenges faced by the healthcare system (Oliveira et al., 2021).

Adapting to New Variants and Socioeconomic Disparities (2022-2023)

The emergence of the Omicron variant in late 2021 led to a surge in cases, prompting renewed public health measures. By early 2022, Brazil had achieved high vaccination coverage, significantly reducing severe cases and mortality rates. The country began easing restrictions, allowing for a gradual return to normalcy. However, the pandemic highlighted persistent socioeconomic disparities, with vulnerable communities continuing to face challenges in accessing healthcare and vaccines. Efforts to address these inequities were crucial in ensuring a more equitable public health response (De Menezes et al., 2023).

Transition to Normal and Lessons Learned (2023-2024)

In 2023, as the World Health Organization declared the end of COVID-19 as a public health emergency, Brazil reflected on its pandemic journey. The country's experience highlighted the importance of coordinated public health strategies, transparent communication, and international cooperation in managing global health crises. Despite the challenges, Brazil's vaccination campaign and public health initiatives played a crucial role in mitigating the pandemic's impact. The lessons learned emphasize the need for ongoing vigilance, preparedness, and equitable access to healthcare to navigate future public health emergencies (Ministério da Saúde, 2023).

Comparative Analysis of both countries scenarios

South Korea's response to the COVID-19 pandemic was marked by proactive governance and effective leadership, which were instrumental in controlling the virus's spread. The country leveraged its experience from the MERS outbreak to establish a robust framework for managing infectious diseases,

[26] The CoronaVac vaccine played a important role during the COVID-19 pandemic, it was produced and distributed locally by the Butantan institute, a public institution of Sao Paulo State, through a partnership with Sinovac, this vaccine enabled a swift and massive immunization campaign, reaching most of the brazilian population amid the global vaccine shortages.

characterized by clear communication, rapid decision-making, and extensive use of technology for contact tracing and testing (Choi, 2020; Lee et al., 2021). In contrast, Brazil's response was hindered by political discord and inconsistent leadership. President Jair Bolsonaro downplaying of the virus and resistance to implementing strict public health measures led to a fragmented response, with state and local governments often acting independently to fill the void left by the federal government (G1, 2023; BBC, 2021).

South Korea's "Three Ts" strategy—Testing, Tracking, and Treatment—was central to its success in managing the pandemic. The government implemented widespread testing and contact tracing, supported by digital technologies, which allowed for early detection and isolation of cases without resorting to lockdowns (Shin, 2020). This approach helped maintain low mortality rates and prevent healthcare system overload. Conversely, Brazil struggled with delayed testing and insufficient contact tracing, exacerbating the spread of the virus. The lack of a coordinated national strategy and the politicization of health measures further complicated efforts to control the pandemic (Ministério da Saúde, 2020).

The socio-political context played a significant role in shaping the pandemic responses in both countries. In South Korea, high levels of public trust in government and compliance with health measures were crucial in curbing the virus's spread. The government's transparent communication and effective use of ICT fostered public cooperation and adherence to guidelines (Noh et al., 2020). In contrast, Brazil faced challenges with public compliance, partly due to mixed messages from political leaders and widespread misinformation. The federal government's inconsistent communication and undermining of scientific advice contributed to public skepticism and resistance to health measures (Ventura, 2021).

CONCLUSIONS

The outcomes of the pandemic in South Korea and Brazil highlight the importance of coordinated public health strategies and effective governance. By August 2023, South Korea had reported approximately 34.5 million cases with a relatively low mortality rate, reflecting the success of its comprehensive response (OECD, 2023). In contrast, Brazil recorded 38 million cases and over 700,000 deaths, underscoring the severe impact of its fragmented response (Ministério da Saúde, 2023). These contrasting trajectories emphasize the need for unified leadership, transparent communication, and public trust in managing health crises. The experiences of both countries provide valuable lessons for future pandemic preparedness, highlighting the critical role of adaptability and cooperation in mitigating the impact of global health emergencies.

The divergent outcomes in South Korea and Brazil during the COVID-19 pandemic underscore the critical role that governance and public health strategies play in managing global health crises. South Korea's success in maintaining a low mortality rate despite a high number of cases highlights the effectiveness of its data-driven decision-making and comprehensive public health measures, such as mass testing, contact tracing, and strict quarantine protocols. This approach was supported by the public's trust and compliance, which were pivotal in controlling the spread of the virus. The country's experience with previous epidemics, such as MERS, provided a valuable framework for its COVID-19

response, proving that preparedness and adaptability are essential components of effective crisis management.

In contrast, Brazil's fragmented response resulted in a higher mortality rate, demonstrating the consequences of delayed and disjointed public health measures. The lack of unified leadership and the spread of misinformation contributed to the public's distrust and non-compliance with health guidelines, exacerbating the pandemic's impact. The Brazilian experience highlights the importance of consistent and transparent communication from government authorities to build public trust and ensure adherence to health measures. As both countries move forward, their experiences offer valuable lessons for enhancing pandemic preparedness, emphasizing the need for robust health infrastructure, clear communication strategies, and the integration of public health policies with socioeconomic considerations to mitigate the effects of future health emergencies.

The experiences that both countries went through offer invaluable lessons for enhancing pandemic preparedness on a global scale. The need for robust health infrastructure, clear communication strategies, and the integration of public health policies with socioeconomic considerations is paramount. The pandemic has demonstrated the interconnectedness of our world and the importance of international cooperation and knowledge-sharing in mitigating the effects of future health emergencies.

Acknowledgements

We would like to express our heartfelt gratitude to the Korea Research Institute for Human Settlements (KRIHS) for their invaluable support and collaboration throughout this study.

We are also deeply appreciative of the financial support provided by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) under Finance Code 001. This support has been crucial in advancing our research efforts.

This research was supported by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) through the Programa de Doutorado Sanduíche no Exterior (PDSE) [grant number 88881.846178/2023-01], under CAPES Edict N44/2022. The PDSE program provided invaluable support for the international exchange and development of this doctoral research. The author gratefully acknowledges CAPES for this opportunity to enhance academic training, expand research networks, and contribute to the internationalization of Brazilian graduate education.

ABSTRACT

The development of Chinese cities is facing the dilemma of more people and less land. Therefore, in the planning and construction of core commercial circles, China vigorously promote the development by the TOD model. In order to better achieve the integration development benefits of TOD model in multiple aspects such as land appreciation, pedestrian flow aggregation, and public transportation. This paper consider the complex geographical environment of Chinese cities, selecting the Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station with TOD built environment forms of mountainous and plain areas to research. From the perspective of transportation systems, the spatial boundaries of accessibility are comparable between the two stations. However, due to the influence of mountainous environments, the walking range of Chongqing Guan Yinqiao Station is smaller than that of Chengdu Chun Xilu Station. In addition, this also leads to poor transfer efficiency between the "subway-bus" at Chongqing Guanyinqiao Station; From the perspective of land use system, the proportion of land functions is relatively similar, but there is still a gap in development intensity and directional diversification of mixed land functions, and the development intensity of Chongqing Guan Yinqiao Station is greater. These results show that the similarity in the TOD built environment forms between the core commercial circles of mountainous and plain cities in China is specifically manifested in the distance effect of functional proportion and development intensity, which has a "fluctuating" trend; the difference lies in the differences in directional diversification of mixed land functions and public transportation. Therefore, The development of TOD in mountainous cities requires a high-density vertical development and construction model, as well as convenient pedestrian space creation. The development of TOD in plain cities requires attention to the coordination of land use functions with a certain accessibility to ensure gradient construction of development intensity.

Keywords Transit-Oriented development (TOD), built environment forms, transportation systems, land use system

INTRODUCTION

The development of Chinese cities is facing the dilemma of more people and less land, this is even more evident in China's commercial circles. So Both the Chinese government and developers are considering how to leverage limited land use to not only increase local land capital and drive economic development, but also better serve a large number of surrounding populations. In response to this situation, the National Development and Reform Commission has issued the "14th Five Year Plan for

the Implementation of New Urbanization (2021-25)", which proposes to promote the Transit-Oriented Development (TOD) model and create integrated station city complexes. Therefore, utilizing TOD model to analyze its built environment forms for guide urban development, especially the development of core commercial circles, has important practical significance.

At present, research on the built environment forms of TOD is mainly conducted based on the 5D indicators (density, diversity, design, transportation transfer distance, and destination accessibility) summarized by Cervero in terms of research objects (Cervero and Kara Kockelman, 1997; Cervero et al., 2009). In terms of research methods, Chinese scholars mainly rely on qualitative judgments in analyzing the built environment forms (Wei and Xu, 2021); foreign scholars mainly focus on quantitative analysis, using multi criteria analysis (MCA) that utilize 5D dimensional indicators as benchmarks and assigning weights to each indicator to evaluate the built environment forms (Singh et al., 2012). In terms of research content, some scholars evaluate the built environment forms of each TOD rail station to form a TOD index (TODness) from overall perspective, which not only determines the overall development direction of TOD model, but also gives development suggestions for different TOD rail stations based on individual differences (Singh et al., 2017; Motieyan and Mesgari, 2018); some scholars also classify and grade the TOD built environment characteristics according to the current situation, indicating that land use and transportation system in the built environment forms are key factors in TOD development (Motieyan and Mesgari, 2018). And corresponding optimization suggestions are put forward for the development intensity, functional formats, and public spaces in the built environment forms from individual perspective (Al-Harami and Furlan, 2020).

Overall, most studies on the TOD built environment forms start from the overall region, and lack discussion on specific types such as commercial districts, residential areas, transportation hubs and other areas. In addition, China has more than two-thirds of mountain resources, and its complex geographical environment also puts forward different requirements for TOD development and construction. In this regard, this paper combines the terrain differences between China's plains and mountains, takes the TOD core commercial circles - Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station as an example, determines the this circles through the differences in walking accessibility caused by the terrain slope and analyzes the built environment forms within the circles, so as to provide a reference for the optimization of the built environment and subsequent development of the TOD area in the core commercial circles.

Transportation system and land use system of TOD built environment forms

Although some scholars have divided the TOD built environment forms into relevant indicators of 5D , these indicators cannot be separated from the material environment formed by the combination of transportation system and land use system (Huang et al., 2023).

The transportation system is the skeleton of the TOD built environment forms. Since the transportation system emphasizes a pedestrian-oriented environment and strengthens the use of public transportation (Liu, 2017), current research is mainly carried out from two aspects: walking accessibility and public transportation. Therefore, American scholar Peter Calthorpe once pointed out in the TOD concept that a "pedestrian-friendly" environment is the core content of the TOD concept, which focuses the research content on the walking scale of the TOD built environment forms (Calthorpe et al., 2014; Liu, 2019). This scale represents the convenient and efficient circles of the

current TOD built environment forms. At the same time, the walking accessibility circles formed by TOD built environment forms often complement public transportation, constructing an overall travel connection system of "walking-bus-subway" to achieve rapid speed of people' travel (Liu, 2019).The TOD land use system is the carrier of the TOD built environment forms. As the transportation system brings a huge flow of people, high-density development and construction are required to ensure the business needs of people within a certain time and space range. Therefore, relevant research focuses on two aspects: land functions and development intensity. Due to the location differences of urban space, different TOD types form different land use development models, resulting in different levels of functional circles in the walking accessibility circles formed by TOD built environment forms. And in terms of development intensity, government and developers pay attention to the relationship between development intensity and development profit, ensure reasonable economic input-output with a reasonable plot ratio, and create a good urban environment for residents (Wang et al., 2011; Zhang et al., 2017).

Overall, the built environment forms of TOD requires the coordination of the transportation system and the land use system, that is, good walking accessibility circles promote the spatial concentration of population and socio-economic activities, and is conducive to the emergence of complex land functions, thereby stimulating appropriate development intensity and ensuring development benefits, which in turn promotes the establishment of a convenient travel connection system and strengthens the pedestrian environment (Figure 1).

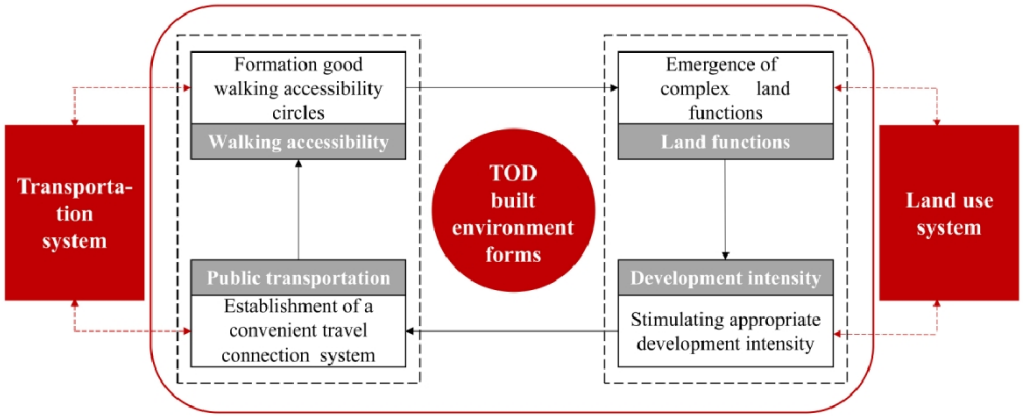

Figure 1. Coordination between TOD transportation system and land use system. Photo credit: Author's own drawing.

TOD built environment forms of core commercial circles with complex geographical environment

At present, there are few single studies on TOD built environment forms of core commercial circles. Related studies focus more on the overall characteristics of TOD built environment forms , that is to understand the TOD development model from the perspective of the spatial layout of the city. Some scholars distinguish the TOD built environment forms of based on urban spatial distance and divide them into three types of town, neighborhood and precinct (Niu et al., 2019).Some scholars also focus on the differences in development with land use to distinguish the TOD built environment forms, which can be generally divided into types such as commercial development, community residence, public transportation, and facility services (Pan and Huang, 2024).

It should be pointed out that the TOD built environment forms dominated by commercial development is often located in the core areas of the city and is extremely sensitive to the control of development intensity. Therefore, relevant scholars have conducted research on the built environment development of this type of TOD. For example, the lower limit of the floor area ratio of the TOD circle is controlled, and the upper limit of the floor area ratio of the urban area outside the TOD circle is controlled (Liu and Shi, 2020). At the same time, great attention is paid to the sustainable operation. For this reason, most cities encourage the development and construction within the TOD circle to be mainly carried out by the rail construction and operation units, while the development and construction outside the circle, in addition to independent development by construction and operation units, also needs to be jointly developed with social investment entities. In the subsequent profit distribution, it is clear that the economic benefits of their development and construction should be used first for TOD rail construction and operation to make up for losses, so as to achieve the TOD sustainable development in the core commercial circles (Liang, 2023). This aspect is inseparable from the complex geographical environment with the development and construction process. Compared with the plain environment, the available development and construction area in the mountainous environment is limited. In order to ensure the income, the vertical development requirements are urgent (Zhang, 2020; Chen et al., 2023). Taking the mountainous TOD commercial complex in Shapingba District, Chongqing, China as an example, its underground space development has currently reached 7 floors.

However, in addition to considering the economic capital brought by land use, the development and construction of the TOD model should not ignore its own purpose - to create a public environment dominated by pedestrian friendliness, so that TOD development and construction also has important public policy value (Liang, 2023). Therefore, it is necessary to explore the TOD built environment forms of core commercial circles in plains and mountains, so as to provide reference for the subsequent coordination of transportation system and land use system.

METHOD

Based on the basic composition of TOD built environment forms, this paper finally analyzes the transportation system and land use system of TOD built environment forms in the core commercial circles. Among them, in the transportation system analysis, the first is to explore the temporal and spatial heterogeneity of the walking accessibility circles; the second is to analyze the efficiency with transportation connection system under the accessibility circles. In the land use system analysis, attention is paid to the proportion and spatial differences of land functions within the circles; the second is to identify the floor area ratio and dominant development direction within the circles. This forms the technical route of Figure 2.

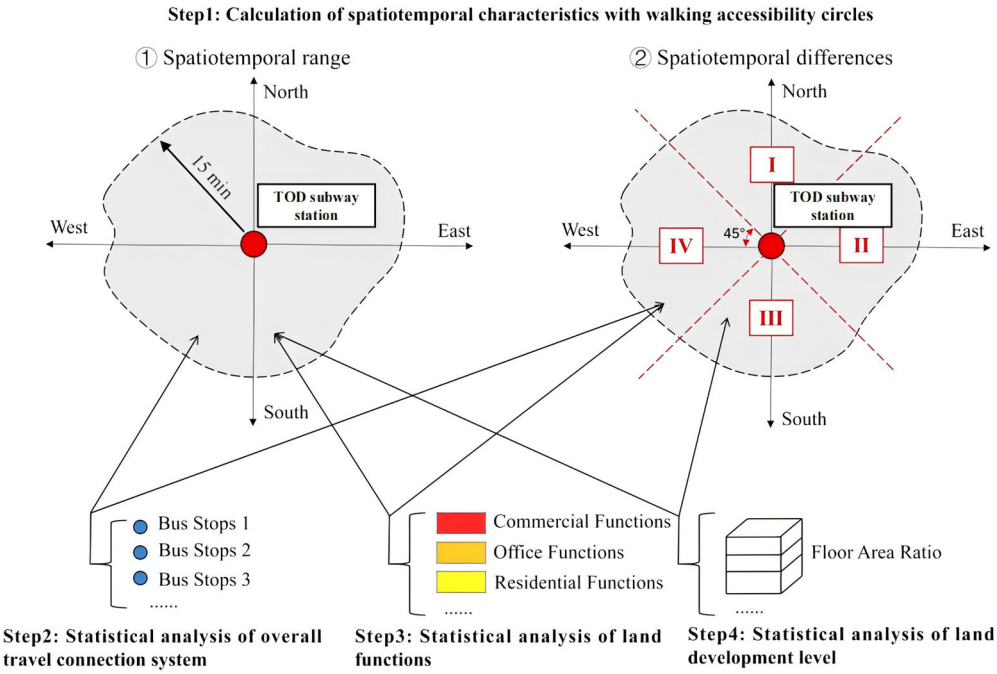

Figure 2. Technical route of this research. Photo credit: Author's own drawing.

Related calculation methods for transportation system

According to step1 and step2 of the technical route, the TOD rail station travel model is established with the help of ArcGIS network analyst module for determining walking accessibility circles. That is, this module in the rail station and road network database - centers, links, nodes and resistances are used to reflect the influence range of people at the TOD rail station (center) along the accessible roads under a certain resistance value (time, distance, cost, etc.). Compared with the traditional 400m, 800m and other regular circles, this irregular time and space range can better express the real travel scenario. Therefore, in order to reflect the complex geographical environment and show the built environment of mountains and plains, according to the relevant literature on exercise physiology (Chen et al., 2014), the pedestrian speed is combined with the slope to assign values (Table 1).

Table 1. Pedestrian speed at different slopes

Slope (%)	Pedestrian speed (m/min)
0-3	60
3-5	54
5-10	42
10-15	36
15-20	30
20-25	24
>25	18

Based on the above database, the spatial resistance model of network analysis is constructed using the "New Network Dataset" function in ArcGIS, and then the service area analysis layer is established. By setting the road time resistance value (road length / pedestrian speed), the accessible area enclosed by the source point along the road network is generated, and the spatiotemporal range of walking accessibility circles is obtained. This article uses the community life circle as an analogy. A

total of 15 time levels of accessible areas of 1-15min were determined. At the same time, in order to better reflect the physical space form under walking accessibility circles. Since area and perimeter are the basic measurement characteristics of studying spatial forms, the boundary dimension is used to calculate the overall accessible balance. The formula is:

$$D = \frac{2\ln\left(\frac{p}{4}\right)}{lnA}$$

In the formula: D is the boundary dimension; A is the accessible surface area; p is the perimeter of the accessible contour. The fractal dimension value is between 1 and 2. When D < 1.5, it means that the accessible boundary tends to be regular, and it has good walking accessibility in any direction; when D > 1.5, it means that the accessible range tends to be complex. The larger the value, the worse the stability, indicating that the accessibility of some directions is stronger or weaker than other directions.

After calculating the accessible area and overall accessible balance, the walking distance is calculated based on the differences in the east, south, north and south directions. Then based on the above accessible areas, the bus stops within the area are counted, and the walking practice from the rail station to the bus stop is counted to express the efficiency of transportation connection. The bus stop statistics are interpreted using satellite images such as Google Maps and on-site investigations. After the Ⅰ to Ⅳ are generated within 90 degrees, 45 degrees on both sides of the four directions of east, west, south and north, the transportation connections in each quadrant are further counted.

Related calculation methods for land use system

According to step3 and step4 of the technical route, This paper's exploration of land functions involves considerations for TOD development and construction. Therefore, it is not simply about the land area occupied by land functions, but rather a comprehensive consideration of the building area of various buildings, and the land area occupied by squares and green spaces. So the land functions are divided into five categories (commercial functions, office functions, residential functions, public service functions and green space functions), and classification and identification adopts a combination of satellite images such as Google Maps, on-site investigations, and planning drawings, so that the proportion of each function in the 15min accessible areas is calculated. And the functional utilization mixing degree of each area is paid attention to. The formula is:

$$M = \frac{S_n}{S_{sum}}$$

$$LU_d(i) = \frac{-\sum_i M * \ln M}{ln(n)}$$

In the formula: M is the proportion of a certain function; $LU_d(i)$ is the mixed degree of land functions; n is the five major functions; S_n is the building area or land area of each function from 1min to 15min accessible area; S_{sum} is the total area of the five major functions from 1min to 15min accessible area.

Then calculate the floor area ratio within the 15min accessible areas, The formula is:

$$R(i) = \frac{\sum_i S_n}{A_{sum}}$$

In the formula: $R(i)$ is the floor area ratio within the accessible area; S_n is the building area or land area of each function from 1min to 15min accessible area; A_{sum} is the acreage from 1min to 15min accessible area.

The data collection of the number of building floors of each function for building area calculation is based on the 2023 China Building Outline Height Data Technology Service. After calculating overall land use functional ratio and floor area ratio, further explore the dominant direction of land functions and development with the specific conditions in the Ⅰ to Ⅳ quadrants.

RESULTS AND DISCUSSIONS

This paper selects Chongqing Guanyinqiao Station and Chengdu Chun Xilu Station as the research objects with the TOD built environment forms of the core business circles in the mountains and plains (Figure 3). Chongqing and Chengdu are both located in the southwest of China. The former is located in the hilly area between the Yangtze River and the Jialing River, surrounded by rolling mountains and is recognized as a typical mountain city in China. Chongqing Guanyinqiao Station is located in the Guan yinqiao core commercial circle of Jiangbei District, Chongqing. It is the transfer station for Chongqing Rail Transit Line 3 and Line 9. In the ranking of the average daily passenger flow of Chongqing rail stations, it has always been in the top three. The average daily passenger flow was 120,000, and the highest daily passenger volume reached 262,000 in 2024; the latter is located in the Chengdu Plain with a flat terrain and typical plain city characteristics. Chengdu Chun Xilu Station is located in the Chun Xilu core commercial circle of Jinjiang District, Chengdu. It is the transfer station for Chengdu Rail Transit Line 2 and Line 3. Its average daily passenger flow has always set new highs, and the highest daily passenger volume in 2024 reached 493,000.

Figure 3. Location with Chongqing Guanyinqiao Station and Chengdu Chun Xilu Station. Photo credit: Author's own drawing.

Analysis results of the transportation system

There are large differences in the accessible areas between Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station. The 15min accessible areas of Chongqing Guan Yinqiao Station are limited by terrain constraints and are all smaller than Chengdu Chun Xilu Station (Figure 4, Table 2). From the perspective of accessibility balance, the pedestrian accessible spatial boundaries of Chongqing Guan

Yinqiao Station and Chengdu Chun Xilu Station are relatively regular, with little difference between the two and they can meet pedestrian needs in different directions, reflecting that although Chongqing Guan Yinqiao Station is restricted by the mountainous environment, the walking efficiency of the crowd has not been reduced. However, from the perspective of walking distances with differences in the east, south, north and south directions, the walking distances of every minute in Chongqing Guan Yinqiao Station is vary significantly, which is reflected in the data such as the range, mean and standard deviation, showing the complexity of the walking environment of Chongqing Guan Yinqiao Station (Table 2).

C

Figure 4. Accessible areas of Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station. Photo credit: Author's own drawing.

Table 2. Accessible areas features and walking distances with different directions in Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station

name	Accessible area features		Walking distances with differences in the east, south, north and south directions				
	15min area (m^2)	overall accessible balance: boundary dimension	Maximum value (m)	Minimum value (m)	Range (m)	Mean (m)	Standard deviation (m)
Chongqing Guan Yinqiao Station	210633.98	1.26	60	13.37	46.63	36.10	11.23
Chengdu Chun Xilu Station	268065.50	1.26	60	32.39	27.01	44.04	7.70

Then through the statistics of bus stops within the accessible areas of Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station, it was found that Chengdu Chun Xilu Station has a total of 24 bus stops within the 1-15 minute reachable area, while Chongqing Guan Yinqiao Station has a total of 16 stops. At the same time, the former only needs 4 minutes to walk to transfer to the bus, while the latter needs 6 minutes to walk to transfer to the bus (Figure 5). Therefore, the subway-bus transfer system is significantly better than Chongqing Guan Yinqiao Station. This connection advantage is even more obvious in the Ⅰ to Ⅳ quadrants. The connection efficiency of Chengdu Chun Xilu Station in all directions is faster than that of Chongqing Guan Yinqiao. The Ⅰ quadrant on the north side only takes

4 minutes to transfer, while in the Ⅱ quadrant on the west side, Chongqing Guan Yinqiao Station takes up to 10 minutes to transfer, making it the least efficient area (Table 3).

Figure 5. Statistics of bus stops of Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station. Photo credit: Author's own drawing.

Table 3. Statistics of bus stops with each quadrant based on different directions in Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station

name	Ⅰ quadrant on the north side		Ⅱ quadrant on the east side		Ⅲ quadrant on the south side		Ⅳ quadrant on the west side	
	Number of bus stops	Transfer time (min)	Number of bus stops	Transfer time (min)	Number of bus stops	Transfer time (min)	Number of bus stops	Transfer time (min)
Chongqing Guan Yinqiao Station	5	6min	2	9min	4	6min	5	10min
Chengdu Chun Xilu Station	7	4min	6	5min	9	6min	2	6min

Analysis results of the land use system

After identifying and dividing categories of the land functions within the accessible area of Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station, it can be found that the two stations have basically formed the land dominant functions of commerce, office and residence. And functional proportion of each land use at the two stations change similarly with the accessible distance (Figure 6). For example, the commercial and office functions show a fluctuating trend of increasing first and then decreasing with the increase of walking time, while the residential functions are just the opposite. The public service functions basically increase with the increase of walking time, while the green space functions decrease with the increase of walking time. However, from the perspective of indicator with the mixed degree of land functions, this indicator with the 5min accessible areas of Chongqing Guan Yinqiao Station is significantly lower than that of Chengdu Chun Xilu Station, only beyond this range, this indicator of the two stations tend to be similar (Figure 7).

Figure 6. Land functions of Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station. Photo credit: Author's own drawing.

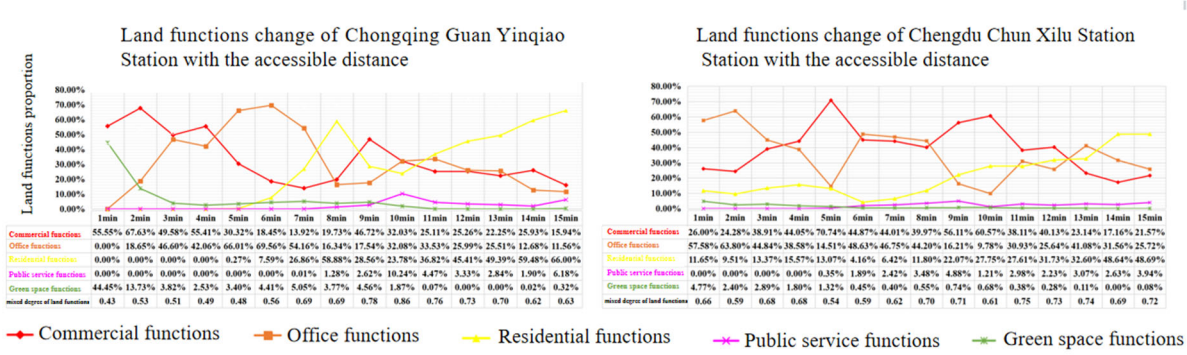

Figure 7. Land functions change with Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station. Photo credit: Author's own drawing.

Further exploration of the land functions of each quadrant generated from walking different directions shows that except for the Ⅰ quadrant on the north side where Chongqing Guan Yinqiao Station focuses on the integration of commercial, office and residential functions. The other quadrants are dominated by residential functions, with the proportion of residential functions in each quadrant exceeding 40% and the land dominant functions are relatively single. Due to the large proportion of residential functions, the supporting public service functions and green space functions in these areas are significantly higher than those of Chengdu Chun Xilu Station. In contrast, only the Ⅲ quadrant on the south side of Chengdu Chun Xilu Station is dominated by residence, while other quadrants focus on the combination of commercial and office functions, or on the integration of commercial, office and residential functions (Figure 8).

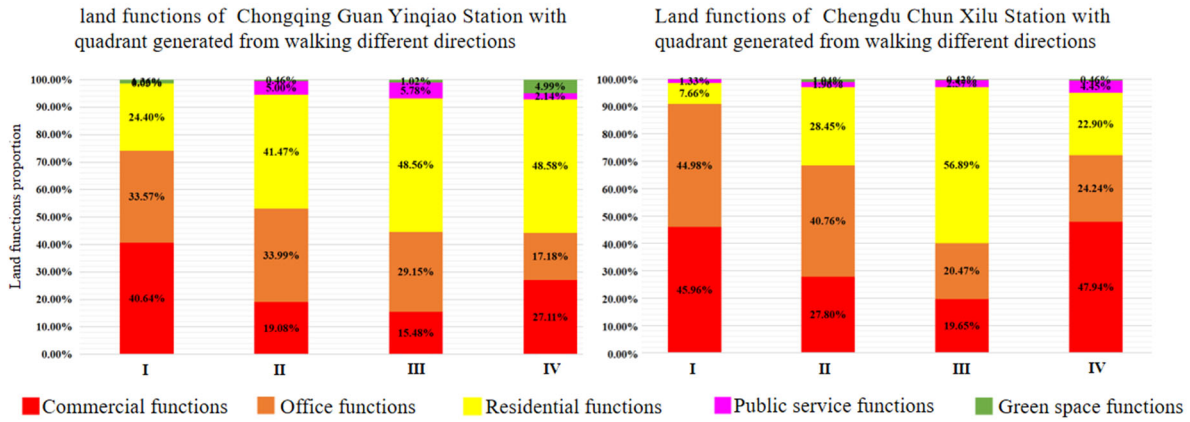

Figure 8. Land functions with each quadrant based on different directions in Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station. *Photo credit: Author's own drawing.*

Finally, from the analysis of development intensity, we can see that the changes in the floor area ratio of the two stations also show a fluctuating trend of increasing first and then decreasing with the change in walking time, but after 2 minutes, the development intensity with floor area ratio of Chongqing Guan Yinqiao Station is significantly greater than that of Chengdu Chun Xilu Station (Figure 9). Further from the perspective of the dominant development direction, the Ⅱ quadrant on the east side and the Ⅰ quadrant on the north side are the dominant directions of Chongqing Guan Yinqiao Station and Chengdu Chunxi Road Station respectively. At the same time, regardless of which quadrant, the development intensity of Chongqing Guan Yinqiao Station is greater than that of Chengdu Chun Xilu Station. Moreover, compared with the homogeneity of the latter's development and construction in different directions, the development intensity of Chongqing Guan Yinqiao Station in the Ⅰ and Ⅱ quadrants is significantly higher than that of other areas, indicating the necessity of its mountainous built environment to carry out high-intensity development and construction in a limited geographical environment (Table 4).

Figure 9. The floor area ratio of Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station. Photo credit: Author's own drawing.

Table 4. The floor area ratio with each quadrant based on different directions in Chongqing Guan Yinqiao Station and Chengdu Chun Xilu Station

Name	Ⅰ quadrant on the north side	Ⅱ quadrant on the east side	Ⅲ quadrant on the south side	Ⅳ quadrant on the west side
Chongqing Guan Yinqiao Station	4.42	5.35	3.51	3.24
Chengdu Chun Xilu Station	3.71	3.66	3.13	3.62

Discussion of similarity and difference

The above research results show that the similarity with the TOD built environment forms of the core commercial circles in mountainous and plain areas lies in the distance attenuation or increasing effect of functional proportion and development intensity. This effect has a "fluctuating" trend. From the perspective of functional proportion, commercial and office functions show a trend of first rising and then falling with the increase of walking time. The bottom of the decline is the Multifunctional core area. After walking for a certain period of time, it continues to show a trend of first rising and then falling, but the functional proportion is not as large as the former. This is because the attraction of commercial and office functions is the greatest around rail stations, which can quickly gather people to increase sales opportunities, improve transportation convenience to ensure work convenience, and promote the appreciation of commercial and office real estate. After walking for a certain period of time, certain commercial and office functions are still needed to meet the living and work opportunities of the surrounding people, so the functional proportion of the two increases again, and then decreases again as the walking time continues to increase; the trend of residential functions is just the opposite. This is because residential functions are not the main purpose of people around rail stations in the core commercial circles. From the perspective of development intensity, it also shows a trend of first rising and then falling. After walking for a certain period of time, it continues to show a trend of first rising and then falling. This is also due to the advantage of the flow of people around the rail station, and after a certain walking time, the living and working security of the surrounding people needs to be guaranteed (Figure 10).

Figure 10. "Fluctuating" trend of functional proportion and development intensity. Photo credit: Author's own drawing.

The difference between the TOD built environment forms of the core commercial circles in mountainous and plain areas lies in the differences with directional diversification of mixed land functions and public transportation. Due to the restrictions of mountainous terrain, the accessible

areas of residents in mountainous environments is obviously smaller than that of residents in plains with the same period of time. At the same time, the walking comfort in each direction varies greatly due to the geographical barriers of mountains compared with plain environment. Therefore, for mixed land functions in each direction can be promoting urban development such as commerce , office and residence, Mountain built environment mainly brings them to concentrate in a certain convenient walking convenient area to reduce the travel costs of residents, this makes the development direction of the mixed land functions more singular. While the walking environment in the plains is more superior, and the above functions can be arranged according to development needs. So they are scattered in different directions to meet the use needs of residents from different directions. Similarly, the walking restrictions in the mountainous environment further cause the high time cost of the overall travel connection system and poor transfer efficiency, and it takes more time to reach the corresponding public transportation station; while the smaller terrain differences in the plain environment and the homogeneity of walking allow residents to meet their own transportation transfer needs in a shorter time.

CONCLUSIONS

This research focuses on the TOD build environment forms of core commercial circles, providing a analysis method with the transportation system and land system. In general, the geographical limitations of the mountainous built environment make the walking environment of TOD rail stations more complex, and also make the overall operation efficiency of public transportation weaker than that of plain areas. In this regard, the TOD build environment forms of core commercial circles in the mountainous areas should pay more attention to gathering the dominant functions such as commercial and office in a good walking environment, and advocates higher density development and construction. Therefore, in the future, the TOD build environment forms of core commercial circles in the mountainous areas not only needs to expand the development area of rail stations, build transportation facilities to connect the surrounding commercial and office buildings, and add more entrances and exits to accommodate people's walking scale in the underground space of the rail stations, but also needs to further strengthen the development of land around rail stations, the high-intensity development plans in the periphery areas can be transferred to the vicinity of the rail stations, and the vertical function of the building can be used to establish a rapid connection between the ground and underground space, and corridors can be set up to connect other buildings. In the above way, the geographical barriers of the mountain can be reduced and the walking time cost can be optimized. In contrast, the TOD build environment forms of core commercial circles in the plain areas should consider the value of mixed land use in the future, especially in the face of the law of the "fluctuating" trend of functional proportion and development intensity, handle the connection between functional proportion and development intensity in the core and secondary core areas, and strengthen the gradient development around and outside the TOD rail stations.

At present, relevant research only focuses on TOD rail stations with Chinese mountainous and plain cities, and the number of samples needs to be further increased in subsequent studies to provide a richer research foundation for subsequent research law verification and development guidance.

ABSTRACT

Technology transfer, especially the transnational dissemination of urban planning concepts has become an important topic in the development of global cities. This study explores the dual influence of American and Soviet urban planning models on the spatial form of Chinese workers' villages in the 1950s, with a focus on case studies from Shanghai and Shenyang. The research aims to understand how these foreign planning principles were adapted to China's unique socio-economic and cultural contexts. Through comparative analysis, it was found that Soviet influence dominated in areas such as architectural standardization and industrial-focused urban layouts, while American planning concepts were evident in the neighborhood design of Shanghai. The study draws three main conclusions: First, socialist ideology, through national policies, shaped residential patterns, leading China in the 1950s to follow the Soviet model more closely. Second, planners exhibited flexibility in local adaptation, as seen in Shanghai, where certain American planning principles emerged. Lastly, local adaptation was central to the process of technology transfer, with workers' villages in different regions reflecting diverse and flexible planning approaches. This research provides valuable theoretical insights into the processes of technology transfer and localization in urban planning.

Keywords: workers' villages, technology transfer, local adaptation, spatial forms, regional comparison.

INTRODUCTION

The process of globalization has accelerated the flow of economic, cultural, and technological elements between countries. Urban planning, as a key field that drives urban development, has also been profoundly influenced by globalization. In this process, technology transfer, especially the transnational dissemination of urban planning concepts has become an important topic in the development of global cities. Among the existing studies, Hall (1996) examined the mutual influences of planning ideas among cities in the UK, the US, and continental Europe; Ward (1999) explored how countries such as the UK, the US, and France impacted urban planning in Canada through the spread

of policies and technologies; Healey (2012) further revealed the fluidity of planning practices between Western countries in the context of globalization.

However, current research on technology transfer largely focuses on interactions between Western countries, with relatively little attention paid to the transfer and interaction of technologies between the East and the West. In particular, studies on the transfer of technology from the West to China and other Eastern countries are relatively scarce, and this academic gap hinders our comprehensive understanding of technological trajectories and the sharing of experiences in the context of globalization. As the largest developing country in the world, China’s urban planning concepts and technological practices in the process of globalization have a significant impact on the global urban development landscape. Therefore, conducting an in-depth study of the technology transfer process from the West to China is of great academic and practical significance.

The 1950s was a pivotal period for technological introduction in China, marking the first large-scale incorporation of Western planning concepts into urban planning in the newly founded People's Republic. During this period of time, urban planning became a critical tool for national modernization when the Chinese government rapidly initiated extensive urban construction and industrial developments. Under the "leaning to one side" foreign policy diplomatic strategy and the domestic agenda of "comprehensive learning from the Soviet Union," China was exposed to Soviet planning concepts, exemplified by the "superblock model" (Sviridov, 1955), particularly in the construction of workers' villages affiliated with the Soviet-aided "156 Projects." At the same time, American planning concepts were introduced by returning Chinese planners and architects who had studied in the United States. Many of these designers, having been educated at American institutions, were subtly influenced by the "neighborhood unit" (Perry, 1929). For instance, Wang Dingzeng studied at the University of Illinois at Urbana-Champaign, Chen Shiwu at Cornell University, and Zhong Yaohua at Harvard University. This led to a dual technology transfer situation in which China adopted both Soviet and American planning ideas. Beyond planning concepts, Western technology transfers to China also included construction techniques, material technology, and other areas.

Workers' villages were a prominent example of urban residential planning in 1950s China. (Yang, C., 2017) As social welfare projects aimed at addressing the housing needs of the working class, their large-scale construction reflected not only the demands of urban development and industrialization but also the practical application of urban planning concepts in China. Overall, these workers' villages embody the specific utilization of technology transfer in the urban construction of the time.

Given China's vast territory, significant differences in climate, geography, culture, and economic foundations between the northern and southern regions influenced the localization and adaptation process of these transferred technologies, as well as the effectiveness of urban planning implementation. Moreover, the construction of workers' villages exhibited regional variations. One type was the independently built workers' village, exemplified by the Caoyang Workers’ Village in the southern region. The other type was the workers' villages integrated into large-scale construction projects, primarily located in northern regions and tied to the "156 Projects." (Luo, G., 2010) Therefore, conducting a comparative study between the northern and southern regions holds valuable insights for understanding the dynamics of technology transfer and its local adaptation.

This study aims to explore the differing impacts of the dual technology transfer from the United States and the Soviet Union on China's residential forms, by comparing workers' villages in northern and southern China during the 1950s. It also seeks to analyze how China localized and adapted these foreign influences in the context of globalization. The research aspires to fill the academic gap in studies on west-east technology transfer and provide a new perspective on technology transfer and local adaptation in the context of globalization, thereby enriching the theoretical framework of global urban planning and technology exchange.

The following sections are included in the study: the Method section outlines the case selection, classification at various spatial levels, and research methods. The Results and Discussion section analyzes the similarities and differences in the forms of workers' villages in northern and southern China through case studies, and further compares them with those in the U.S. and the Soviet Union to examine the dynamics of technology transfer and local adaptation. The Conclusion section summarizes the morphological characteristics of workers' villages under the influence of technology transfer and localization, and offers insights for modern urban planning.

METHOD

This study primarily adopts a case study approach. Utilizing regional urban theory, the research classifies the residential forms of workers' villages into three levels: city, neighborhood, and housing. Through morphological analysis, it examines the spatial forms and layout patterns and further compares them with those of the United States and the Soviet Union to analyze the specific manifestations of technology transfer and local adaptation.

In terms of case selection, the study first identifies the representative cities in northern and southern China as Shenyang and Shanghai. Both cities share similar industrial development histories and large-scale construction of workers' villages, and their existing workers' villages are well-preserved, making them suitable for comparative research. Subsequently, representative workers' villages were selected from these cities: the Caoyang Workers’ Village and the Hudong Residential Area (comprising Changbai, Kongjiang, Fengcheng, and Anshan workers’ Villages) in Shanghai, and Tiexi, Santazi, and Hemulu Workers' Villages in Shenyang. These representative cases span the early, mid, and late 1950s in terms of construction periods and are geographically distributed across different parts of the cities, covering almost all types and development models of workers' villages in both locations. This study combines literature review and field research, using horizontal comparisons and summaries to provide data support for the case studies.

In the course of the discussion, this study primarily employs regional urban theory to conduct a multi-layered analysis of the spatial forms of workers' villages across three scales: city, neighborhood, and housing. Specific methods include the creation of comparative morphological diagrams to visually analyze the similarities and differences between workers' villages in northern and southern China, in conjunction with a comparative study of planning concepts from the United States and the Soviet Union.

At the city scale, the study explores the relationship between the location of workers' villages and the urban spatial structure. This section first analyzes the connection between the workers' villages and

their associated industrial areas and then examines the spatial relationship between the workers' villages and the city center, thus revealing the characteristics of site selection and layout.

At the neighborhood scale, the study investigates the internal planning structure of workers' villages. This part compares four aspects: road Layout, building layout, green space system, and public facilities system. It discusses both the external openness and the internal cohesiveness of the workers' villages.

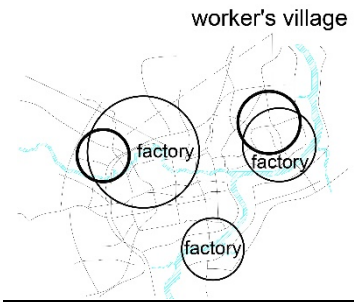
At the housing scale, the study examines the residential building design within the workers' villages, including building floor plans and façade designs. By comparing the internal structures and standardized construction techniques of residential buildings in northern and southern workers' villages, the research further reveals the influence of Soviet and American technology on Chinese housing design.

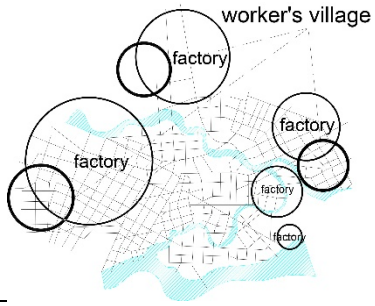
RESULTS AND DISCUSSIONS

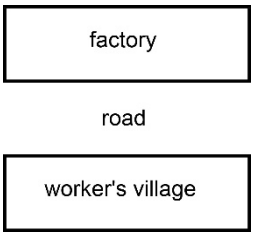
Urban scale

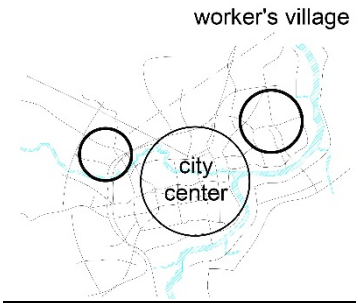
This section analyzes the siting and layout of workers' villages in Shanghai and Shenyang from the urban scale. The primary purpose of planning workers' villages was to provide residential facilities supporting industrial production, addressing the housing needs of workers. As a result, the spatial relationship between workers' villages and industrial zones was a critical issue in urban planning during that era.

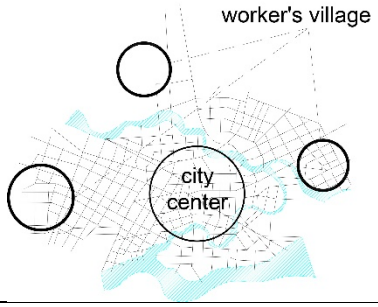
Table 1. Distribution of workers' village in relation to industrial zone and city center

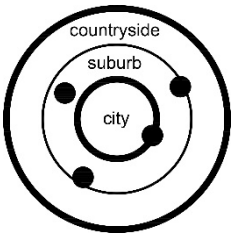
Shanghai	Shenyang	Conclusion
				












The study found that workers' villages in both cities were closely tied to industrial zones and located in the suburb (Figure 1). This proximity to industrial zones reduced commuting times for workers and facilitated unified factory management. At the same time, siting these villages in suburban areas aligned with the economic conditions of the time, avoiding large-scale demolition in city centers and effectively utilizing the vast available land and existing industrial infrastructure in the suburbs. This

layout reflects the policy orientation of "production first, living second," embodying the spatial strategies of rapid industrialization.

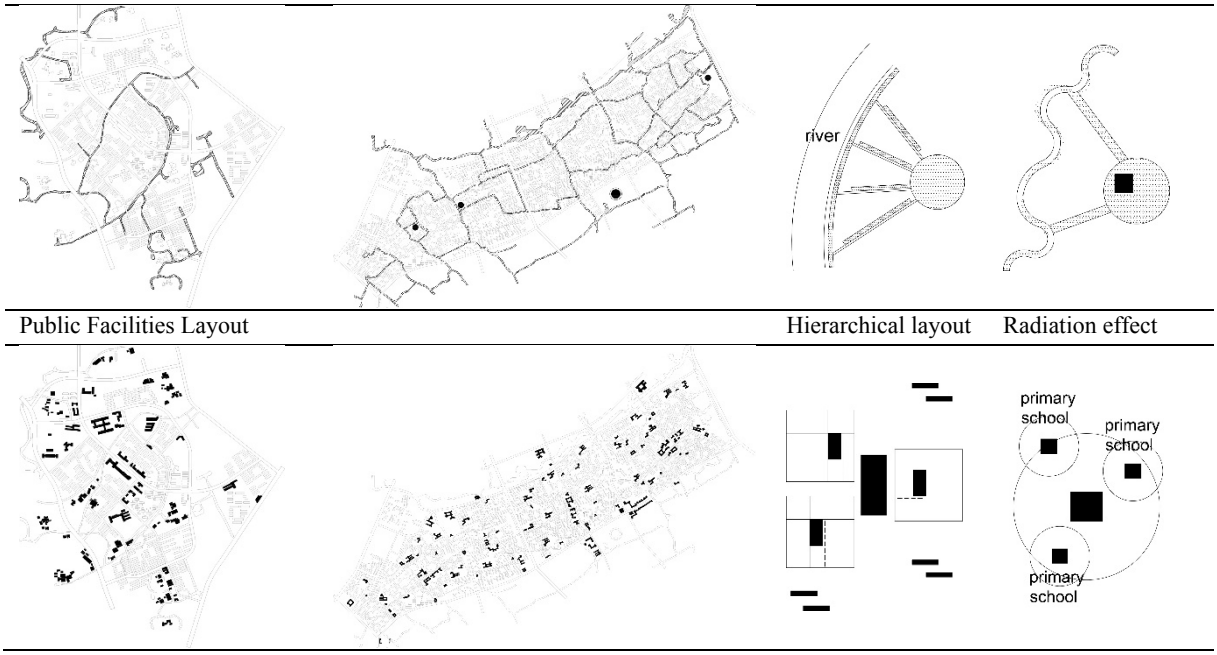
This approach closely resembles the Soviet superblock model, which emphasized the prioritization of industrial production. Soviet planning concepts focused on establishing a clear functional relationship between residential areas and industrial zones, with most industrial residential districts maintaining close spatial ties to industrial areas. In contrast, American urban planning ideas placed more emphasis on functional zoning and the comfort of residential environments, with strict separation between residential and industrial areas, highlighting the division between living and working spaces.

From the perspective of contemporary urban planning, the strategy of avoiding large-scale demolition in city centers and instead developing suburban areas shows continuity with current trends in urban renewal. However, this approach also raises concerns about the difficulties in extending urban infrastructure and public services to suburban locations. Additionally, with the growth of the tertiary sector, the need to continue planning residential areas in close proximity to industrial zones requires re-evaluation, and further in-depth analysis should be conducted based on specific cases.

Neighborhood scale

Table 2. Spatial form analysis of Shanghai. The original base map data of Caoyang workers' village is sourced from Wang, D. ,1956, data of Hudong workers' village is sourced from Xu, J. and Fang, R.,1958.

Caoyang workers' village	**Hudong workers' village**	**Drawing of analyses**	
Road Layout		Planning	Cluster
			Building Layout		Planning	Cluster
			Green Space Layout		Hierarchical layout	Radiation effect



Public Facilities Layout | Hierarchical layout | Radiation effect

Figure 2 compares and summarizes the representative residential areas in Shanghai based on four spatial elements: roads, buildings, greening, and facilities. The study reveals the following findings:

1)Road Layout: The road network in Shanghai's workers' villages demonstrates high flexibility and adaptability, following natural waterways and existing road patterns to create a free-form, fishbone-shaped network. At the neighborhood scale, the road organization presents a circular-radial layout, while at the cluster level, the layout is primarily fishbone-shaped.

2) Building Layout: The building structure in Shanghai’s workers' villages is predominantly organized in rows, with the buildings generally aligned parallel to the roads. At the neighborhood level, the layout is flexible, forming irregular patterns in response to roads and waterways. However, within clusters, the layout is more regular, adopting a grid-like structure.

3) Green Space Layout: The green space layout in Shanghai makes full use of the natural waterways and resources, combining strip-shaped and planar configurations. The types of green spaces can be categorized into three main groups based on their location: central gardens, front-yard greenery, and riverside parks. The distribution of green spaces is flexible and highly integrated with the natural environment. Central green spaces are often combined with community public facilities, forming a vibrant public space system.

4) Public Facilities Layout: The layout of public facilities in Shanghai's workers' villages exhibits both flexibility and a multi-core structure. Facilities are arranged along roads or rivers, blending organically with the natural landscape, demonstrating strong spatial adaptability. Additionally, the villages feature a clear multi-core structure with a hierarchical radial system. At the neighborhood scale, the community center serves as the core, concentrating various public service facilities. At the cluster level, primary schools form the core, ensuring that basic needs are met within a 7-8 minutes walking distance for residents.

In summary, when linking these findings to the planning concepts of the United States and the Soviet Union, it becomes evident that Shanghai's planning shares a high degree of alignment with the American "neighborhood unit" concept, while also partially aligning with Soviet planning principles.

In terms of road layout, the "neighborhood unit" emphasizes a "connected but not through" design to reduce through-traffic and enhance community safety and livability. Similarly, Shanghai's circular-radial and fishbone road layouts, while following natural waterways and existing road patterns, also avoid excessive through-traffic.

In terms of building layout, Shanghai's flexible response to the natural environment aligns with the "neighborhood unit" principle of integrating community design with natural landscapes.

In terms of green space, the flexible design of strip-shaped and planar green spaces in Shanghai, which maximizes natural resources and waterways, aligns with the "neighborhood unit" objective of creating more public activity spaces to foster community interaction and cohesion.

In terms of public facilities, the multi-core and hierarchical radial structure in Shanghai is also consistent with the multi-center service structure of the "neighborhood unit," ensuring that residents can access basic services within a walkable radius centered around primary schools.

At the same time, Shanghai's cluster-level building layout and the concentration of certain public facilities reflect Soviet planning principles, particularly in their emphasis on centralized planning and functionality within residential areas.

Table 3. Spatial form analysis of Shenyang. The original base map data of Hemulu workers' village is sourced from Xu, M. and Zhao, X.,2012, data of Hemulu workers' village is sourced from Li, S.2015.

Hemulu workers' village	**Tiexi workers' village**	**Drawing of analyses**	
Road Layout		Planning	Cluster
			Building Layout		Planning	Cluster
			Green Space Layout		Hierarchical layout	Radiation effect

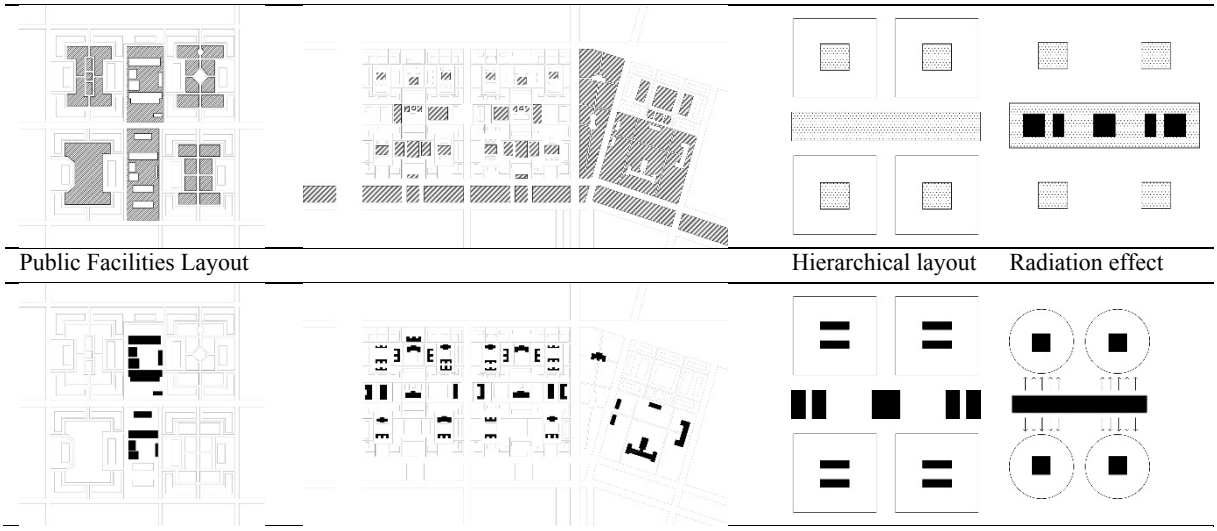


Figure 3 compares and summarizes the representative residential areas in Shenyang based on four spatial elements: roads, buildings, greening, and facilities. The study reveals the following findings:

1) Road Layout: The road structure in Shenyang's workers' villages demonstrates strong orderliness and enclosure. The road organization features a geometric grid layout, emphasizing symmetry and structure. At the neighborhood level, the roads are arranged in a symmetrical grid pattern, while at the cluster level, Shenyang' s road layout shows clear enclosure characteristics.

2) Building Layout: Shenyang's building structure reflects symmetry and enclosure. At the neighborhood level, residential clusters are arranged symmetrically along an axis centered on a public building complex. At the cluster level, corner buildings are often "L"-shaped, forming an enclosed layout with other surrounding buildings.

3) Green Space Layout: Shenyang's green space layout mainly adopts a planar distribution that complements the enclosed building arrangement. Green spaces can be divided into those within and between clusters, with the greenery between clusters closely integrated with public facilities.

4) Public Facilities Layout: The layout of public facilities in Shenyang's workers' villages is centralized and symmetrical. At the neighborhood level, large-scale public facilities are concentrated in the center of the residential area, distributed evenly along the main arterial roads, forming a distinct strip-like core zone. At the cluster level, facilities are integrated with the enclosed buildings, further emphasizing the symmetrical and radial nature of the planning.

In summary, when linking these findings to American and Soviet planning concepts, it becomes evident that Shenyang's planning is highly consistent with the Soviet "superblock model," while also partially aligning with American planning principles.

In terms of road layout and building organization, both Shenyang and the Soviet model emphasize geometric symmetry, with clearly defined axes and buildings aligned along roads. This arrangement creates a clear boundary between internal and external spaces, giving the urban form a strong centripetal character. Furthermore, the layout of public facilities and green spaces in Shenyang reflects the Soviet planning ideals of centralization, symmetry, and the creation of a core zone.

Overall, Shenyang's alignment with the Soviet superblock model can be attributed to the influence of the "Learn from the Soviet Union" campaign and the direct involvement of Soviet planners and architects. However, traces of American influence are also evident, such as in Shenyang's road system, which, while following the superblock model, incorporates the American "neighborhood unit" principle of "connected but not through" roads to reduce cross-traffic.

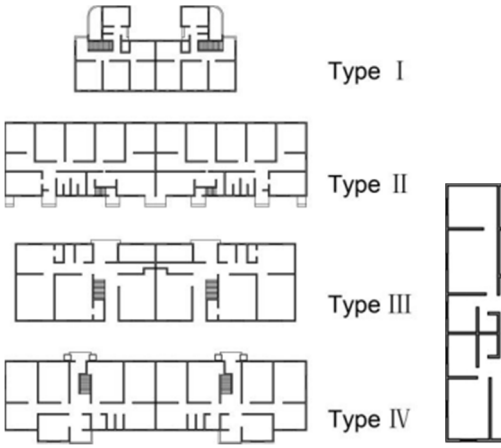
Table 4. Summary and comparison of spatial elements.

	Shanghai	**Shenyang**	**Commonality**
Road Layout	Fishbone-shaped	Grid	Connected but not through
Building Layout	Determinant	Enclosed	Ignoring orientation
Green Space Layout	Linear and area-based combined	Area-based	Integration of greening and facilities
Public Facilities Layout	Decentralized, point core	Concentrated, strip core	

The comparison between the spatial forms of Shanghai and Shenyang highlights the distinct impacts of American and Soviet technology transfers on these two cities. (table 4) First, the primary line of influence is evident: American planning concepts influenced Shanghai, while Soviet planning concepts shaped Shenyang. While there were some instances where Soviet ideas influenced Shanghai and American ideas affected Shenyang, these secondary influences were relatively limited compared to the dominant forms of technology transfer. Second, despite the limited influence of secondary ideas, there is evidence of local adaptation in the technology transfer process, demonstrating that the transfer was not a direct application of foreign concepts but involved localized adjustments to suit regional needs.

Building scale

At the residential scale, the influence of American and Soviet technology transfers on the spatial form of workers' housing can be observed from a more human-centered perspective, focusing on the design of apartment layouts and façades.



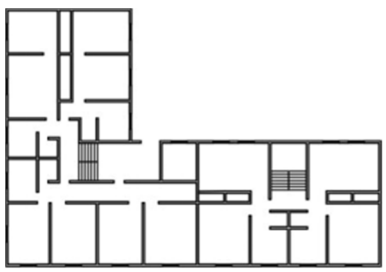


Figure 1. Four plan types in Caoyang Workers' Village. Figure 2. "L" plane type of Tiexi Workers' Village.Figure 3. High-rise residences in Hudong Workers' Village,drawing credit: Huangying Li.

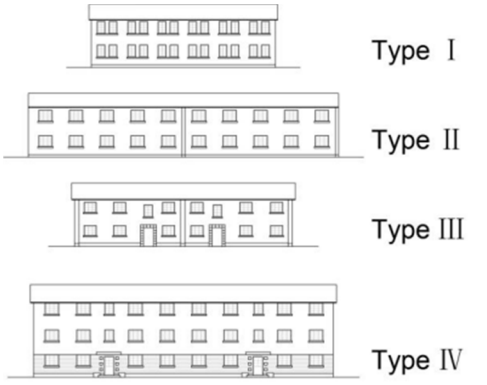
In terms of floor plans, one of the key features of 1950s workers' villages was the diversity and compactness of housing unit designs. For example, in the Caoyang Workers' Village, the single-story floor plan offered four different apartment types (Figure 1). Similarly, the Tiexi Workers' Village

included L-shaped corner layouts (Figure 2), and the Hudong Workers' Village introduced high-rise residential designs (Figure 3). The variety in apartment layouts reflected the designers' consideration of different family structures and living needs. Moreover, compactness was another significant feature of workers' housing. For instance, in the Caoyang Workers' Village, internal corridors separated the living areas from the kitchen and bathroom spaces, with communal kitchen and bathroom facilities provided for multiple households to share.

In terms of façades, workers' housing from the 1950s displayed a blend of Western and Chinese architectural styles alongside a trend toward simplification. Specifically, the façade design of Tiexi Workers' Village had clear classical elements, though these were simplified for practical purposes. Additionally, some buildings featured traditional Chinese decorative patterns, such as the "hui" motif at the entrances, reflecting an effort to integrate local cultural elements. In contrast, the façades of the Caoyang Workers' Village were much more minimalist, with almost no decorative features. The design was purely functional, with flat walls and minimal articulation, focusing on necessary functional elements like staircases and balconies. This pared-down approach not only minimized ornamental considerations but also reflected the emphasis on building functionality in a resource-constrained context.



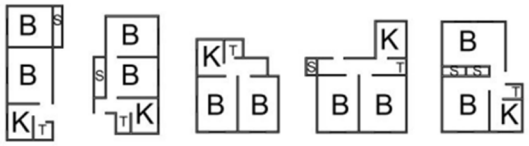


Figure 4. Four elevations in Caoyang Workers' Village. Figure 5. Composition of Tiexi Workers' Village,drawing credit: Huangying Li.

In addition to the previously discussed features, another significant characteristic of the workers' villages of the 1950s is standardized construction. The residential units in the Tiexi Workers' Village, for example, strictly adhered to standardization principles (Figure 4). The use of uniform floor plans and standardized components significantly improved construction efficiency. In terms of façade design, standardization was also evident in the uniformity of elements such as doors and windows (Figure 5), which further reinforced the uniformity and controllability of the social structure within the housing developments.

These three characteristics—diverse and compact floor plans, architectural style design, and standardized construction—are all closely linked to the Soviet technological transfer.

The diversity of floor plans addressed the varied needs of working-class families during rapid urbanization, exemplifying the Soviet housing system's principle of "standardization combined with adaptability." The focus on compact design also echoed the Soviet emphasis on functionality and efficiency in collective housing, where shared spaces like kitchens and bathrooms were central to reducing resource waste and construction costs while fostering a communal atmosphere. The

architectural style reveals China's imitation and simplification of Soviet classical aesthetics, while the widespread adoption of standardized construction techniques reflects the Soviet influence on mass housing construction, an approach that China implemented during the "156 Projects" to support its rapid industrialization.

In summary, the design of 1950s workers' villages—whether in the diversity and compactness of apartment layouts, the façade styles, or the standardization of construction—demonstrates the profound impact of Soviet technological transfer. These influences were centered on the functionality, efficiency, and adaptability of large-scale workers' housing, aligning with China's needs during its period of rapid industrialization and urbanization. At the same time, this process of technology transfer also incorporated local adaptations, particularly in consideration of China's economic conditions and the preservation of traditional cultural elements. This balance between foreign influence and local adaptation shaped the unique architectural and social functions of the workers' villages.

CONCLUSIONS

By comparing the Shanghai and Shenyang workers' villages, this study reveals the unique influence of American and Soviet urban planning models on Chinese residential spatial forms in the 1950s. The dual technical transfer from these two global powers played a crucial role in the design and construction of these workers' residential areas, while China's local adaptation was key in integrating these foreign concepts into its specific socio-economic and cultural contexts.

The results show that, at the urban scale, the siting and layout of Chinese workers' villages were deeply influenced by Soviet planning principles. These villages were typically attached to industrial zones and located on the city's outskirts, reflecting China's alignment with the Soviet industrialization strategy. At the residential scale, the interweaving of both American and Soviet influences is evident. In Shanghai, the organization of roads and public spaces was significantly influenced by the American "neighborhood unit" model, emphasizing community autonomy and integration with the natural environment. In contrast, Shenyang's residential areas followed the Soviet "superblock" model, characterized by centralized and geometrically symmetrical layouts. At the architectural scale, the Soviet influence was more pronounced, manifesting in compact floor plans, simplified architectural styles, and highly standardized construction methods, all of which closely resembled Soviet residential design models of that period.

In conclusion, this study draws the following key points:

1) During China's early industrialization phase, Soviet technical transfers played a dominant role, particularly in urban siting and the standardization of buildings, profoundly impacting Chinese workers' villages. This was largely driven by socialist ideology, which influenced national policy and, in turn, shaped residential forms. In the 1950s, as China explored its path toward socialism, it leaned heavily toward the Soviet Union, a fellow socialist state.

2) American influence primarily surfaced through the flexible application of planning concepts by individual planners. Although China's political alignment tilted towards the Soviet Union during this

period, Shanghai still demonstrated elements of American planning principles, indicating the agency of planners in adapting foreign ideas within the constraints of state policies.

3) Local adaptation was central to the process of technical transfer. By adjusting foreign concepts to address China's varying economic, cultural, and climatic conditions, workers' villages in different regions demonstrated the diversity and flexibility of planning concepts.

The limitations of this study lie in its focus on design concepts, with less exploration of technical adjustments made during the construction process. Due to factors such as resource limitations and changes in technical conditions, the final form of the residential areas may have deviated from the initial designs. Future research should more deeply explore the full process of technical transfer across the design, implementation, and operational stages. Furthermore, the geographic scope of this study is relatively limited. Expanding the research to more regions would provide a broader understanding of the varied responses to technical transfers in different cultural and economic contexts, helping to build a more comprehensive theoretical framework on technical transfer and local adaptation.

Overall, this study offers a fresh perspective on the technical transfer and local adaptation in Chinese workers' villages of the 1950s. It not only deepens our understanding of China's urban planning history but also provides theoretical insights and practical references for modern urban planning in the context of globalization.

ABSTRACT

The urban centre rehabilitation process involves the proper correlation and compatibility of different factors. Among these factors, predicting population growth is crucial for the adequate use of the installed infrastructure, respecting the morphologic type configuration of existing structures. In this scenario, the incompatibility of conventional urban rules with the construction of new structures emerges as a challenge to be overcome. This is the case of Porto Alegre, Brazil. Porto Alegre´s urban rules are based upon a conceptual model that attached typologies to ideal lots to achieve the plan's goals. In this context, methods to correlate density and form in order to identify different typologies emerge in the scientific literature. This research applies GIS technology to employ these methods in examining Porto Alegre´s block DNA, guiding alternative rules for urban design that can more efficiently execute the strategies envisioned in Porto Alegre´s Historic Centre Rehabilitation.

Keywords: urban center; center rehabilitation; urban morphology.

INTRODUCTION

The urban centre rehabilitation process is a challenge as it involves the proper correlation and compatibility of different factors. Social, natural and economic issues must be addressed in order to provide the best suited environment aiming at the best use of the installed infrastructure. Among these factors, the prediction of population growth, essential for the adequate use of the installed infrastructure, must be made possible while respecting the morphological type and configuration of the existing structures. In this scenario, the incompatibility of conventional urban rules with the construction of new structures emerges as a challenge to be overcome. Leinberger (2005), when listing the fundamental steps for carrying out revitalization processes in central areas, highlights that "often well-intended setback and floor-area ratio rules mean that new construction cannot maintain consistency with older historic structures".

This is the case of Porto Alegre, Brazil. Porto Alegre´s urban rules are based upon a conceptual model that attached typologies to ideal lots in order to achieve the plan's goals. Berghausen Pont and Haupt (2009) in Spacemate present a method to correlate density and form in order to identify different

typologies through four parameters: GSI, FSI, OSR, and Height. This research applies GIS technology in order to use Spacemate to examine Porto Alegre´s block DNA, guiding alternative rules for urban design that can more efficiently execute the strategies envisioned in Porto Alegre´s Historic Center Rehabilitation.

METHOD

Case study: Porto Alegre, RS, Brazil

Porto Alegre, the capital of the southern Brazilian state of Rio Grande do Sul, is a significant urban centre with a rich history and dynamic socio-economic landscape. Founded in 1772, the city has evolved from a modest colonial settlement into a bustling metropolitan area, currently housing over 1.5 million residents. Porto Alegre is strategically positioned at the confluence of the Guaíba River and the Lagoa dos Patos estuary, making it a crucial hub for trade, industry, and cultural exchange in the region.

Throughout the city's development over its 252 years since its founding, the Historical Center has been losing its prominence. This phenomenon is not exclusive to Porto Alegre; major metropolitan areas around the world have been undergoing the same process.

According to studies conducted by the Urban Planning Coordination team of the Municipal Department of Environment, Urbanism, and Sustainability (PORTO ALEGRE, 2021), the Historical Center has been under study since the 1970s and 1980s. Based on the information obtained, urban rehabilitation studies for this area began in the 1980s and 1990s, which included the establishment of the Historical and Cultural Heritage Team, among other initiatives.

The Porto Alegre Historical Center Rehabilitation Program was conceived within this context with the initial goal of enabling the overall rehabilitation of the Historical Center area. The program aims to restore residential functions, recover public spaces, and revitalise economic activities, taking into account the new scenarios brought about by the pandemic, which have caused profound transformations in the general relationship between society and cities.

Typological description of pre-existences

The territory under analysis for the Porto Alegre Historic Centre Rehabilitation Program can be examined from four (4) levels of aggregation: city, urban structuring units, sector, and block (Figure 1). Considering the level of consolidation of the existing built fabric, with limited space for the renewal of the built environment and the need to define a local strategy, the typological description was chosen based on the smallest level of aggregation, the block.

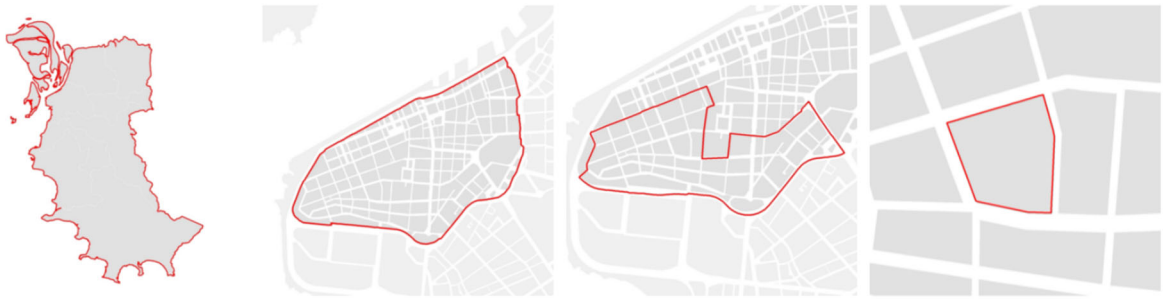

Figure 1. Possible levels of aggregation for analyzing the study area: city, urban structuring units, sector, and block. PORTO ALEGRE, 2021.

Pont and Haupt (2009) propose a model for the morphological classification of urban occupation patterns based on four (4) basic measures: floor area ratio, occupancy rate, height, and open space ratio. Henrique and Turkienicz (2021) test the application of this model as a way to establish occupation patterns on the built fabric of Porto Alegre. Through tests aimed at consolidating existing morphological type patterns, the authors demonstrate the direct relationship between this consolidation and improved performance in terms of habitability, particularly sunlight exposure and illuminance.

The model proposed by the authors was reproduced and applied to 113 selected blocks in the Historic Centre of Porto Alegre, resulting in the description of typological patterns presented in the following figures:

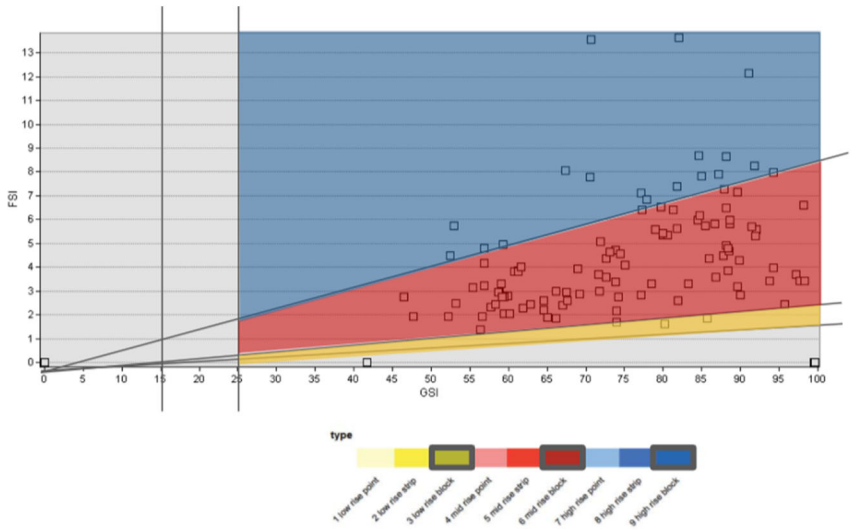

Figure 2. Morphological type patterns for the selected blocks. Source: Adapted from HENRIQUE and TURKIENICZ, 2021.

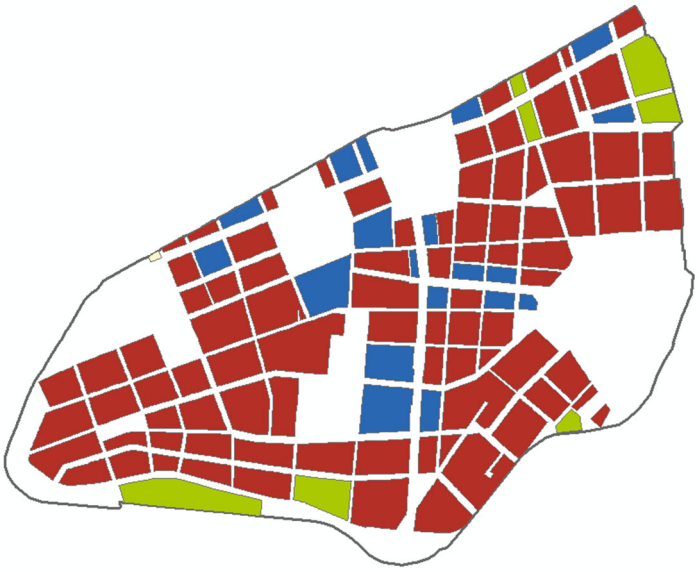

Figure 3. Spatialized morphological type patterns for the selected blocks. PORTO ALEGRE, 2021.

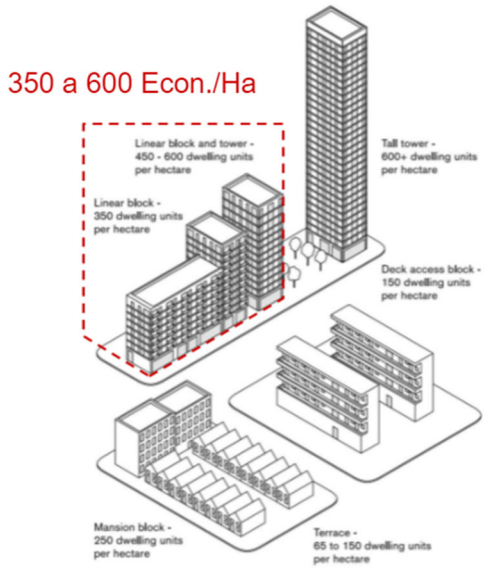

Figure 4. Most frequent morphological type patterns in the area under analysis. Source: Adapted from APA, 2012.

Regarding the most frequent morphological type pattern occurring in the analysed blocks of Porto Alegre's Historic Centre, the mid-rise block (medium height block) is notable. This typology is already recognized in the literature as highly compatible with urban qualities such as high urbanity and vitality of adjacent public spaces (SIM, 2019). In blocks with a medium to high level of consolidation, the need to preserve this pattern is emphasised, as it consolidates the identity and contributes to local habitability.

Viewsheds

The concept of a visual basin refers to a specific geographic area that is visible from a particular point in space. In the Urban Environmental Development Master Plan of Porto Alegre, this concept is related to the preservation of visual interests connected to the natural environment in the so-called "visual emergency points." For the Rehabilitation Program of the Historic Center of Porto Alegre, the idea is to extend this concept to points of interest within the built heritage, particularly in constructing visual

basins of reference elements in the landscape of the Center. The proposed concept is aligned with the strategy adopted in the conception of urban planning regimes in other cities around the world, such as in the case of London (Figure 5).

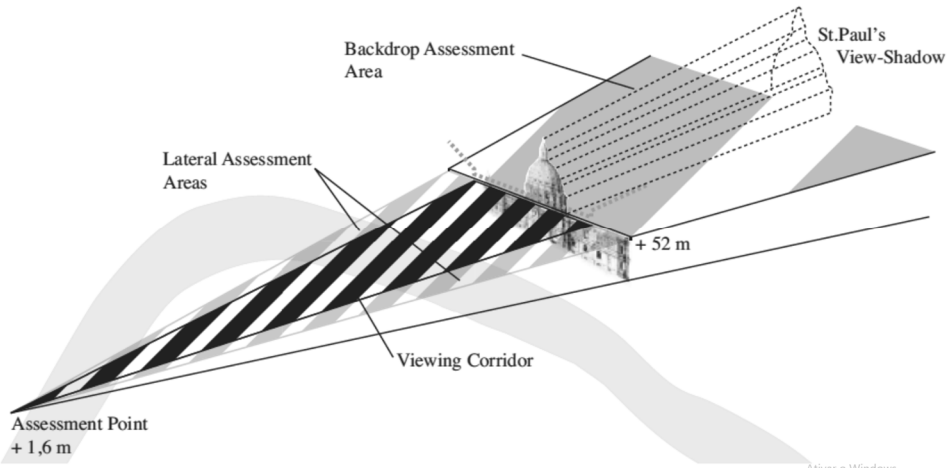

Figure 5: Views protected by geometric definition from observation points and target elements in the urban landscape. Example: the surroundings of the dome of Saint Paul's Cathedral, London. Source: Adapted from LEHNERER, 2010.

The first step for the analysis of the territory based on the visual points of interest in the Historic Centre involved establishing observation points at the intersections of the road axes within the area of analysis (Figure 6).

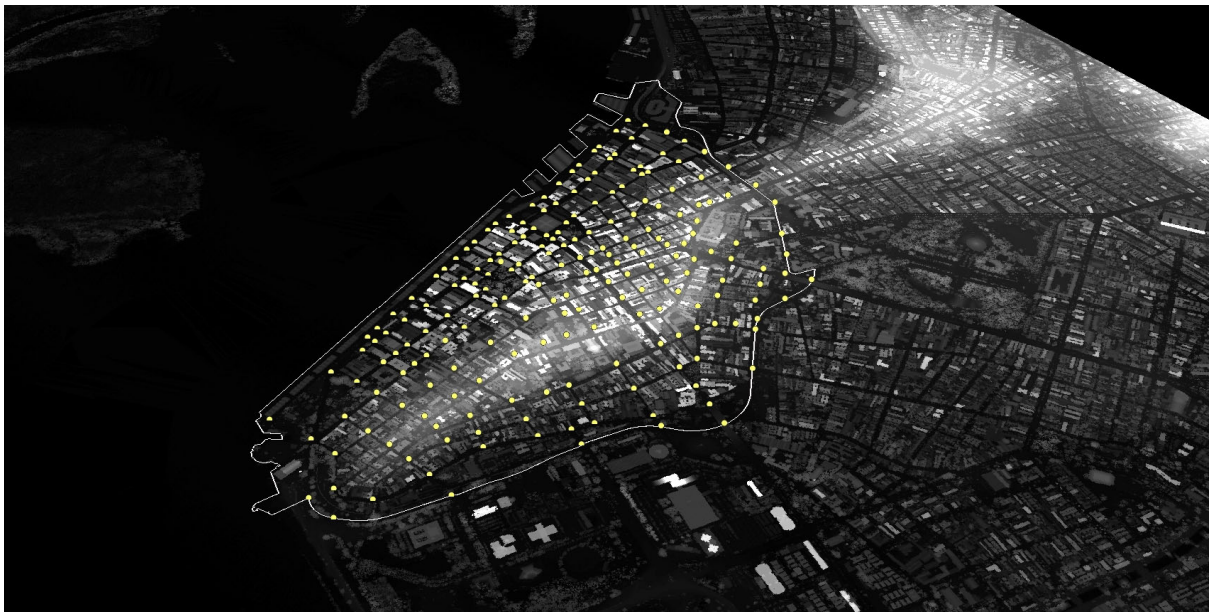

Figure 6: Observers positioned along the street network in Porto Alegre´s Historic Centre. PORTO ALEGRE, 2021.

From these points, the visibility analysis of the adjacent fabric was conducted. Figure 7 shows a point cloud over the area under analysis within the limits of the Historic Centre, classified according to the frequency of observation. The map highlights buildings and areas of interest, particularly the surroundings of the Public Market and the cluster of buildings near the waterfront. At the interface

between the Historic Centre and the adjacent neighbourhoods, taller buildings and a set of viaducts are evident.

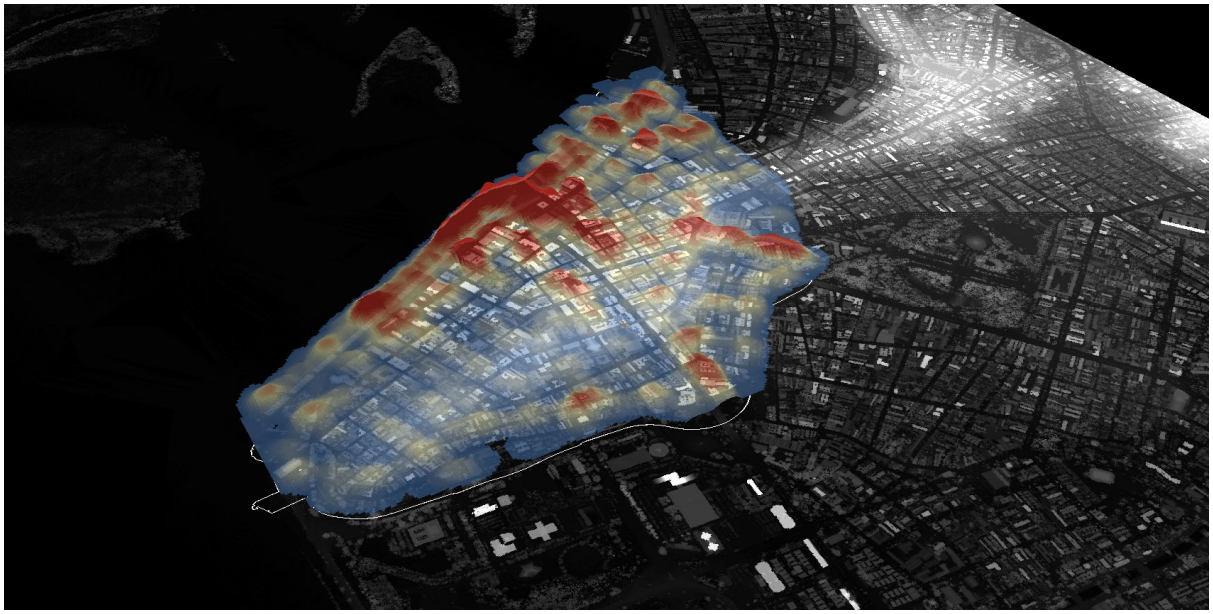

Figure 7: Point cloud classified according to the spaces observed with the highest frequency in relation to the positioned observers. PORTO ALEGRE, 2021.

Figure 8 shows the buildings observed most frequently within the point cloud. In Figure 9, the same buildings are classified to isolate those related to elements of historical and cultural interest, specifically: 41 listed properties and 92 structuring properties.

Figure 8: Highlight of the buildings seen with the highest frequency. PORTO ALEGRE, 2021.

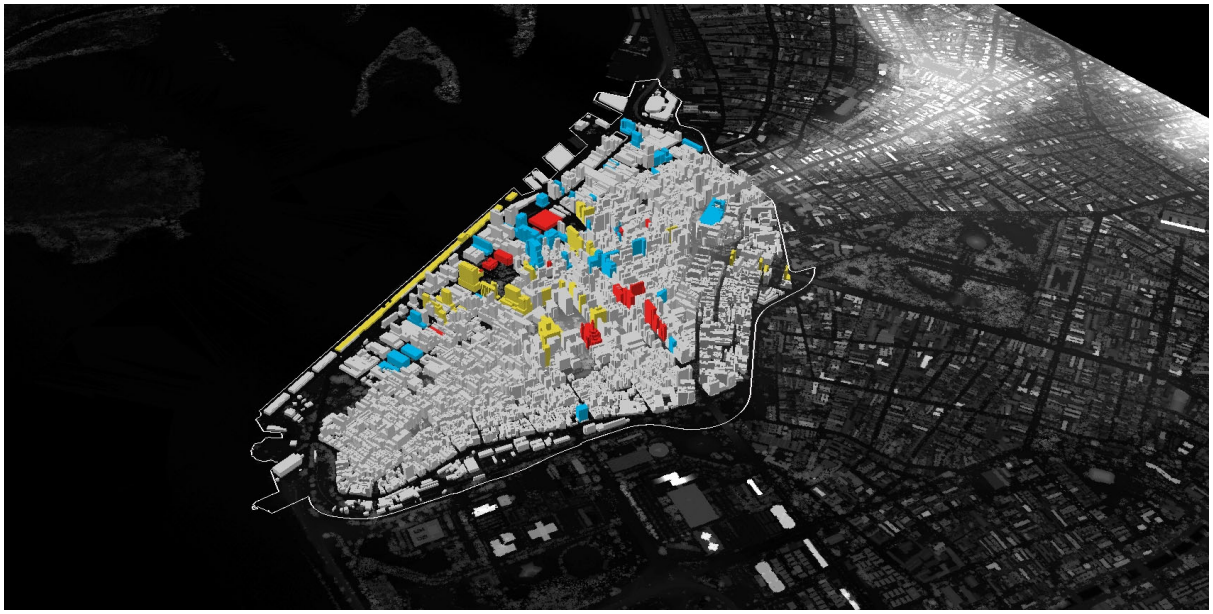

Figure 9: Buildings of interest observed with the highest frequency: listed properties (in red); properties in the vicinity of listed buildings (in yellow); and structuring properties (in blue). PORTO ALEGRE, 2021.

Figure 10 presents the visibility analysis for one of the points of interest: the dome of the Metropolitan Cathedral. In the model, it is possible to highlight road axes of interest for observing the building from the public spaces of the Center: Caldas Júnior Street and General Câmara Street.

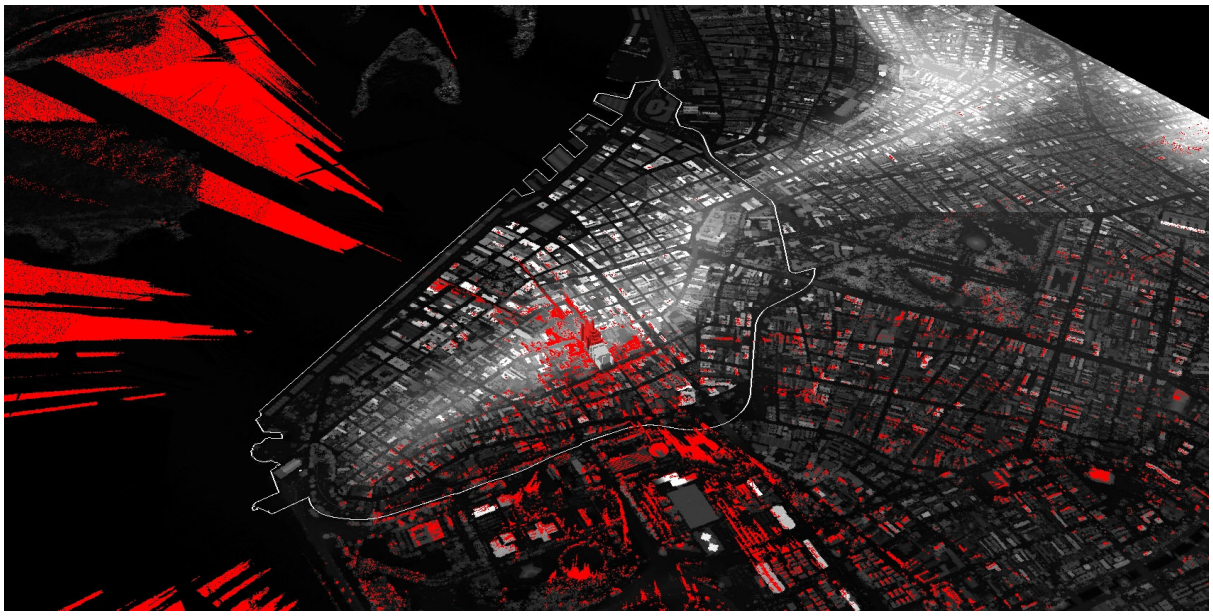

Figure 10: Spaces from which the dome of the Metropolitan Cathedral is observed. PORTO ALEGRE, 2021.

Habitability

The performance of urban form concerning habitability reference parameters, particularly in relation to ventilation, solar exposure, and illuminance, is directly related to the volumetry of buildings. The construction of scenarios to test the parameters for densification of the Historic Center of Porto Alegre considered two typical situations: (i) the construction of the maximum possible volumetry on the lots according to the current urban planning rules; and (ii) the projection of maximum volumetry according to performance criteria. For initial testing, a block on Washington Luiz Street was selected. The

automatic generation of buildings according to the current urban planning regime and proposed modifications was carried out in the CityZoom environment (TURKIENICZ, XXXX).

The evaluation of the generated forms concerning sunlight considered the simulation of impact for the winter solstice, June 21, 2021, with maximum sunlight exposure at 10:13 AM (sunrise at 7:20 AM and sunset at 5:33 PM), performed using the same software. The following images highlight in red the faces of the buildings with less than two hours of daily sunlight exposure for each scenario. The graph illustrated in Figure 14 presents a comparison of the building faces in each of the scenarios according to the hours of solar incidence for the analysis period.

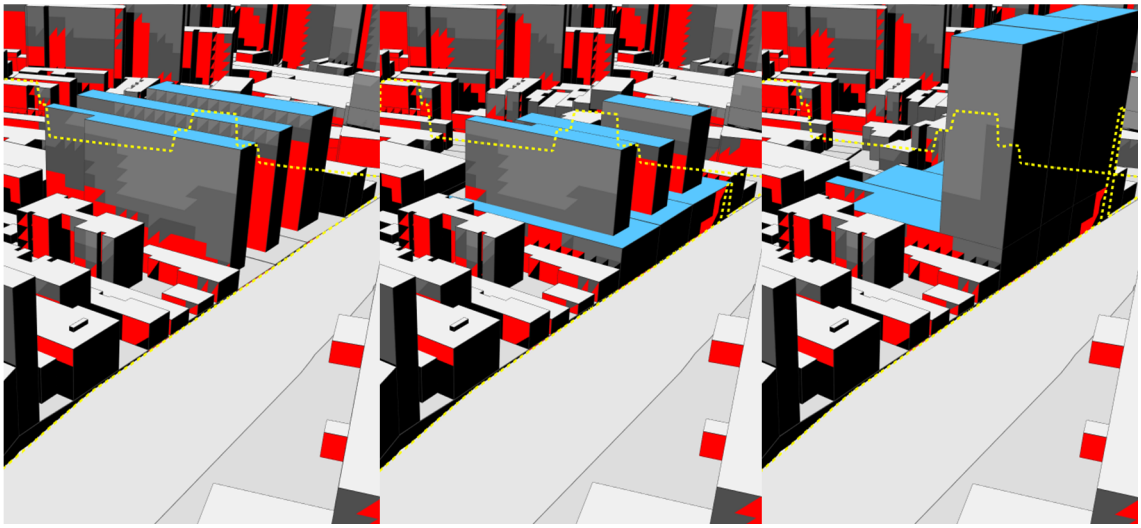

Figure 11: Scenario A-B-C, in red highlighting for faces with solar exposure < 2h/day. PORTO ALEGRE, 2021.

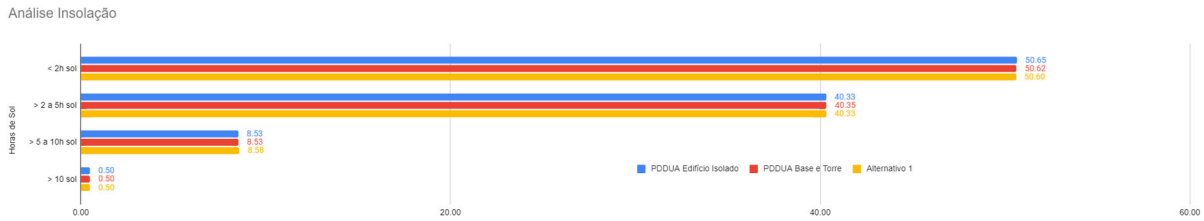

Figure 14: Sun hours for the three analysed scenarios. PORTO ALEGRE, 2021.

Regarding the presented scenarios, with tests on the compatibility of typologies in the Historic Centre, preservation of visual basins of built and natural elements of interest, and reference parameters for the habitability of buildings, it is important to note that these are tests aimed at highlighting potential approaches for developing alternative urban planning regulations for the territory. Based on this concept, the following section presents estimates for the construction potential of the territory, as well as the definition of construction stocks compatible with the proposed densities.

Building potential

For detailing the construction potential suitable for the proposed densities in the Historic Center of Porto Alegre, the blocks were classified according to their renewal potential considering three factors: (a) the level of consolidation of the blocks, low, medium, or high; (b) the current land structure pattern, with small, medium, and large lots; and (c) the level of impact according to visual basins, with low, medium, and high impact.

Figure 16: Blocks classified according to the scale of renewal potential and examples: (A) Very High; (B) Very High; (C) Low; and (D) Medium. PORTO ALEGRE, 2021.

For detailing the lots and simulating the additional construction potential, the following criteria were considered: (i) the executed utilisation rate: calculated based on data from the Municipal Department of Finance; and (ii) the preservation of historically significant buildings and urban facilities, with no increase in built area for the purposes of this estimate.

According to the results, the data were normalised according to the value scale identified below:

- 0 (zero) for lots with low renewal potential, including those with historically significant buildings and those with built area equal to or above the maximum index provided in the Plan;
- 1 (one) to 50 (fifty) for lots with medium renewal potential, with utilisation exceeding 50% of the construction potential indicated in the Plan;
- 51 (fifty-one) to 100 (one hundred) for lots with high renewal potential, with utilisation below 50% of the construction potential, reaching 100% renewal potential in the case of vacant lots.

Considering the three levels of renewal potential—high, medium, and low—the figure below illustrates the patterns according to the proposed categorization.

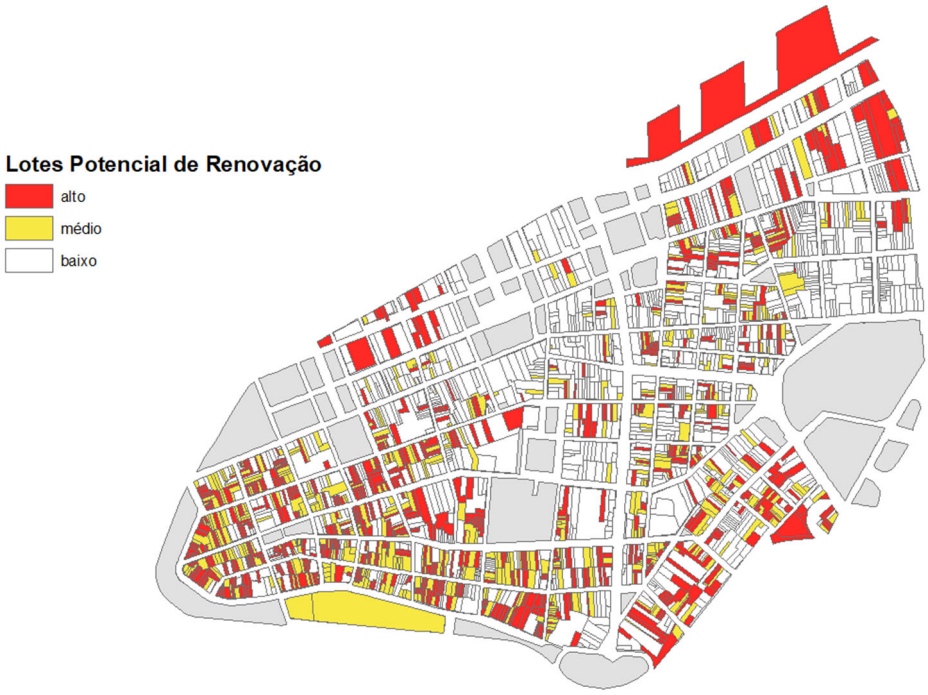

Figure 17: Lots classified according to renewal potential. PORTO ALEGRE, 2021.

A method for controlling volumetry: building envelope

Considering the tests conducted regarding parameters and metrics for land use and occupancy in the Historic Centre, it is proposed as a tool for volumetric control of buildings and the regulation of maximum volumetric limits by block. This solution mirrors the logic employed in other cities around the world, such as Barcelona, and the proposals presented in the Masterplan for the 4th District (UFRGS, 2016).

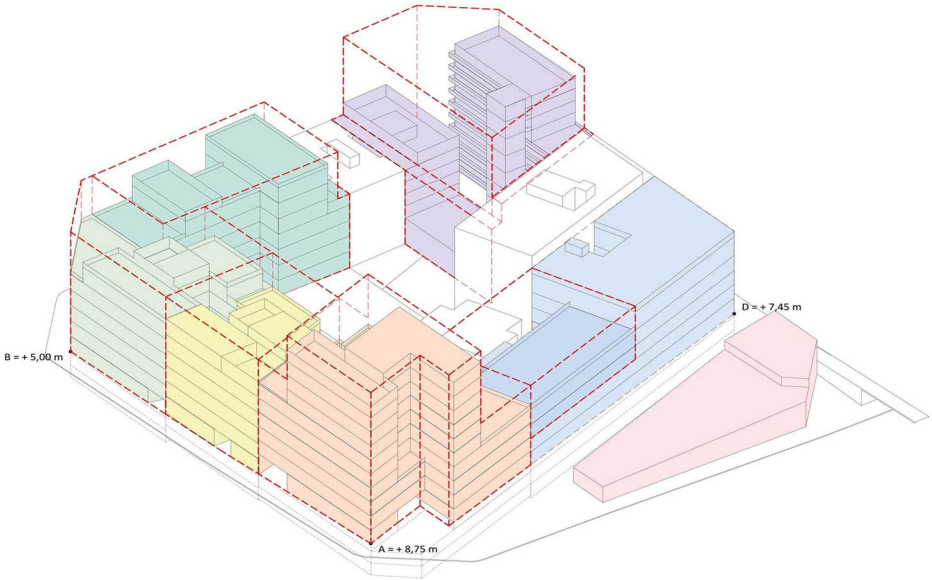

Figure 18: Study of maximum occupancy limits for a block in Barcelona. Source: Adapted from https://gde.barcelona/en/proyecto/zapp/.

According to the simulations conducted and presented in the previous sections, three criteria are established for the design of these maximum occupancy limits, especially in defining volumetric standards, to be detailed within the limits of the Adherence Perimeter of the Rehabilitation Program for the Historic Center of Porto Alegre:

TYPOLOGICAL DESCRIPTION: Evaluation of the typological morphological trends of consolidated blocks and axes, involving:

- Front setback defined, preferably by existing alignment or to be defined, considering specific urban or environmental situations;
- Exemption of lateral setbacks in defining the limits, ensuring the need for minimum clearances from adjacent properties, with a preference for continuity of the facade at the sidewalk level;
- Rear setback defined by compatibility with adjacent properties.

VIEWSHED:

- Respect for visual basins to be established in areas interfacing with elements of Historical Heritage and Lake Guaíba, and the city skyline;
- Differentiated volumetries at nodal points, landmarks, boundaries, and axes, in harmony with the consolidated surroundings;

HABITABILITY: Assessment of building performance according to standards of sunlight, illuminance, and ventilation.

BUILDING POTENTIAL: Assessment of building performance according to standards of sunlight exposure, illuminance, and ventilation.

RESULTS AND DISCUSSIONS

The overlay of the restrictions defined by the three parameters—height, visual landmarks, and habitability—resulted in the proposed building envelopes for the blocks within the study area. This is clearly illustrated in the 3D visualization, which demonstrates the relationship between the height of the buildings and the city's skyline, with the Gasômetro chimney serving as a key reference point, marking the lowest allowable elevation. The analysis highlights how the proposed design integrates with the existing urban landscape, preserving important visual corridors. Furthermore, the example of a proposed building, reviewed by the municipality's technical team, demonstrates how these guidelines can be applied in practice, ensuring that new developments respect the established parameters while enhancing urban cohesion.

Figure 23: Porto Alegre Flood, 2024.

CONCLUSIONS

The extreme climate event in May 2024 in Porto Alegre marked an unprecedented moment in the city's history, highlighting the urgent need to revise urban and construction strategies with a focus on resilience. Analysis of the affected areas revealed the critical importance of avoiding residential uses on floors at risk of flooding as a preventive measure against material and human losses. Additionally, it was observed that building infrastructure must be redesigned to ensure that electrical and logical systems are not exposed to vulnerability. Another key aspect was the necessity to plan new facilities that can play a strategic role during emergencies, such as shelters and support centers. These directions clearly point towards the adaptation of building codes and urban planning regulations, emphasising the importance of incorporating resilience strategies in response to the challenges posed by climate change.

Exploring periurban landscapes and river corridors: dynamics and planning in Zaragoza, Spain

Carmen Díez Medina[1], Javier Monclús[2] Miguel Ángel Laurenzana[3] Cecilia Sanz García[4]

ABSTRACT

Traditional peri-urban areas in European cities have been the result of the interaction between human and natural forces. However, contemporary processes of growth in peri-urban areas are transforming the adjacent natural and agricultural landscapes into a complex mosaic, a palimpsest characterised by fragmentation, dispersion, vacancy and a variety of land uses. The emergence of what are commonly referred to as 'new peripheries' or 'peri-urban zones' has been greatly facilitated by the proliferation of infrastructure, particularly roads and railways. To maintain and improve environmental, visual and landscape quality, identity and open space management, a wide range of tools are used. The aim of this paper is the identification and evaluation of the strategies that have been implemented in recent decades in the city of Zaragoza (Spain) and its surroundings. The analysis focuses on 12 case studies located in the Ebro River corridor, 6 upstream and 6 downstream, in order to explore the conventional and emerging urban planning and landscape instruments. Despite their 'ordinary character', these peri-urban areas have a distinct identity with important eco-cultural values. An analysis of local plans and interventions in both areas reveals the sectoral impacts and inequalities in the conservation of this particular heritage.

Keywords: urban landscapes, planning tools, territorial governance, eco-cultural assets

INTRODUCTION

Traditional peri-urban areas in European cities have historically evolved as a result of the interaction between human and natural forces. However, contemporary processes of urban expansion are transforming adjacent natural and agricultural landscapes into a complex mosaic, a palimpsest characterized by fragmentation, dispersion, voids, and a variety of land uses.

This paper raises questions related to the governance of these territories, exploring both conventional urban planning — municipal General Plans — and other emerging strategies — sectoral plans, natural or cultural protection regulations, landscape studies, etc. — in order to evaluate the adequacy of current policies on peri-urban areas.

This study is part of the research project "Peri-Urban Strategic Areas in Transformation: Eco-cultural challenges in urban regeneration processes in Spanish Cities" (PER-START), which analyses twelve peri-urban areas in six Spanish cities. The analysis of the two areas in Zaragoza developed in the PER-START project, Huerta de Las Fuentes and Ranillas-Juslibol meander (frames c-d in Figure 2), is complemented here by the study of two new zones that allow this research to extend to the peri-urban landscape along the Ebro River corridor (frames a-b). The work has been carried out in six municipalities upstream (Alagón, Bárboles, La Joyosa, Pinseque, Sobradiel, and Torres de Berrellén) and another six downstream (Alfajarín, El Burgo de Ebro, La Puebla de Alfindén, Nuez de Ebro, Pastriz, and Villafranca de Ebro). These are areas that are undergoing profound transformations with some kind of degradation process.

The geographer José Sancho Martí defined this area at the end of the eighties as follows: "The peri-urban space of Zaragoza is located in the centre of the Ebro depression; at the confluence of a series of tributary rivers […] which through their action have decisively influenced the original site of the city, the geomorphological configuration of the territory, as well as its human use from an agricultural or industrial point of view, by having acted as true axes around which the different urban manifestations are most intensely felt."27 In recent decades, these axes have developed through new infrastructural and industrial components, often outpacing urban planning, which is especially weak and diverse on the periphery, as recognized by the General Plan itself: "the peri-urban space [of Zaragoza] is being overwhelmed by the irrational and continuous growth of the city and is suffering intensely from the progressive degradation of its natural and cultural values."[28]

Figure 1. Peri-urban landscapes in the Ebro River corridor. Photo credit: authors, 2023.

METHOD

[27] "El espacio periurbano zaragozano se localiza en el centro de la depresión del Ebro; en la confluencia de una serie de ríos tributarios […] que con su acción han influido decisivamente en el primitivo emplazamiento de la ciudad, en la configuración geomorfológica del territorio, así como en su utilización humana desde el punto de vista agrario, industrial u otros usos, por haber actuado como auténticos ejes en torno a los cuales se dejan sentir con más intensidad las diferentes manifestaciones urbanas." (Sancho Martí, 1989)

[28] "El espacio periurbano [zaragozano] está siendo arrollado por el crecimiento irracional y continuado de la ciudad y sufre intensamente la degradación progresiva de sus valores naturales y culturales." (Anejo 11 del PGOUZ, 1999)

The methodology used in this research involves identifying and consulting urban planning, environmental, and project-based instruments that have been implemented in the two delimited areas over the past fifty years (1970-2020). Once all this information has been gathered, and in view of the experienced evolution, the existing strategies for the peri-urban space of Zaragoza, particularly in the 12 case studies, are analysed, compared, and finally evaluated.

The open-source software QGIS Desktop 3.28.15 has been used to generate two maps that synthesize the impact of these initiatives at a territorial scale. Thanks to this tool and the work on the data sources indicated later, it is possible to quickly locate land classifications according to all current municipal General Plans (Figure 4) and the active cultural or natural protections in the area (Figure 5).

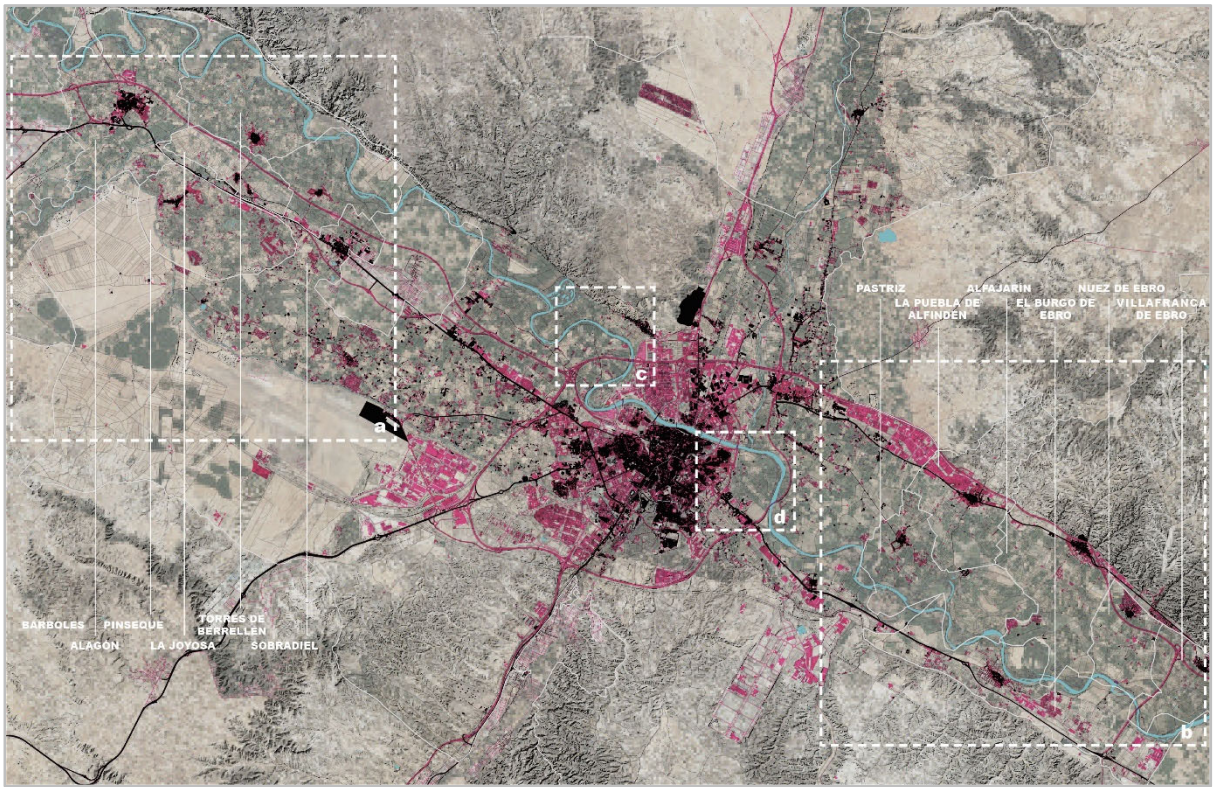

Figure 2. Urban explosion (pink) in both two areas, upstream and downstream (frames a-b). Frames c-d correspond to areas of 4x4 Km and indicate the case studies already analysed in the PER-START project. Photo credit: authors with QGIS Desktop 3.28.15 and PNOA ortophoto.

RESULTS AND DISCUSSIONS

Urban planning in the Ebro River corridor

The study area of this research encompasses 12 municipalities situated in the Ebro valley floor, whose General Plans, mostly adaptations of 'normas subsidiarias', have been drafted by different teams in each case, with the exception of 4 upstream municipalities, which were handled by the team led by Lorente.[29]

[29] PROINTEC group, PGOU Pinseque (2001). Architect J.A. Lorente Fernández, PGOU La Joyosa (2002). Architect J.A. Lorente Fernández and geographer Javier Albisu Iribe Sáez, PGOU Sobradiel (2004). Figure 3. Left: chronology of the current General Plans in the study area. Right: record of their modifications (light gray) and developments (dark gray), ordered from the shortest to the longest distance from Zaragoza. Photo credit: authors with SIUA data. https://idearagon.aragon.es/SIUa/archivo/buscador

Two distinct groups of plans can be identified based on their general intentions. The municipalities with better accessibility from Zaragoza, and thus subjected to greater urban influence and pressure, predominantly aim for industrial development supported by the city's entry-exit infrastructure. They consider their rural origins or agricultural exploitation as part of the past. In this regard, Alagón currently plays a decisive role as the head of the Ribera Alta del Ebro region, and Figueruelas — bordering the study area to the west — acts as an attraction pole for the establishment of large industries. Downstream, La Puebla de Alfindén and Villafranca de Ebro advocate for the creation of a metropolitan area where proximity to Zaragoza becomes a real driver of economic and demographic growth.

On the other hand, the municipalities more independent from urban dynamics pay greater attention to the territorial context in which they are situated. This group includes Sobradiel, Torres de Berrellén, La Joyosa, and Bárboles, with plans drafted by the Lorente group, which show a certain willingness for coordination and continuity in preserving natural spaces along the banks of the Ebro and Jalón rivers. Among the downstream case studies, only Pastriz's plan emphasizes promoting high edaphological value irrigated cultivation and continuing to integrate with the environment through existing canals and paths.

Nuez de Ebro (2005). Architects Daniel Olano Pérez and Alberto Mendo Martínez, PGOU Villafranca de Ebro (2007). Architects Miguel Ángel Navarro Trallero and Mª de Loreto Navarro Monte, PGOU El Burgo de Ebro (2012).

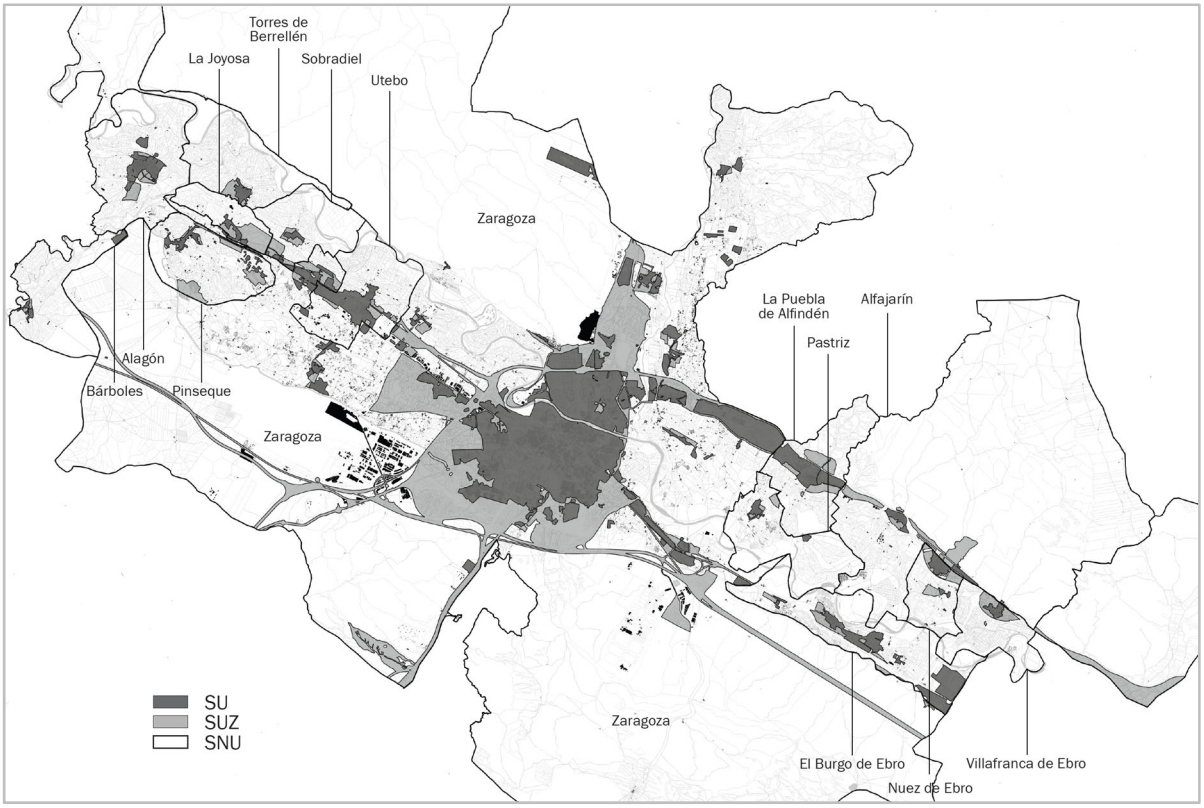

Figure 4. SU ('Suelo Urbano' or urban land, dark grey), SUZ ('Suelo Urbanizable' or developable land, light grey), and SNU ('Suelo No Urbanizable' or non-developlable land, white). Classification according to the General Planning in the study area. Photo credit: authors with QGIS Desktop 3.28.15 and ICEARAGON data.

Regarding the classification of land as non-developable, each General Plan applies its own criteria to define protections. Downstream, the continuous alignment of the Urdana canal sometimes serves as the natural boundary for non-developable land — such as in La Puebla de Alfindén before the 2015 modification, and Nuez de Ebro — while in other cases it is overlooked — such as in Alfajarín and Villafranca de Ebro — (Figure 4).

Lastly, there is an issue referenced by all the plans that affects the non-developable land on the periphery extensively: illegal subdivision of land, along with various types of constructions, irregular connections to public services, exposure to river flooding, and associated loss of crops. Regarding this conflict, each municipality adopts a different stance. Nuez de Ebro identifies and maps three major illegal subdivisions — "La Fuen", "Tozaletes", and "Contiendas" — and classifies them as SUNC (non-consolidated urban land), awaiting the subsequent drafting of a PERI (special interior reform plan) to provide them with urban services. Pastriz, on the other hand, maintains the classification of SNU (non-developable land) entirely and considers two scenarios: when illegal subdivision is included in SNU-E (non-developable land with special protection), it must follow the regulations of the natural resource management plan (PORN), and when included in SNU-G (non-developable land with generic protection), it can undertake actions to be classified as SUNC through modifications of the current General Plan and a specific PERI. Given the high number of illegal subdivisions, particularly in Pastriz, the plan includes an annex that meticulously maps and analyses all these allotments.

Other instruments in the Ebro River corridor

In addition to conventional General Planning instruments, there are several cultural and/or environmental strategies that apply to the study area and are considered in this communication.

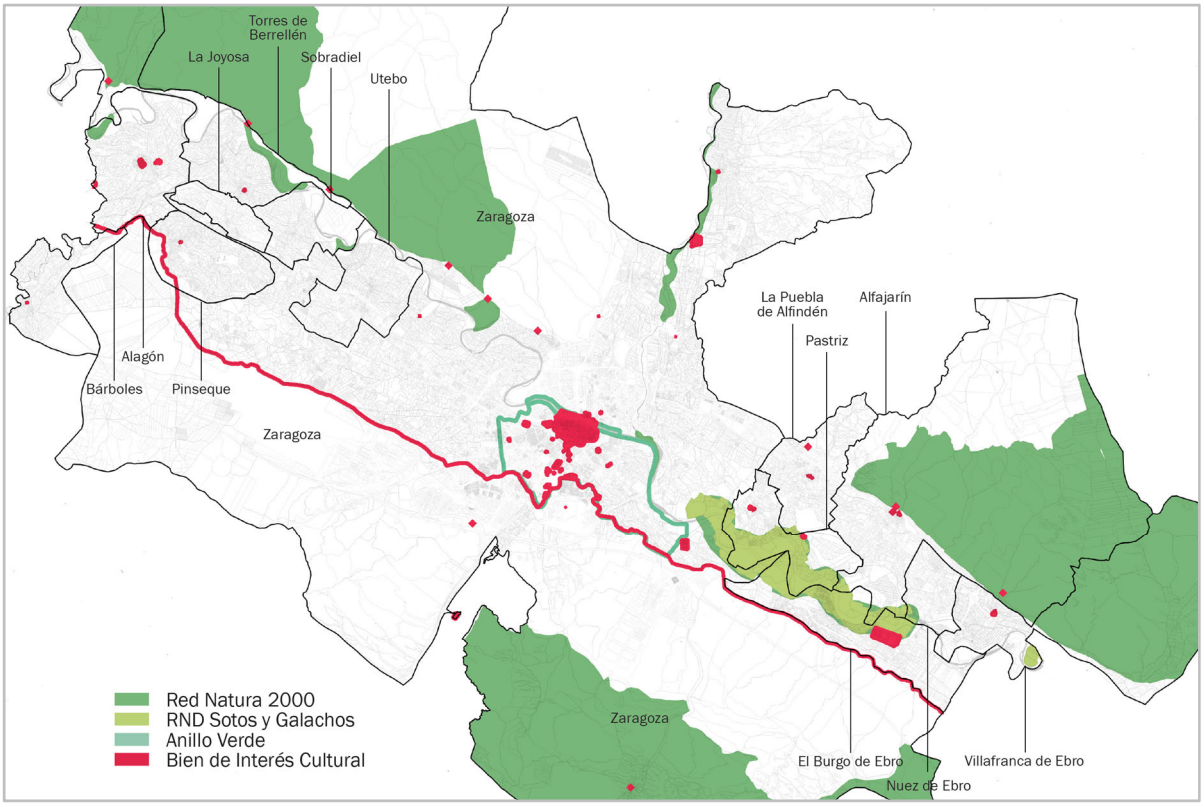

Figure 5. Figures of protection for cultural and natural heritage in the study area. Photo credit: authors with QGIS Desktop 3.28.15 and ICEARAGON data.

Firstly, as a link between the previous section and this one, the Catalogues collected from the General Plans assign different levels and conditions of protection, which are usually detailed in the corresponding 'normas urbanísticas'. Additionally, according to regional heritage legislation, 16 properties in the area are identified as assets of cultural interest (BIC). All BICs are included in the Catalogues, but not all catalogued buildings are BICs.[30]

Regarding natural heritage protection figures, it is notable the definition of the Reserva Natural Dirigida de los Sotos y Galachos del Ebro in 2011. This area, already recognized as a protected natural space in 1991, manages the river corridor environment: it carries out tasks for biodiversity conservation, cleaning, signage and trail mapping, and the promotion of interpretation centres, among other activities. It covers an area of 1,536 ha and is included in the European Natura 2000 network, where it overlaps with two Special Areas of Conservation (SAC) and one Special Protection Area for Birds (SPA). A plan for natural resource management (PORN, 2007) and a management and use plan (PRUG, 2022) have been approved for this space. Additionally, upstream, some isolated enclaves are included within the Natura 2000 network: Sites of Community Importance (SCI) near the

Ebro, covering areas of Alagón, Torre de Berrellén, Sobradiel, and Utebo; and a large SPA in the Plana del Castellar of Torres de Berrellén.

Other environment-related and climate action instruments of European origin include the LIFE Programs.[31] For this research, two grant agreements signed in 2012 are of particular interest: Huertas LIFE Km0 and ZARAGOZA+ NATURAL. The first aims to "restore the environmental system of the peri-urban fertile soil of Zaragoza, traditionally used for cultivating fruits and vegetables and now in a state of regression"32, while the second wants to "protect, improve, enhance, understand, and publicize Zaragoza's Green Infrastructure, which includes the SCIs and SPAs, as well as the Green Belt and other areas of natural interest."33 In relation to the latter Program, the City Council had previously attempted to promote the Zaragoza Green Belt initiative, a continuous 30 km route for pedestrians and cyclists, which coincides within the study area with the GR 99 or Camino Natural de La Alfranca.

Finally, the elaboration of the Aragón Landscape Maps between 2015 and 2018 is noteworthy. These are public territorial information documents that "identify the landscapes of the different regions of Aragón, analyse their characteristics and the forces and pressures that transform them, identify their values and conservation status, and propose the landscape quality objectives that must be met."34 There is one Landscape Map for each Aragón region and, following the guidelines of the European Landscape Convention (ELC, 2000), it consists of 16 documents arranged in a logically studied sequence.[35]

Projects in the Ebro River corridor

Most projects on non-developable land consist of maintenance or improvement works along the riverbanks, rural roads, remnants of irrigation canals, old public washhouses and mills, or other municipal properties in a state of abandonment or ruin. These small-scale local works are mostly financed by the Diputación General de Aragón through the unified subsidy plan (PLUS) program, which has been operational since 2017. Most municipalities allocate these funds "to improve basic services such as street paving, water supply or sewerage, and also note an increase in requests for sports facilities and for building, rehabilitating, or equipping municipal housing to attract new residents."[36]

Notable cases include, for example, the project promoted by Zaragoza Ecuestre in 2006 to build an equestrian centre in the 'paraje Vicentón', belonging to La Puebla de Alfindén and very close to the Pastriz border. Due to objections from the latter, this project was abandoned and today it stands as a sort of 43,000 m² rubble dump in the irrigated area. Upstream, there is the project to develop a tree-lined pedestrian walkway on the left bank of the Almozara canal, which crosses the areas of La Joyosa and Sobradiel. However, this initiative also remained incomplete due to a lack of agreement between the involved municipalities and the absence of continuity in public offices.

More recently, disagreements between neighbours, property owners, environmental entities, political factions, and developers have made headlines regarding the implementation and regulation of renewable energy plants on the peri-urban 'huerta' (orchard). In particular, Movera faces strong pressure and a convergence of interests, with more than five ongoing projects for the installation of photovoltaic parks, some of which already have favourable urban compatibility certificates, environmental impact declarations, and administrative authorizations. These areas, close to the industrial development of Malpica and the A-2, have also been proposed in recent months for the establishment of large-scale regional projects, such as a new logistics hub (with large areas for companies like Inditex or Lapesa) or a future industrial complex named the Ebro valley agri-food logistics centre (CLAVE).

CONCLUSIONS

The following common features have been identified from the study and comparison of the General Planning of the analysed municipalities:

- Strong land demands in the municipalities most accessible from Zaragoza to accommodate new infrastructures and peri-urban uses, facilities or structures that are difficult to integrate into the urban fabric.

- Discontinuities in the classification, protection regime of non-developable land, and methods for regularizing illegal subdivision due to the lack of an integrated vision of the peri-urban area at a territorial scale.

- A passive protection regime, based on 'freezing' rural and riverside areas, lacking management plans, improvements, or enhancement efforts. Inaction in the face of abandonment and degradation of heritage and traditional agricultural activities. These plans

[36] "para mejorar servicios básicos como la pavimentación de calles, el abastecimiento o el alcantarillado y también destaca el aumento en las peticiones para instalaciones deportivas y para construir, rehabilitar o equipar viviendas municipales que sirvan para atraer nuevos pobladores." https://www.dpz.es/noticias/la-diputacion-de-zaragoza-aprueba-el-plan-unificado-de-subvenciones-2024-50-millones-de-euros-para-que-los-292-municipios-de-la-provincia-hagan-1-287-actuaciones-de-todo-tipo-1

usually contain much information about the local community's physical environment, but are rather descriptive, with less space devoted to efficient planning tools.

- Lack of coordination in the protections over special non-developable land (Table 1) and weak control over generic non-developable land. For example, El Burgo de Ebro rigorously defines protection guidelines for areas of cultural-archaeological interest — considering the number of sites included in the area —, livestock trails — including a study of the five main ones —, and infrastructure — many of which are recently constructed —. However, it neglects the presence of irrigation canals, or the zoning of spaces protected at the European level.

- Unequal references to other sectoral regulations such as natural resource management plans, sectoral guidelines on livestock activities and installations, or existing legislation on various elements that appear in the peri-urban landscape — power lines, roads, railways, industry, and extractive activities — especially regarding the definition of zones of impact and easement applicable to the area.

Alagón	X	X			X	X	X	X	X	X
Bárboles		X	X	X	X	X	X	X	X	X
La Joyosa					X	X	X	X		X
Pinseque				X	X	X	X	X		X
Sobradiel	X	X			X		X	X	X	X
Torres	X	X			X	X	X	X	X	X
Alfajarín										
El Burgo			X	X	X	X			X	X
La Puebla			X			X				X
Nuez									X	X
Pastriz	X	X					X	X		
Villafranca	X	X	X			X	X		X	X

The following conclusions can be drawn from the study and comparison of the strategies implemented in the analysed municipalities:

- Limited dissemination regarding the protection of buildings of interest and other elements in each municipal area. Without management aimed at activating peri-urban, natural, or cultural heritage, much of the local population is unaware of or does not recognize its value.

- The declaration of the Aragonese section of the Imperial Canal as a BIC is still pending resolution since the initiation of its file in the year 2000. Currently, a visit to the site shows deterioration in the crossings between its banks — Puente del Jubo in Pinseque, Puente del Camino in Alagón — and in the adjacent buildings — Almenara de Santa Emilia in Pinseque, or Almenara de San Martín in Grisén —.

- In retrospect, the efforts of HUERTAS LIFE to promote organic farming in Zaragoza's peri-urban 'huerta' have not been consolidated: the LIFE Km0 Market Garden Network only grouped 27 local farmers, and the municipal farm of Torre de Santa Engracia (Movera), conditioned as

Parcela Cero and as the Km0 Agricultural School, only hosted 21 students during the two training cycles held before being abandoned. On the other hand, this Program has left valuable publications such as “Diagnóstico de la Huerta de Zaragoza” (2014), “Planimetría de la Huerta de Zaragoza” (2014), and the book “Patrimonio Hidráulico en la Huerta de Zaragoza” (Rivas, 2017).

- ZARAGOZA+ NATURAL has been more fruitful, successfully promoting the drafting of several plans: management plan for the Barranco de Las Almunias, Zaragoza Natural action and tourism promotion plan, special plan for the protection of the Vedado de Peñaflor (2014), management plan for Monte de Torrero (2014), special plan for the Estepa (2016), and the Green Infrastructure Master Plan (2017).[37]

- The Green Belt has not been fully completed. It is still interrupted around the Delicias intermodal station, with an eastern closure too far from the city centre.

Figure 7. Almenara de Santiago Apóstol of the Imperial Canal as it passes through Pedrola in a state of deterioration. Photo credit: Miguel Ángel Laurenzana, 2022. Parcela Cero on the Movera-Pastriz road, abandoned after its initial boost by the Huertas LIFE Km0 in 2015. Photo credit: Cecilia Sanz, 2023.

The following conclusions can be drawn from the study and comparison of the projects supported in the analysed municipalities:

- The lack of agreement among the various stakeholders interested in peri-urban land often results in projects never being realized or remaining unfinished.

- Actions on non-developable land are limited to the improvement of urban services. Since these measures depend on various factors such as the sensitivity of the municipal team, their continuity over time, or the economic availability of the municipalities, projects aimed at peripheral areas, or the natural surroundings are rarely implemented.

[37] This Program also promoted ecological improvement actions on the banks of the Gállego River and signage operations through panels and brochures in the River Corridors of the Ebro, Gállego, and Huerva, and in the alluvial dolines of the municipality. Additionally, several documents were published regarding the groves and banks of the Ebro (2014): proposals for 21 itineraries, ecological valuation sheets, studies on the evolution of the river channel…

Figure 8. Balsa de la Marlofa (La Joyosa) undergoing conditioning works. Photo credit: Miguel Ángel Laurenzana, 2019. Abandoned structure for the equestrian project (La Puebla de Alfindén). Photo credit: Heraldo de Aragón, 2016.

Ultimately, the persistence of biodiversity loss and degradation processes is confirmed. It is evident that the proliferation and overlapping of regulations and instruments of all kinds do not guarantee adequate preservation, much less the revitalization of peri-urban landscapes. Although some strategies have worked well, particularly those aimed at the natural protection of exceptional sites with heritage value, the application of protection and revitalization instruments is insufficient, especially in ordinary landscapes, including peri-urban ones. In addition to the renewal of advanced intervention strategies and instruments, it is clear that reversing these processes requires greater awareness of the eco-cultural values of these peri-urban landscapes.

Exploring the impact of urban form on social dynamics in Quintas within the Historic Center of Lima: a comparative study before and after COVID-19

Roberto Flores Hidalgo[1]
[1] Department of Architecture, Faculty of Architecture, University Applied Sciences, Perú
roberto.flores@pucp.pe,PCARRFLO@upc.edu.pe

ABSTRACT

This study delves into the intricate relationship between urban form and social dynamics in quintas within the Historic Center of Lima, focusing on pre and post-COVID-19 periods. The goal is to comprehend how the layout of these historical neighborhoods influences daily interactions, providing insights for urban planners, architects, and community members seeking to enhance living spaces in this culturally significant area. Emphasizing the impact of the pandemic, the primary objective is to understand the connections between the urban form of quintas in the Historic Center of Lima and inhabitants' dynamics.

Objectives encompass researching space utilization patterns, assessing social interactions, and gauging resident satisfaction with design elements in this historic context. Using a multi-faceted approach, the study integrates direct observations, surveys, interviews, and a review of previous research. Observations capture daily activities and traffic flow within the quintas, both pre and post-COVID-19. Surveys and interviews gather subjective perspectives on how urban form impacts experiences and interactions, considering the evolving needs and behaviors of residents during the pandemic.

Preliminary findings reveal discernible patterns in space utilization, with specific aspects of urban form influencing social interactions within the quintas of the Historic Center of Lima. Residents express varying satisfaction levels with communal spaces and neighborhood layout, emphasizing the unique historical context and evolving dynamics post-COVID-19. This study aims to illuminate the complex interplay between urban form and social dynamics in quintas within the Historic Center of Lima, offering opportunities for informed urban planning improvements that respond to the changing needs and behaviors of residents after the pandemic.

The case study involves two quintas in Lima, representing distinct moments in the city's urban form creation. The research underscores the importance of adapting urban planning strategies to foster resilient and responsive communities that honor historical context while addressing contemporary challenges.

Keywords: quintas, social dynamics, neighborhoods, covid 19

INTRODUCTION

Urban form plays a pivotal role in shaping social dynamics within residential environments. This relationship becomes especially evident in compact, historically dense residential typologies, such as quintas, which are commonly found in the Historic Center of Lima. Quintas are characterized by their narrow pathways, shared courtyards, and the compact arrangement of housing units, resulting in spatial conditions that necessitate social interaction among residents. The COVID-19 pandemic, however, brought about significant disruptions to daily life, particularly in spaces where social proximity is unavoidable, raising questions about the adaptability of these urban forms in a post-pandemic world.

This research examines how the urban form of quintas has influenced social behavior, focusing on the comparative periods before and after the COVID-19 pandemic. Specifically, it seeks to answer the following research question: How has the urban form of quintas in Lima affected social interactions, community cohesion, and the use of shared spaces, particularly in response to the changes brought about by COVID-19?

Figure 1. Quinta in the historic center of Lima. El Comercio News.

The objectives of this study are threefold: (1) to analyze the morphology and physical characteristics of selected quintas in Lima's Historic Center, (2) to explore the social dynamics and interactions within these quintas, and (3) to compare how the urban form has influenced the use of communal and private spaces before and after the pandemic. By focusing on two case studies—Quinta Los Huérfanos and Quinta Baselli—this research will offer insights into how historical urban forms can adapt to modern challenges, particularly in terms of fostering social interactions while maintaining public health measures.

The findings of this study will provide valuable contributions to the fields of urban planning, architecture, and social theory, particularly concerning the resilience of historical residential forms in the face of unprecedented global challenges such as the COVID-19 pandemic.

Research problem and objectives

This research investigates how the urban form of quintas—defined by their dense spatial layout, narrow pathways, and limited public spaces—affects socio-spatial dynamics, particularly regarding social interaction, community cohesion, privacy, and access to shared spaces in these compact residential environments.

Main objectives:

- Analyze the morphology and physical characteristics of the selected quintas, considering changes before and after the COVID-19 pandemic.
- Explore the social dynamics and coexistence within these quintas, with a focus on how these dynamics have shifted due to the pandemic.
- Compare how urban form influences the use of common and private spaces, assessing differences in spatial usage before and after COVID-19.

Conceptual framework

To analyze the relationship between urban form and social dynamics in Lima's quintas, this research draws on key theoretical frameworks that examine the interplay between the built environment and human behavior. Two foundational theories guide this study: Amos Rapoport's theory of the built environment and social behavior, and Christian Norberg-Schulz's phenomenological approach to the sense of place. These frameworks provide a comprehensive understanding of how spatial arrangements influence social interactions and emotional connections to the environment.

Conceptual Framework

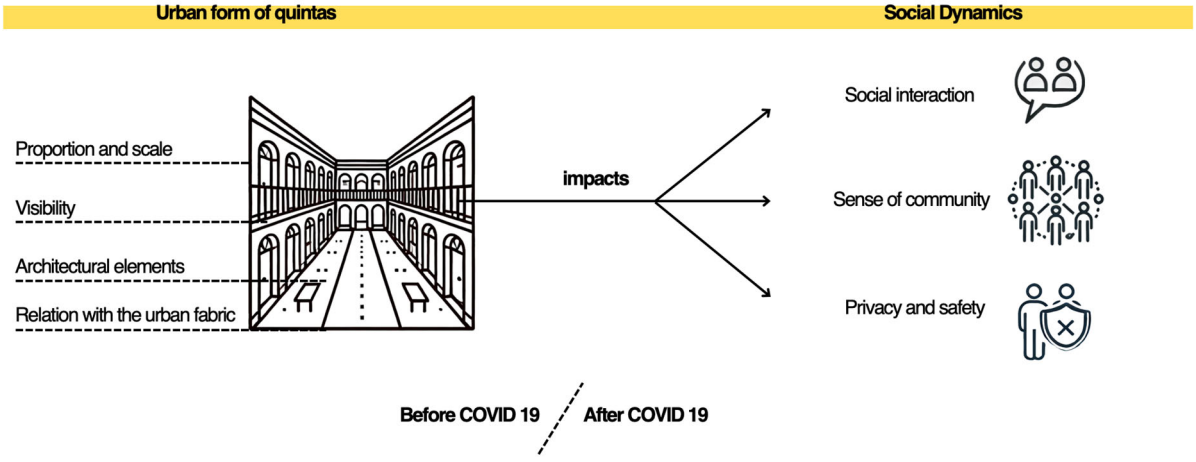

Figure 2. Conceptual framework as a conclusion from the literature review. *Own elaboration, 2024.*

Amos Rapoport – built environment and social behavior (1977)

Amos Rapoport's theory posits that the physical characteristics of a built environment, including its spatial organization, proportions, and the arrangement of public and private spaces, profoundly influence how people behave and interact within that space. Rapoport emphasizes the importance of spatial hierarchy, which refers to the gradation between public, semi-public, and private spaces. This hierarchy directly impacts the frequency and nature of social interactions within a given environment.

In the case of quintas, the dense spatial layout and narrow pathways create a setting where semi-public spaces, such as courtyards and corridors, serve as extensions of private spaces, leading to frequent interactions between neighbors. However, the **proportions and scale** of these spaces are critical. If communal spaces are too small or poorly designed, they can discourage social engagement, leading to a reduction in interaction and community cohesion. Conversely, appropriately scaled spaces can facilitate casual encounters and foster a sense of belonging among residents.

Additionally, visibility and access play a crucial role in shaping social dynamics. Communal spaces that are easily accessible and visible from private areas—such as corridors that face onto shared courtyards—encourage informal surveillance and interaction. In the context of this research, Rapoport's theory will help to assess how the spatial design of the quintas influences social behavior, particularly in light of the changes imposed by COVID-19. The pandemic has heightened awareness of personal space and health safety, making the role of spatial hierarchy even more critical in understanding post-COVID social dynamics.

Christian Norberg-Schulz – phenomenology and sense of place (1980)

Christian Norberg-Schulz's phenomenological approach to architecture focuses on the emotional and existential experience of space, particularly how the design of a space creates a sense of place. According to Norberg-Schulz, architecture does more than provide shelter; it shapes how individuals feel and interact within their environment. The built form can evoke feelings of belonging, safety, and connection, or, conversely, alienation and discomfort.

In the context of Lima's quintas, the concept of sense of place is particularly relevant. The communal spaces within quintas, such as shared courtyards and pathways, are not just functional areas but also social spaces that contribute to residents' emotional connection to their environment. Before the pandemic, these spaces fostered social cohesion by providing areas for informal gatherings and casual interactions. However, as the pandemic introduced new health risks, these same spaces may have become sources of anxiety and discomfort, altering the residents' emotional attachment to the place.

Norberg-Schulz also highlights the importance of architectural elements, such as proportions, visibility, and openness, in creating environments that support social interaction. In the case of Quinta Baselli, for example, the architectural layout may have continued to support social interactions even during the pandemic, as residents found ways to maintain a connection to the space despite health concerns. In contrast, in Quinta Los Huérfanos, the emotional detachment from the communal spaces may have contributed to social isolation during the pandemic. By applying Norberg-Schulz's theory, this research aims to explore how the emotional and cultural significance of space influences social behavior in the quintas, particularly in response to the disruptions caused by COVID-19.

Independent Variables (Architectural Features)	Description	Indicators
Proportions and Scale	Refers to the dimensions (height, width, and depth) of communal spaces like courtyards, pathways, and corridors, which can influence how residents perceive and use these spaces. Larger proportions may facilitate social gatherings, while confined spaces could restrict interaction.	Proportions of communal spaces like courtyards and pathways (height, width, depth) and their effect on social behavior.
Visibility and Sightlines	How well communal spaces are visible from windows, doors, or other vantage points. Greater visibility might promote a sense of safety or encourage social interaction, while limited visibility could lead to more privacy or social isolation.	Visibility from windows, doors, and pathways, and its impact on residents' sense of safety and connection.
Architectural Elements (Windows, Doors, Materials)	Focuses on the size, placement, and materials of key architectural components like doors and windows. These elements can affect residents' comfort, interaction, and security by shaping how they connect with their environment and with each other.	Placement and size of windows and doors, as well as how material choices affect comfort and interaction.
Dependent Variables (Social Dynamics)		**Indicators**
Social Interaction	Refers to the frequency and type of interactions among residents in communal spaces. This variable looks at how often residents engage in conversations or social activities and how these behaviors have changed before and after the pandemic.	Frequency and type of social interactions before and after COVID-19 through observations and interviews.
Sense of Community	Represents residents feelings of belonging and emotional connection to their neighbors and communal spaces. This variable examines how architectural features contribute to fostering or weakening the sense of community within a neighborhood.	Residents sense of belonging and community connection by examining how architectural features influenced emotional and social experiences.
Privacy and Safety	Refers to residents perceptions of their privacy and safety in communal and semi-private spaces. Architectural elements like windows, doors, and proportions can either support or hinder the feeling of security and personal space.	Residents perception of privacy and safety changed based on architectural features like visibility, space proportions, and materials.

Figure 3. Operationalization. Own elaboration, 2024.

METHOD

This chapter outlines the methodological framework employed to explore how the urban form of quintas in Lima's Historic Center influences social dynamics, focusing particularly on the shifts that occurred before and after the COVID-19 pandemic. The methodology integrates qualitative research methods, utilizing case studies to provide an in-depth understanding of both the spatial characteristics of quintas and their social outcomes. By employing observations, interviews, and architectural analysis, this study captures the complexities of communal living in two distinct historical quintas: Quinta Los Huérfanos and Quinta Baselli.

Figure 4. Quinta Baselli and Quinta Huerfanos, historic center of Lima. PROLIMA archive.

Research design

The research employs a qualitative case-study approach to allow for a detailed examination of the complex interactions between urban form and social behavior. This approach is particularly suitable for exploring the dynamics within small, contained environments such as quintas, where a range of social interactions and spatial variables coexist in a single physical setting.

The use of case studies allows for the examination of both social phenomena (e.g., interaction frequency, community cohesion, privacy) and architectural features (e.g., layout, proportions, visibility). This methodology provides an opportunity to study the quintas holistically, considering how

residents engage with their built environment both before and after the pandemic. By comparing the two case studies—Quinta Los Huérfanos and Quinta Baselli—the research identifies how urban form can produce varied social outcomes in similar architectural settings.

The qualitative nature of the study enables the collection of rich, descriptive data, which is essential for understanding the nuances of social interactions within these historical urban forms. This research design ensures that the complex relationship between architecture and social behavior is captured, providing insights that are both context-specific and potentially generalizable to other historical residential environments.

Data collection methods

The research relies on three primary methods of data collection: observations, semi-structured interviews, and architectural analysis. Each method plays a complementary role in building a comprehensive picture of how the quintas' physical form influences social dynamics.

Observations

Observational research was conducted to record the spatial use of communal areas such as courtyards, corridors, and entryways in both quintas. Observations were made before the pandemic (when possible, from resident accounts) and after, allowing for a comparative analysis of social behavior across these periods. The researcher observed both day-to-day interactions and special events in the quintas, noting changes in spatial use and resident behaviors.

Key aspects of observation included:

- Patterns of movement: How residents moved through and occupied communal spaces.
- Frequency of interaction: How often residents engaged in informal or formal gatherings.
- Modifications in use of space: Changes in how residents used courtyards or corridors before and after the pandemic, including avoidance or adaptation for social distancing.
- Space appropriation: How communal spaces were personalized or used by specific groups of residents, for example, in decorating or maintaining areas.

These observations were supplemented by photographic documentation and field notes, capturing the physical characteristics of the communal areas and how they were inhabited by residents.

Interviews

Semi-structured interviews were conducted with a diverse group of residents from both quintas. The semi-structured format allowed for flexibility, enabling the researcher to explore key themes while adapting the conversation based on residents' personal experiences. The interviews provided qualitative insights into how residents perceived the built environment, particularly how they navigated communal spaces and how their social interactions were affected by the pandemic.

The interview guide was structured around the following key topics:

- Perceptions of community and interaction: How often residents interacted with neighbors and the nature of these interactions.
- Use of communal spaces: How residents utilized courtyards, pathways, and other shared areas.
- Impact of COVID-19: How the pandemic altered their use of communal spaces and affected their sense of privacy and safety.
- Architectural influence on behavior: How elements such as the layout, lighting, and visibility of communal areas affected their social behavior and feelings of community.

Interview data were transcribed and coded using thematic analysis to identify common patterns and unique perspectives. By coding for key themes such as community cohesion, privacy, and social isolation, the study was able to draw connections between architectural features and social outcomes.

Architectural Analysis

The architectural analysis focused on the physical layout and design features of each quinta, including the spatial distribution of units, the size and accessibility of communal spaces, and specific architectural elements such as windows, doors, and pathways. This analysis was essential for understanding how the built environment facilitated or hindered social interactions.

Measurements were taken of key spaces to determine the proportions of communal areas relative to the number of residents, as well as the visibility between private and public spaces. The analysis also assessed the condition of materials, including whether the communal areas were well-maintained or deteriorating. This helped to identify whether the physical state of the space influenced residents' willingness to use it.

The analysis drew on the theoretical frameworks of Amos Rapoport and Christian Norberg-Schulz, which were used to interpret how specific spatial features influenced residents' sense of place and social behavior. By examining how residents interacted with these spaces, the study linked the architectural elements of the quintas to broader social outcomes.

Selection of Case Studies

The decision to focus on Quinta Los Huérfanos and Quinta Baselli was made based on their contrasting social outcomes despite their similar architectural characteristics. Both quintas are located within the same historical district and exhibit similar layouts, yet the social behavior within them diverged significantly in response to the pandemic.

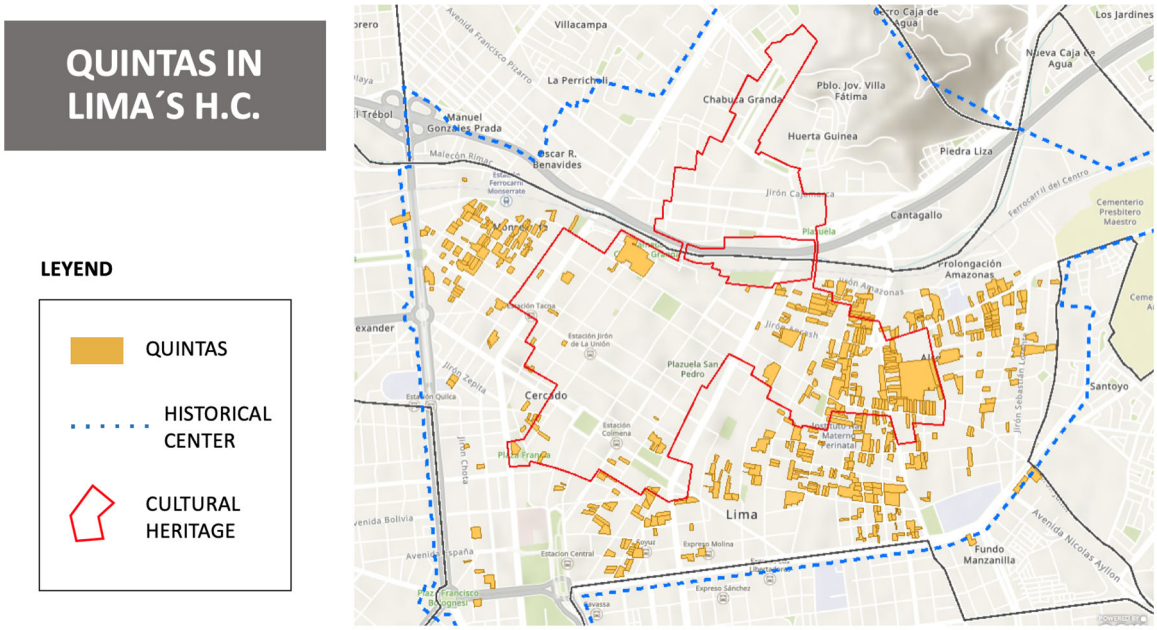

Figure 5. Quintas in Lima historic Center. PROLIMA archive.

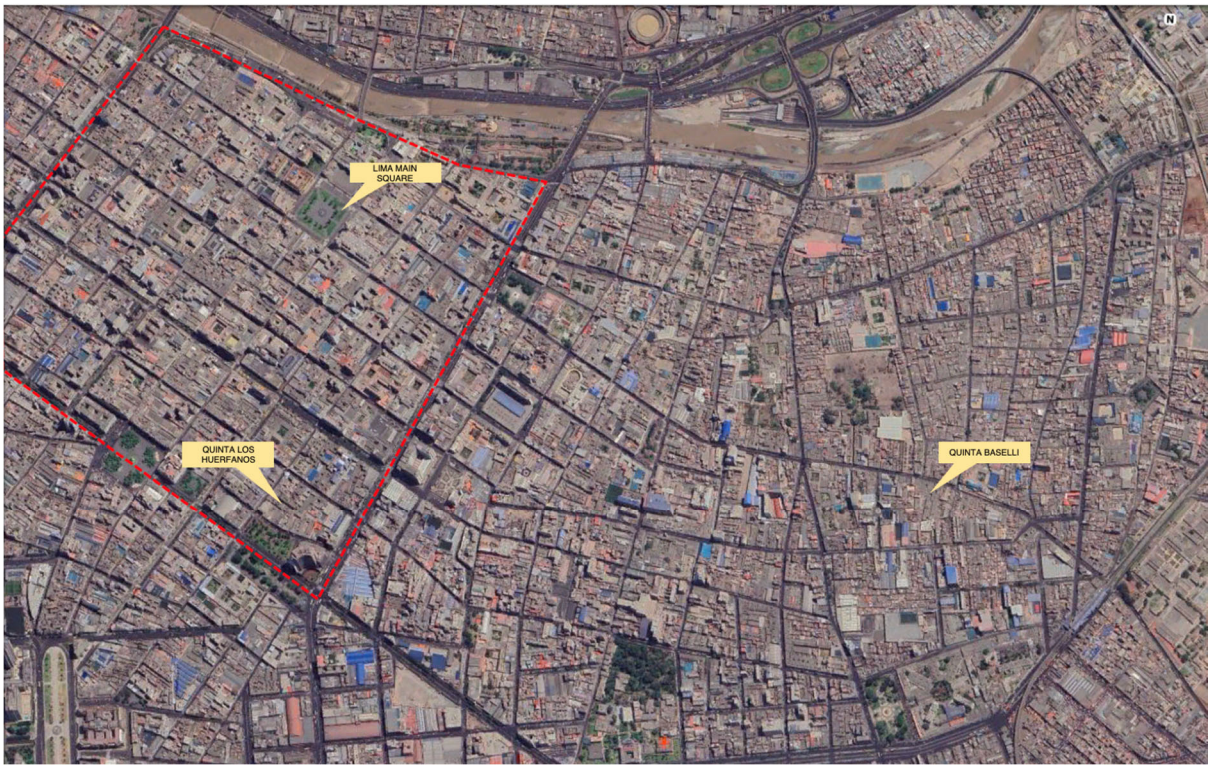

Figure 6. Location of Quintas in Lima historic Center. Own elaboration.

Quinta Los Huérfanos was selected because it exemplified a decline in social cohesion after the pandemic, with residents becoming more isolated due to health concerns and changes in spatial use. Quinta Baselli, on the other hand, was chosen because it exhibited resilience and adaptability, with residents continuing to engage in social interactions and even organizing collective efforts to improve the communal spaces during the pandemic.

These contrasting outcomes made the quintas ideal for a comparative analysis, allowing the research to explore how similar urban forms can produce different social dynamics depending on how they are inhabited and adapted by their residents.

Figure 7. Quinta Los Huerfanos,, 2024. Personal Archive.

Figure 8. Quinta Baselli, 2021. PROLIMA Archive.

Data analysis

The data from the observations, interviews, and architectural analysis were analyzed using a combination of thematic analysis and comparative case-study analysis.

- Thematic analysis: This method was used to identify and categorize key themes that emerged from the interviews and observations, such as privacy concerns, social distancing practices, use of communal spaces, and community initiatives. The themes were coded and grouped to allow for comparisons between the two quintas.

- Comparative case-study analysis: This approach enabled the research to systematically compare the findings from each quinta, drawing attention to the ways in which urban form and resident behaviors influenced social outcomes. By comparing the pre- and post-COVID-19 periods, the analysis was able to highlight how changes in spatial use and interaction patterns differed between the two quintas.

Findings and discussions

This section explores how the **independent variables**—the architectural features of quintas, such as **proportions and scale**, **visibility**, and **architectural elements**—affect the **dependent variables**—the social dynamics of **social interaction**, **sense of community**, and **privacy and safety**. These relationships are analyzed through observations and interviews conducted in **Quinta Los Huérfanos** and **Quinta Baselli**. Each architectural feature influences specific social outcomes, as detailed below.

Independent variables (architectural features)

Proportions and Scale

Proportions and scale refer to the dimensions (height, width, and depth) of communal spaces such as courtyards and pathways. These proportions influence how residents perceive and use these spaces, with larger areas often facilitating social gatherings and smaller areas potentially restricting interaction.

In Quinta Los Huérfanos, the communal courtyard is relatively small and confined. Before the pandemic, this space was sufficient for informal gatherings, but after the outbreak of COVID-19, residents found it too cramped to maintain social distancing, which led to a significant reduction in its use.

One resident noted: *"The courtyard is just too small now. We don't feel comfortable meeting there because we can't keep a safe distance."* (Interview 2, Quinta Los Huérfanos)

In contrast, Quinta Baselli has a larger communal courtyard, which allowed for continued, though limited, social interaction during the pandemic. The increased size of the space enabled residents to maintain distance while still using the area for small gatherings.

A resident from Quinta Baselli explained: *"We've been able to use the courtyard safely because there's enough space to spread out."* (Interview 7, Quinta Baselli)

The findings highlight that larger proportions in communal spaces provide flexibility for social interaction, even during periods of restricted mobility, while smaller, confined spaces can limit such interactions, particularly during a public health crisis.

Visibility and sightlines

The visibility of communal spaces from individual units, such as through windows and doors, plays a significant role in shaping social interactions and perceptions of safety. Higher visibility allows residents to engage in passive surveillance, enhancing their sense of security while promoting informal interactions.

In Quinta Los Huérfanos, visibility between the private and communal spaces is limited. Residents often keep their windows and doors closed for privacy, which reduces the opportunities for casual exchanges and informal social monitoring. This limited visibility has further contributed to the reduction in social interaction post-pandemic.

One resident remarked: *"We don't see much of what's happening in the courtyard anymore because most people keep their windows shut."* (Interview 4, Quinta Los Huérfanos)

On the other hand, Quinta Baselli benefits from higher visibility, with windows and doors that face the courtyard, allowing residents to keep an eye on communal activities and engage in informal conversations without having to leave their homes. This layout facilitated continued interaction during the pandemic, even when physical gatherings were restricted.

A resident explained: *"We can see each other through our windows, so even when we can't meet in person, we still greet each other and keep in touch."* (Interview 9, Quinta Baselli)

The findings indicate that high visibility promotes both a sense of safety and informal social interactions, while limited visibility can contribute to social isolation and a reduction in community cohesion.

Architectural elements (windows, doors, materials)

The placement, size, and materials of windows, doors, and other architectural elements influence residents' ability to interact with their environment and each other. These elements can either facilitate or hinder social engagement, depending on how they are designed.

In Quinta Los Huérfanos, the architectural elements were designed to prioritize privacy, but this has also reduced the opportunities for spontaneous interaction. Residents reported that while the closed-off design provided a sense of security, it also made them feel more isolated during the pandemic, as they could no longer engage in the informal exchanges they were used to.

One resident stated: *"Our windows and doors are great for privacy, but now we feel more disconnected because we don't talk as much as we used to."* (Interview 5, Quinta Los Huérfanos)

In Quinta Baselli, the architectural elements strike a better balance between privacy and interaction. The placement of doors and windows allows for casual communication between neighbors, even when residents are inside their homes. This layout helped maintain a sense of community during the pandemic, as residents could engage in informal conversations without the need for face-to-face meetings.

A resident shared: *"The windows and doors are well-placed, so we can still chat with our neighbors, even from a distance."* (Interview 10, Quinta Baselli)

The findings suggest that architectural elements that prioritize privacy can inadvertently reduce social engagement, while elements that allow for informal interaction help to maintain community connections.

Dependent variables (social dynamics)

Social interaction

Social interaction refers to the frequency and type of interactions that occur among residents in communal spaces. The architectural features of the quintas play a crucial role in either facilitating or hindering these interactions.

In Quinta Los Huérfanos, the confined proportions of the communal spaces and limited visibility from individual units led to a significant reduction in social interaction, especially after the outbreak of COVID-19. Residents reported feeling uncomfortable gathering in the courtyard due to its small size and lack of sufficient spatial separation.

A resident noted: *"We don't interact as much anymore because the courtyard is too small for us to gather safely."* (Interview 3, Quinta Los Huérfanos)

In contrast, Quinta Baselli experienced a more moderate decline in social interaction. The larger courtyard, combined with the high visibility of communal spaces from individual units, allowed residents to continue engaging in informal exchanges, even during periods of social distancing.

A resident explained: *"We still greet each other from our windows and doors, so we haven't lost that sense of connection."* (Interview 9, Quinta Baselli)

These findings illustrate that larger, well-designed communal spaces with good visibility are better able to support social interaction, even during periods of restricted mobility.

Sense of community

The sense of community reflects residents' feelings of belonging and emotional connection to their neighbors and communal spaces. Architectural features that encourage interaction and visibility can help strengthen this sense of community, while features that prioritize privacy may weaken it.

In Quinta Los Huérfanos, the sense of community was significantly weakened during the pandemic. The reduced use of communal spaces and the closed-off design of windows and doors contributed to residents feeling more isolated from their neighbors.

A resident shared: *"We used to feel like a close-knit community, but now, with the pandemic, everyone is more withdrawn."* (Interview 4, Quinta Los Huérfanos)

In Quinta Baselli, the sense of community remained strong despite the challenges posed by the pandemic. The architectural features that allowed for informal interaction, combined with the residents' continued use of the courtyard, helped maintain a sense of connection and belonging.

One resident remarked: *"Even though things have changed, we still feel like a community because we can interact with each other in small ways."* (Interview 10, Quinta Baselli)

The findings indicate that architectural features that promote interaction help to foster a strong sense of community, while features that prioritize privacy may hinder the development of these connections.

Privacy and safety

Privacy and safety refer to residents' perceptions of their privacy and physical safety in communal and semi-private spaces. Architectural elements such as windows, doors, and proportions can either support or hinder these feelings.

In Quinta Los Huérfanos, the confined communal spaces and limited visibility reduced residents' sense of safety. The lack of spatial separation made it difficult for residents to feel secure in communal areas, leading to a decline in their use.

One resident expressed: *"I don't feel safe using the courtyard anymore because it's too small and there's no privacy."* (Interview 5, Quinta Los Huérfanos)

In Quinta Baselli, the larger courtyard and higher visibility contributed to residents feeling safer in communal spaces. The ability to monitor activities from their windows and doors provided a sense of security, which encouraged continued use of these areas.

A resident explained: *"The fact that we can see what's happening in the courtyard makes us feel safe, even when we're not outside."* (Interview 9, Quinta Baselli)

These findings highlight that architectural features that support visibility and spatial separation can enhance residents' perceptions of safety, while features that limit visibility may reduce these feelings.

Comparative overview of findings

In this comparative overview, we examine the different outcomes of the architectural features (independent variables) and social dynamics (dependent variables) in Quinta Los Huérfanos and Quinta Baselli. Both quintas share certain architectural characteristics—such as communal courtyards and narrow pathways—but the way these features influenced social interactions, sense of community, and perceptions of privacy and safety differed significantly between the two.

Proportions and scale

- Quinta Los Huérfanos: The proportions of the communal courtyard were too confined to support socially distanced gatherings after the pandemic. Before COVID-19, the space had functioned well for social interactions, but the pandemic highlighted the limitations of smaller, more enclosed communal spaces. This resulted in a drastic reduction in social interactions, as residents felt uncomfortable using a space where they couldn't maintain physical distance.

  Key Impact: Smaller spaces became restrictive, causing a reduction in social interaction and contributing to a weakened sense of community.

- Quinta Baselli: The larger courtyard in Quinta Baselli allowed residents to continue using the space, even with social distancing measures in place. The flexibility provided by the larger dimensions supported informal gatherings in a safe manner, helping to preserve social interaction and the sense of community.

  Key Impact: Larger, more flexible spaces enabled ongoing interaction, maintaining community ties even in difficult circumstances.

Quinta	Proportions and Scale	Impact on Social Dynamics
Quinta Los Huérfanos	Small, confined courtyard	Reduction in social interaction, weakened sense of community due to spatial restrictions.
Quinta Baselli	Larger, more flexible courtyard	Maintained social interactions and sense of community by allowing socially distanced gatherings.

Table 1. Comparison in proportions and scale of the case studies. Own elaboration.

Visibility and sightlines

- Quinta Los Huérfanos: Visibility between units and the communal courtyard was limited, as residents tended to keep their windows and doors closed for privacy. This reduced the opportunities for informal surveillance, which in turn diminished both social interaction and residents' feelings of safety. The lack of visual connection between private and communal spaces contributed to feelings of isolation.

  Key Impact: Limited visibility reduced both social interaction and residents' sense of security, weakening the overall sense of community.

- Quinta Baselli: The design of Quinta Baselli encouraged higher visibility, with windows and doors facing directly onto the courtyard. Residents frequently opened their windows and doors to observe activities in the communal space, engaging in informal monitoring and interaction. This allowed for a continuous sense of social connection, even when physical gatherings were restricted.

  Key Impact: High visibility enabled informal interactions and increased feelings of safety, supporting ongoing social cohesion and community ties.

Quinta	Visibility and Sightlines	Impact on Social Dynamics
Quinta Los Huérfanos	Limited visibility between units and courtyard	Reduced interaction and sense of security, contributing to social isolation.
Quinta Baselli	High visibility between units and courtyard	Informal interactions and sense of safety maintained through visual connections between units.

Table 2. Comparison in visibility and sightlines of the case studies. Own elaboration.

Architectural elements (windows, doors, materials)

- Quinta Los Huérfanos: The placement of windows and doors prioritized privacy, but this came at the cost of reduced social engagement. The materials and layout offered security but limited opportunities for spontaneous interaction between residents. During the pandemic, these architectural features amplified feelings of isolation, as there were fewer opportunities for informal exchanges.

  Key Impact: Architectural elements favored privacy over interaction, reducing social cohesion and contributing to isolation.

- Quinta Baselli: In Quinta Baselli, the placement of windows and doors allowed for easier communication between residents. The materials provided a balance between privacy and openness, enabling spontaneous interactions and maintaining a sense of community. Even during the pandemic, residents were able to interact from a distance by using windows and doors as points of contact.

Key Impact: Architectural elements facilitated informal interactions, contributing to a sustained sense of community despite the limitations imposed by the pandemic.

Quinta	Architectural Elements (Windows, Doors, Materials)	Impact on Social Dynamics
Quinta Los Huérfanos	Closed-off design for privacy	Reduced opportunities for interaction, contributing to social isolation and weakened community ties.
Quinta Baselli	Open design facilitating informal interactions	Encouraged spontaneous exchanges, maintaining social cohesion and a sense of community.

Table 3. Comparison in architectural elements of the case studies. Own elaboration.

Dependent variables: social dynamics

Social interaction

- Quinta Los Huérfanos: Social interaction declined significantly due to the confined proportions of the courtyard, limited visibility, and architectural elements that prioritized privacy. The pandemic exacerbated these limitations, making it difficult for residents to engage in even casual exchanges.

  Key Impact: Social interaction became infrequent, weakening the overall sense of community.

- Quinta Baselli: Social interaction was maintained through the use of larger communal spaces and higher visibility between units. The architectural features allowed for continued interaction, even during times when physical gatherings were limited.

  Key Impact: Social interaction remained relatively stable, helping to sustain a strong sense of community.

Sense of community

- Quinta Los Huérfanos: The sense of community weakened over time as residents became more isolated due to the limitations of the architectural features. Reduced interaction and a lack of visual connection between units contributed to feelings of disconnection.

  Key Impact: A weakened sense of community as social isolation increased.

- Quinta Baselli: Despite the challenges posed by the pandemic, the sense of community in Quinta Baselli remained strong. The layout and use of communal spaces, combined with the architectural elements that encouraged interaction, helped maintain residents' feelings of belonging.

  Key Impact: A strong sense of community persisted, supported by design features that facilitated ongoing interaction.

Privacy and safety

- Quinta Los Huérfanos: Residents in Quinta Los Huérfanos felt less secure in communal areas due to the confined proportions and limited visibility. The lack of spatial separation and opportunities for informal monitoring led to a decrease in both privacy and safety.

Key Impact: Reduced feelings of safety in communal spaces, contributing to further isolation.

- Quinta Baselli: In Quinta Baselli, residents reported feeling safer due to the higher visibility and the ability to monitor communal spaces from their windows and doors. This sense of security helped maintain the use of communal areas and contributed to a continued sense of community.

  Key Impact: Stronger perceptions of safety supported by the layout, visibility, and continued use of communal spaces.

Quinta	Social Interaction	Sense of Community	Privacy and Safety
Quinta Los Huérfanos	Declined significantly due to space constraints and limited visibility.	Weakened as social interaction decreased and isolation increased.	Residents felt less safe due to confined spaces and poor visibility.
Quinta Baselli	Maintained through larger communal spaces and informal interactions.	Strong sense of community despite challenges posed by the pandemic.	Residents felt safer due to higher visibility and informal monitoring.

Table 3. Comparison in architectural elements of the case studies. Own elaboration.

Key insights from the comparative overview

The comparative analysis between Quinta Los Huérfanos and Quinta Baselli reveals that while both quintas share similar architectural elements, the outcomes in terms of social dynamics vary greatly due to differences in proportions, visibility, and design priorities. The primary insights include:

1. Proportions and Scale Matter: Larger, flexible communal spaces enable residents to maintain social interactions even during times of restricted mobility, whereas smaller spaces limit interaction and weaken community ties.

2. Visibility Enhances Safety and Interaction: High visibility between units and communal areas promotes informal interactions and a sense of security, whereas limited visibility contributes to isolation and reduced social engagement.

3. Architectural Elements Influence Community Dynamics: Features such as windows and doors that balance privacy with openness support spontaneous interactions and help maintain a sense of community, while features that prioritize privacy at the expense of interaction may lead to isolation.

4. Resident Adaptability Plays a Crucial Role: In both quintas, residents' ability to adapt their use of space, particularly during the pandemic, significantly influenced social outcomes. Architectural features provided the framework, but it was the residents' responses that ultimately determined the strength of social cohesion.

CONCLUSIONS

The analysis of Quinta Los Huérfanos and Quinta Baselli provides a comprehensive understanding of how architectural features influence social dynamics within residential environments, particularly in the context of a global pandemic. While both quintas share common architectural characteristics, such as communal courtyards and narrow pathways, the outcomes in terms of social interaction, sense of community, and perceptions of safety varied significantly. This variation is largely attributable to differences in the proportions and scale of spaces, visibility and sightlines, and the design of architectural elements like windows and doors.

The conclusions drawn from this comparative study are as follows:

Proportions and scale are critical for social interaction

The proportions and scale of communal spaces, such as courtyards and pathways, play a critical role in facilitating or limiting social interaction. In Quinta Los Huérfanos, the confined communal spaces became barriers to interaction during the pandemic, leading to a reduction in the use of these areas. The inability to maintain physical distance in such confined spaces made residents feel uncomfortable and less likely to gather, weakening the overall sense of community.

In contrast, the larger proportions of Quinta Baselli's communal spaces provided residents with the flexibility to continue interacting safely, even under social distancing measures. The ability to spread out within the courtyard allowed for informal gatherings, helping to sustain social interactions and maintain community cohesion.

Conclusion: Larger communal spaces support flexible social interactions, even during periods of restricted mobility, while smaller, confined spaces become restrictive, reducing interaction and weakening the community.

Visibility and sightlines enhance safety and foster interaction

The visibility between private units and communal spaces emerged as a key factor in determining both social interaction and perceptions of safety. In Quinta Los Huérfanos, the lack of visibility from private spaces to communal areas contributed to feelings of isolation and reduced social engagement. Residents were less likely to monitor or casually interact with their neighbors due to the limited sightlines between units and communal spaces.

By contrast, in Quinta Baselli, the higher visibility provided by well-placed windows and doors allowed residents to engage in passive surveillance and informal social interactions. Residents could monitor activities in the courtyard and greet their neighbors from their windows, maintaining a sense of connection even when physical gatherings were not possible. This visual connection also contributed to an increased sense of safety, as residents could observe their surroundings.

Conclusion: High visibility between private units and communal spaces fosters informal interactions and enhances perceptions of safety, while limited visibility can lead to social isolation and reduced feelings of security.

Architectural elements shape privacy and social engagement

The design of architectural elements such as windows, doors, and materials significantly influences residents' ability to balance privacy and social interaction. In Quinta Los Huérfanos, the placement of windows and doors prioritized privacy, but this came at the expense of spontaneous interaction. The

closed-off design elements led to a reduction in casual exchanges, particularly during the pandemic, as residents sought to protect their privacy and security.

In Quinta Baselli, the architectural elements provided a balance between privacy and openness, allowing for informal communication between neighbors. Windows and doors facing communal areas facilitated spontaneous interactions, helping to sustain social engagement and maintain the sense of community. The ability to balance privacy with interaction proved crucial in maintaining social ties during periods of restricted mobility.

Conclusion: Architectural elements that balance privacy with openness promote spontaneous social interactions and help maintain community cohesion, while designs that prioritize privacy can limit social engagement and lead to isolation.

Resident adaptability is key to sustaining social dynamics

While architectural features set the framework for social interactions, the adaptability of residents in using these spaces plays an equally important role in shaping social dynamics. In Quinta Baselli, residents were able to adapt their use of communal spaces and windows to maintain interactions even during the pandemic. This adaptability helped preserve the sense of community and ensured that social ties remained strong.

In Quinta Los Huérfanos, the architectural limitations of the communal spaces, combined with the lack of adaptability, contributed to a more pronounced decline in social interactions. Residents felt constrained by the small communal areas and reduced visibility, leading to feelings of isolation and a weakening sense of community.

Conclusion: Resident adaptability in using communal spaces is crucial in sustaining social dynamics, particularly in challenging circumstances like a pandemic. Architectural features can facilitate interaction, but how residents respond to these features ultimately determines the strength of social cohesion.

Architectural design should prioritize flexibility and connection

The findings from this study have significant implications for the design of residential environments, particularly in historical settings like Lima's quintas. While preserving the architectural integrity of these environments is important, it is equally essential to prioritize features that allow for flexibility in how communal spaces are used and facilitate connection between residents.

- Communal spaces should be designed with flexibility in mind, allowing residents to use them for a variety of activities, including social gatherings and safe distancing.
- Visibility should be integrated into the design to enable residents to monitor communal spaces and engage in informal interactions, enhancing both security and community ties.
- Architectural elements such as windows and doors should be placed to balance privacy and openness, ensuring that residents feel both secure and connected.

Conclusion: Future urban and architectural designs should prioritize flexible, adaptable spaces and architectural elements that facilitate social interaction, enabling residents to maintain social ties even in challenging circumstances.

Final thoughts

The comparative analysis of Quinta Los Huérfanos and Quinta Baselli demonstrates that architectural design plays a pivotal role in shaping the social dynamics of residential communities. However, the findings also highlight that architecture alone is not enough to sustain social cohesion—residents' adaptability and engagement with their environment are equally important. Design flexibility, visibility, and balanced architectural elements are essential in fostering strong, resilient communities, particularly in historical urban settings where communal living spaces play a central role in daily life.

As cities continue to evolve and adapt to new challenges, particularly in the wake of global health crises, the lessons learned from these quintas can inform the future of urban design. The balance between privacy, openness, and flexibility will be crucial in designing spaces that not only preserve social dynamics but also enhance them in times of uncertainty.

Acknowledgements

I would like to express my deepest gratitude to those who supported me throughout the completion of this research on the impact of urban form on social dynamics within Lima's quintas. Without their invaluable assistance and encouragement, this study would not have been possible.

First and foremost, I would like to thank Angela Chapman, my partner in many projects, for her insightful feedback, and unwavering support. Her expertise in urban studies and architectural theory was instrumental in shaping the direction of this research.

I would like to extend my sincere thanks to the residents of Quinta Los Huérfanos and Quinta Baselli, who graciously participated in the interviews and observations. Their openness and willingness to share their experiences were vital to understanding the social dynamics within these unique urban environments.

I am also indebted to PROLIMA and its archive for granting me access to the resources and archival materials necessary to complete this research.

Finally, I would like to thank my family and friends for their emotional support, patience, and encouragement throughout this process. Their belief in my work kept me motivated during the most challenging stages of this research.

To all those who played a role, large or small, in helping me complete this research, I offer my heartfelt thanks.

Exploring the integration of urban morphology as a methodological framework in urban planning

Beyza Karadeniz[1]
[1] City and Regional Planning Department, Faculty of Architecture, Karadeniz Technical University, Turkiye, bsenktu@gmail.com

ABSTRACT

This study investigates the integration of morphological analysis methods into the urban planning process as a design control tool, specifically within the Turkish context. It underscores the critical relationship between urban morphology and planning, emphasizing its role in zoning plan formulation. The research aims to elucidate the significance of urban morphology studies in planning, outline the integration process of these methods into zoning plans, and demonstrate the contributions of a proposed morphological analysis approach. A five-step morphological analysis method, incorporating the Spacematrix quantitative approach, was applied to an urban settlement in Turkey to map urban density and identify regions. The study confirms the method's effectiveness in identifying character regions and their relationships, establishing its value in regional zoning plans. The proposed method provides planners with a systematic tool for analysing urban structure, aiding in informed planning decisions and controlling fragmentary urban interventions. This research enhances the understanding of urban morphology within urban planning, offering a practical tool for regional planning in Turkey.

INTRODUCTION

The development and improvement of all individuals in society (their health, skills and tendencies, life expectancy, productivity, morality, and family life) became one of the fundamental aims of states with the establishment of nation-states in the 20th century. While the state guarantees the peace and security of individuals, it expects them to comply with a prescribed set of rules (Scott, 2008). These rules apply to individuals, society, and the environments in which society exists. Therefore, rules also play a role in the planning and design of the environments we live in. Alongside technological and industrial advancements, cities began to be planned and designed systematically and hierarchically. Over time, different planning approaches have been adopted during various periods. Sometimes these approaches reflect the ideological manifestations of absolute state control, and sometimes they stem from efforts to adapt to the changing and evolving world, leading to various transformations in space (Scott, 2008).

The emergence of planning as a discipline dates back to the 1950s. Early planning approaches were based on improving living conditions, particularly in industrialized cities. To overcome these problems, construction activities were carried out in cities within the framework of comprehensive plans and programs through infrastructure and redevelopment efforts. With the planning approaches that emerged in later periods, a regulatory system was established to ensure the balanced use of the natural and human resources cities possess.

Planning involves making multi-faceted decisions within a system of mutual relationships to achieve a set goal and to develop objectives. Based on these decisions, the "formation of urban space is directed through long-term and multi-dimensional actions within a comprehensive planning approach" (Suher, 1996; 65).

The fundamental approach in comprehensive planning is to organize the city into a coherent and understandable spatial structure at a large scale. Ensuring order across the entirety of the city is crucial for preventing health problems and improving living standards. Plans encompassing the whole city shape the environment in which individuals live, within the framework of building regulations. In turn, individuals produce on the building scale according to the rules set forth by these plans, and this reciprocal relationship establishes the dynamic of the place from the smallest scale to the city as a whole. The way this dynamic functions also affects the form and structure of the city. In this process, the integrity of the individual, space, and urban system must be ensured, and a healthy operational mechanism must be established. The changes and transformations the city has undergone throughout its historical process are also significant within this system. Therefore, planning processes that consider all local dynamics should be defined.

However, in today's urban development, large-scale transformations that resemble each other are occurring in planned cities. Plans that fail to anticipate these changes cannot prevent the erasure of historical or existing traces in the urban fabric and the creation of new urban patterns disconnected from the past. Change and transformation occur based on legal and administrative tools in regulations, and the legislation that defines minimum design and planning standards. While these regulations and legislation guide the shaping of space and the planning process, they have limitations in maintaining local character. Consequently, effective control tools and approaches are needed within the current planning system to guide the shaping of urban space.

In this context, studies of urban morphology are important. Kropf (2011) emphasizes the guiding role of urban morphology in the planning process, particularly in relation to urban design, conservation, and planning practices. His research demonstrates how urban morphology tools can provide a foundation for understanding, organizing, transforming, and managing the structure and complexity of the built environment. Similarly, Moudon (1997) notes that studies of urban form and morphology can be integrated into every type of construction process (transformation, new area development) in cities, and they offer a guiding scope for city planning, architecture, and real estate fields. From the 2000s onwards, many theorists have advocated for the guidance of morphological approaches in the development of large metropolises and modern urban fabrics, in addition to traditional and historical environments (Barrett, 1996; Scheer and Petkov, 1998; Moudon and Hess, 2000; Stanilov and Scheer, 2004; Waldheim, 2006; Tatom, 2006; Whitehand, 2007).

Even though the term "urban morphology" is not explicitly defined in planning and design studies, urban morphology methods are applied in a significant portion of these works. Furthermore, the use of urban morphology methods across various fields such as historical environment conservation, urban character, environmental performance, movement analyses, planning control tools, and urban design highlights their importance. These wide-ranging studies provide informative and guiding insights for the disciplines of urban design, city planning, and architecture.

It is essential to understand and define the morphological change and transformation in cities' developmental processes. These studies allow for a clear inquiry into the past and future, enabling a better understanding of the layering in urban structures, urban fabric patterns, and the dynamics that shape them throughout history. Urban morphology should not be viewed merely as a physical historical record of the city. In this process, while conducting the spatial reading of the city, traces of social life are also documented, and significant data related to the social structure is obtained. This is because urban planning is a discipline that encompasses physical, economic, and social dimensions. In the context of the relationship between planning and morphology, several studies have focused on these dimensions.

A good example of the social dimension of urban planning is the urban character study conducted by Hansen and Thompson in 2009 in Brighton & Hove. This comprehensive study examined the fabric characteristics of different neighborhoods in Brighton & Hove, aiming to contribute to future planning policies and thus support decision-making processes in planning (Brighton & Hove City Council, 2009). The study included land use and zoning analyses regarding the perceptions of residents, identifying how/when/how often/for what purposes the urban fabric was used by different groups. This research is significant in revealing the relationship between social structure and urban fabric.

Another crucial area in the urban planning process is the studies carried out using the space syntax method developed by Bill Hillier, which discuss the relationship between urban mobility and urban morphology. These studies, fundamentally based on questioning the physical structure of urban space without ignoring the presence of social structure, originated from the search for solutions to the failure of social housing projects and the lack of a sense of community in the social housing developments in the United Kingdom during the 1960s and 70s. Space syntax is used as a mathematical spatial analysis technique to address this issue. This method was developed to understand the structure of urban fabric and its effects on human movement, based on people's spatial experiences. Using space syntax, planning and design efforts are guided by conducting studies at various and large scales, from building components to regional levels, while considering not only the physical space but also the social and economic structure.

Studies in urban morphology that guide comprehensive planning efforts have become widespread, especially since the 2000s. One example is the "Plan Local d'Urbanisme (PLU)" plan for the city of Rennes in the Brittany region of France. In the PLU, urban fabric analyses were used as a planning tool for implementation (Kropf, 2009). Through morphological analyses, the city was divided into different regions, with distinct fabric typologies defined. The characteristics of these defined fabrics (roads, parcels, buildings) were identified. These character definitions were later used as a guide in the regulations for similar areas.

A similar approach was adopted in the preparation of the 'Stratford-on-Avon Design Guide' in the UK. The study included an analysis of urban character, where morphological components such as street fabric, parcel structure, and building-parcel relationships were examined and connected to the urban planning terminology to create a guide (Kropf, 2009). The guide is a comprehensive study that includes morphological characteristics of various areas in the city, from building level to fabric level. These studies, in which morphological data were effectively integrated into urban development and spatial production processes, highlight the significance of morphological analyses. However, in Turkey, such approaches that guide urban development have yet to be effectively incorporated into the planning process.

In Turkey, which is undergoing a rapid urbanization process, state policies, incentives, and the free market system over the past 20 years have led to the reproduction of urban space (Şengül, 2009). In this reproduction process, especially in city centers, original urban fabrics are being demolished and rebuilt according to new construction regulations and systems. These areas are often large functional spaces left idle and residential areas that have developed without planning within the city. On the outskirts of cities, residential areas are generally being planned for middle- and upper-income groups. Urban space is being produced not for all citizens but rather by specific individuals or groups (Balamir, 1975). In other words, newly developing and transforming urban areas are being formed while ignoring the existing morphological character. In this case, planning and urban design interventions that could be made effective through planning tools (laws, regulations, plans, guides, etc.) often fall short. Additionally, in Turkey, no morphological analysis method has been defined within the urban planning process. In this context, it is both important and necessary to define morphological analysis methods that are compatible with the country's planning system and tools and that can be used in planning practice.

The implementation tools (laws and regulations) developed in parallel with planning periods influence the formation of urban form and urban fabric. When examining Turkey's urbanization experience, it can be said that, at times, laws have been very strict and restrictive, or they have consisted of a series of regulations aimed at legalizing spontaneously developed urban fabrics. Moreover, urban fabrics are shaped at the block and parcel level through parcellation plans prepared by surveyors lacking the basic morphological knowledge required by urban planning. As a result, over time, cities have developed spatial patterns that remain unchanged, following uniform plans. To prevent this uniformity, a process that considers local data and dynamics must be defined. In this process, it is essential to define the spatial structure of cities in light of morphological data. This can only be achieved through a clear understanding of the city's morphological structure, and there is a need to define analysis methods that can guide planning efforts accordingly.

Historically, Turkish planning efforts, initiated during the Tanzimat period in the 19th century, have been conducted under various laws and regulations. The legal framework of the modern Turkish urban planning system, based on early construction regulations, was established in the 1930s as part of the Republic's comprehensive modernization program. Initially, legal regulations were developed at the street and building scales, later expanding to encompass the urban scale, providing legal support for urban planning. In 1930, the Municipality Construction and Roads Law was enacted, requiring all municipalities to prepare maps and plans in accordance with the development policies set by law (Ersoy, 2017). After World War II, rapid urbanization necessitated a new and comprehensive development law, leading to the enactment of Law No. 6785 in 1957. This new legislation introduced

the concepts of "Master Development Plans" and "Development Planning" (Keleş, 1972; Tekeli, 2013). The master plans aimed to control the macro structure of cities, while regulations defined the basic standards for small-scale implementation plans controlling the formation of individual parcels.

In urban planning practice, local character, social structure, economic and environmental factors are critical elements influencing the morphological structure of cities. Understanding and defining the morphological transformations and changes in the development processes of cities is crucial for future planning decisions. To prevent the uniformity in cities, processes that take local data and dynamics into consideration should be defined. In this process, it is essential to define the spatial structure of cities through morphological data. This can be achieved through a proper reading of the city's morphological structure and by defining analytical approaches and methods that can guide planning decisions.

The purpose of this study is to discuss how morphological analysis methods can be integrated into Turkey's urban planning process and practice as a control tool. In this context, the relationship between urban morphology and planning is examined, emphasizing the significance of urban morphology methods in the preparation of zoning plans. Accordingly, the study proposes a morphological analysis method and outlines its steps. In line with these objectives, the following questions are addressed:

- What is the role and importance of urban morphology studies in the urban planning process?
- How can urban morphology methods be integrated into the zoning plan preparation process?
- What contributions will the proposed morphological analysis approach make to the planning process?

A MORPHOLOGICAL APPROACH INTEGRATED INTO THE URBAN PLANNING PROCESS

The aim of the study is to explore how morphological analysis methods can be incorporated into the urban planning process and practice as a regulatory tool, and to define a morphology-based analysis method that can guide zoning plans. The tracking of changes in the city's morphological structure has allowed for the identification of local dynamics and the examination of the current state of residential fabrics and their transformations over time. In this way, the layered structure of the city’s morphological development across different periods has been systematically analyzed, and its relationship with the urban planning process has been questioned. Five interrelated steps have been defined for the analysis method.

A morphology-based analysis method consisting of five steps has been developed for incorporating urban morphology data into the planning process in Turkey. In defining this method, a Historical-Geographical approach was followed, and Spacemate (Urban Density Analysis) was used as a numerical method. The steps of the method defined in the study are:

Field Study (Collection of Data Related to the City/Area)

Publications related to the city's history, such as research reports and written documents about the study area, historical maps, and city plans of various scales, are important references for a morphological analysis. These documents were gathered from the municipal archives of the city of

Görele, which is the study area. Additionally, scientific publications related to the city were reviewed by conducting research in national and university libraries. Past and present photographs, as well as local publications concerning the area, were also examined.

Planning process-related data:

Spatial plans and reports, aerial photographs, and current maps necessary for evaluating the morphological changes and transformations of the city were obtained from various individuals and institutions, including the Municipality, General Directorate of Mapping, İller Bankası, and engineers and planners.

Field study:

A thorough analysis of the study area is important for evaluating the city's current land use, identifying its growth trends, center analysis, and understanding the city's natural structure and thresholds. The current state was analyzed through observations and interviews with individuals and experts (architects, planners, surveyors, etc.). In-situ observations were conducted on the natural and built environment of the city, and photographs were taken. In addition, information was gathered from third parties/experts who have witnessed the city's morphological development and have either directly or indirectly influenced its changes, but whose contributions are not documented in many written sources. Interviews provide insight into the urban formations and multilayered structure of the city across different periods. During the interviews, aerial photographs and old images were examined, and the locations of demolished buildings (such as public, commercial, and monumental structures) were identified. Furthermore, oral information about the city's socioeconomic structure, major urban planning activities (such as road construction and sewer infrastructure), and public investments was collected and analyzed in relation to the spatial context.

Evaluation and Analysis of Data, Identification of Regions

Morphological development of the city from its first settlement period to the present:

Spatial data, such as maps, aerial photographs, and plans from different historical periods, along with cadastral records, population records, tax registers, reports, writings on the city's history, research, travelogues, and records on buildings (such as schools, pharmacies, post offices, etc.) as well as information gathered from interviews, were analyzed. Maps of the city from different periods were created.

Natural and artificial environmental features influencing the city's morphological structure: Natural environment analyses, such as topography (slope and elevation) and aspect analyses, along with land use, solid-void (buildings and parcels), transportation, building heights, and FAR (Floor Area Ratio) and GSI (Ground Space Index) analyses, were conducted. Each analysis was converted into spatial data, and the effects of both natural and built environmental features on the city's morphological structure were examined.

Identification of Character Regions

The identification of character regions was based on the morphological region definitions of M.R.G. Conzen and J. Whitehand. According to Conzen, urban development should be perceived as a process, and in order to accurately analyze the changes within this process, the smallest units that constitute the city (buildings, parcels, streets, etc.) must also be included in the analyses. One of the key actions in defining a city's physical development is to divide it into morphological regions. A morphological region can be defined as an area that is distinct from its surroundings and possesses internal cohesion

(Whitehand, 2001; Conzen, 2009). Morphological regions refers to the process of identifying and mapping morphological regions. The fundamental elements of such zoning are the historical and geographical structure of the settlement. The textures within the settlement represent the urban fabric formed during various periods. Through regions, the textures created during different periods are defined. In order to understand the textures in an urban area, various urban fabric components, the regulations that guide the formation of these fabrics, spatial formations, and their relationships with one another should be evaluated (Whitehand, 2009).
Based on these definitions, natural and built environment analyses played a decisive role in identifying the regions within the study area. The natural structure analyses were overlaid to create a synthesis of natural data, identifying regions that are homogeneous in terms of their natural features. When defining the boundaries of these regions, parcel boundaries, zoning plan limits, and roads were used as references. Similarly, analyses of the built environment were overlaid, and in the structural synthesis map that was produced, different regions with distinct urban characters were identified.

Selection of Fabric Samples from Identified Regions

Housing fabric samples to be evaluated using the Spacemate (urban density analysis) method have been selected from each of the regions. There are several considerations that should be considered when selecting fabric samples. The first consideration is the scale at which the selected fabric will be analysed. For instance, information at the level of an individual building is collected at the parcel scale, but this may not be sufficient or appropriate for analysing the entire city. Therefore, determining at what stage and at which scale the obtained data will be analysed is crucial for the application of the Spacemate (urban density analysis) method (Berghauser Pont and Haupt, 2009). In selecting the fabrics to be analyzed, this consideration has been taken into account, and certain criteria have been observed:

In defining the boundaries of the sample housing fabrics, the cadastral status (parcel boundaries) has been taken into account. The building conditions on the parcels have been considered, and parcels without any structures have been excluded from the fabric (Figure 1).

Figure 1 . Sampling Urban Fabrics, photo credit: Beyza Karadeniz, 2020.

Care has been taken to ensure that the selected sample housing fabrics are areas with identical structures. To identify identical regions, all structural analyses (land use, FAR, GSI, number of floors, and parcel size) have been overlapped in a GIS (Geographic Information Systems) environment to create a single spatial map. Codes have been defined for the colors on the map. Areas composed of identical colors represent a homogeneous fabric, while areas where color identities could not be matched represent a more heterogeneous fabric with similar color distributions. With all these considerations and assumptions, the boundaries of the sample housing fabrics have been defined (Figure 1).

Analysis of Fabric Samples Using Spacemate (Urban Density Analysis)

Housing fabrics selected from each region have been analysed using Spacemate, allowing for the identification of fabric typologies and density characteristics. Queries have also been conducted using Spacemate in the context of the proposed building forms in the zoning plans for the examined housing fabrics (Figure 2). This approach enabled a comparison between the existing structure of the housing fabrics and the fabric that would result from the plan. The transformation of housing fabrics throughout the historical process has been analysed at the block scale using Spacemate, in relation to the level of morphological layering. The adequacy of the road network, parking, and lighting levels has been examined by comparing the existing fabric, the fabric to be formed by the plan, and the alternatives developed according to the Spacemate analysis method.

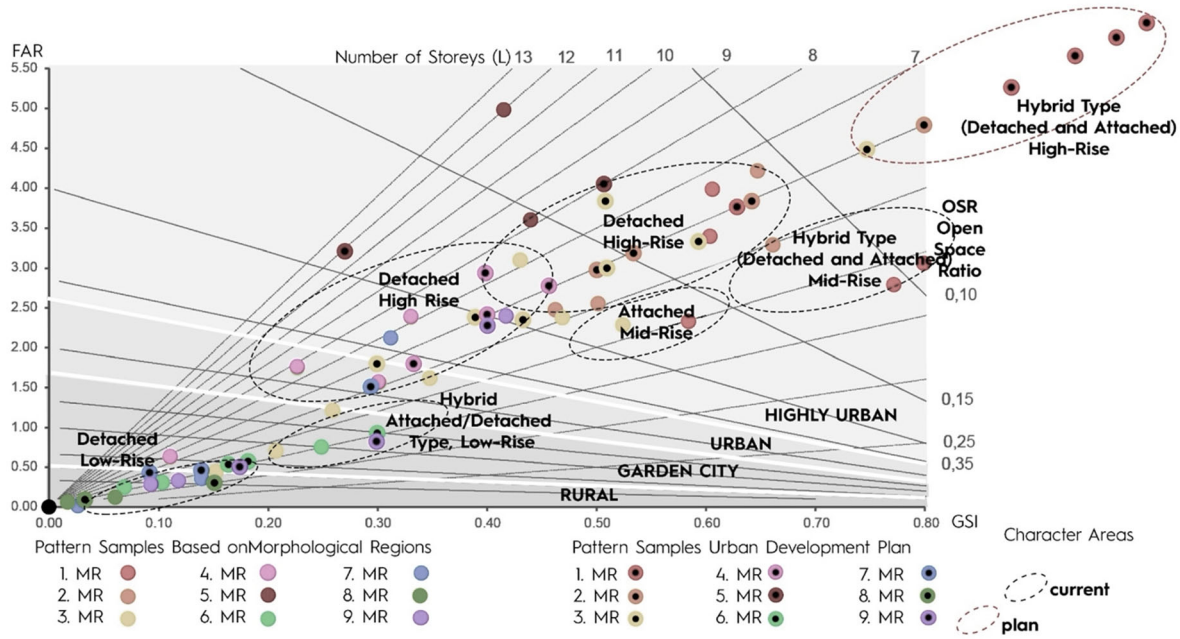

Figure 2 . Analysis of Fabric Samples, photo credit: Beyza Karadeniz, 2020.

Housing fabrics selected from each region were analysed separately, and subsequently, all fabrics within the character regions were collectively evaluated to conduct the Spacemate analysis for that specific region. There is a relationship among the four fundamental variables of Spacemate analysis: FAR (floor area ratio), GSI (ground space index), OSR (open space index), and L (building height). Specifically, the OSR (open space index) is inversely proportional to the values of GSI, FAR, and L. In contrast, there is a direct proportionality between the FAR value and the values of L and GSI. However, two fabrics with the same FAR value may have different L (number of stories) and GSI values. Similarly,

two fabrics with the same OSR (open space index) value may have different FAR, GSI, and L values. Therefore, the morphological characteristics of the fabrics should be interpreted by considering the relationships among these variables.

RESULTS AND DISCUSSIONS

The method has been tested in a specific urban settlement. As a result, the application of the defined analysis method has enabled the identification of the regions of the city, the distribution of urban density within these regions, and the relationships between them. Thus, it has been demonstrated that the method can serve as a tool to guide planners in the process of creating urban plans. This tool is also effective in controlling fragmented interventions within urban fabrics. In summary, the defined method is suitable for integration into the planning process. This allows for the establishment of a systematic process aimed at analysing the morphological structure of the city, providing significant clues and references to guide anticipated planning decisions.

The significance of defining regions in this study lies in their ability to guide plans regarding relationships and transitions between these regions. Developing building forms and associated density decisions that are appropriate to the natural and physical structures of character regions is important for both urban quality and aesthetics, as well as for feasibility and economic viability. This step of morphological zoning is also crucial as a foundation for density zoning studies used in the preparation of master plans.

The analysis and definition of regions are followed by the selection and analysis of the urban fabrics to be examined. The method of color coding defined in this study has been used to analyze the residential fabrics within the identified regions. This approach addresses the fact that not all residential fabrics in the city are planned and distinct, and it aims to clarify the boundary definition, which is the most decisive factor in residential fabric analysis. This technique can be used/recommended/developed as a boundary determination tool for analyzing modern residential fabrics.

For the analysis of residential fabrics, the Urban Density Analysis (Spacemate) developed by Pont and Haupt in 2009 has been used. The reason for utilizing this method in this thesis study is that it presents a morphological approach that addresses current changes in urban planning and design practices and aims to provide a tool based on the relationship between physical density and urban form. In this context, various residential fabrics identified in the study area have been examined (Figure 3).

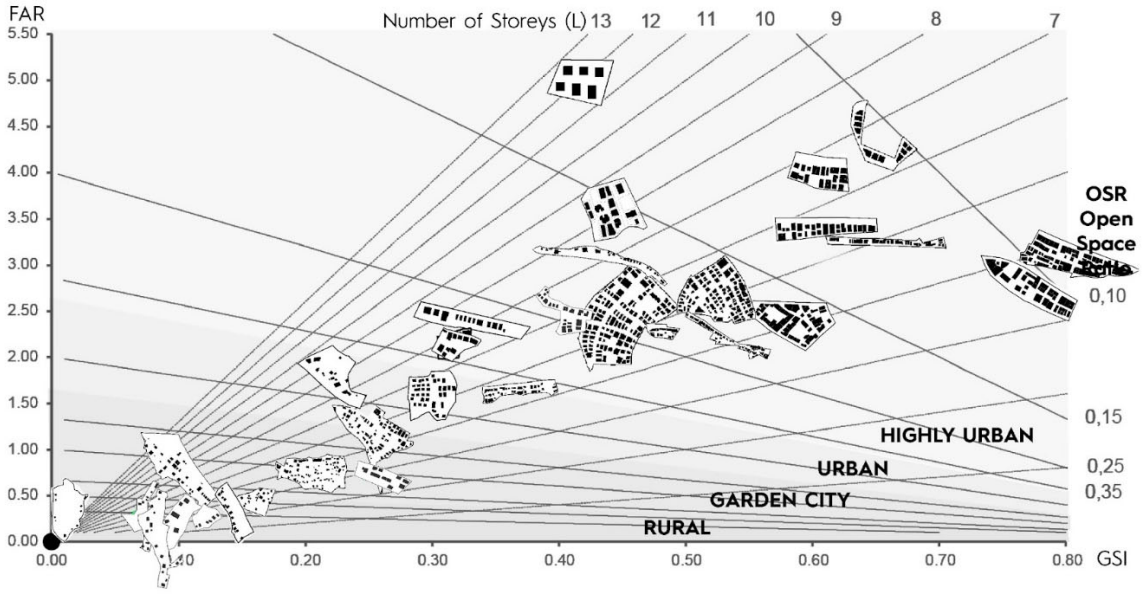

Figure 3 .Placement of Sample Urban Fabrics on Spacemate, photo credit: Beyza Karadeniz, 2020.

This morphological atlas, which can be referred to as Figure 3, serves as a foundation for planners when making development decisions regarding the related fabrics and the vacant areas within their respective regions. While the Spacemate method provides a basis for analyzing the fabrics, it is crucial that these fabrics are not limited to purely mathematical values without on-site examinations. As mentioned in the findings section, it is essential to analyze the formal characteristics (such as building-parcel relationships, slope, etc.) in relation to the urban context.

CONCLUSIONS

Morphological studies in Turkey began later than in Europe, initially focusing on historical and conservation areas. However, a systematic process for these studies has yet to be clearly defined. Urban morphology extends beyond special areas, examining the components of urban space, their configurations, and the transformations cities undergo over time, making it a unique research field that guides urban planning and design.

The role of urban morphology in Turkey's urban planning process is still not well-defined. Various experts conduct urban fabric analyses and density zoning using different techniques, but these approaches lack sufficient discussion across schools of thought. Symposiums organized by the Turkish Urban Morphology Network, starting in 2015, have been significant for addressing the relationship between urban morphology and planning. Recent publications on analytical techniques in urban planning have also contributed valuable insights into a process-oriented approach.

Recent housing developments have often been created independently of local character, leading to the loss of many unique urban fabrics under market pressures. This situation arises from a master plan approach that neglects the structural components and sensitivities of urban areas, leading to a top-down determination of urban fabric without strategic elements. Additionally, many changes and revisions to implementation plans occur independently of the decisions made in the master plans.

Urban planning encompasses studies on how cities should be shaped and structured. Urban morphology guides this process with various approaches and analytical methods aimed at

understanding urban form. Urban morphology studies rely on a process-oriented approach, necessitating intensive and systematic work and archiving. Continuous updating and recording of new information are vital. The relationship between urban planning and urban morphology cannot be separated; however, the connection is often fragmented. Studies aim to establish this relationship, allowing planners to visualize and discuss the third dimension of space through professional terminology rather than intuition. Recent regulations in Turkey seek to address this disconnect. For instance, the Spatial Planning Regulation states that proposed plans will be evaluated regarding urban fabric and liveability aspects. Additionally, it is specified that existing building density and fabric analysis must be conducted in the preparation of implementation plans. However, uncertainties about how these analyses should be conducted persist.

The morphological analysis approach defined in the thesis can serve as an effective tool for systematically analyzing existing urban fabrics and density relationships. Moreover, the character regions approach proposed in this study can act as a supportive framework and boundary-setting tool for urban areas under market pressures in the planning process. This approach may facilitate feedback between planners and relevant institutions, helping prevent erroneous density decisions in plans. Despite the emergence of various housing types and building technologies in recent decades, a design control approach responding adequately to these typologies has not been developed.

Urban morphology studies should evaluate fabrics created in different periods alongside contemporary planning experiences. Thus, the systematic analysis approach defined in the thesis can be integrated into the planning process. A key challenge in these studies is the unique complex structure of the process, comprising different historical periods, each with distinct social and economic reasons behind its physical changes. The analysis phase and methods must be detailed in a morphological context, ensuring each analysis is interpreted toward the specified objectives. The analytical approach developed in the study can identify issues in existing urban fabrics and inspire new building regulations, serving as a descriptive document for cities undergoing transformation and providing data for comparative studies in similar urban contexts.

ABSTRACT

The relationships between built environment and urban street vitality have been widely studied. The role of virtual spaces like social media in promoting urban street vitality has also gained attention in recent years. However, most existing urban street vitality research fail to reveal the relationships between virtual space features and urban street vitality. Moreover, the complex relationships between physical and virtual space features, as well as their threshold effects, are rarely explored. In response, this study uses multi-source urban data and XGBoost model to explore the nonlinear relationships between physical and virtual space features and urban street vitality. Since social media plays an important role in the renewal of historic areas, this study takes a typical Shanghai historic and cultural area as an example. Based on the '5D' built environment theory and a literature review, the study selects physical and virtual space features as independent variables and street vitality as dependent variable. Based on the quantitative calculation results of these variables, an XGBoost machine learning model of this series of variables and urban street vitality is constructed. Specifically, physical space features play a significant role in enhancing street vitality, with subway station accessibility demonstrating a particularly strong effect. Furthermore, the nonlinear impacts of both physical and virtual space features on vitality are prominent. Notably, negative threshold effects on street vitality are observed when the proportions of road, building density, and virtual popularity exceed certain critical thresholds. The study also highlights the interaction effects among key features. This research not only advances the understanding of urban street vitality and addresses theoretical gaps in built environment studies, but it also offers a theoretical framework for targeted urban regeneration and the revitalization of historic and cultural area

Keywords: Historic and cultural area; urban street vitality; nonlinear relationships; physical and virtual space features

INTRODUCTION

Research Background

It is widely recognized in the field of urban design that the vitality of urban streets is an important indicator for assessing the attractiveness and spatial quality of urban neighbourhoods (Jacobs, 1961).

As both physical and social spaces for human activities, the built environment of urban streets is closely related to vitality (Yue *et al.*, 2021). Many urban design theories have been proposed to promote the vitality of urban street. Extensive research has been conducted into the mechanisms by which relevant physical environment variables (e.g., building density, building type, etc.) affect the vitality of urban streets (Ye, Li and Liu, 2018). It is noteworthy that the nonlinear effects of physical environment variables have been shown to be prevalent in these relationships, yet they have not received much attention until recent years (Han et al., 2024).

With the development of information and communication technologies, the number of users posting content on social media platforms, such as Twitter and Facebook, continues to increase. The creation of social media has triggered new behavioural patterns (e.g., ‘check-in activities’) that geographically correlate digital virtual spaces with physical urban spaces. These behavioural patterns demonstrate the impact that virtual spaces can have on urban spaces by altering people's daily lives, such as increasing street life to promote street vitality (Jacobs, 1961).

Literature Review

In order to create attractive cities, many studies have been conducted on how the built environment stimulates street vitality. It was first suggested that the physical spatial features of the built environment, such as functional mix, neighbourhood scale, and density of street intersections, are the key factors influencing street vitality (Jacobs, 1961). With the generation of urban multi-source data and the development of quantitative urban morphology, scholars have made finer and more precise quantitative calculations of built environment features, further confirming the relationship between urban morphological elements and street vitality, such as greening rate (Lopes and Camanho, 2013), street interface continuity, underlying interface transparency (Zeng, Zhang and Yuan, 2019) and traffic accessibility (Zhang *et al.*, 2021) are elements that are strongly related to street vitality. However, traditional research methods using linear regression models can no longer meet the need to reveal the complex relationships between street vitality and built environment variables. With the development of emerging algorithms such as machine learning, a number of studies have emerged in recent years using machine learning models to explore the nonlinear relationship between street vitality and built environment (Li *et al.*, 2022; Han *et al.*, 2024; Doan *et al.*, 2025). However, there are still few studies exploring the nonlinear relationship between the built environment and urban vitality in historic districts, and there is a lack of studies revealing the relationship between virtual space activities and urban street vitality.

With the rise of social media, people can post on social media platforms with geolocation information. These location-based social media platforms are creating a new kind of space (Ash, 2009; Ash, Kitchin and Leszczynski, 2018), which can be defined as a virtual space (Kellerman, 2014). Users express their attitudes towards locations through a series of activities (e.g., liking, commenting, sharing) within the virtual space (Lloyd and Cheshire, 2017), which we call virtual activities. Based on social media recommendation algorithms, the more frequently a post receives virtual activities such as likes and shares, the more likely it is to be pushed to more interested users. Different sizes of exposure enable virtual locations to also produce location locational features similar to those in physical space. At the same time, by changing people's daily life and consumption behaviour (Bissell, 2020), a close relationship between virtual and physical spaces is created (Leszczynski, 2020). Taking the example of the popularity of ‘clocking activities’ in China, people are interested in attractive posts and are

motivated to visit these places on-site (Cao, 2024), thus contributing to the vibrancy of a particular place. However, current research in the field of urban design related to social media focuses more on the new urban intentions it generates (Huang et al., 2021), and there is a lack of research on the relationship between virtual spaces and the vitality of urban streets.

Research gaps and the significance of the study

Overall, current research has discussed a wide range of built environment elements that have an impact on urban street vitality and explored the nonlinear relationship between the two. However, few research results have revealed the relationship and threshold effects of virtual space activities and urban street vitality, as well as the lack of interactive effects between virtual and physical space features in influencing urban street vitality. Therefore, the study aims to explore the nonlinear relationships between virtual and physical space features and urban street vitality. The results of the study can provide a reference for the creation of vibrant street spaces in urban design, and provide a theoretical framework for the vitality revitalization of historic and cultural areas.

The first part of this paper describes the background of the study. The second part describes the research framework and experimental methods. The third part takes Hengfu historic and cultural area in Shanghai as an example for the statistical analysis. The fourth part summarizes the innovation and value and presents the limitations of this study.

METHOD

Research Framework

Figure 1 illustrates the research framework of this study. Based on the ‘5D’ built environment theory and a literature review, the study selects physical and virtual space features as independent variables and street vitality as dependent variable. Taking Hengfu historic and cultural area in Shanghai as an example, this study combines urban multi-source data such as LBS, POIs, Xiaohongshu, Meituan and other spatial analysis software such as ArcGIS Pro to calculate each variable in detail. Lastly, a XGBoost machine learning model was built using python programming language, and SHAP values were used to explain the nonlinear and interaction effects of these features, thus providing insight into the relationship between physical and virtual space features and urban street vitality.

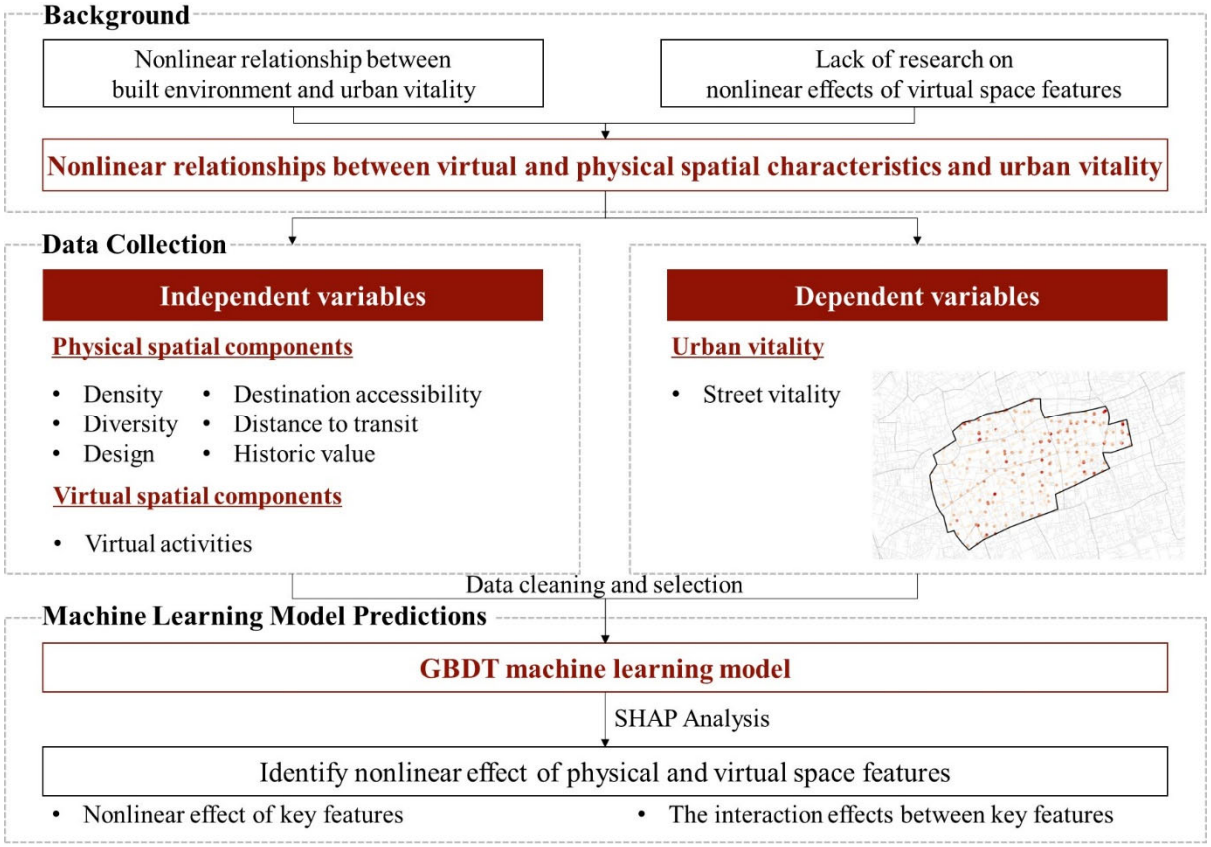

Figure 1. Research framework

Study area

The Hengshan Road-Fuxing Road Historic and Cultural Area, or Hengfu historic and cultural area for short, is one of the first 12 historic and cultural areas in Shanghai to be publicly announced by the Shanghai Municipal Bureau of Planning and Natural Resources. It is also the largest historic and cultural area in the central city of Shanghai, with the largest number of outstanding historic buildings and the most complete historic landscape pattern. In particular, Hengfu historic and cultural area is a high-density built-up area, with complete data of the built environment and a higher density of social media data. Consequently, 1515 street segments in this area were selected as the data set, and the detailed information of the selected area is shown in Figure 2.

Figure 2. The study area

Data and variables

Table 1 presents the independent variables used in the study. The independent variables were classified into two categories: physical space variables and virtual space variables. In the physical space variable, the "5D" dimension (Ewing and Cervero, 2010), which describes the characteristics of the built environment, is employed to construct a system of indicators for the physical space characteristics in terms of density, diversity, design, accessibility to destinations, and distance to transportation facilities. Furthermore, given the pivotal role played by historic value in the resilience of historic and cultural areas, the independent variable of historic building density was incorporated into the study to delineate the historic environment (Zhang and Han, 2022). In calculating the physical space variables, two calculation ranges are used, a 55-meter street buffer (Guo, Chen and Yang, 2021) and a 500-meter street buffer, which represents the walking distance from the street (Zhang *et al.*, 2019). In the virtual space variables, the behaviours of individuals within virtual space (e.g., virtual visits, virtual ratings, etc.) are employed to characterize the virtual space.

Table 2 presents the dependent variable used in the study. The study used street activity intensity as a proxy for urban street vitality. Temporal and spatial records of mobile users' activities were obtained from location-based service (LBS) data (Zeng *et al.*, 2018), that is, anonymized user geolocation data provided by Amap. LBS data for one week (24 hours per day for 7 days) within the first month of 2020 was selected and the average daily activity intensity data for the seven days of the week was used as the total street activity intensity.

Table 1. Independent variables

Major	Dimension	Variable	Description	Data source
Physical space	Density	Building density	Proportion of base area of buildings within 500m buffer of the street to the area of the zone (%)	OSM
		Floor area ratio	Average land-use intensity of adjacent blocks	
		Road density	Length of streets per square meter within 500m buffer of the street	
		Intersection density	Number of junctions per square meter within 500m buffer of the street	
	Diversity	Function diversity	The entropy of the POIs within 55m of the street using the method of Shannon's Diversity Index	Amap
		Function density	Number of POIs per meter within 55m buffer of the street	
	Design	Vegetation	The average value of the tree proportions in all the street view images on the street	Baidu map
		Sky	The average value of the sky proportions in all the street view images on the street	
		Building	The average value of the building proportions in all the street view images on the street	
		Sidewalk	The average value of the sidewalk proportions in all the street view images on the street	
		Road	The average value of the road proportions in all the street view images on the street	
		Furniture	Number of street furniture per 100 meters	
	Destination accessibility	Walking accessibility	Walking accessibility using the betweenness in sDNA when the radius is 800m	OSM

		Vehicle accessibility	Walking accessibility using the betweenness in sDNA when the radius is 9500m	
	Distance to transit	Distance to bus stop	The Euclidean distances from the midpoint of each street to the nearest bus station	Amap
		Distance to subway station	The Euclidean distances from the midpoint of each street to the nearest subway station	
		Bus stop (counts)	Number of bus stations within 500m buffer of the street	
	Historic value	Historic building density	Number of historic buildings per meter within 500m buffer of the street	
Virtual space	Virtual activities	Virtual visiting activities	Number of virtual visits (likes, comments, favorites, shares) to premises addresses within 55m buffer of the street	Xiaohongshu
		Virtual popularity	Ratio of the number of times a premises address in the street 55m buffer has been virtually visited to the number of times the address has been mentioned	
		Virtual score	Average rating of addresses of locations within the 55m buffer zone of the street	Meituan

Table 2. Dependent variable

Major	Variable	Description	Data source
Urban vitality	Street vitality	Average of daily summaries of the density of people active during the week within 55m of the centre line of the street to either side	Amap

Upon completing the data collection process, ArcGIS Pro 3.0 was employed to calculate the variables. Subsequently, a preliminary correlation analysis was conducted (Figure 3). The results of the correlation analysis indicate that the analysis revealed a strong positive correlation between the Density dimension and the Design dimension within the physical space features. Conversely, the virtual space features demonstrate a relatively weak positive correlation with the majority of the physical space features. Finally, in response to the multicollinearity between indicators, the vegetation and building variables have been excluded from the analysis, as they exhibited VIF values exceeding 7 and a correlation coefficient exceeding 0.6 with either variable.

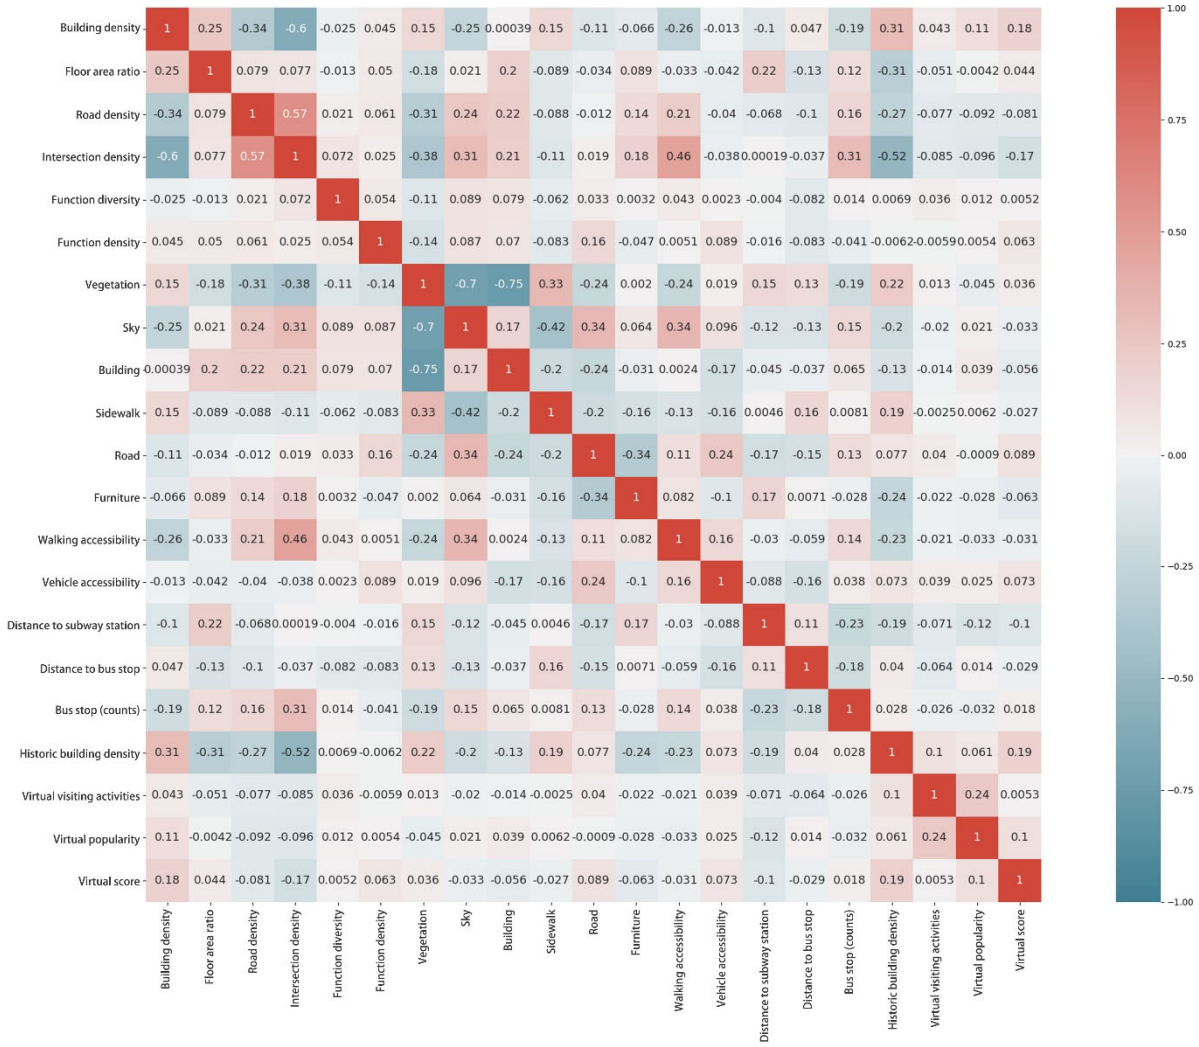

Figure 3. Correlation matrix

Modelling approach

The study applied Ensemble learning to construct a street vitality prediction model that is based on both physical and virtual space features. The study employed Random Forest, GBDT, and XGBoost models for regression modelling and evaluation and compared the performance of each model based on accuracy evaluation metrics such as MAE (Mean Absolute Error), RMSE (Root Mean Square Error), and R^2 (coefficient of determination). After a comprehensive comparison of the performance metrics of each model, XGBoost shows better performance in all metrics. In comparison to traditional linear regression models, XGBoost, a gradient boosting-based decision tree algorithm, is capable of achieving efficient model training and prediction by optimizing the objective function and introducing parallel computing (Chen and Guestrin, 2016).

Table 3. Performance comparison of the three machine learning models

Performance	Random Forest	Gradient Boosting	XGBoost
MAE	149.994	154.501	144.118
MSE	47839.322	53664.945	45815.322
RMSE	218.722	231.657	214.045

R^2	0.364	0.286	0.391

The study employed the xgboost package (Python 3.9.13) to estimate the XGBoost model. For XGBoost model, key parameters such as n_estimators, learning rate, and maximum depth are of significant importance in determining the model's overall performance. The learning rate controls the step size of each round of boosting, with lower values resulting in slower learning but improving generalization and preventing overfitting. The max_depth largely determines the complexity of the model, and higher values may result in better performance, but carry the risk of overfitting. The results of the testing phase demonstrated that the combination of n_estimators = 500, learning_rate = 0.05, subsample = 1, colsample_bytree = 1, and min_child_weight = 1 yielded the highest R-squared value of 0.403 for XGBoost, indicative of enhanced model performance.

RESULTS AND DISCUSSIONS

To examine the local effects of independent variables and their interaction effects in conjunction with other variables, the SHAP package (Python 3.9.13) was utilized to interpret the XGBoost model. SHAP, which is based on game theory, can be used to enhance machine learning explanations (Lundberg and Lee, no date). The SHAP approach offers a comprehensive analysis of global, local and interaction effects that cannot be effectively captured by partial dependency graphs and cumulative local effects methods. In previous studies of urban planning, SHAP and XGBoost were employed to elucidate that the built environment and road vehicle factors exhibit positive nonlinear relationships with urban vitality (Doan *et al.*, 2025).

Relative importance of variables

The relative importance of each feature is calculated and ranked based on the mean absolute SHAP values. The relative importance of variables implies their ability to make a successful prediction. The features are visualized collectively, with a dot on the right representing a street sample, where a redder colour means a larger feature value.

Physical space variables contribute more to the successful prediction. Among the physical space features, the Distance to transit dimension has the highest relative importance of 24.92%, followed by the Design, Density dimension. Specifically, the Distance to subway station variable, Percentage of sidewalks in the street, and Vehicular accessibility are more important than other features. Street segments closer to subway stations, a higher percentage of sidewalks, and a higher level of vehicle accessibility have higher street vitality. This indicates that accessibility plays a more critical role in promoting street vitality than other urban form characteristics. In addition, streets with high density of historic buildings in historic and cultural districts usually have lower vitality, which may indicate that most of the historic buildings have not fully utilized their historic value and their attractiveness needs to be improved.

Among the virtual space features, virtual popularity has the highest importance, and most of its high value points correspond to negative SHAP values, i.e., higher virtual popularity corresponds to lower street vitality in historic and cultural areas. The possible reason for this is that stores at lower street vitality in historic and cultural districts are more inclined to advertise on virtual platforms such as social media and attract crowds of people to hit them, but the number of people hitting them is still a small percentage of the total number of people in the total amount of vitality. It suggests that the popularity of a location in virtual space has some degree of influence on street vitality in reality.

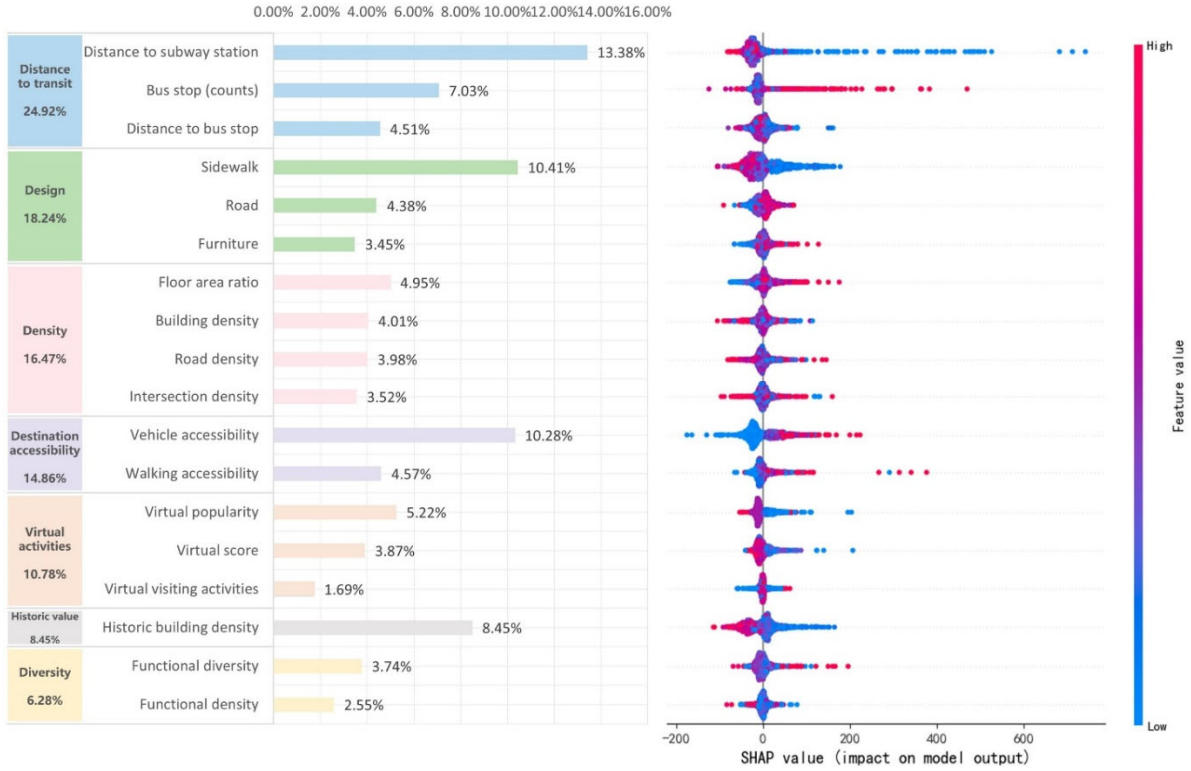

Figure 4. *The relative importance of variables*

Nonlinear effect of key features

The SHAP dependence plots of key features (relative importance greater than 3%) are shown in Figure 5 to show the nonlinear relationships and threshold effects of physical and virtual space features with urban street vitality(Friedman, 2001). Sample point-fit curves (Locally Weighted Scatterplot Smoothing, LOWESS) were generated to the plots to better identify trends of the local effect. A steeper slope of the curve indicates a higher marginal benefit and a rising curve indicates that the independent variable is positively correlated with street vitality and vice versa. It can be found that the relationships between the key features of this study and the vitality of the city streets all show a complex nonlinear relationship.

Physical space major

When there are more than 10 bus stops within the 500m buffer zone of a street, street vitality increases sharply with the number of stops; when the distance from the nearest subway station is less than 200m, vitality decreases sharply, and when it is greater than 200m, the change tends to be stabilized; and when the distance from the nearest bus station ranges between 100-200m, the increase in distance has a negative effect on vitality. Compared to similar studies examining industrial cities, the thresholds for distance from public transportation stops in this study are relatively smaller, consistent with the high-density characteristics of historic urban areas.

In the design dimension, the proportion of sidewalks tends to decrease in the range of 0.01-0.12, while driveways and street furniture show an overall increasing trend, but have a negative impact on vitality when the proportion of driveways exceeds 0.32.

Regarding density dimension, increases in floor area ratio within the range of 0-2.5 and improvements in road network density can enhance street activity intensity. However, excessively high building density may lead to overcrowding and compression of public space, potentially reducing street activity. Additionally, further increases in intersection density beyond a certain threshold do not significantly affect street vitality.

In the accessibility dimension, the local effects of both pedestrian and vehicular accessibility are generally on the rise, indicating that not only residents traveling on foot, but also a larger number of tourists traveling by car, are active within the historic and cultural areas.

In terms of historic value, the threshold effect of density of historic buildings shows an overall decreasing trend, indicating that most of the historic buildings still have not fully utilized their historic value and their attractiveness needs to be improved. In terms of diversity, when functional facilities are richer and more diverse, they will have a positive impact on street vitality, which is consistent with common sense.

Virtual space major

The threshold effect of virtual popularity decreases at the beginning and then increases slightly, although the overall trend is decreasing, which may be due to the fact that the people who carry out visiting activities in the virtual space come from all over the country, and only some of them have a high likelihood of being able to reach the real location, so as the heat of the virtual visit increases while the number of the people who actually visit the physical location does not have a large change, popularity is negatively correlated with street vitality. The threshold effect of virtual score likewise shows an overall decreasing trend.

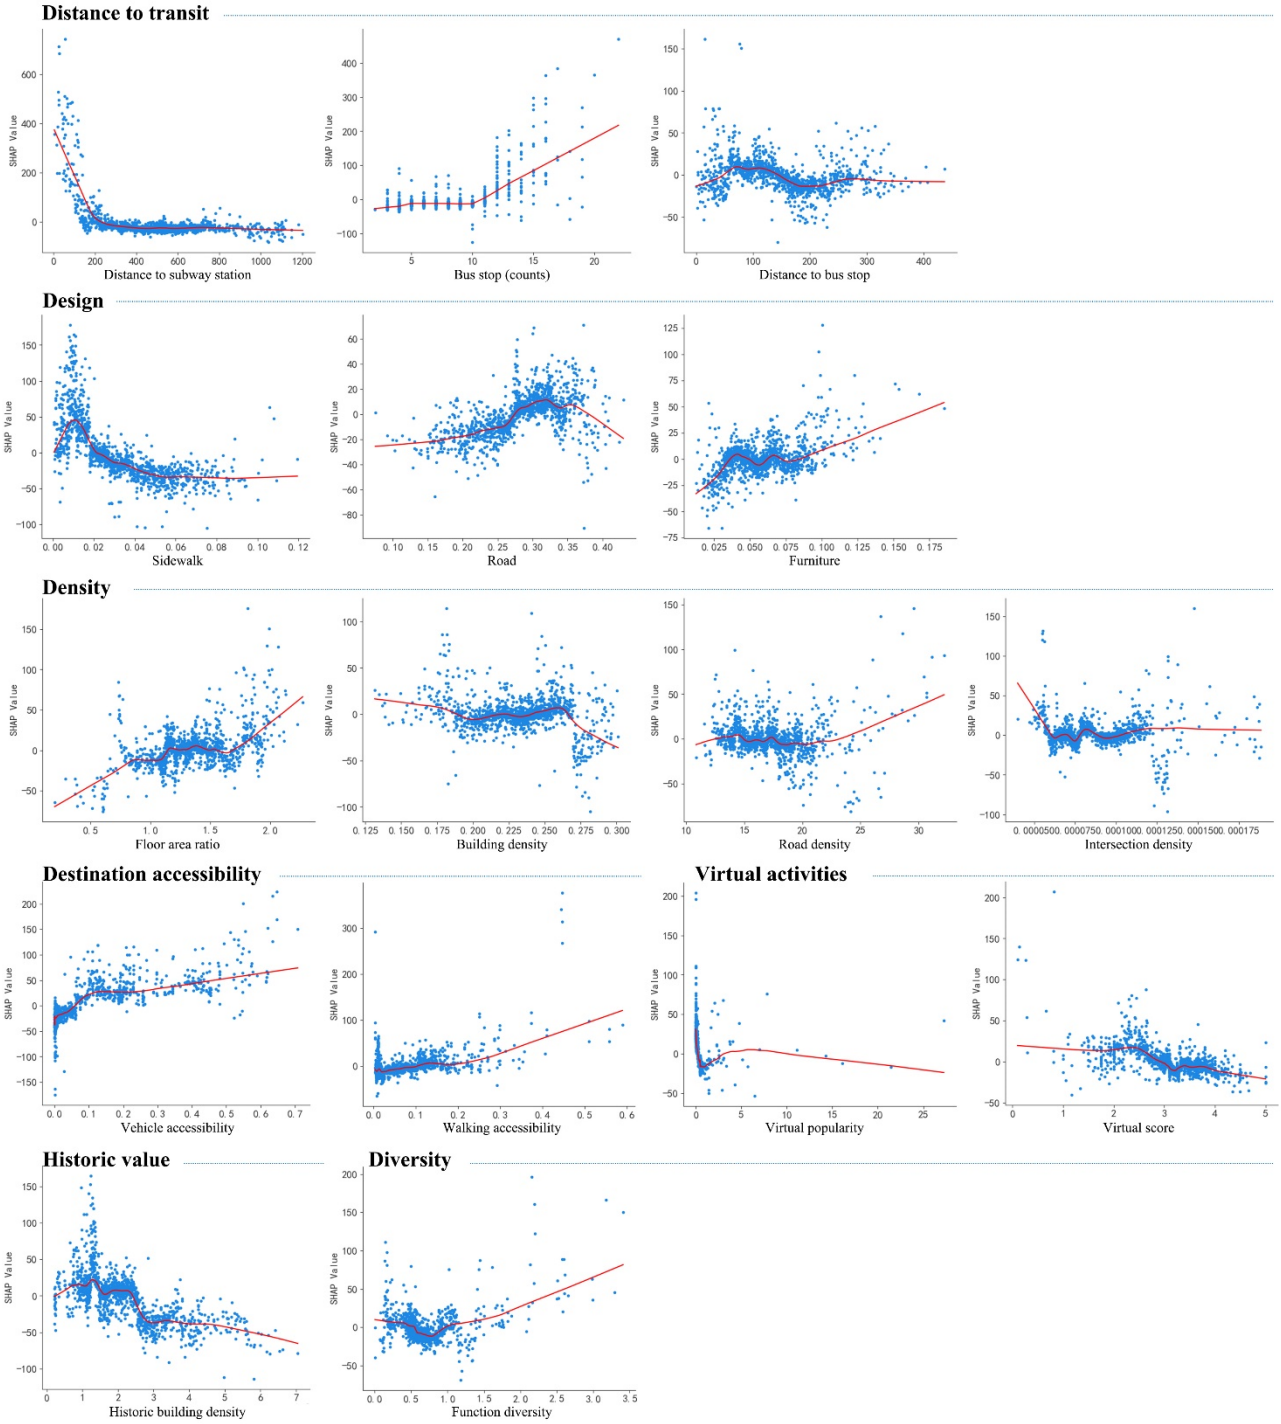

Figure 5. *Nonlinear effect of key features*

The interaction effects between key features

Figure 6 illustrates how the effect of one feature on street vitality depends on another through a SHAP dependency plot. Each point in the plot represents a sample, the X-axis represents an independent variable, the colour bar indicates the size of the other independent variable with which it has the

strongest interaction, and the Y-axis represents the SHAP value. It can be found that there are two interaction effects between the key features - synergistic interaction and inverse interaction.

There is a negative synergistic interaction between the number of bus stops and subway station accessibility, leading to a detrimental effect on street vitality when both are at low or high levels. It indicates that too many public transits may cause wastage of space and hinder the generation of street vitality instead, so the number and density of both bus stops and subway stations should be kept within appropriate limits.

There is an interaction effect between virtual activities and design, as well as the distance to transit. Virtual popularity and sidewalk presence have opposite effects on street vitality. The two interact positively only when the sidewalk percentage is below 0.02 and virtual popularity is high. When the sidewalk percentage exceeds 0.02, virtual popularity at a low level does not strongly impact street vitality negatively. Additionally, an increase in the number of bus stops negatively affects vitality when the virtual score is below 3; the interaction effect is not significant when the score is higher. A similar inverse interaction exists between historic building density and floor area ratio. At low levels of historic building density, higher floor area ratios are linked to lower vitality, as overly dense urban spaces create negative spatial perceptions that harm street vitality.

Vehicle accessibility and sidewalk have opposite effects on street vitality. The greater the proportion of sidewalk, the greater the negative effect on vitality when vehicle accessibility is below 0.1, and vice versa. This may be due to the fact that as the city expanded, the number of lanes on major roads in the historic urban area no longer meets the demands of today's vibrancy growth.

Both pedestrian accessibility and intersection density show a negative synergistic interaction. That is, low levels of both characteristics exacerbate the weakening of street vitality and conversely strengthen it. However, when pedestrian accessibility is below 0.2, increasing intersection density has no effect on street vitality, suggesting that urban design with small neighbourhoods and a dense road network is less helpful in enhancing street vitality when the area is not sufficiently walkable.

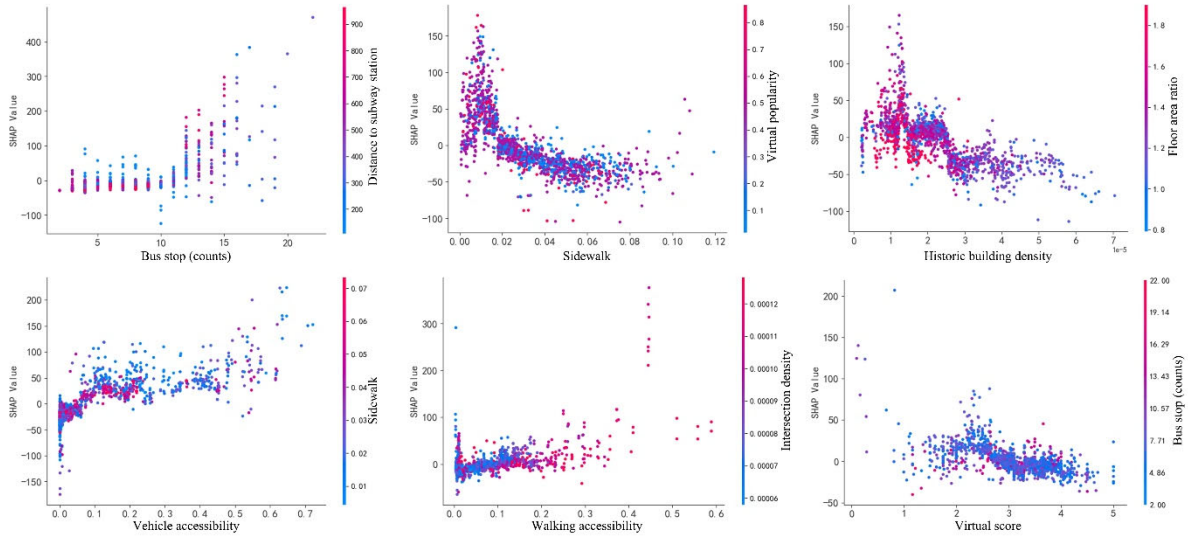

Figure 6. *The interaction effects between key features*

CONCLUSIONS

Overall, based on multi-source urban data and machine learning algorithms, this study establishes a XGBoost model for 21 physical and virtual space independent variables and the dependent variable of urban street vitality. Using the Shanghai Hengfu historic and cultural area as a case study, the study explores the nonlinear relationship between these independent variables and street vitality and examines their interaction effects using SHAP.

However, this study has certain limitations. Firstly, urban vitality is a complex concept that may not be fully expressed in terms of social activity intensity, and a wider variety of data can be added to jointly describe urban vitality in future research. Secondly, the optimal walking distance for calculating urban form features may vary across cities and regions, while the model performed well in this study, the applicability of 55m and 500m in Shanghai's historic and cultural area can be further verified in future studies. Finally, this study was limited to extracting location information from social media text, and future research could explore extracting more information from images for more in-depth studies.

Form, design and urban codes. A study on Rimini (Italy)

Dr. Martina Crapolicchio[1]
[1] Research Fellow (Transitional Morphologies Research Center, Department of Architecture and Design, Politecnico di Torino) Italy, martina.crapolicchio@polito.it

ABSTRACT

As stated by Ben-Joseph (2019), designers, planners and those who wish to work on the built environment cannot easily escape the obligation to create and maintain places where rules do not oust physical qualities. This thinking underlies the concept of quality of place and at the same time the flexible performance of urban rules in a formal action perspective. In this sense, codes could be used in a generative way, to specify generic urban elements and relationships, such as the type of building, the way buildings relate to the hierarchies of pathways, and so on, in order to create a number of variations around the formal theme. The research here presented analyses the historical centre of Rimini (north-east coast of Italy) with the objective of triggering urban regeneration mechanisms, arguing that it is possible to deepen the concepts of street and block as composite units for an inter-scalar vision of the urban environment in order to generate new rules based on form. The research methodology reflects the principles of the Italian school of urban morphology with particular reference to the urban studies by Saverio Muratori and Gianfranco Caniggia in a transitional perspective. What needs to be questioned is the ability of codes to mediate between individual interests and common goals (Marshall, 2011), fostering the connection between urban form and design devices. The essential aspect of codes as generic specifications naturally tends to promote a combination of flexibility and continuity over time, as well as consistency across scales and between multiple actors. Above all, codes can contribute to the creation of an overlapping and interconnected urban vision associated with traditional, route-based urban fabrics where the designs of buildings, streets and blocks are intertwined with each other.

Keywords: transitional morphologies, urban design, urban codes, historical centre, Italy

INTRODUCTION

The quality of space

The approach here presented is founded on the concept of quality of places while promoting the flexible application of urban rules within a formal action framework. In this context, codes can be utilized in a generative way to define general urban elements and relationships—such as building types and how they interact with the network of streets—leading to various formal design outcomes. In a generative code, while the specific elements and relationships are controlled, the final form emerges organically from the development process. An emergent structure possesses qualities that are not explicitly predefined in the rules governing its creation, such as guidelines for construction, layout, or aggregation (Marshall, 2011). The term *emergent urban structure* refers to a settlement

pattern that forms naturally, without strict planning or predetermined design. These patterns arise from individual decisions, user adaptations, and spontaneous interactions, producing a seemingly organized configuration that evolves over time. Historic centres exemplify emergent structures, having taken shape over centuries as streets, buildings, and public spaces gradually adapted to human needs and social dynamics. Key scholars such as Christopher Alexander (1977; 2008) and Michael Mehaffy (2008; 2020) have explored these concepts. Their theories, along with research by Michael Batty (2005; 2018) on generative algorithms and urban science, and Bill Hillier's (1996) work on spatial interaction networks, advocate for the use of generative codes over traditional master plans. The framework thus offer a new perspective on city-making (Plater-Zyberk, 2008). Theories on urban permanence and variation, as studied by Muratori (1959) and Caniggia (& Maffei, 1979), also suggest that urban form can be a key generator of codes and vice versa. In addition, these methods highlight how the arrangement of elements at one scale influences the integration of components at larger scales, creating a cohesive urban vision. For instance, the combination of buildings and public spaces forms specific types of streets, while the interplay of walls, doors, and windows shapes a building façade. In traditional urban layouts, where streets serve as the primary matrix of settlements, there is a clear interconnection between buildings, streets, and public spaces (Marshall, 2011). Urban elements are composed of smaller sub-elements, which contribute to a larger whole (Alexander, 1977). In fact, Alexander critiqued the overly simplistic hierarchical design of urban environments, which lacks the richness of complex overlapping elements. Planners often struggle to conceptualize and implement such complexity on the ground (Alexander, 1966).

Based on these theories, the Rimini case study was conducted with the goal of initiating urban regeneration within the historical urban fabric. This process began with a formal analysis and concluded with the creation of new design guidelines. The study is structured into three key sections. The first, Reading the form of Rimini, analyses the urban form of Rimini's historic centre, identifying the major elements shaping the area. It categorizes urban structures into morphological clusters, which are parts of the urban fabric with shared characteristics in terms of building types or patterns of aggregation. In the second part, each cluster is used to explore potential meta-design interventions, referred to as "devices", drawing on the concepts of "dispositive" and "device" from Foucault, Deleuze, and Agamben. Finally, in the third part, a synoptic matrix is produced that offers an early vision of an urban code, providing direction for the future development of the historic centre, which, in Italy, often serves a symbolic role regardless of its actual value.

Reading the form of Rimini

To thoroughly describe the composition of Rimini's urban fabric, it is crucial to use the right tools and methods to grasp the complexity of the urban landscape. Recognizing that the visible appearance of the urban environment results from various processes—each with its own logic and origins—that intersect and overlap over time, leaving traces, defines the urban territory as a palimpsest, continuously reshaped (Corboz, 1983). These processes together create an urban landscape where transformations are difficult to reverse, and the sum of these transformations represents the territorial fixed capital, which both enables and restricts regeneration efforts. In working with established urban fabrics, it is necessary to clearly identify certain key elements that make up the structure of a historic centre. First, the structural elements, which are components of the urban environment that have remained almost unchanged over time and form the identity of the historic

centre. These elements include the street layout—an overlay of Roman, medieval, and later systems—and the natural hydrography, such as Rimini's Marecchia canal. Second, the settlement systems, which are clusters of urban buildings that are interdependent on these structural elements but follow internal rules (such as old Roman insulae now forming closed blocks, open blocks, or linear and terraced developments). These settlement systems contain some homogeneous morphologies, or clusters defined by specific building densities, layouts, and prevalent types. Homogeneous morphologies group together similar architectural typologies and building arrangements, such as closed blocks or linear fabric. The coexistence of these elements and the layering of urban transformations form the city's inherited identity. Describing the city's form is not the end of urban analysis; rather, it opens up various design possibilities rooted in understanding the complexities of these formal layers (Albrecht & Galli, 2021). This kind of analysis helps to establish a taxonomy of the built environment by recognizing different patterns of aggregation based on typological units (Caniggia & Maffei, 2017). In Rimini's historic centre, five distinct homogeneous morphologies have been identified, each contributing to the city's urban identity. These include a compact fabric of layered blocks, a fabric with special buildings, fringe fabric with uneven elevations, buildings aligned along streets, and urban areas containing structures that are out of place in relation to the traditional urban fabric. Together, these morphologies paint a diverse and complex picture of Rimini's historic core (Fig. 1).

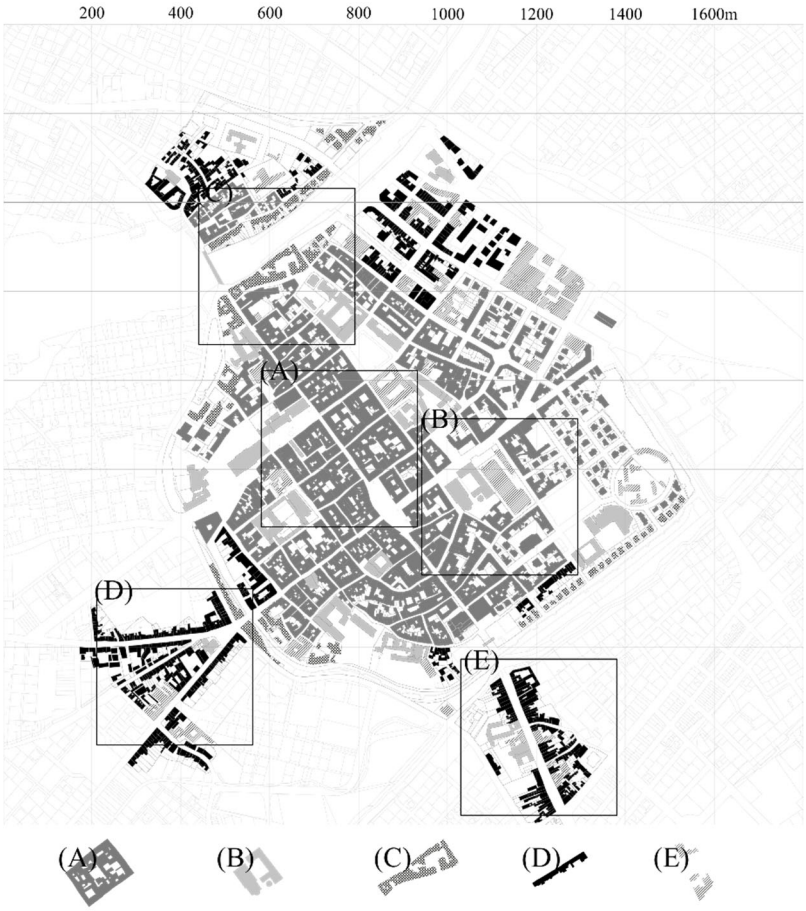

Figure 1. Morphological clusters in the historical centre of Rimini. Author, 2023.

The clusters were classified based on the typologies and forms defined by Caniggia and Maffei (2017) for basic buildings. To understand these clusters better, each has been examined through a sample

of its urban fabric. A morphological analysis and a meta-design (or device) were conducted on each sample. These devices not only propose preliminary urban configurations aligned with the area's identity, but also generalize these findings across similar urban fabrics. The study of clusters involved analysing the formal transition of the urban samples, identifying recurring patterns and variations over time. The accompanying table (Fig. 2) illustrates how the evolution of each sample reveals its unique characteristics, enabling comparisons. For example, sample A, representing the compact block fabric, shows that the block structure is sometimes disrupted by a porous quality. Sample B, containing special buildings, highlights how the continuity of the blocks has been compromised over time. In the fringe fabric (sample C), there is a reconfiguration of the cluster, revealing aspects of fragmentation and disintegration. Sample D, composed of buildings aligned along streets, reveals a clear relationship between urbanization, street layout, and building façades. Lastly, in sample E, which contains buildings out of scale with the surrounding structures, although urbanization phases are visible, the disruptions caused by these typologies are less obvious. Despite their differences, these extraneous buildings often align with the overall urban fabric's aggregation principles but still stand out due to their distinct architectural and typological features.

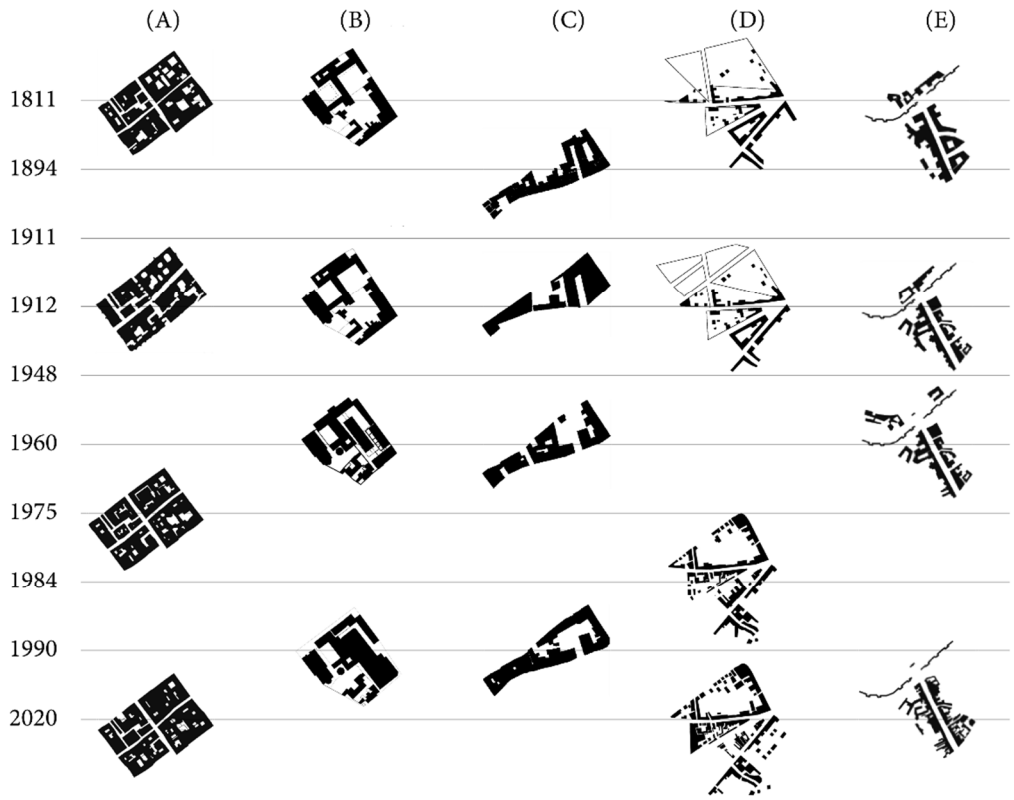

Figure 2. Formal urban transition of the study samples of the five morphological clusters in Rimini. Author, 2023.

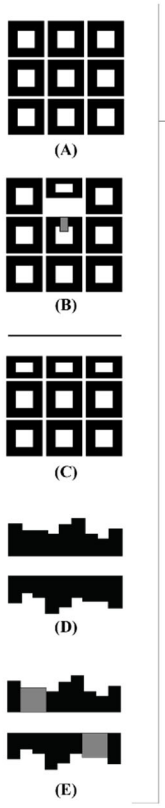
Samples laboratory

The analysis of morphological transitions alone, as seen with sample E, doesn't capture all characteristics of historic urban fabrics. To address this, each sample was assessed using a typological abacus to better outline qualities within the urban fabric across multiple scales. A summary table (Fig.

3) was created for an integrated view of all clusters. In the first three columns, this table captures the main characteristics and relationships of the forms analysed, while the final two columns present areas for action and suggested strategies to foster urban regeneration based on the data. The table is organized hierarchically, descending from settlement patterns to architectural components. For each scale, intrinsic and extrinsic characteristics and relationships are outlined. Qualitative aspects point to areas for potential intervention, such as courtyards or roof elements, while quantitative goals aim to guide regeneration of the consolidated urban fabric, preserving identity while addressing multiple scales.



Field of observation	*Characteristics of elements*	*Intrinsic and extrinsic relationships*	*Qualitative specifications (interventions)*	***Quantitative specifications (objectives)***
Settlement (Rimini)	Mixed urban areas with a mixture of typologies	Position and relationship with the natural and anthropic territory	Urban landscape	**Urban regeneration of compact fabrics while preserving local identity**
Urban fabric (cluster)	Compact fabric with blocks (A) Fabric with the presence of special buildings (B) Margin fabric (C) Townhouse Fabric (D) Fabric with presence of extraneous buildings (E)	Porosity (A) Influence of the poles (B) Discontinuity and fragmentation (C) Continuity with the eaves line (D) Extraneous typologies and blind fronts (E)	Internal courtyards, facades and roofs (A) Exceptionality in the urban fabric (B) Private and collective space (C) Relationship with the road (D)	**Increase in building capacity in terms of surfaces and volumes** **Greater use of collective spaces**
Streets and collective space	Driveways (A, C, D, E) Pedestrian routes (A, B) Public squares (A) Cycle routes (E) Parking (A, B) Courts (A, B, C)	Ratio between squares and driveways (A, B, C) Ratio between the different degrees of transit (D, E) Ratio between inside/outside of thr block(A, B, C)	Path hierarchy distribution (A, B, C, D, E)	**Accesses** **Openings** **Facades and height of buildings**
Building typologies	Courtyard buildings (A,B,C,D) Special buildings (A, B) Ordinary building (A, B, C, D, E) Buildings arranged in line (D, E)	Position of lots in relation to the road hierarchy (A, B, C, D, E) Setbacks (B) Property boundaries (A, B, C, D, E)	Maintaining Architectural Principles (B) Maintenance of morphotypological and identity characters (A, B, C, D)	**Surface reports** **Dimensions of the building** **Height of buildings** **Distances**
Building Components	Roof typology (B, D, E) Elevations and facades (A, C, D, E) Structural components Porches, balconies, overhangs (C, D, E)	Relationship between openings (doors and windows) (A, C, D, E) Eaves lines (D) Railings (D)	Materials (A, B, C, D, E) Ornaments and decorations (A, B, E) Green roof (A, E) Superelevations (D, E)	**Dimensions of surface and volume additions** **Roof slopes** **Maximum overhangs and overhangs**

Figure 3. Qualities and Quantities summarised after the analysis of the sample in Rimini. Author, 2023.

This analysis enabled design experimentation on each sample through the use of a "device." In the compact fabric with blocks (Sample A), the focus was on small-scale, temporary urban acupuncture interventions to retain local identity. For Sample B (urban fabric with special buildings), the approach involved reshaping the fabric through competitions and design that enhance monument-centered areas. The marginal fabric (Sample C) allowed for the use of "parasitic" architecture and residual spaces. Sample D, the fabric with buildings in line, was tested with a dynamic growth device, where a building can be extended upward in line with its tallest neighbours. For Sample E, featuring buildings incongruous with their surroundings, strategies involving air rights were explored. Below is a detailed overview of the approach on Samples C and D.

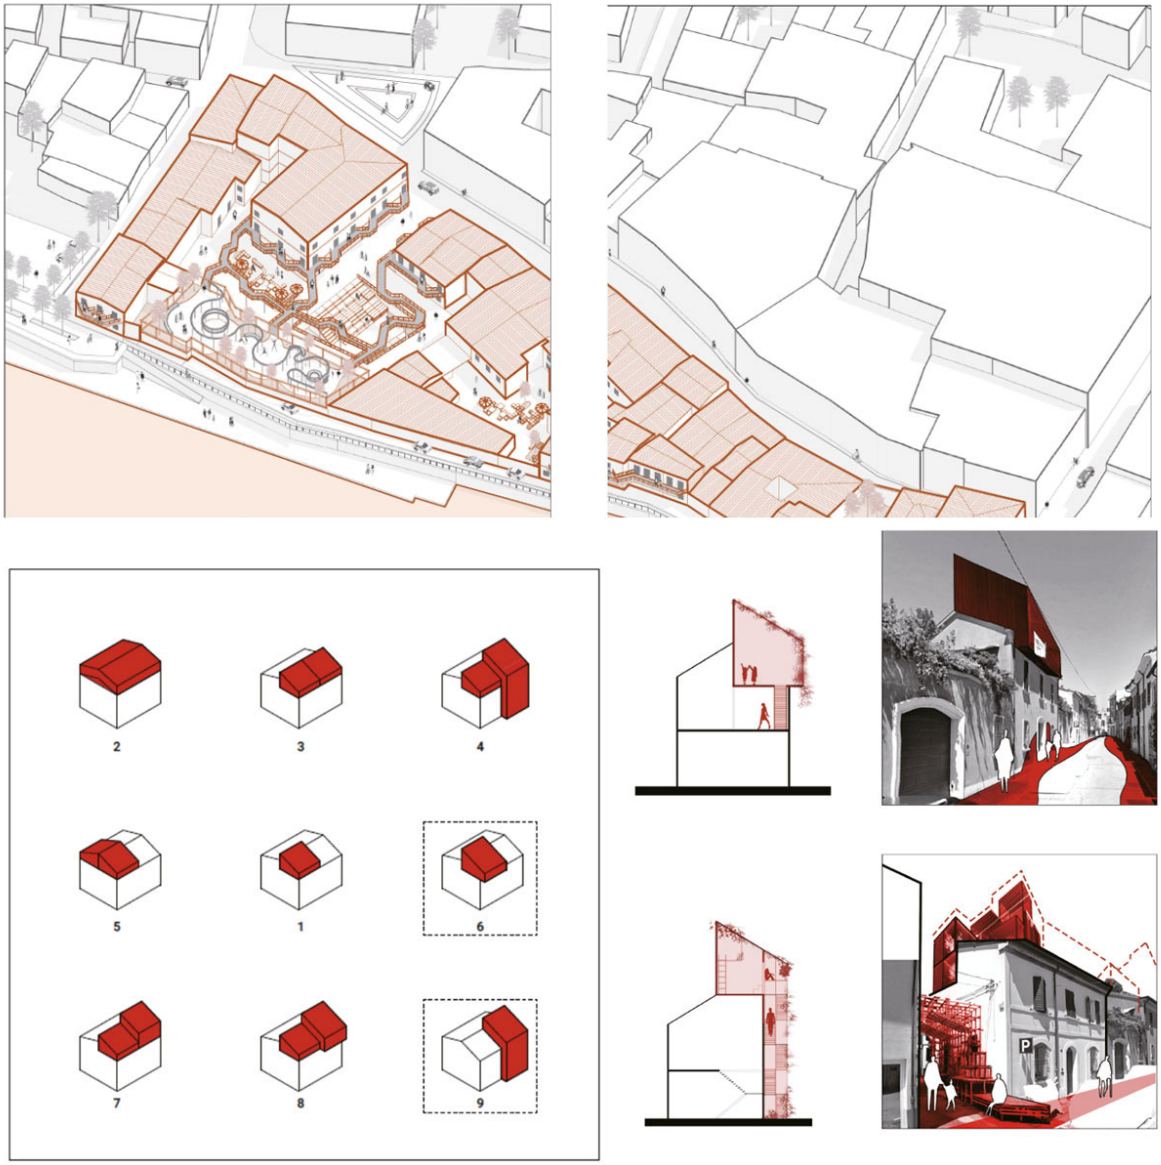


Figure 4. Devices visualisation on sample C and D in Rimini. Author, 2023.

(C) Within mixed urban fabrics that combine various building types, the marginal fabric can be identified by semi-open blocks with internal courtyards, used both collectively and individually by lot owners. These areas are predominantly occupied by ordinary buildings, with heights consistently ranging from one to five stories, featuring structural components like arcades, overhangs, and balconies arranged in a regular manner. There is a strong connection to the natural and infrastructural surroundings, contributing to the characteristic discontinuity and fragmentation typical of marginal areas. Given these characteristics, intervening in the mix of private and collective spaces becomes a valuable asset in these fabrics. Experimenting with the addition of architectural intrusions and interferences in underused spaces within marginal fabrics can increase building capacity both in terms of surface area and volume. In this way, the margin becomes a design category, not only to fill social or formal gaps but to generate new relationships that, to some extent, mend urban fragmentation (Fig. 4).

(D) The fabric with buildings arranged in a line is identifiable by the dissolution of the closed block and the strong connection each lot has with the street. Here, the courtyard becomes the rear and assumes the layout of divided lots, sometimes in an irregular manner. Under these formal conditions, the features that gain the most value are the façades and the continuity of the eaves line along the street, which acts as an attractor and hierarchically dictates the alignment of the lots. The morphological analysis of these fabrics shows a growth trend aimed at increasing height in terms of volume and/or surface area for each unit. This growth is derived from observing eave lines and building layouts, along with the need to maintain a connection to the street—key identity features of this fabric. Therefore, dynamic growth could include solutions for volume additions, either fully or partially based on the lot area, relative to adjacent units. Codifying this strategy from a transformational perspective allows the prediction and control of urban fabric growth (even simultaneously), preserving Rimini's architectural identity and solutions. Thus, this device takes on a meta project role where the growth of each individual building unit is related to adjacent units over time (Fig. 4).

Decoding Rimini

The synthesis of Rimini's urban fabric analysis shows that every urban regeneration proposal is rooted in a morphological approach. This involves analysing fabric structures, aggregations, and typological cells, which form the foundation for any prescriptive or regulatory framework. The devices, in turn, serve as experimental models, suggesting design actions that support regeneration objectives. These insights pave the way for creating a synoptic matrix that connects formal analysis to actionable devices, providing a foundation for drafting an urban code. The table in Fig. 5 outlines the five morphological clusters, including the intervention zone requirements (IF), possible actions within urban fabrics based on device testing (ALLOWED), the entities responsible for regeneration (PROMOTERS), benefits for stakeholders (ADVANTAGES), and limits or operational measures in each cluster (LIMITS/QUANTITIES). While the table encapsulates findings across all samples, two examples (C, D) are elaborated below.

URBAN FABRIC (cluster)	IF (morphological characters)	IS ALLOWED (operations permitted)	PROMOTERS	ADVANTAGES	DEVICE	LIMITS QUANTITIES
	There are conditions of compact building fabric with closed blocks and stratifications	Rethinking the urban space to make the fabric more porous through: • temporary interventions on the system of voids (courtyards and courtyards); • interventions on the internal facades; • interventions on roofs and flat roofs.	Private owners	• Remediation • Incentives on environmental taxes • Increase of surfaces	Urban Acupuncture 	• Occupation of private land by the public on private concession • Surface increase in accordance with the building typology.
	Types of special buildings that have polar characteristics with respect to the surrounding urban fabric	• Remodel the urban fabric while maintaining the layout of the special building; • Recognize the morphogenetic archetypes of the tissues affected by polarity; • Parametrically modulate the interventions between the identified morphogenetic archetypes.	Public administration	Increase in surfaces and volumes as a percentage of the urban fabric under analysis.	Morphological replasmation of tissues 	• Occupation of private land by the public on private concession • Surface increase in accordance with the building typology.
	Margin tissue conditions are present with proximity to topographical and/or anthropic borders	Recover cubage through: • the increase in surfaces and volumes served by walkways or paths; • the temporary occupation of private open spaces (courts and courtyards if any) by the public administration to create public spaces or gardens.	Private owners Investors Public administration	Increase of surfaces and volumes	Parasite architecture 	• Occupation of private land by the public under concession • The overhangs must respect a maximum overhang comparable to the addition of balconies on the street facade • The "parasitic architectures" must occupy no more than 20% of the façade on which they are built.
	There are compact urban fabrics with typologies arranged in line (row houses)	• Increase the building capacity of surfaces and volumes by addition while preserving the characteristics of the original typology • The elevation of buildings is enabled through a dynamic index which is governed by the height of the tallest adjacent building	Private owners Investors	• For urban quality, the preservation of local identity • For investors, increase in area/ volume	Dynamic growth 	Height raising with dynamic index: • h h near +1 • traditional standard maximum height • 5 floors Adding volume to the facade: • Maximum projection: 1 m • Coverage of the existing facade: max 20%. • No addition of ground floor towards the public road. Roof: • Compensation gauge (partial or total • Residential destination • Addition of dormer window • Partial removal max 20%
	There are compact urban fabrics that have extraneous typologies (out of scale and that have blind facades)	Increase the cubic capacity by adding volumes and surfaces through the transfer of air rights.	Private owners Investors	Increase of surfaces and volumes	Air Rights 	• Occupy all or part of the outline of the lowest lot with structures that are catalysts of good urban qualities. • adding maximum volume between buildings (private spaces); • added as a percentage of the maximum volume (private spaces); • addition of volume to connect two buildings (collective spaces); • addition of the maximum volume for more than one building (collective spaces).

Figure 5. Synoptic Matrix. Author, 2023.

(C) In the presence of marginal fabric conditions close to topographic or man-made edges, it is permissible to recover volume through: increasing surface areas and volumes accessible by walkways or paths; and the temporary occupation of private open spaces (courtyards or patios, where present) by the public administration to create public spaces or gardens. The promoters are private owners or investors, with participation from the public administration. The benefits include increased surface areas and volumes through the use of parasitic architecture devices. The limitations of these interventions concern the public's occupation of private land under concession; overhangs must respect a maximum protrusion comparable to balcony additions on street-facing façades; and parasitic structures must occupy no more than 20% of the façade they are built on.

(D) In compact urban fabrics with building types arranged in a row (terraced), it is permitted to increase building capacity in terms of surface area and volume through additive processes while preserving the characteristics of the original typology. Elevation of buildings is allowed through a dynamic index regulated by the height of the tallest adjacent building. The promoters are private owners and/or investors, with benefits including concessions for increasing volume and surface area and preserving local identity. The device for these morphologies is dynamic growth, with building elevation based on a dynamic index (h = height of adjacent building +1), up to the traditional standard height of five stories. Façade volume addition is allowed with a maximum overhang of one meter, and coverage of the existing façade must not exceed 20%. Additions are not permitted on the ground floor. Roof operations are allowed through partial or total compensatory silhouettes, with the usage remaining residential.

This framework, applied to all generalized areas based on morphological-typological patterns, establishes relationships between spaces, entities, and intervention guidelines for Rimini's historic centre. Flexibility in interventions is maintained by allowing variations within these established systems. Typological-morphological analysis enables the identification of components and configurations, defining potential adjustments within Rimini's historic centre's established structure.

A historic centre urban model

Future research directions may also be mentioned. The selection of analysis samples began with identifying Rimini's urban forms, chosen for their intrinsic potential to support new dynamics. Reflecting on the analysis, two main perspectives emerge: morphological analysis and devices. First, Rimini's historic centre was found to be predominantly compact, with much of it organized in closed blocks. However, this does not suggest a uniform interpretation; rather, the historic centre consists of distinct spatial configurations and morpho-typological subcategories. Each cluster represents a unique expression of compact fabric, with at least three of the five samples (A, B, C) presenting unique block aggregations that transcend mere block categorization. This indicates that urban fabric analysis involves both general classifications (such as compact urban fabric) and local variations (deformations or replacements), each contributing uniquely to the relationships between urban entities at different scales.

Secondly, categorizing urban fabrics into clusters facilitated the development of devices with varied impacts on urban design. These devices can be classified according to their transformative influence, stemming from the identity recognition of specific locales. For example, the convergence of cardus and decumanus—the city's traditional main streets—marks a prime location for significant power and representational structures, where deeply ingrained morpho-typological and architectural traits define the central core of the historic area. This differentiation suggests two regeneration tempos: a slower, more concentrated rhythm within the historic core and a swifter, more dynamic one for outer areas.

This methodology offers promising generalizability. The matrix produced for Rimini—summarizing morphological transitions, formal criteria, dimensional standards, and transformation devices derived from local morphology—could be adapted to other historic contexts. The primary advantage is that each recommendation is tailored to the site, enhancing and preserving local identity. Broadly speaking, this approach suits any established urban fabric, relying on an existing built environment with a coherent visual identity to inform form-based analysis. Thus, this methodology could guide transformations of both prominent city areas, like historic cores, and more ordinary or peripheral zones, acknowledging their distinct urban roles.

Future research should focus on interdisciplinary integration, bridging urban design with public law and parametric design (Oxman, 2017). Public law could inform regulatory frameworks that support dynamic, morphology-based urban codes, while parametric design could provide digital tools to model the multiple morphological outcomes under dynamic growth regulations. Additionally, tools like Space Syntax (Hillier, 1996) could complement this work by addressing spatial issues central to land-use strategy, such as promoting economic growth, revitalizing core areas, enhancing social sustainability, and improving cycling and pedestrian access. With its data-driven approach to accessibility and walkability, Space Syntax could test and validate strategic urban interventions.

While urban codes encompass more than physical form, also addressing land use and planning, they can foster diversity by balancing aesthetic goals and mediating individual and collective interests. Urban codes, far from merely preserving the status quo, offer alternatives to conventional planning perspectives, incorporating input from planners and other stakeholders. In conclusion, this generative approach to the urban environment can shape a proactive, dynamic urban form that evolves alongside the community's needs.

Grande ABC regional masterplan: rediscussing intermunicipal urban morphology through natural aspects

Bruno dos Santos Andrade[1], Eunice Helena Sguizzardi Abascal[2]

ABSTRACT

Urban form studies start from delimitations based on political limits that range from macro to microscale, revealing configurations of the formation and development of the cities. However, in the context of metropolitanization of cities, local configurations are dependent on regional configurations. In Brazil, there is a provision in law for joint governance: Intermunicipal Consortia. It is an instrument for shared management of conurbated municipalities within metropolitan regions. To analyze the possibility of applying intermunicipal governance through this instrument, it is necessary to consider the federalism of the Brazilian State, which establishes the powers of each entity in the country. Consortia are provided in Brazilian law Federal Constitution of 1988 and gained more objective contours with the Law of Consortia (Law Nº. 11.107/2005) and the Statute of the Metropolis (Law Nº. 13.089/2015). Within the Brazilian experiences of intermunicipal associations, the one that stands out most is the Consórcio Intermunicipal Grande ABC. This Consortium developed, in partnership with the Federal University of ABC (UFABC), in 2016, a Regional Masterplan with perspectives for the joint development of the seven cities that make up the sub-region called “Grande ABC”, a sub-region part of the Region Metropolitan of São Paulo. This Regional Masterplan was pioneer at the national level and is relevant for covering the economic, urban and environmental aspects with a multidimensional perspective. From the spatialization of plans and data through georeferenced bases processed in GIS (global information system) software, it is possible to verify that the influence of urban planning goes beyond municipal logic, enabling a morphological analysis based not only on its political-administrative limit. Thus, natural and urban aspects become the real delimiters of regional morphology. Finally, we conclude that there are possibilities for advances in local and regional development when territories are understood jointly, even if considering local municipal characteristics.

Keywords: intermunicipal consortia, regional masterplan, urban morphology, local development, environmental aspects

INTRODUCTION

Studies in the field of urban morphology initially require a necessary definition of its scope. The analysis seeks to encompass streets, blocks, and urban infrastructure that make up a municipal-scale analysis, as well as to investigate and understand the relationship of this scale with the local level: buildings, their patterns, and their relationships with the city and where they are situated. Borges

(2020) points out that, although the etymology of the term naming this disciplinary field dates back to the late 18th century, it is evident that urban form has been more widely studied and disseminated in the last three decades. The author also notes that there are few studies that use São Paulo as an object of analysis, with an emphasis on urban morphology.

In this context of constructing the scope of the disciplinary field, the contribution of articles and papers presented at academic events such as the International Seminar on Urban Form (ISUF) is of great value. In a paper presented at ISUF, Moudon (1997) establishes the basic principles that urban morphology analysis encompasses, among them being the recognition of scales of analysis. The author identifies four scalar levels: buildings, streets, cities, and regions. In the context of São Paulo, these scales are important for the scope of this article because, in addition to the micro-scale represented by its buildings and neighborhoods, its processes of conurbation make the city of São Paulo one of the largest metropolises in the world. Neighboring it are 38 municipalities, constituting what is called the Metropolitan Region of São Paulo (RMSP). Within the limits of the RMSP, this article focuses on the group of municipalities known as "Grande ABC," composed of a cluster of seven municipalities that share a common genesis and have become so conurbated due to accelerated development that it is difficult to interpret the boundaries of this group. Despite this recognition of Grande ABC as a grouped entity, considering the Brazilian administrative structure, these municipalities do not constitute a region per se if the concept of region is understood through the criteria for establishing metropolitan regions.

The creation of metropolitan regions is governed by the Metropolis Statute (Law No. 13,089/2015); however, the formulation criteria remain ambiguous. As Barreto (2012) points out, the first nine RMs created in the 1970s had populations exceeding two million inhabitants and were centered around a state capital, a criterion that ceased to exist after the promulgation of the Federal Constitution (CF) of 1988. With the CF, municipalities gained greater management power, and state governments were given the responsibility of creating new RMs, leading to a weakening of the criteria for their establishment. Bringing this discussion to the context of Grande ABC, considering its population and the integration between municipalities, it is understood that it would be possible to delineate it as an RM, with Santo André and São Bernardo do Campo as its centers. However, because they are within the influence of São Paulo, the ABC was incorporated into the RMSP, which, due to its magnitude and extensive size, is divided into five sub-regions, one of which is Grande ABC (RMSP's southeastern sub-region). This division of sub-regions is understandable if the concept of a region is understood through the concepts of "geographic region," "natural region," and "homogeneous region," as discussed by Cunha (2000) to explain that a regional cluster can be constituted for various justifiable reasons. It should be noted that the definition of the scope and coverage of a region resides in a more complex realm than mere administrative delineation.

In Brazil, the responsibility for managing and liaising at the regional planning scale lies with state governments. They have autonomy in the management and allocation of resources for regions, following the compositions provided for in Brazilian law, such as metropolitan regions (RMs), urban agglomerations (AUs), and integrated development regions (Rides). Thus, applying the principle defined by Moudon (ibid.), it is understood that the constitution and characterization of regions are objects of study for urban morphology, although it is possible to visualize an impasse between the formal administrative characterization of regions in Brazil and the intense conurbation shared by municipalities within the metropolis, which more closely resemble the concepts of a geographic region

and a homogeneous region. Therefore, it is possible, morphologically, to extract elements and clues that justify the transformations that have occurred in municipalities over the past century. With a particular focus on Grande ABC, the joint development of its cities finds answers and justifications in its formation processes, which corroborates the principle defended by Moudon that urban morphology can only be understood historically, given that urban organisms are in constant mutation. Recognizing the similarities between the municipalities and understanding that their challenges and problems are shared, the city halls of the seven cities undertook the founding of an associative body for the formulation and implementation of policies, actions, and programs aimed at integrated development. This is the Intermunicipal Consortium of Grande ABC, founded and managed in a democratic and equitable manner, aiming at joint action to achieve the established goals. Throughout its operation, notable examples of actions that have brought about territorial transformations in fields such as health, education, and public management, among others, have been recorded.

As mentioned, the Consortium has a constitutionally democratic and equitable management system, so its leadership is exercised through a rotating system among the current mayors of the municipalities. Although only one of the seven mayors serves as president, the other six comprise the executive board, collectively discussing the actions to be allocated to the territories. Due to its participatory association origins, the Consortium has historically also given voice to social participation, culminating in the drafting of multi-year plans with the assistance of civil society through participation in public hearings, generating important documents of guidelines and perspectives for action. In 2016, the Consortium drafted and launched, in partnership with the Federal University of ABC (UFABC), the ABC Regional Master Plan (PDR). This is a document with specialized readings of the territory, identifying the region's characteristics and deficiencies for the formulation of new projects and policies for its development. This initiative was pioneering at the national level, with no other similar experiences for local comparison, and therefore allows for analysis in the urban field from various perspectives, including that of urban morphology.

To facilitate the discussion of the regional planning scale from the perspective of urban form, this article initially presents a brief review of the existing literature, seeking to delineate the concept of urban morphology, its theoretical scope, and scales of coverage to meet the objectives of the work. Based on the theoretical framework, the characterization of the municipalities of Grande ABC is structured, focusing on the role of the Intermunicipal Consortium as a development driver, also considering the Brazilian legislation that underpins public policies applied at the regional level. From this, through the acquisition of cartographies and data developed by the Regional Master Plan produced by the Consortium, it is intended to analyze its territory in light of the theoretical framework, based on the reading provided by the cartographies, considering the concept of homogeneous regions[38] and their governance. The objective is to understand how the urban form, in the study region of ABC Paulista, is delineated and discussed based on homogeneous, physical, and natural aspects. It is expected to confirm that local and regional urban morphology within the boundaries of Grande ABC are congruent with each other, confirming the hypothesis that neighboring municipalities are not

[38] According to Nóbrega (2015), a homogeneous region consists of a grouping based on similar characteristics, making the components of the homogeneous region distinguishable from other entities outside the region that do not follow the same organizational logic. In the case of cities, morphological elements are the most commonly used for identifying homogeneous characteristics.

merely grouped by the chance of geographic proximity but share common formative traces that justify their current configurations, and therefore, their association.

THEORETICAL FRAMEWORK

The applicability of the term morphology to the urban domain has been shaped over decades through the work of various authors, such as Muratori (1959), Conzen (2004), and Moudon (1997). As a general idea, the use of the terms urban morphology or urban form has become standard to designate the object of this field of knowledge, which focuses on the study of cities, their street layouts and subdivisions, their buildings, and open spaces. Thus, it is possible to simultaneously encompass, through a morphological analysis, the micro-scale—represented by buildings and their typological patterns—and the macro-scale, represented by the city as a whole, its subdivisions and occupancy, as well as the inclusion of these elements within the natural landscape that contains them (Costa and Gimmler Netto, 2015). In this way, urban form describes not only what cities are but also their identities. When investigating the historical processes of foundation and development of municipalities, it is possible to see the decisive role of utilizing physical and natural aspects as boundaries for administrative and political delimitations. In this context, one can observe the importance of the morphological aspect in the field of history and urban morphology for the shaping of a city. But what about metropolises and metropolitan regions? How are they formed? In this scenario of conurbation between municipalities in the metropolis, do urban forms still distinguish themselves and persist despite the mutation of cities? To seek clues to these questions, it is important to analyze Brazilian regionalism and the historical foundation of municipalities.

Focusing on the regionalist context, regarding the Brazilian administrative structure, it is evident that the primary form of articulation of a regional territory is the metropolitan regions. These are municipal associations formed by neighboring cities that are generally conurbated, starting from core municipalities. The first metropolitan regions (RMs) in Brazil were established in 1973, and the concept quickly spread and intensified, as there were initially only nine, and currently, there are 84[39] (Blanco Junior, 2021). Researchers such as Klink (2013) criticize the organizational structure and management model of these arrangements, classifying them as “ungovernable.” Although they are officially recognized by the Brazilian state and have regulations for their establishment and maintenance, the RMs still require better delineation of their planning and operational possibilities, so that the objectives of joint development and regional integration can be achieved by all participating entities. Furthermore, Klink (ibid.) points out that other forms of metropolitan association could achieve better results in intermunicipal management. An example is the Consórcio Intermunicipal Grande ABC. This Consortium, established in 1990, aims to formulate, implement, and promote plans, projects, and actions in various fields such as economy, environmental management, economic development, mobility, among others, enabling the development of a group of seven neighboring municipalities located within the São Paulo Metropolitan Region (RMSP), collectively known as “Grande ABC” or “ABC Paulista” (Consórcio Intermunicipal Grande ABC, 2024a).

The seven constituent municipalities of ABC Paulista are Santo André, São Bernardo do Campo, São Caetano do Sul, Diadema, Mauá, Ribeirão Pires, and Rio Grande da Serra. Together, they form the

[39] Currently, Brazil has 76 metropolitan regions, five urban agglomerations, and three integrated development regions, totaling 84 regional planning units institutionalized based on Brazilian law (Blanco Junior, ibid.).

southeastern region of the RMSP, concentrating over 10% of the population residing in this RM. United, the seven cities total nearly three million inhabitants and a Gross Domestic Product (GDP) that would be the fifth largest in Brazil if they were a single city (Consórcio Intermunicipal Grande ABC, 2024b). Seeking justifications that explain the joint interpretation of these municipalities, the main hypothesis lies in the formation processes of each city. Originally, the town of Santo André da Borda do Campo was founded in 1553, located near the top of the Serra do Mar. This town was later incorporated into the town of São Paulo de Piratininga and ceased to exist. Three centuries later, with the establishment of the São Paulo Railway, the intense flow of people and goods gave rise to a series of settlements near the railway stops, leading to the re-emergence of Santo André near the end of the 19th century (Prefeitura de Santo André, 2024). After changes in the municipality's name, the two largest municipalities in the region, Santo André and São Bernardo do Campo, consolidated between the 19th and 20th centuries, giving rise to the other five municipalities through a series of political emancipations and territorial divisions. In 1964, the city of Rio Grande da Serra was founded after its emancipation from Ribeirão Pires, being the most recent of the seven municipalities. With the intense industrial activity installed in the region, processes of accelerated development began, making ABC the largest industrial hub in Latin America (Yamauchi and Tourinho, 2021).

This common initial root for all the municipalities of ABC dates back to the period of the “boom” of Brazilian urbanization during the 20th century, which Milton Santos (1996) describes as a “generalized” urbanization, with Brazil later entering a stage of macro-urbanization and metropolization. Despite this, the author points out that, during this period, the process of generating new cities was greater than the process of urbanization itself. It is also worth noting that, from the 1940s onwards, the country experienced a significant increase in industrial activity, which Santos (ibid.) understands as a complex social process, as, besides the actual creation of industries, a national market was also being formed, consumption was expanding, and the country was integrating. All this greatly expanded urbanization, increasing the urban population throughout Brazil. Grande ABC became a major industrial hub, especially as it received a large part of the automotive industry that began to settle in the country. Although the automotive industries were mainly established along the Anchieta Highway in the municipality of São Bernardo do Campo, they contributed to the overall development of the region by occupying the other municipalities with industry workers, as well as the development of other industrial, commercial, and service activities that followed the booming industrial activity of that period. It was possible to find traces of the intrinsic subsistence relationship between the municipalities of ABC.

The scenario of economic instability experienced in the post-military dictatorship period in Brazil culminated in significant impacts on the territory. The shifts in economic policy, combined with currency changes, exchange rate fluctuations, uncontrolled inflation, and the fiscal war between municipalities paved the way for a process of industrial deconcentration, with Grande ABC being greatly affected. Many industries left the region and moved to other localities where there was a greater availability of tax incentives (Santos and Silveira, 2003). Thus, there was a gradual decline in the industrial sector's participation in the region's economy and a significant increase in the services sector's participation. Parallel to this movement, the Consórcio Intermunicipal Grande ABC was being created in the 1990s. Initially conceived as a committee for discussing pollution control policies and promoting the protection of the Billings Reservoir, the association soon took the form of a multisectoral consortium, encompassing, among its various fronts, the challenge of the region’s

economic and productive restructuring. Here, there is a progressive vision of the role of urbanism and associative governance as a driver of development, recognizing that the entities are interdependent and that actions in one territory have almost simultaneous consequences in another.

According to Moudon (ibid.), the historical genesis of an urban fabric is a fundamental element for understanding its urban morphology. Given this, it is consistent to read the different territories of ABC as an integrated association, considering that their joint action was desired even before the formation of the consortium entity for their management (Klink, 2009). Considering the entire territory, we have a rich variety of situations and thematic elements that constitute it. Among the natural elements, we can mention the environmental protection areas bordering the Serra do Mar, the presence of the Billings Reservoir, and the large ecological parks on its shores. Among the infrastructural elements, there is the railway connecting the municipalities to the city of São Paulo, in addition to the major highways such as Anchieta and Imigrantes, which provide access to the São Paulo coast (Consórcio Intermunicipal Grande ABC, 2024b). Between the natural elements and the constructed infrastructures, the presence of induced urbanity is observed in all seven municipalities in the region, with commercial, leisure, service, residential activities, and all other aspects necessary for the primary condition of a city being evident, even though economic disparities are present when comparing the municipalities. Fix and Pereira (2013) assert that there is a contemporary consensus that the municipal scale is not the most appropriate for most public policies, recognizing that urban problems do not occur and are not resolved solely within the municipalities themselves. This argument supports the logic of interdependence among the cities that make up ABC Paulista, regarding environmental preservation and the need for joint action to achieve the objectives of the associated action among them.

METHOD

The methodological procedures adopted are based on the consolidation of the concepts of urban morphology and region. The foundation of the scope of urban form is established through a brief review of the existing literature, identifying authors who have contributed to the delineation of the objectives and actions of this field of knowledge. Parallel to the conceptualization of morphology, an effort was made to identify, distinguish, and understand different notions of what constitutes a region. In this topic, concepts applied in the field of geography were used, seeking a multiscalar approach to regionalism present in Brazil and identifying the concept most appropriate to the hypotheses that justify the association of the Grande ABC municipalities in the form of a consortium.

Based on the consolidation of the state of the art on urban morphology and regionalism, the Regional Master Plan of Grande ABC (PDR) was examined, seeking data and cartographies that would allow for a spatial analysis of plans applied to the territory. Through these cartographies, the aim was to verify the application of instruments in an integrated manner, beyond the political-administrative boundaries of the municipalities. Furthermore, these cartographies sought to position the main physical delimiters and natural aspects of this region, understanding them as structuring elements of the regional urban form. With these surveys, the intention was to cross-reference the consulted literature with the cartographic practice produced by the Consortium to discuss the hypotheses outlined as the basis of this article.

RESULTS AND DISCUSSIONS

As mentioned, the Grande ABC is part of the São Paulo Metropolitan Region, forming the southeastern sub-region of the RMSP. As shown in figure 1, the grouping proposed for these sub-regions follows an administrative and geographical logic, although in the case of Grande ABC, this logic also aligns with the historical processes of technical-political genesis of the municipalities that comprise it.

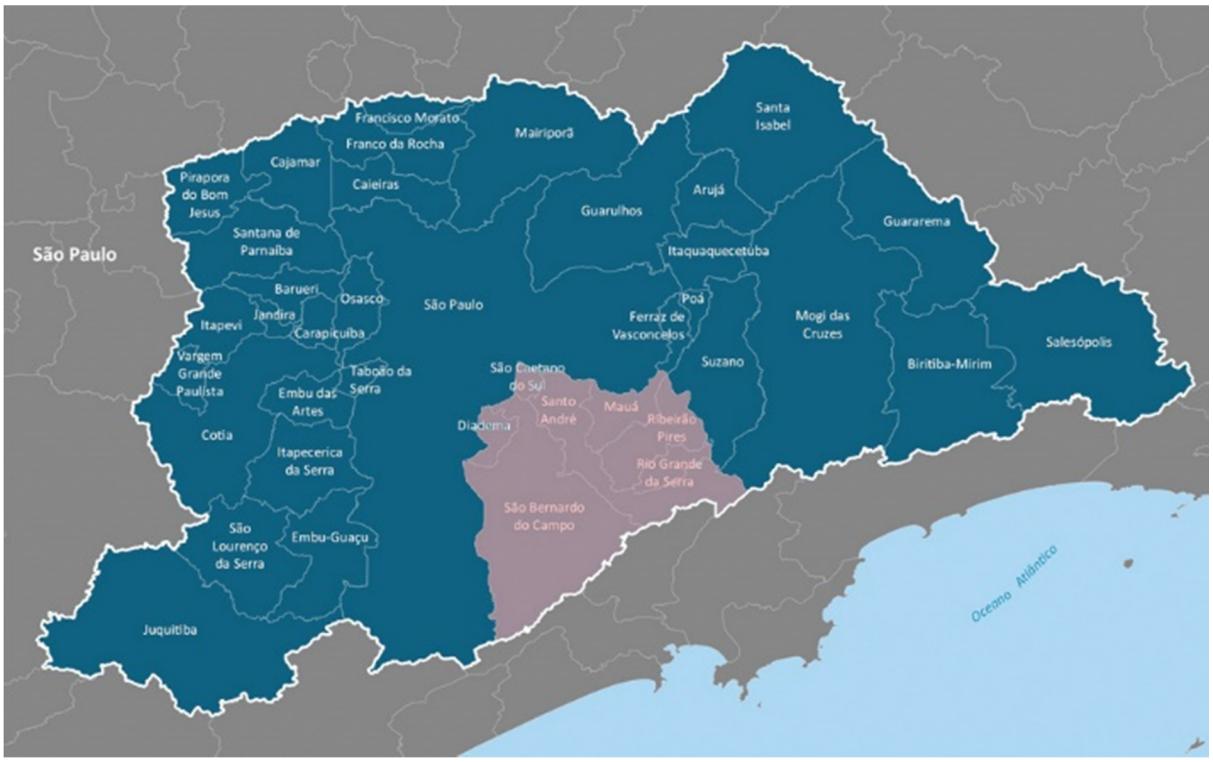

Figure 1. Map of the Metropolitan Region of São Paulo with emphasis on the southeastern sub-region (Grande ABC). Source: modified by the authors based on FNEM, 2018.

The map shows the privileged location of the region, situated between the city of São Paulo and the Serra do Mar, forming an important route linking the major metropolis to the sea. This location was chosen for the establishment of the Village of Santo André da Borda do Campo in the 16th century precisely because of its strategic position, which allowed for the protection of the territory by the natural barrier imposed by the Serra do Mar (Prefeitura de Santo André, ibid.). Three centuries later, when the municipality was reestablished, its geographical position again played a decisive role, as it was chosen as the route for the São Paulo Railway due to its position on the axis formed by the municipalities of Jundiaí and São Paulo, leading towards the Baixada Santista. This path established a faster route between São Paulo and the Port of Santos, facilitating the flow of coffee production destined for export (Mazzoco and Santos, 2005).

Through these historical factors, it is evident that, beyond the use of natural aspects as a foundation for economic development, the entire region was shaped according to the homogeneous characteristics of the morphology of its municipalities. The seven municipalities, formed from the division and emancipation of a single initial entity, have distinct political-administrative boundaries. In urban areas, the boundaries are based on avenues and other transportation infrastructure, while in undeveloped green areas, there is not always an easily identifiable pattern explaining the boundary lines. As illustrated by figure 2, which shows the Billings Reservoir basin in the target region, the political-administrative boundaries do not align with the natural green and blue web of the region,

such as the Alto Tietê watershed, remnants of the Atlantic Forest reserve, Billings Reservoir, and water source protection areas, in addition to ecological parks and proximity to other natural assets such as the Guarapiranga Reservoir and the Serra do Mar (Plano de ação de enfrentamento às mudanças climáticas do Grande ABC, 2017).

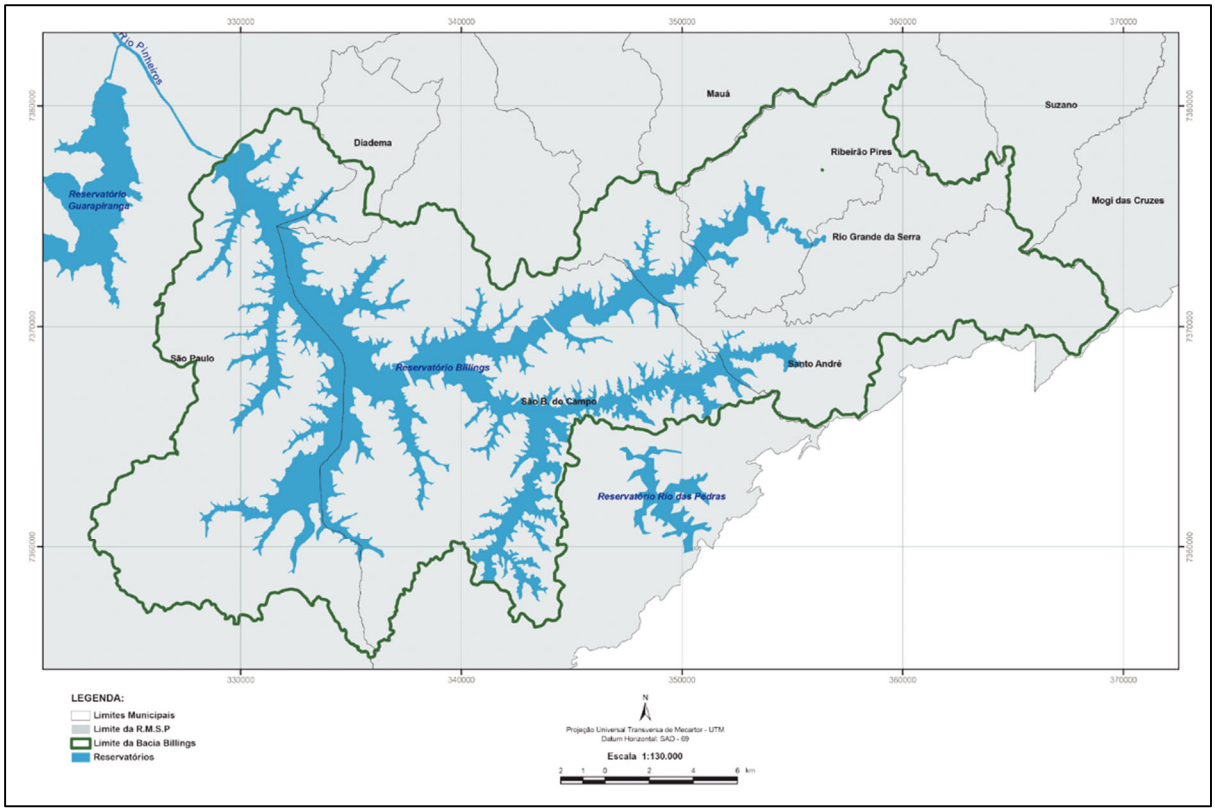

Figure 2. Map of the Billings Basin within the Grande ABC. Source: Plano de ação de enfrentamento às mudanças climáticas do Grande ABC, ibid..

This morphological pattern, based on the understanding of natural aspects, is the subject of study in the Regional Master Plan produced by the Grande ABC Intermunicipal Consortium (Plano Diretor Regional do ABC, 2016). Of the three initial guidelines in the document, two align with environmental factors as key premises for development: the formation of a compact city-region and sustainability with environmental justice (Plano Diretor Regional do ABC, ibid.). Initially focusing on the concept of a city-region, Magalhães (2008) defines it as "the urban form of the metropolization process." The metropolization process in the region is evident through the expansion of the urban area, with visible conurbation among the municipalities, not only within the ABC region but also with other municipalities in the Metropolitan Region of São Paulo (RMSP), as shown in figure 3. The figure highlights that, in addition to the ABC municipalities, several other RMSP municipalities, such as Guarulhos, Osasco, and Itaquaquecetuba, merge with the city of São Paulo at various borders. This conurbation phenomenon allows the Grande ABC cities to be assimilated as a single entity in the form of a region.

Figure 3. Urban areas of the municipalities merge in such a way that it becomes difficult to identify their administrative boundaries. Source: created by the authors based on Google Earth, 2024.

Regarding the second PDR guideline on environmental justice, its motivation is understood, given that approximately 41% of the region is covered by forests and other vegetation, thus requiring specific preservation plans (Russo, 2010). As mentioned, crossing the political-administrative boundaries of the cities toward the natural axes of the region (Billings Reservoir, ecological parks, and the top of the Serra do Mar), it is evident that these boundaries do not necessarily delimit the municipalities administratively. However, in the PDR, they are understood as major foundations for sustainable development plans for the region. As shown in figure 4, which illustrates the actions proposed by the PDR to integrate infrastructure programs throughout the region, it is clear that environmental preservation and containment of urban expansion into protected areas are integral parts of the intended urban form for the cities within the context of integrated development.

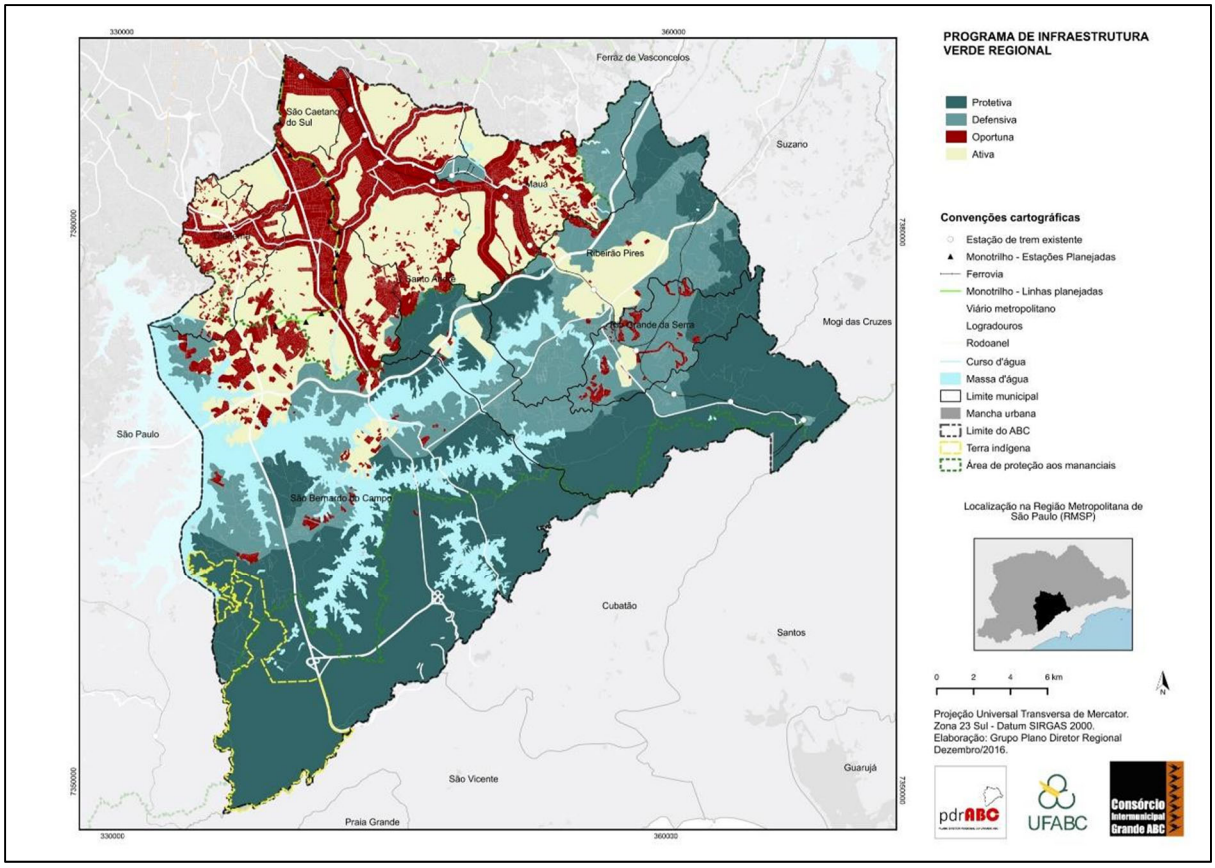

Figure 4. Map of the implementation of green infrastructure programs proposed by the PDR. Source: Plano Diretor Regional do ABC, ibid..

As also evident in figure 4, the PDR offers a comprehensive view of the territory regarding green infrastructure strategies, even in fully urbanized areas. Figure 5 shows that the regional urban area is concentrated in the northern sector of the ABC, with the municipalities of Diadema and São Caetano do Sul fully encompassed within the urbanized area, and the municipalities of Mauá, Santo André, and São Bernardo do Campo being densely populated. It is possible to observe intense conurbation up to the edge of the Billings Reservoir to the south, which, despite being an environmental protection area, has occupations along its margins, revealing another significant challenge faced by regional urban planning regarding conflicts between urbanization and preservation (Alvim, Rubio, and Marques, 2023). Figure 5 also reveals the PDR's understanding of the need for regional integration, even though major transportation axes may conflict with the layout of green infrastructure such as the reservoir and natural green reserves in ecological parks and water source areas. As a guideline, the PDR adopted a maximum distance of 2 km between the urban area and a transportation axis, equivalent to a walking distance of less than 30 minutes, recognizing the importance of mobility access and its structuring role in the territory, as it allows for the dispersion of social infrastructure across the territory and also enables balanced development among locations. The PDR also acknowledges that a grid transportation system better aligns with the regional characteristics, as it facilitates integration and movement between the region's municipalities, not just outward from the region, as predominantly established in the study area with a radial system primarily planned for the transportation of goods. Although the structural proposals outlined by the PDR align with contemporary urban planning best practices by promoting mass public transportation as a structuring element for cities, less than 10 years after its launch, a review of this proposal is already necessary, considering that the planned monorail, which is included in the map below, was canceled by the state government, highlighting once again the political challenges faced by regional planning as an obstacle.

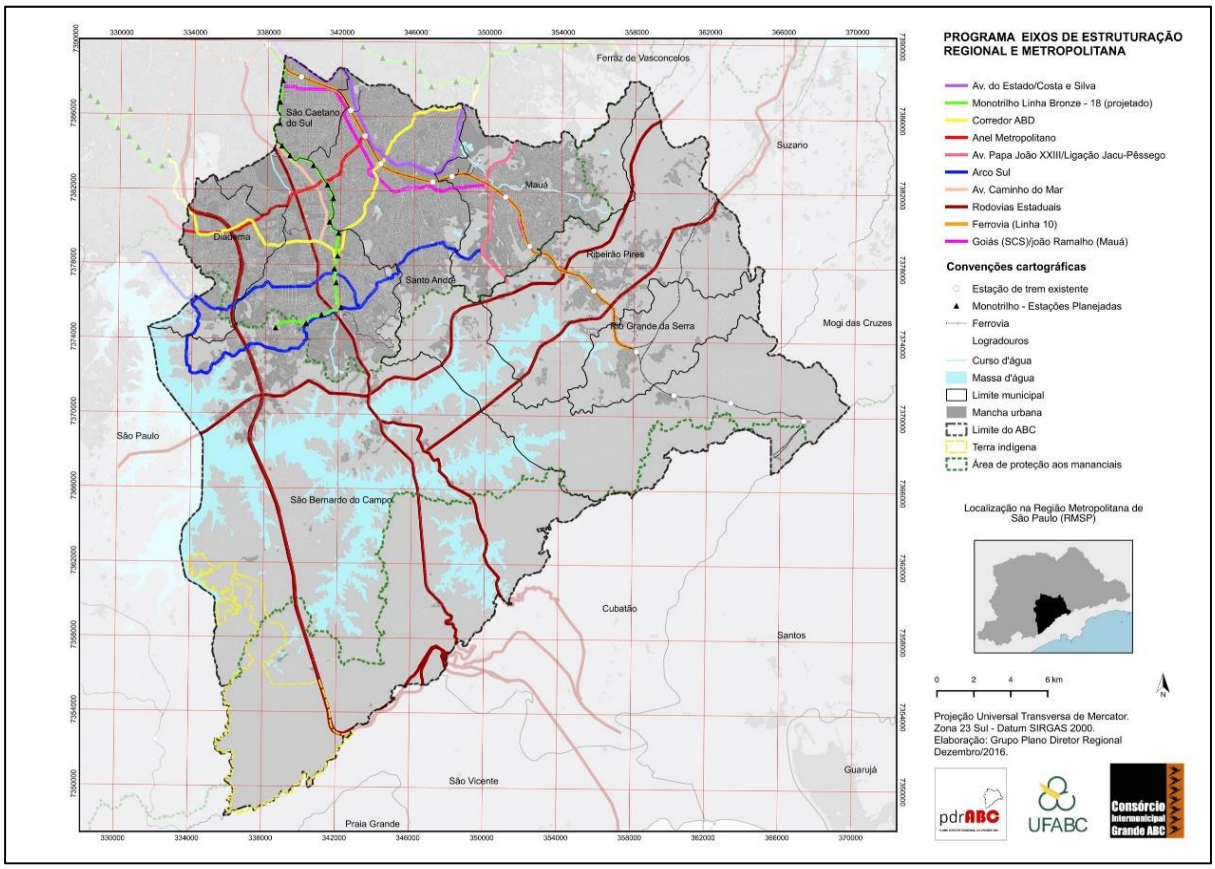

Figure 5. Map of regional and metropolitan structuring axes in the Grande ABC region. Source: Plano Diretor Regional do ABC, ibid..

The central areas of the municipalities of Santo André, São Bernardo do Campo, São Caetano do Sul, Diadema, and Mauá are primarily encompassed within the macrozone of urbanization consolidation, as shown in figure 6. These areas are fully urbanized but still have potential for improving housing density and increasing the supply of social interest housing, aiming to bring economically vulnerable populations closer to areas with higher concentrations of employment and income. Practically delimiting the areas of urbanization consolidation, the metropolitan structuring macrozone is arranged around major transportation axes, representing an attempt to develop the areas through denser occupation near mobility infrastructure, generating concurrent social and economic development. As these axes connect the region to its different sectors, they pass through sections with physical natural elements such as vegetation areas and reservoirs. As seen in figure 6, the reservoir practically divides the region in two, clearly showing that the plans for the area above the reservoir are primarily focused on structuring, while the primary objective for the area below is environmental preservation. Although this approach may seem obvious, considering that urban concentration is closer to São Paulo while environmental concentration is closer to the Serra do Mar, the practical application of this guideline in the territory is of great importance to contain the expansion and density in precarious areas, which pose joint social and environmental risks. In the region, precarious occupations can be observed in areas represented on the map by the macrozone of vulnerability reduction and environmental recovery, constituting an impasse that highlights the urgent need to design interventions that minimize environmental damage while respecting the population's right to housing (Alvim, Rubio, and Marques, ibid.).

CONCLUSIONS

The intersection of the theoretical literature in the field of urban morphology with the ABC Regional Master Plan facilitated the reflection on the role of urban form as a theoretical field in the practical application of its precepts in the regional territory. In the study area, there is a clear common genesis of the municipalities, and therefore their current forms reflect homogeneous characteristics that justify their reading as a grouped entity, even though the levels of development and urbanization vary among municipalities. Although they are municipalities with their own administrative structures, as neighboring and conurbated entities, there are interdependencies among them that become evident when studying the individual characteristics of each one. Additionally, there is an understanding of the associative contribution as a means of obtaining resources from higher planning bodies and an understanding of the interdependent relationships between each municipality regarding management, resource use, environmental preservation, and the implementation of plans in the territories.

Overall, the understanding of the grouped entity as a region in the homogeneous sense of the word corresponds to the urban planning proposed by the PDR. However, being an urban policy, it encounters resistance in its formulation and even greater obstacles in its effective implementation in the territory. As mentioned, even though it has been less than 10 years since its promulgation, parts of the PDR study can already be considered obsolete, especially in the field of mobility, where projects have been revised, discontinued, and even extinguished, making way for other plans that do not necessarily follow the same design logic. The obstacles in the process create opportunities for future studies, seeking project practices that are adaptable to political instability and the passage of time in

the metropolis, considering short, medium, and long-term scenarios that may affect implementation conditions, in addition to the search for interventions that can be implemented in full or in parts without compromising the proposed objective.

It is also concluded that the apprehension of regions through the morphological pattern of local scales enables the understanding of territories, allowing the understanding of current processes based on historical formation processes. Although development is necessary and desired, there is a global movement to adapt cities to climate change and perspectives on the necessary transformations of cities to achieve a sustainable future. In this context, urban morphology as a field of knowledge enables the identification of territorial characteristics, making urban projects more effective when aligned with sustainable practices suitable to local realities.

ABSTRACT

The text addresses the issue of historical and morphological inventory of neighbourhoods in São Paulo city, since the municipality is made up of a diverse set of urban fragments that reflect the specificities of different times of foundation of its subdivisions and territorial diversity identified in its vast territory. The problem identified is that São Paulo historiography still presents significant gaps that must be filled by studies to complement its historical collection. Therefore, the objective is to contribute to partially filling this gap by presenting the history of Sete Praias neighbourhood, located on Billings Reservoir banks, in the south zone of São Paulo. The choice is because it is a garden neighbourhood according to the classification of the Municipal Planning Department, which carried out research between 1984 and 1985 and grouped 31 subdivisions into 22 sets of garden neighbourhoods in the city. The research methodology is historiographical, and the results of the investigation demonstrate the urgency of discussing the diversity of forms of occupation of the city's watershed area, which is recognized as a peripheral region marked by its contrasts between social and economic vulnerabilities and cultural and environmental strength. The morphological and environmental qualities of Sete Praias neighbourhood date back to its origins in the mid-20th century and have been preserved for more than a century, constituting an important setting for the tradition of garden neighbourhoods.

Keywords: urban morphology, garden neighbourhood, São Paulo historiography

INTRODUCTION

Between 1984 and 1985, a team of professionals from the Municipal Planning Department of the City of São Paulo conducted a comprehensive study called “Registration of Significant Wooded Areas in the Municipality of São Paulo – 1984-85” with the aim of surveying, mapping and identifying significant tree groups and specimens in the municipality. Given the impressive results achieved, years later the Environmental Department of the State of São Paulo edited and published this work in the book “Significant Vegetation in the Municipality of São Paulo” in 1988, as an incentive to protect the environment and to encourage the proposal of legislation related to the permanent preservation of plant species.

The groups and tree specimens were registered in files grouped into the following categories: reserves and protected areas; state and municipal parks; squares and public spaces; areas of public and/or institutional use; cemeteries; clubs and private recreation areas; schools; garden neighbourhoods; tree-lined neighbourhoods; tree-lined streets; residential gardens; industries; groupings of tree-lined spaces; unoccupied plots in urbanized areas; remaining farms in urbanized areas; areas predominantly occupied by farms and ranches; reforested areas; secondary forests; large secondary forests and isolated specimens.

The publication divided the identified neighbourhoods into two distinct categories: Garden Neighbourhoods and Tree-lined Neighbourhoods. What differentiates the two categories are the formal configurations of the streets, blocks, lots and buildings, since tree-lined neighbourhoods can be made up of horizontal or vertical housing, that is, neighbourhoods with multi-story buildings; the lots can be smaller and the buildings can occupy a large part of the lot area; the residences do not necessarily have trees, and sometimes, they do not even have green areas in their open spaces.

Garden neighbourhoods, as defined by SEMPLA[40], were identified as such because they represent a "set characteristic of a certain era, its way of life or its aspirations for a new style of living" (SEMPLA, 1988, p. 285). The period mentioned refers to the early 20th century, when neighbourhoods intended for the coffee aristocracy turned to hygiene concerns and the first Brazilian garden neighbourhood was built, Jardim América, a project designed by Barry Parker in 1915. The proposal was carried out by Companhia City[41], a company with French and English capital, which imported the subdivision model inspired by the precepts of Ebenezer Howard (Garden Cities of Tomorrow, 1902).

Thus, garden neighbourhoods present a particular configuration that characterizes a predetermined landscape intention, both from the perspective of the whole, composed of the streets and blocks, and from the point of view of the minimum land unit:

> The lots, not always regular between the curvilinear streets of these neighbourhoods, are, as a rule, sufficient to accommodate a house isolated from its limits. This form of occupation, in addition to the usual backyard, implies appreciable setbacks that allow or require gardening. Plants of all types and sizes blend in with the abundant trees of the public road and with the occasional planted square, through low walls and railings, required from the beginning, or high walls, more recent and the result of other care. Although not exclusive in the country and despite so many changes, these gardens have been preserved in such a way that they constitute decisive and characteristic elements of the São Paulo landscape. And they make up, together with many others, more cramped, but more suggestive of certain sectoral landscape preferences, a complex, difficult to evaluate, but extremely rich, sample of home gardening in the last decades in the City of São Paulo (SEMPLA, 1988: 286).

In the category of garden neighbourhoods, the study had identified 31 subdivisions grouped into 22 sets, namely: Horto Florestal, Vila Marieta, Vila Albertina, Tremembé, Alto da Lapa, Alto de Pinheiros, Jardim das Bandeiras, Sumaré, Pacaembu, Jardim São Bento, Morumbi, Jardim América, Jardim Europa, Jardim Paulistano, Vila Nova Conceição, Jardim Novo Mundo, Alto da Boa Vista, Jardim Santo Amaro, Jardim Petrópolis, Jardim Cordeiro, Jardim dos Estados, Brooklin Paulista, Vila Lusitania,

[40] Municipal Planning Secretariat of São Paulo
[41] City of São Paulo Improvements and Freehold Land Co Ltd

Granja Julieta, Chácara Pouso Alegre, Jardim Hípico, Chácara Flora, Vila Nova Caledônia, Interlagos, Sete Praias and the portion close to the University City (Figure 1).

Among these neighbourhoods, some have already been the subject of research and publications, such as: Lapa (Santos, 1969), Jardim América (Bacelli, 1969; Wolff, 1985), Jardim Europa (Reale, 1982), and Higienópolis (Homem, 1980; Macedo, 2012). Other garden neighbourhoods in São Paulo, however, have not yet been covered by historical research, or have been partially investigated under specific aspects, as is the case of Interlagos, analysed in the master's dissertations of Galhardo (2010) and Martins (2012) and in scientific articles (Oliveira et al., 2021); Higienópolis with the doctoral theses of Silvio Soares Macedo (1988) and Denise Antonucci (2005); Chácara Flora (Oliveira and Pronin, 2020).

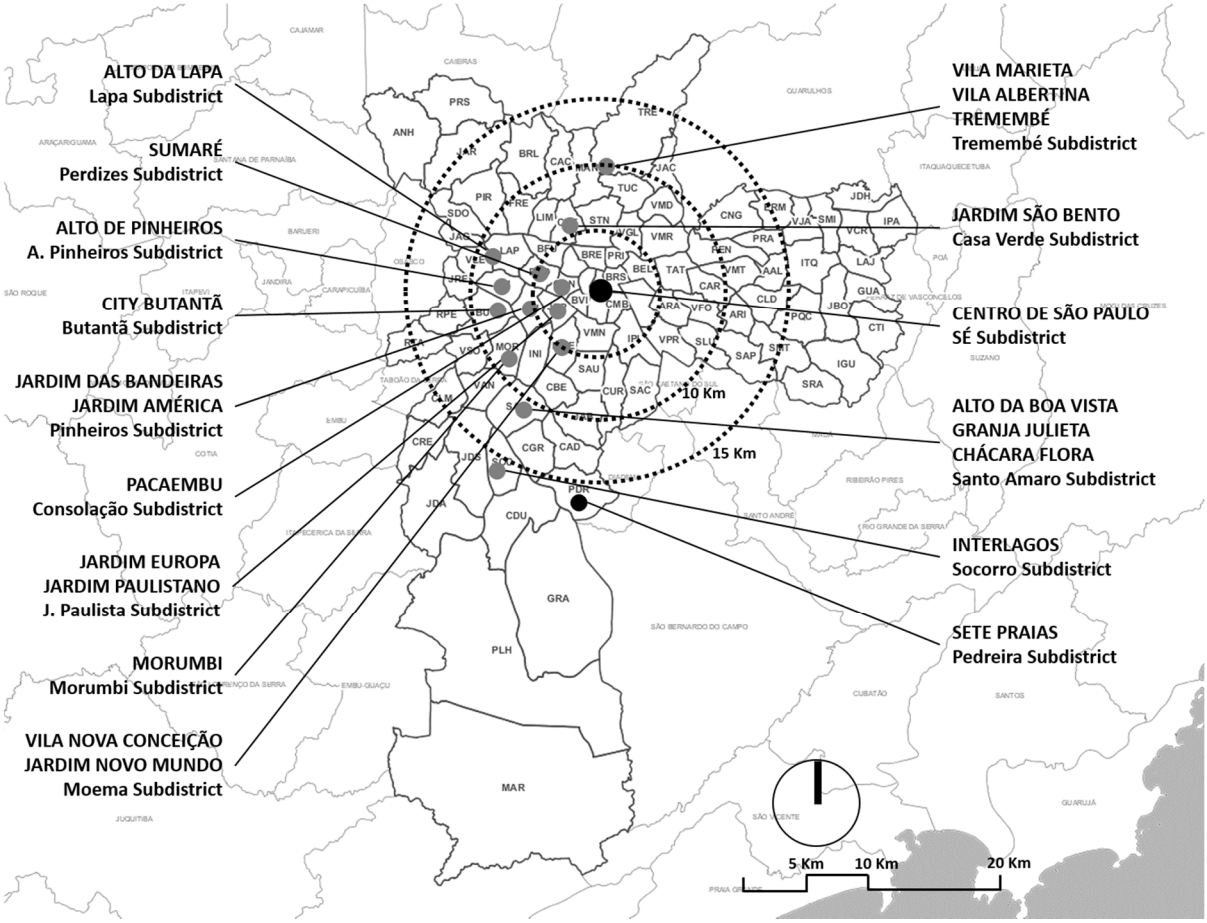

Figure 1. Location map of the 22 sets of garden neighbourhoods identified by SEMPLA in 1988 - Municipality of São Paulo, source: prepared by the authors based on Geosampa, 2024.

Given the scenario presented, the objective is to help fill a gap in the historiography of São Paulo's garden neighbourhoods. Thus, among the 22 garden neighbourhoods classified by SEMPLA, Sete Praias was selected as the object of study. This is the garden neighbourhood located to the south, on the banks of the Billings Reservoir, in the Pedreira district, belonging to the Cidade Ademar Subprefecture (Figure 2). Among the garden neighbourhoods, only two of them are in a water source protection area: Interlagos, located on the east bank of the Guarapiranga Reservoir, and Sete-Praias, which is located on a peninsula in the eastern portion of the Billings Reservoir.

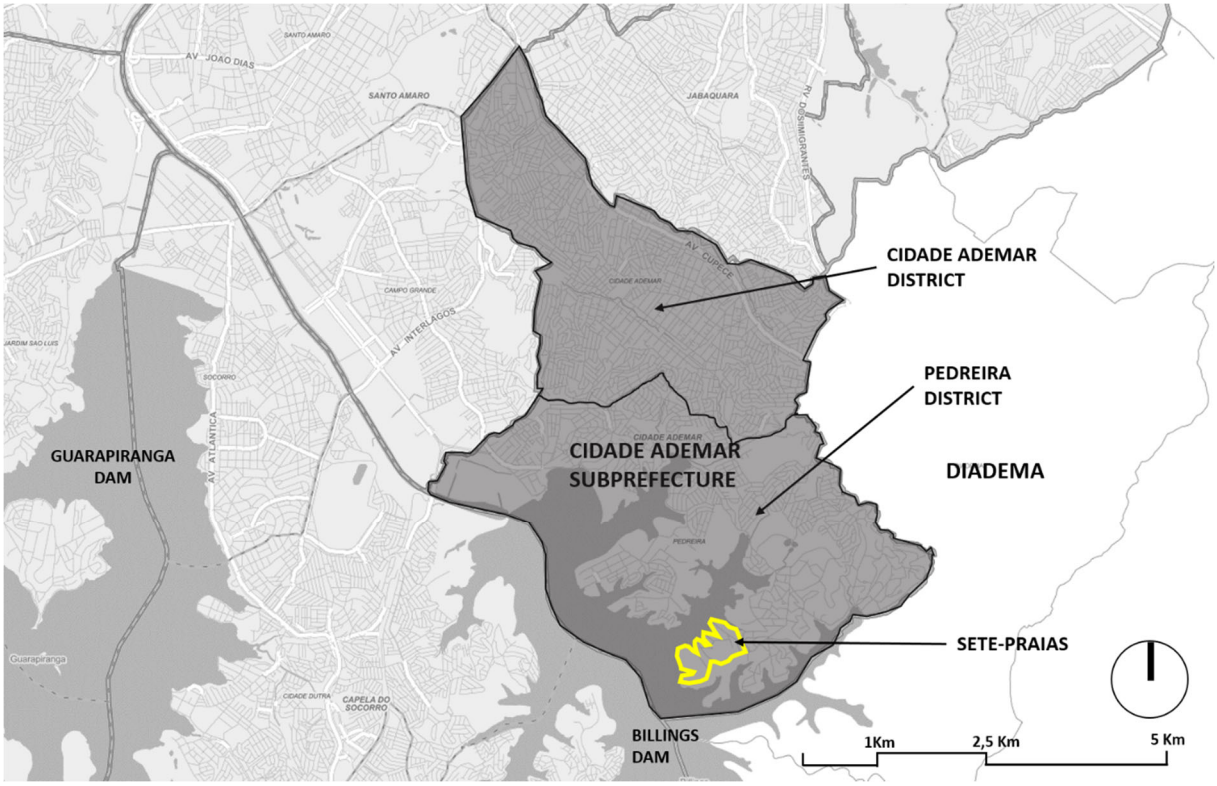

Figure 2. Location map of the Sete-Praias neighbourhood, in the Pedreira district, Cidade Ademar Subprefecture, source: prepared by the authors based on Geosampa, 2024.

Interlagos was a project conceived by the British engineer Louis Romero Sanson, a partner in the company S/A Auto-Estradas, who invited the French architect Alfred Agache (1875-1959) to develop the urban design of a garden neighbourhood. The first conversations between Louis Romero and Agache began in 1928 and 1929, when the Interlagos region still belonged to the former municipality of Santo Amaro, which would be annexed to the municipality of São Paulo in 1935.

However, the implementation of the Interlagos residential subdivision only began in 1937 due to the delay in acquiring the chosen land, at the time called Haras Palmeiras and belonging to Colonel Juliano Martins de Almeida, a businessman and breeder of competition horses (Oliveira et al., 2021).

Unlike Interlagos, the Sete-Praias subdivision was not originally conceived as a garden neighbourhood, nor was it designed by a renowned urban planner of the time. Since it is located on the banks of the Billings Reservoir, it is important to draw a parallel between the history of the subdivision's implementation in relation to the creation of water reservoirs and the forms of occupation of the spring areas in the southern zone of the city of São Paulo.

METHOD

The research methodology is historiographical and uses two approaches that are similar to the English school of urban morphology: the reconstruction of the historical context of the period in which the urban fragment was formed and the analysis of the urban form, considering issues related to its implementation on urban land based on the layout of roads and blocks, the division of lots and the occupation of buildings within the lots.

RESULTS AND DISCUSSIONS

The Sete Praias subdivision is located between the Guacuri and Grota Funda streams, 3 kilometers in a straight line from the Pedreira Pumping Plant, located on the Jurubatuba River, an arm of the Pinheiros River. The "Approximate Map of the Former Municipality of Santo Amaro", dated 1938, indicates that the land belonged to Theodoro Putz and the area was called "Paraiso da Represa" (Figure 3).

Figure 3. Map of the former municipality of Santo Amaro, in 1935. On the left, location of the land of the current Sete Praias condominium, called at the time "Paraiso da Represa", property of Mr. Theodoro Putz, source: prepared by the authors based on Museu Paulista, 1938.

The Austrian industrialist, naturalized Brazilian, Theodoro Putz joined forces with the engineer Alfredo Luthold in a commercial partnership called Theodoro Putz & Cia and in 1913 they set up the first rubber factory in the state of São Paulo (Correio Paulistano, 1913: 10).

The partnership was dissolved a few years later, in 1917, when Theodoro Putz left the company, which remained in the same line of business under the name Fábrica Nacional de Artefatos de Borracha, remaining under the management of Alfredo Luthold (O Combate, 1917).

In 1932, Theodoro Putz was the Austrian Consul in São Paulo and was the CEO of the company Sociedade Industrial de Borracha Elastic S.A., headquartered at Rua Abílio Soares, in the 1940s (Diário Oficial: 1947). Theodoro Putz died at the age of 75 on October 20, 1966.

No information was found about when and why the Sete Praias lands were sold by the Putz family, but on October 14, 1982, the subdivision of the region was regularized at the request of Abílio Ashcar (1909-2000), together with other partners and owners of the area.

Abílio Ashcar was Brazilian and became an important industrialist and businessman, president of the Association of Watch Manufacturers of the State of São Paulo. The industrialist was elected Secretary Director of the company Relógios Brasil S.A. in 1962, leaving his previous position as Superintendent Director. He died on November 8, 2000, at the age of 91.

Long before Abílio Ashcar requested the regularization of the subdivision, the region was already a prestigious location, visited and frequented by politicians and businessmen since the mid-20th

century. There was a restaurant there called “Sete Praias”, which hosted dignitaries for lunches. On May 9, 1940, the then mayor of the city of São Paulo, engineer Francisco Prestes Maia (1896-1965), who had been appointed by federal interventor Adhemar de Barros in 1938, was honoured for the 2nd anniversary of his administration at a luncheon offered by the directors and assistants of the City Hall Departments. The guests left the central area in a convoy of cars to the event venue and after lunch they took a tour of the Santo Amaro region:

> After lunch, the Mayor of the capital, accompanied by his friends and admirers, made a long visit to several picturesque spots in the surrounding area, Interlagos, the Autodromo, the Health Center and Villa de Santo Amaro (Mourão, 1940: 1).

In addition to local politicians, the restaurant and the region were also visited by politicians from other states. On June 22, 1940, Antônio Novaes Filho, governor of Recife, came to São Paulo and took a tour to see the city's urban developments. On that occasion, the then Mayor Prestes Maia hosted a lunch at the Sete Praias restaurant.

> His Excellency was present at this warm meal, accompanied by his wife and his secretary, Dr Francisco Oiticica. Also present at the lunch were Dr Sebastião Medeiros, Secretary of the Government; Tito Franco da Rocha, official in the Mayor's office; Constantino Pereira Rodrigues Junior, technical assistant to His Excellency; Francisco Pati, director of the Department of Culture; and His Excellency. After lunch, which took place in a pleasant and cordial atmosphere, the guests headed to the dam, which they toured by boat, kindly accompanied by Dr. João Baptista Monteiro Filho, from the superintendence of Light and Power Co. They also visited Interlagos, Santo Amaro and Congonhas Airport (Mendes, 1940: 3).

On June 21, 1947, another lunch was held for the then governor Adhemar de Barros:

> A banquet will be held today at 1:00 p.m. at the restaurant in Sete Praias, Eldorado, in honour of Mr. Adhemar de Barros and state authorities, including Mr. Teixeira Pinto, mayor of Santo Amaro, and Mrs. Tereza Delta, mayor of S. Bernardo. The banquet will be offered by residents and friends of Eldorado, as a sign of recognition for the promise of public improvements for that place, by the competent authorities (Monteiro, 1947: 4).

After its closure, the restaurant and other buildings were abandoned and became a safety problem for the neighbourhood.

In the 1950s, the Eldorado and Sete Praias neighbourhoods were praised as a very pleasant region in the south of São Paulo, despite the difficult access to the area and the lack of urban infrastructure:

> There are no public places or locations accessible to the residents of São Paulo or tourists, whether domestic or foreign, except for the places where the Anchieta and Anhanguera highways pass, so that they can spend a few days and, especially, the weekends. And so, the pleasant, picturesque locations near the capital of São Paulo, such as Represa Nova, the “Sete Praias” and Eldorado, true attractions for those who live in this capital and those who visit us, are no longer visited, solely due to the lack of electricity and roads. For this reason, their residents and visitors, most of whom are car owners through us, are asking Light and the competent departments of the Santo Amaro Subprefecture and the Department of Transportation, respectively, to install lights and pave or asphalt the existing road. This one, a little over twelve kilometers, starts in the Jabaquara neighborhood. The light that

> reached Chácara dos Fernandes, about eight kilometers from Eldorado, could reach the place with a few more kilometers after passing through the town of Diadema, which, in turn, can be supplied with light from the Nova dam, by the Guacuri quarry. All the towns mentioned, with thousands of residents and visitors, would undoubtedly benefit greatly from the extension of the light and from the paving of the horrible existing road, where cars wear out and people get bored, not to mention those who intend to drive the future foreign tourists who should flock to the upcoming celebrations of the fourth centenary of São Paulo (Netto, 1953: 1).

The 1958 aerial photo shows that the land already had defined streets and there were few buildings built on the site (Figure 4).

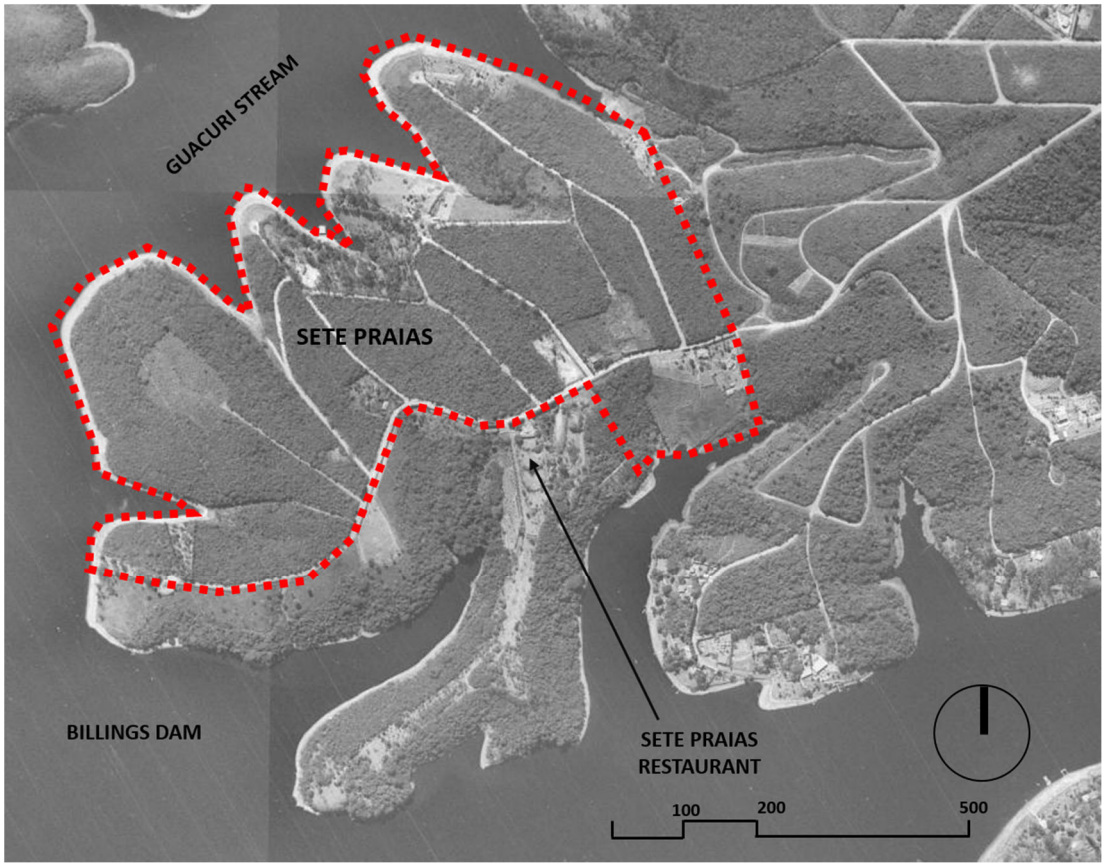

Figure 4. 1958 aerial photo of the Sete Praias Condominium, showing the streets already in place and few buildings, source: prepared by the authors from Geoportal, 2024.

The formation of the Billings Reservoir and the process of occupation of its banks

The Billings Reservoir, created by damming several rivers, is linked to the history of São Paulo, since, before the flooding, the Estrada do Mar (Sea Road) used by D. Pedro I on his trips back and forth from the coast to São Paulo passed through its lands.

It consists of two lakes connected by the Summit Control, known as the Schimit Canal. At the top of the Serra do Mar, near São Paulo, there are two reservoirs: the first, the Rio das Pedras, with a surface area of 7.6 square kilometers and 727 meters above sea level, and the second, the Rio Grande, with a total volume of approximately 1.2 trillion liters of water (Castilho, 1997). Its surroundings were initially

occupied without major harm to the native fauna and flora, with developments such as Praia Vermelha, in Eldorado, and Sete Praias (Neto, 1981). The construction of the Billings Dam was approved by Decree No. 16,844 of March 27, 1925, signed by President Arthur da Silva Bernardes (1875-1955). The decree responded to a request from the concessionaire The São Paulo Tramway, Light & Power Company Limited to use some tributaries of the Tietê River as hydraulic power to generate low-cost electricity, taking advantage of the height difference of the Serra do Mar, approximately 700 meters. The legislation allowed the expropriation of land and improvements made by the former owners to create the reservoir. Thus, initially the waters of the dam were used primarily for the generation of electricity from the operation of the Henry Borden plant (Sobral, 1996).

The dam was named Billings in 1949, in honour of the American engineer Asa White Kenney Billings, born in 1876, who arrived in Rio de Janeiro in 1922 with the task of being an inspector of the electrical system of Light Company. He graduated in electrical engineering from Harvard University and had already worked on the construction of hydroelectric plants in Cuba, Mexico and Spain. In 1924, the Pombos Generating Plant in Rio de Janeiro was completed under his supervision and, in 1925, he began the project in Serra do Mar that would become one of the largest in the world at the time, with the source of its driving force being the dam then called Rio Grande (Castilho, 1997; Mc Dowall, 2008).

To increase the hydroelectric potential of the dam, the Light Company carried out an ingenious operation in the 1940s, when it reversed the direction of the waters of the Pinheiros River, which stopped flowing towards the Tietê River and started flowing towards the dam. In this process, in addition to the water, the reservoir began to receive pollutants and sewage, which was not a problem for the operation of the plant, since the quality of the water was not relevant to the operation of the turbines.

From 1958 onwards, the Billings dam became a water supply source and began to provide drinking water for the growing population of the ABC region of São Paulo[42]. However, due to the compromised quality of its waters, which became polluted by the backflow of sewage discharged into the Tietê and Pinheiros rivers, its reservoir had to be separated by a dam that allowed only an unpolluted arm to be used for water supply.

Back in the 1950s, the Represa Nova region was considered a pleasant, picturesque place, relatively close to the capital of São Paulo, especially the Eldorado neighbourhood and the Sete Praias subdivision. However, the area had problems such as a lack of electricity and good roads, which discouraged tourism and visitors (Netto, 1953).

From the 1970s onwards, the southern region of the city of São Paulo was one of the regions most affected by illegal subdivisions and invasions due to peripheral urban expansion. Urban planner Regina Monteiro states that the problems began at this time, with the zoning law implemented by the Integrated Development Master Plan/PDDI-Law No. 7.688/71, which divided the city into 19 different zones and the water source areas were classified as Z-14 and Z-15. Both zones allowed predominantly residential use with low population density and the lots had to have areas greater than 2,000 and 5,000 square meters respectively. Since the minimum lots were very generous and with a restricted occupation area, between 12 and 26% of the lot area, this ended up encouraging subdivisions and division of land into smaller fractions, of 125 or 250 square meters. The developers based their

[42] Municipalities: Santo André, São Bernardo, São Caetano, Diadema, Mauá, Rio Grande da Serra e Ribeirão Pires.

decisions on Federal Law No. 6,766 of 1979, which dealt with the Subdivision of Urban Land, and which ended up allowing changes in the dimensions of lots in other types of areas of the municipality (Moreira, 1998). Thus, the smaller lots were marketed as irregular, but with the hope that in the future they could be regularized by Law No. 6,766 (1979).

It was also in the 1970s that the first state laws emerged: Law No. 898, of December 18, 1975, which regulated the use of land for the protection of water sources, courses and reservoirs and other water resources of interest to the Greater São Paulo Metropolitan Region; and Law No. 1,172, of November 17, 1976, which delimited the areas that should be protected.

However, the legislation was unable to slow down or interrupt the occupation process that was already underway in the region, since despite its distance from the city center and the lack of infrastructure, the region ended up becoming attractive, especially for migrants who came to São Paulo in search of employment. Among the neighbourhoods that initially faced the problem of illegal subdivisions in watershed areas were: Sete Praias, Praia Azul, Jardim Recreio, Vista Alegre and Rubilene (Moreira, 1998).

It was only in October 1992, that three years after the enactment of the State Constitution on October 5, 1989, that the Billings Reservoir stopped receiving the pumping of polluted water from the Tietê and Pinheiros rivers, as stated in the law:

> Article 46 - Within three years, counting from the promulgation of this Constitution, the State and Municipal Public Authorities are obliged to take effective measures to prevent the pumping of sewage, waste and other polluting substances into the Billings dam (Constituição Estadual, 1989).

Furthermore, with the installation of industries in the greater ABC region and the lack of sanitation in the region, several environmental disasters occurred, causing illnesses and infant deaths, in addition to the death of fish caused by the dumping of toxic substances into the water (Castilho, 1997).

Even in the face of so many serious and adverse events, it was only 20 years after the enactment of the first state laws that a review of the guidelines and standards for the protection and recovery of the hydrographic basins of the sources of regional interest in the State of São Paulo was carried out, which led to the approval of Law 9.866, of November 28, 1997. The Law defined the Water Source Protection and Recovery Area (APRM) as one or more hydrographic sub-basins of the sources of regional interest for public supply and determined that each APRM would indicate its areas of intervention and respective specific environmental and urban guidelines and standards based on the creation of individual state laws. Currently, 5 APRMs have their own regulations in the State of São Paulo: Guarapiranga, Billings, Alto Juquery, Alto Tietê Cabeceiras and Alto Cotia.

APRM Billings was created and defined by Law 13,579 of July 13, 2009, that is, 74 years after the damming of the region's waters, ratifying the situation of pollution of its waters and the intense irregular occupation of its banks.

According to Law 13,579 (2009), the Sete Praias condominium is classified as a Low-Density Occupation Sub-Area – SOB – which belongs to the Environmental Compartment of Central Body I,

which suggests that the minimum lot size be 500 square meters; utilization coefficient 0.5; Permeability Rate 40% and Vegetated Area Index 20% (Figure 5).

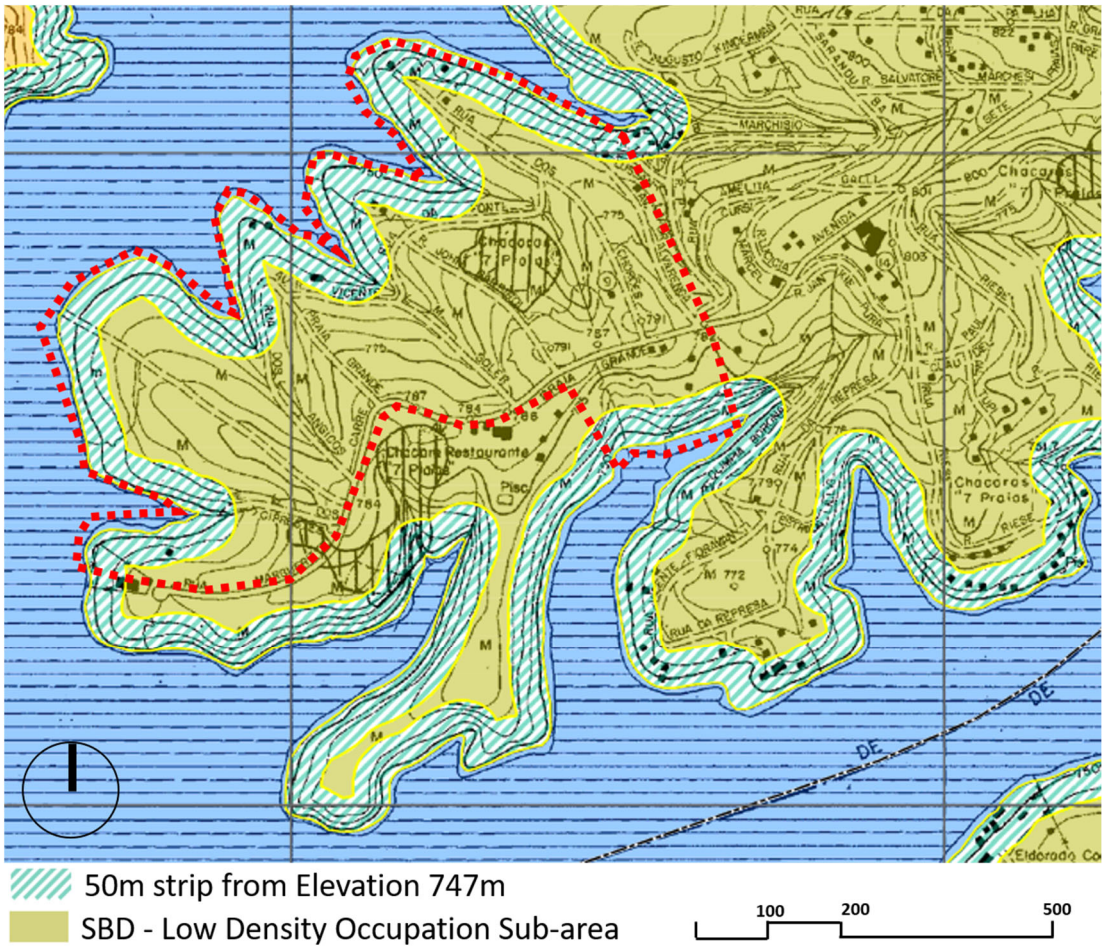

Figure 5. Map of the Sete Praias Condominium area, indicating the classification of the region as a Low-Density Occupation Sub-Area, according to Law 13,579 of 2009, source: prepared by the authors from Geoportal, 2024.

According to the classification of Law No. 16,402, the Zoning Law of the Municipality of São Paulo, the Sete Praias condominium is an Exclusively Environmental Residential Zone – ZERA, which indicates the following occupation parameters: Minimum lot of 500 square meters; maximum utilization coefficient of 1; Permeability rate of 30% and Vegetated Area of 18%.

The same law provides that in the zones included in the protection and recovery area of the water sources, the pertinent state legislation applies, when more restrictive, according to § 2 of article 5 (Law No. 16,402). This reservation is relevant, since the parameters of the Water Sources Law are more restrictive than the Zoning Law of the municipality, becoming an important instrument for regulating and monitoring the ongoing process of occupation of the region's lands.

Study of the Urban Form of the Sete Praias condominium

The Sete Praias Condominium area is contained in the Ribeirão Guacuri micro-basin, which is part of the Billings Hydrographic Basin. The condominium has four streams that flow into the Billings Reservoir. The highest point of the land is located to the southeast of the area, at an elevation of 790

meters, from where it drops 45 meters to an elevation of 745 meters towards the banks of the Billings Reservoir (Figure 6).

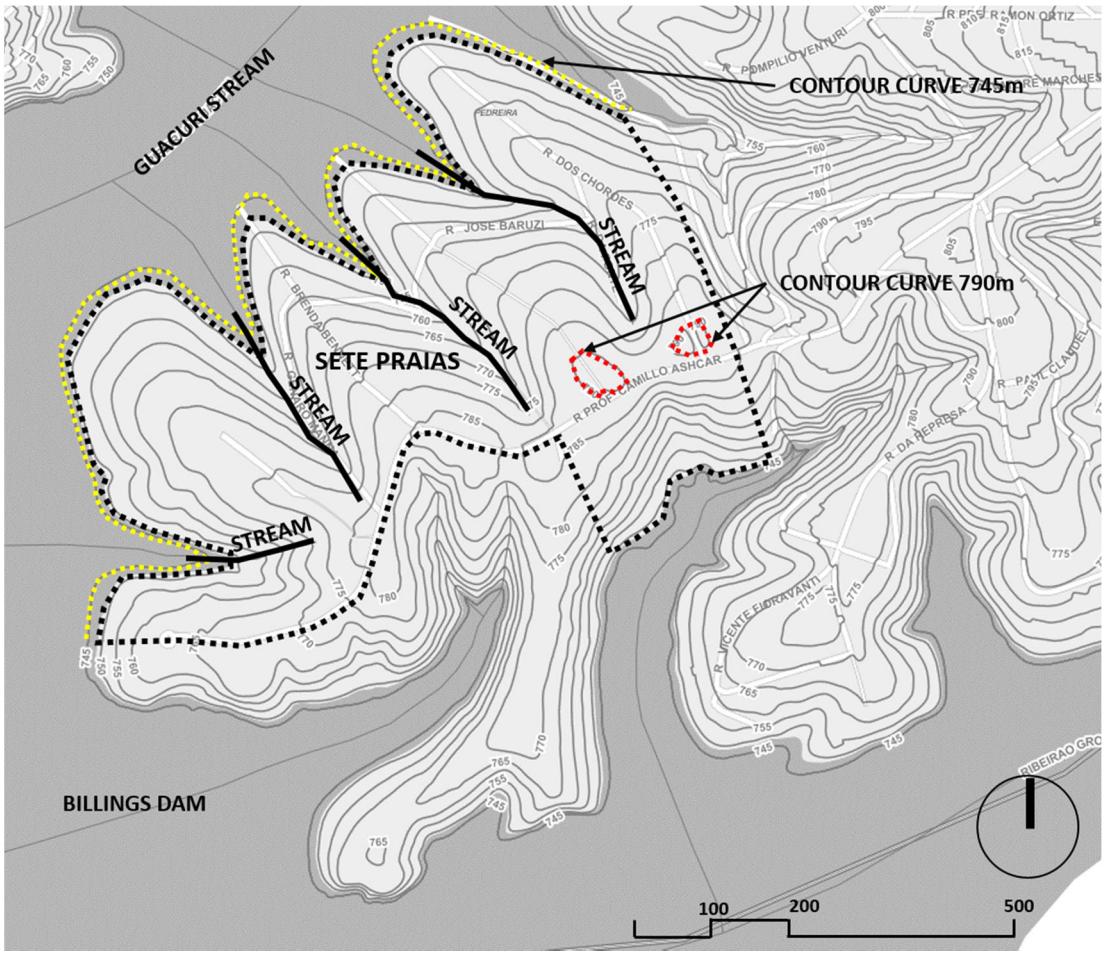

Figure 6. Map of the Sete Praias Condominium, with streets, hydrography and contour lines every 5 meters, source: prepared by the authors from Geoportal, 2024.

The organic design of the road system follows the slope of the terrain, with a main road, Professor Camilo Ashcar Street, which follows the ridge in an east-west direction, from where the other roads start and descend towards the lowest level on the edge of the dam. Most of the streets do not have sidewalks for pedestrians, nor are they paved (Figures 7 and 8).

Figure 7. Rua dos Chorões, with curves that follow the slope of the place, source: Rafael Schimidt, 2024.

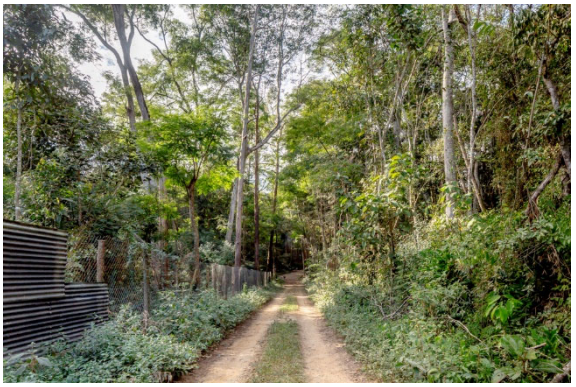

Figure 8. Vicente Soler Street, without sidewalks for pedestrians, source: Rafael Schimidt, 2024.

Currently, the area comprising the Sete Praias Condominium is 486,000 square meters. Based on the survey carried out on the Digital Map of the City of São Paulo (Geosampa, 2024), it was found that the condominium has 99 lots distributed across 9 blocks and 8 streets: Professor Camilo Aschar Street, Vila dos Ciprestes Street, Vicente Martin Soler Street, Brenda Bennett Street (formerly Praia Grande Street), Genaro Manna Street (formerly Angicos Street), John Barbirolli Street, José Baruzi Street (formerly Fonte Street) and Chorões Street. The changes to the names of public thoroughfares in Sete Praias occurred as of Decree No. 38,705, of November 25, 1999, during the administration of Mayor Celso Pitta (São Paulo, Municipality, 1999). The largest lot is 118,956 square meters and the smallest lots are approximately 1,900 square meters.

The condominium has three portions of open green areas shared by residents: at the end of Rua dos Chorões; on Rua José Baruzi and at the intersection of Rua Vicente Martin Soler and Rua José Baruzi (Figure 9).

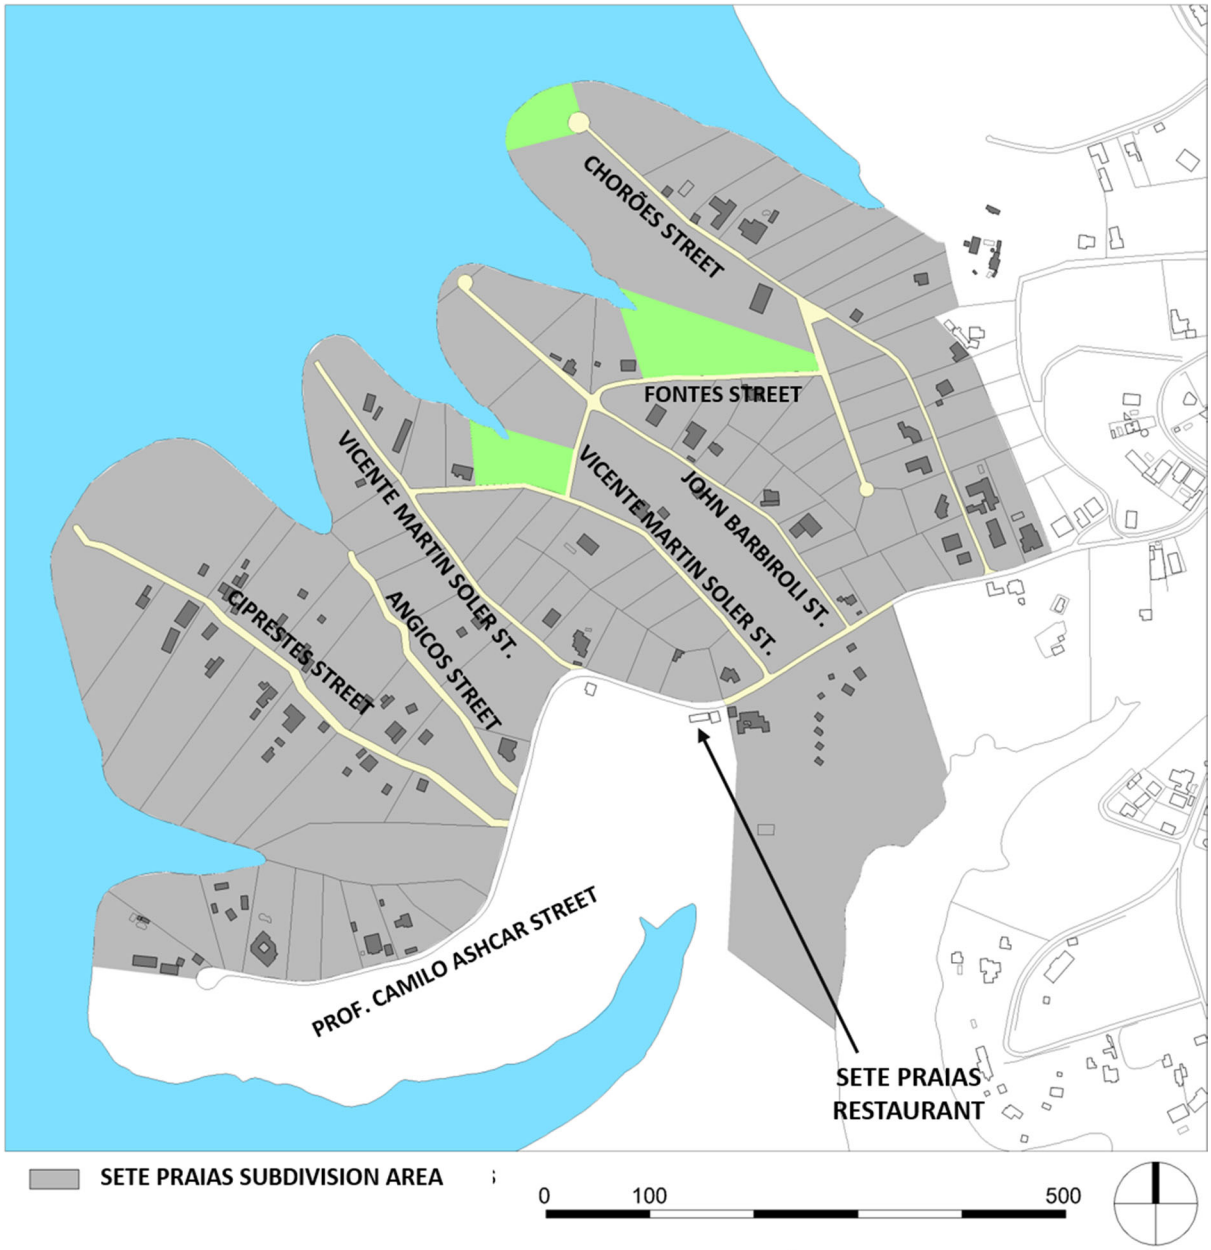

Figure 9. Map of the Sete Praias condominium, indicating the streets, lots, buildings up to 2010 and the three public green areas, source: prepared by the authors based on Geosampa, 2024.

The 2020 orthophoto shows the predominance of green areas still very present in the region, but deforestation has already been observed, creating a clearing on Rua dos Ciprestes, in the western portion of the subdivision (Figure 10).

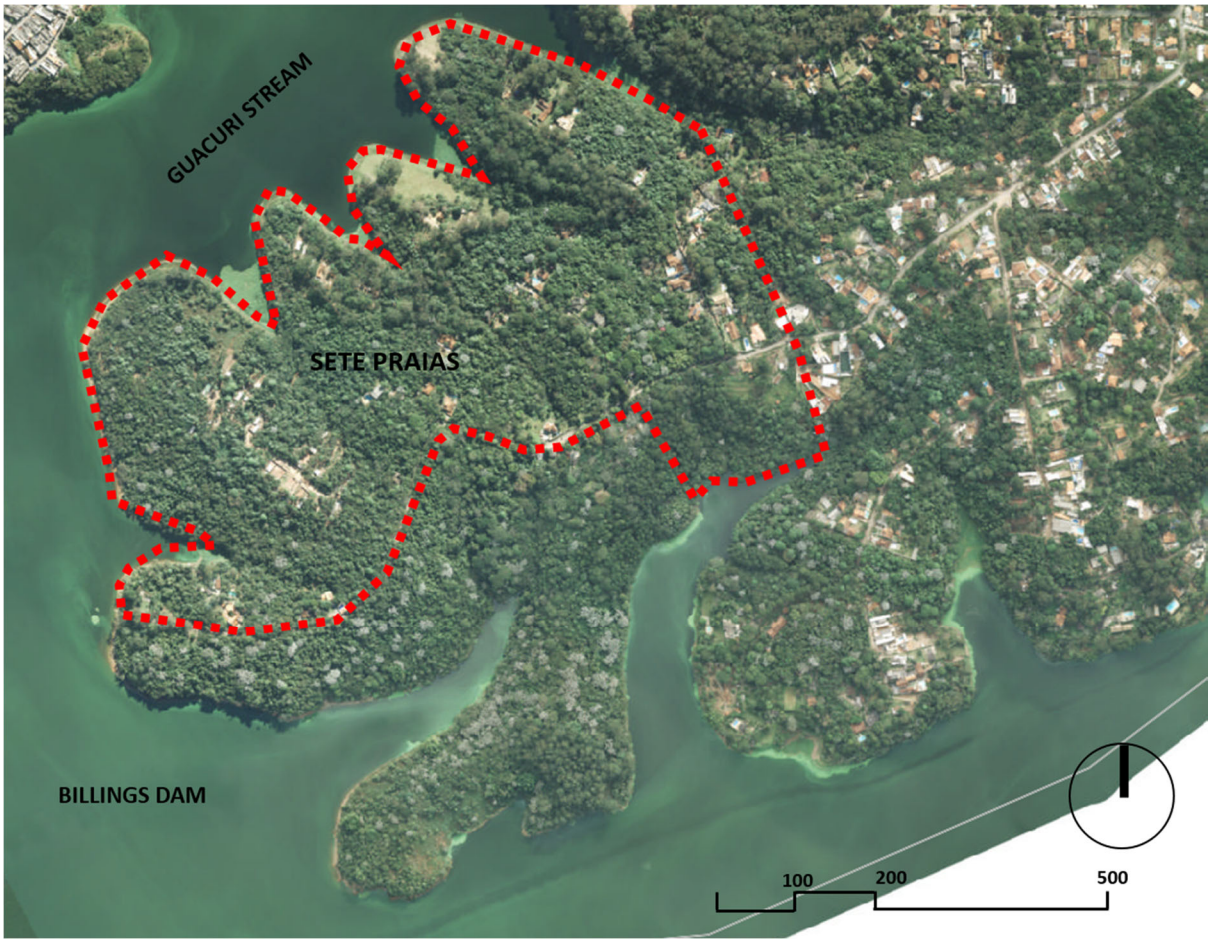

Figure 10. 2020 orthophoto of the Sete Praias condominium, where the predominance of green areas can be seen, source: prepared by the authors based on Geosampa, 2024.

CONCLUSIONS

The Sete Praias condominium, despite having the qualities and morphological characteristics that led to its identification and classification as a garden neighbourhood, according to the survey carried out by SEMPLA in 1988 (Environmental Secretariat, 1988), is a subdivision that achieved this classification, unlike other neighbourhoods in the southern part of the city that were designed based on the principles of garden neighbourhoods, such as: Chácara Flora (1915), Interlagos (1935) and Granja-Julieta (1956).

Initially, the area around the Billings Reservoir attracted the attention of entrepreneurs interested in subdividing the region because it was a pleasant and picturesque place, but in the 1950s it still had problems with infrastructure, water supply, road circulation and a lack of public transportation. When the 1971 Zoning Law was implemented, it imposed specific rules for land use and occupation in the areas surrounding the water sources. The standard followed the principles already adopted in the Sete Praias subdivision, considered a good occupation model.

Therefore, while the Sete Praias subdivision can be considered a good solution for occupying areas close to watercourses, on the other hand, due to the size of the lots and the resulting standard of construction, it may represent an elitization of the areas close to water bodies. This is not a reflection

that applies only to the Sete Praias subdivision, since in São Paulo, garden neighbourhoods are mostly intended for the high-income population, due to the high value of urban land.

ABSTRACT

In delta regions characterized by complex water environments, the relationship between humans and water is one of the decisive factors in the formation, growth, and transformation of human settlements. In the current context of global climate change and increasing water-related risks, an in-depth study of the water systems in estuarine delta human settlements is of particular importance and practical significance. This paper focuses on the human settlements in the Pearl River Delta Water System (PRDWS) as the research object. It adopts a dual-scale morphological analysis framework, examining both the geographical scale and the settlement cluster scale, to explore the various patterns of human-water relationships in this region. This paper arrives at three main conclusions: 1) The dynamic interplay between natural hydrological elements and human productive and living activities is the core process determining the development of the Pearl River Delta (PRD). 2) The human settlements within PRDWS exhibit highly diverse and complex characteristics, encompassing a consistent range of natural substrate types and built-up area development types. 3) Based on the natural substrate and built-up area development types, PRD can be classified into four categories: weakly urbanized areas with plateau-hilly terrain and limited water resources, marginally urbanized areas in the lower reaches of various rivers with delta water networks, core urbanized areas with composite delta water networks, and areas of intense change in the coastal zones of estuarine alluvial plains. This study plays a crucial role in uncovering the interactive and symbiotic processes between natural hydrological elements and human productive and living activities. It deepens our understanding of the complexity and diversity of both natural and cultural characteristics in PRD. Furthermore, it is significant in exploring contemporary directions for the adaptive and ecological construction of water cities in PRD.

Keywords: Regional Water System, the Pearl River Delta, Morphological Mapping, cross-scale, complexity

INTRODUCTION

Natural hydrological conditions have consistently been a primary consideration influencing human settlement patterns throughout history. While river systems have provided essential conditions for human habitation, production, and livelihood, the expansion and development of settlements have also faced threats from various hydrological features such as rivers, lakes, and coastal areas. To establish safe and stable living spaces, humans across different periods have engaged with natural

hydrological processes through corresponding artificial management methods. These efforts have led to the comprehensive utilization of water resources, ultimately forming regional water systems that support the development of human settlements in the area.

The Pearl River Delta (PRD) is one of the world's most dynamic and densely populated regions, as well as one of China's areas with the most rapid economic development and highest degree of urbanization. The region boasts a well-developed water system with abundant water resources. However, its subtropical monsoon climate, characterized by high temperatures and heavy rainfall, coupled with coastal influences, makes the area frequently susceptible to water-related disasters such as floods and storm surges. Global climate change has exacerbated these challenges, with rising sea levels and more frequent extreme weather events intensifying the destructive impact of coastal phenomena such as typhoons, rainstorms, and floods. Consequently, the issue of sustainable human-water relationships in PRD has garnered increasing attention.

The dynamic equilibrium between water systems and human-built environments has consistently been a core issue in the development of PRD. Based on long-standing experiences of coexistence, symbiosis, and co-governance with water, PRD has nurtured a rich and diverse human settlement landscape system dominated by water systems, which serves as a significant carrier of the region's geographical characteristics. This landscape system achieves a dynamic balance of human-water coexistence over extended periods and across multiple scales, maintaining sustainable development of human-land relationships by providing adaptive ecosystem services. Analyzing the adaptive and interactive characteristics of PRDWS helps deepen the understanding of the diversity and complexity of the region's human settlements. Furthermore, it has positive implications for exploring ecologically resilient design methods for urban and rural human-water cohabitation spaces in PRD.

METHOD: DUAL-SCALE MORPHOLOGICAL ANALYSIS FRAMEWORK AND PROCESS OF PRDWS INTRODUCTION

PRDWS represents a complex landscape of human-water cohabitation, characterized by diversity, dynamism, and adaptability typical of complex systems. Traditional research approaches often focus on single-scale or single-case, lacking systematic integration of multiple scales. There is a need to construct a cross-scale systematic research paradigm that enables cognitive analysis through comprehensive patterns of spatial and temporal associations among numerous factors.

This study focuses on PRDWS and its human settlements, employing morphological analysis theory as its core. It constructs a morphological research framework by selecting geographical and settlement cluster landscape scales. The research process first establishes a continuous scale division framework, then integrates five steps: theme identification, sample determination, information reduction, hierarchical decomposition, and pattern extraction. This approach interprets spatial types and characteristics at different scales. Finally, based on the morphological analysis results at various scales, it integrates continuous scale spatial slices from macro to micro levels, from systemic commonalities to individual characteristics, to construct a morphological atlas of PRDWS.

Conducting morphological analysis simultaneously across multiple scales helps uncover the complex system's scale-nested behaviors and dynamic process characteristics of PRDWS. This approach emphasizes the landscape as a materialized spatial regional entity, highlighting the ongoing interactive changes and adaptive relationships with the water system. Through comprehensive allocation and

utilization of resources, it ultimately achieves a dynamic equilibrium state of human-water symbiosis within a certain range of natural climate variations.

Dual-scale morphological analysis framework

The formation of deltas is a result of combined natural and human actions. In the process of delta formation, sedimentation, river channel changes, and coastline development are considered the main natural driving forces (Lange, 2019). The primary human driving forces include the construction of levees, land reclamation, aquaculture, fish pond construction, major road development, and settlement expansion (Xiong, 2020). The interaction between natural and human forces shapes three types of human settlement environment processes in deltas: geological evolution, landscape formation, and settlement development.

Geological evolution is the earliest occurring process and forms the foundation for all natural ecological processes in the delta. Accompanying the geological evolution process is the formation of large-scale geomorphology and human settlement landscapes, which includes two sub-processes: the formation of mountain and water landscapes, and the formation of settlement cluster landscapes. The settlement development process is the primary human activity process, encompassing three sub-processes: settlement formation and development, housing agglomeration and place-making, and the formation of activity and communication spaces.

Different scale hierarchies correspond to distinct scale domains, and spaces within the same scale domain exhibit certain similar characteristics. By extracting the characteristic scales within a scale domain, one can most effectively demonstrate the spatial pattern features at that scale (Wu, 2014). In this study, the discussion of PRDWS and its human settlement processes corresponds to two levels of spatial morphological organization: the geographic pattern and the settlement cluster landscape pattern.

The geographic pattern scale reveals the morphological characteristics of the natural substrate layer and the interactive relationship between the natural substrate and human productive and living activities over a large area. The settlement cluster scale displays the specific morphological structure and characteristics of human activities.

According to scale domain theory, by mapping the generation of morphological processes and the display of morphological characteristics at different scales onto actual spaces, specific morphological quantification operation scales can be determined. Specifically, these are: 200km-400km for the geographic pattern scale, and 40km-60km for the settlement cluster scale.

Multiple map selection experiments were conducted to determine the characteristic scales. During the experimental process, it was necessary to avoid both the mixture of elements in the selected area due to overly large scales and the loss of typical characteristics of the scale domain due to overly small scales. Finally, specific parameters for characteristic scales at each level were determined, each scale level was coded, and the main research content and corresponding morphological analysis elements were identified (Table 1).

Table 1. The two study scales and the content of each scale.

Study Scale	Code	Study Field	Content	Mapping Elements

Geographic pattern scale	G	400km×400km	Geographical pattern of mountains, waters, and cities in PRD from a physical geography perspective	Distribution patterns and combinatorial characteristics of mountains, waters (rivers and sea), cities, and fields in PRD
Settlement cluster scale	La	50km×50km	Different urban-water landscape pattern types in PRD from an urbanization perspective	Morphological structure and main features of the urban-water Landscape Pattern

Dual-scale morphological analysis process

Further analysis of the cross-scale morphological analysis process for PRDWS can be divided into five steps: theme determination, sample determination, information reduction, hierarchical decomposition, and pattern extraction.

Study subject

Due to the inconsistency of spatial structures and primary characteristic elements across different scale levels, it is first necessary to determine the main research themes and content for each scale according to the research objectives. Based on this content, the morphological analysis elements should be further specified (Table 2).

Table 2. Data source of two study scales.

Study Scale	Sample Range	Data Sources
G (400km×400km)	9 cities in PRD administratively: Guangzhou, Foshanm Zhaoqing, Shenzhen, Dongguan, Huizhou, Zhuhai, Zhongshan, Jiangmen	Google satellite maps, vector data from and geospatial data platforms, historical maps, and literature materials
La (50km×50km)	Zoning with different geographical characters based on the pattern relationships between natural landscapes and built-up Areas	Google satellite maps, historical maps, and literature materials

Study sample and data

The determination of research precision at each scale is related to grain and extent. Grain refers to the characteristic length, area, or volume of the smallest discernible unit. Extent refers to the spatial spread or continuity of the object of study (Wu & Li, 2006). Based on these two fundamental concepts, three types of scale transformations emerge: extent scaling, grain scaling, and simultaneous extent and grain scaling (Wu, 2014).

Extent scaling involves expanding the extent range while maintaining a constant grain, which means changing the size of the selection frame. Grain scaling refers to maintaining a constant selection frame size while adjusting the grain size, resulting in images of the same area with different levels of clarity. Simultaneous extent and grain scaling involves changing both the size of the extent and the grain, producing images with different levels of clarity and varying study areas.

In this study, as the scale progresses from large to small, a scaling method that reduces both extent and grain is adopted. The two scales are uniformly represented on a 20cm × 20cm canvas at 300 dpi. The actual lengths represented by the smallest grain at each scale are 169.35m, 21.17m respectively. At this point, the transformation from natural inherent scales to research scales is essentially complete.

Information reduction

Upon completion of data collection, it is necessary to screen, reduce, and extract the required information for each scale of research. This process primarily involves the following three steps:

(1) Overlay multi-source data for samples at each scale, performing preliminary screening and correction through data matching to obtain an accurate understanding of the sample area;

(2) Identify important spatial elements that need to be retained in the study, in conjunction with the research objectives and content for each scale;

(3) Extract structural characteristics of similar elements, reduce irrelevant information in spatial elements, and transform complex multi-source data into symbolized spatial drawing information to create morphological tracing maps with geographic coordinates.

Layering Analysis

The tracing maps reflect the complexity of PRDWS landscape. Through a layered analysis method, it is possible to further understand the interactive relationships between different morphological elements. In 1996, Dutch scholars De Hoog, Sijmons, and Verschuuren proposed a layered model for complex spatial systems (Van & Klaasen, 2011), focusing on the driving forces and processes of spatial development. Based on the dynamic characteristics (rate of change) of spatial elements, they established a three-layer model consisting of 'substrate layer - network layer - occupation layer'.

Dutch Delta Urbanism further developed this layered model, proposing that all urbanized deltas globally can be abstracted as complex systems dynamically composed of three subsystems: substrate, networks, and occupation (Meyer & Nijhuis, 2013). The substrate layer, located at the bottom of the layered model, includes natural elements such as water and soil. It has the lowest dynamicity, typically requiring several centuries to produce substantial changes. The network layer, positioned in the middle of the layered model, primarily consists of basic production and living infrastructure elements. It creates conditions for human settlement, economic activities, and mobility. Infrastructure projects often require substantial costs and complex technologies; therefore, their rate of change is slower compared to cities but faster than the natural systems in the substrate layer. The occupation layer, situated at the top of the layered model, encompasses urban forms and human activities. This layer typically experiences very rapid changes, with substantial expansion or transformation occurring within relatively short periods.

This study draws upon the research methods of Delta Urbanism, interpreting the current state of PRDWS as comprising three layers: a natural substrate layer characterized by geographical environment, an agricultural network layer influenced by agricultural landscape, and a settlement occupation layer (SOL) primarily characterized by built-up areas. The rate of change in morphological elements gradually increases from the natural substrate layer to the settlement occupation layer, while the stability of spatial structures progressively decreases.

Mode refining

The deconstruction and analysis of complex landscapes can distill the spatial characteristics of each subsystem and the spatial relationships between subsystems, summarizing spatial structures and determinant spatial elements. In this process, the spatial composition logic of the samples gradually emerges. By extracting this spatial composition logic, we can obtain the typical spatial characteristics of the samples. Subsequently, through multi-sample comparison, we can determine typical spatial prototypes and draw abstract spatial pattern maps.

In the following sections, this study will conduct cross-scale analysis experiments on the macro-morphology of PRDWS and the meso-morphology of the Northwest River complex delta, based on the dual-scale morphological research framework.

GEOGRAPHIC PATTERN: MORPHOLOGICAL ANALYSIS OF PRDWS (400KM × 400KM)

Mapping of PRDWS at the Geographic Pattern Scale

In urban planning-related fields, PRD typically refers to the south-central part of Guangdong Province, the flourishing region of Cantonese culture, encompassing nine cities: Guangzhou, Foshan, Zhaoqing, Shenzhen, Dongguan, Huizhou, Zhuhai, Zhongshan, and Jiangmen. A 400km × 400km sampling frame is used to capture the complete area of the nine PRD cities. Satellite imagery data (2020) for the sampling area is obtained through Google Earth and placed within a 20cm × 20cm, 300dpi data frame, establishing a minimum grain size of approximately 169.35m (Figure 2). At this scale, spatial elements and their characteristics corresponding to the extent and resolution precision are identified, and a tracing map is drawn (Figure 1).

Through the deconstruction and analysis of PRD at the geographic scale (400km×400km), the following characteristics can be observed in its layered structure and inter-layer relationships:

The natural substrate layer presents four mountain-water geographical patterns: The outermost circle is characterized by towering hills with rivers winding around them; the second circle consists of plain terraces with unobstructed rivers; the third circle features compound plains with networked rivers; and the fourth circle displays a mix of plains and terraces with a denser river network.

The agricultural network layer exhibits a structure that varies from the mountains to the coastline, in accordance with the changing geographical patterns. Mountain agriculture is distributed on the flat lands and terraces between mountains. Agriculture and aquaculture typical of hot and humid plains are concentrated on the delta plains of the lower reaches of various rivers. The compound deltas in the lower reaches of rivers are convergence areas for dike-pond agriculture, while the coastal sandy fields are characterized by strip-like agriculture.

The settlement occupation layer exhibits a concentrated form in the central areas and a scattered distribution in the periphery. Over 90% of the built-up areas are concentrated in the PRD plain, while the sparse, scattered built-up areas in the surrounding mountainous regions align with the river courses.

The natural substrate layer has the longest formation history and the highest degree of stability. The formation and differentiation of both the agricultural network layer and the settlement occupation layer occur on the foundation of this established natural geographical pattern. Comparatively, the former one is more dependent on the natural substrate layer. However, with the progression of urbanization, the settlement occupation layer has shown a significant increase in differentiation.

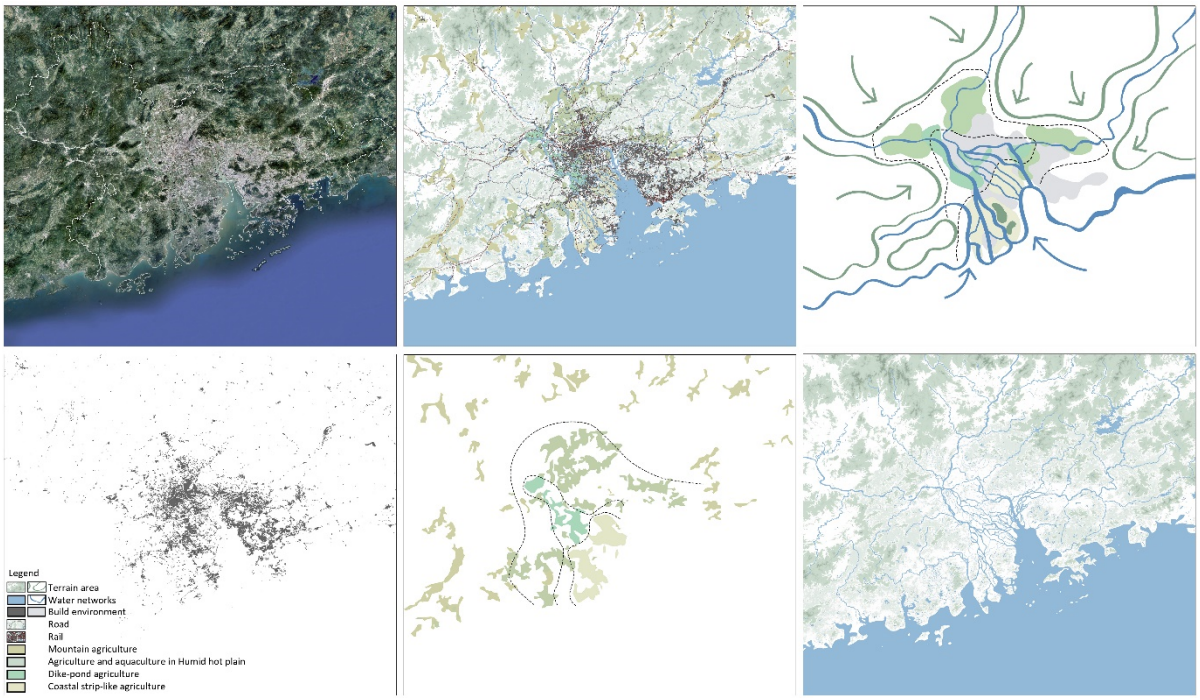

Figure 1. Mapping at the geographical pattern scale. image credit: drawing by author.

Morphological analysis of PRDWS at the Geographic Pattern Scale

At the geographic pattern scale, PRD presents four distinct geographical patterns characterized by mountains, water, cities, and fields, as well as varying degrees and characteristics of urbanization. These can be specifically categorized into:

(1) Zone One: Plateau and hilly areas with sparse water networks - weakly urbanized regions;

(2) Zone Two: River network areas in the lower reaches of various rivers' deltas - peripherally urbanized regions;

(3) Zone Three: Compound delta river network areas - core urbanized regions;

(4) Zone Four: Coastal zones of alluvial plains at river mouths - regions undergoing intense changes.

Zone One encompasses the peripheral plateau and hilly areas, characterized as a weakly urbanized region. Being the highest terrain segment in PRD, its geographical pattern is relatively the most stable. The mountain-water geographical configuration in this zone was largely established in prehistoric times. Early migrants to PRD predominantly settled in this area. However, due to topographical constraints, settlements in this segment are scattered across the flat lands between mountains and on plateaus. Consequently, the urbanization density is extremely low, and the degree of urbanization is the weakest in this zone.

Zone Two comprises the lower delta regions of various rivers with enclosed fields, representing the urban expansion periphery. The mountain-water configuration in this zone was also formed in prehistoric times. This segment has relatively higher terrain, and its water network system is not complex. Settlements are predominantly distributed near streams, with some urbanized areas along the rivers. This zone serves as the peripheral radiation area for the urbanization of PRD's core region.

In the process of rapid urbanization, this area has gradually received industrial relocation and influence from the Guangzhou-Foshan urban core. Consequently, the built landscape exhibits a highly mixed and fragmented pattern of industrial, agricultural, and residential functions.

Zone Three is the compound delta area with enclosed fields, representing the core region of PRD's urban agglomeration. The compound deltas in the lower reaches of various rivers were formed from the early historical period to the Tang and Song dynasties. This area has relatively flat terrain, consisting of plains formed by river sedimentation. It was primarily developed through the joint efforts of Han migrants who moved south from the Song dynasty onwards and local indigenous inhabitants who were gradually sinicized through economic and cultural exchanges. This zone has been the core area of PRD since ancient times.

During the Ming and Qing dynasties, this segment began to form a contiguous characteristic Lingnan watertown landscape, with mulberry dike-fish pond systems as the primary mode of production. In modern times, leveraging the central positions of Guangzhou and Foshan, the urban areas in this region have rapidly expanded and become highly developed.

Zone Four is the sandy field area of the estuary's alluvial plain in PRD, representing the region experiencing the most dramatic urban changes. The formation of the alluvial plain in this area results from the combined actions of rivers, sea, and islands. Part of the river sediment impacts small islands in the sea, forming accumulations around them; another part collides with seawater, causing gradual sedimentation near the coastline. Thus, the alluvial plain is formed by the joint effects of sediment accumulation around islands and seaward deposition.

On the alluvial plain in this segment, the water network system is complex, forming watertown settlements in sandy field areas characterized by strip-shaped landscapes, primarily dominated by rice cultivation, with dike-pond agriculture as a secondary feature. As the degree of development and utilization intensifies, human intervention in the landscape spatial evolution of the Pearl River estuary has gradually strengthened.

The transformation trend of the PRD's estuarine coastal zone is predominantly seaward extension, mainly due to coastal engineering construction, tidal flat reclamation, sea enclosure for land creation, and artificial aquaculture. Artificial land creation stands as the primary driving factor in this process.

LANDSCAPE PATTERN: MORPHOLOGICAL ANALYSIS OF PRDWS (50KM × 50KM)

Mapping of PRDWS at the Settlement Cluster Scale

Based on the geographic pattern scale, we conducted an investigation into the geographical patterns of mountains, water, cities, and fields in PRD. This led to the identification of four major types of geographical segments. Representative samples were then selected for experimental graphic analysis at the settlement cluster scale, coded as La1, La2, La3, and La4 (Figure 2).

Satellite imagery data (2020) for each sampling area was obtained through Google Earth. The data was placed within a 20cm×20cm, 300dpi data frame, establishing a minimum granularity of approximately 21.17m. Based on this scale and research precision, we drew tracing maps and identified different landscape pattern characteristics of mountains, water, cities, and fields, as well as the morphological types of settlement clusters in PRD.

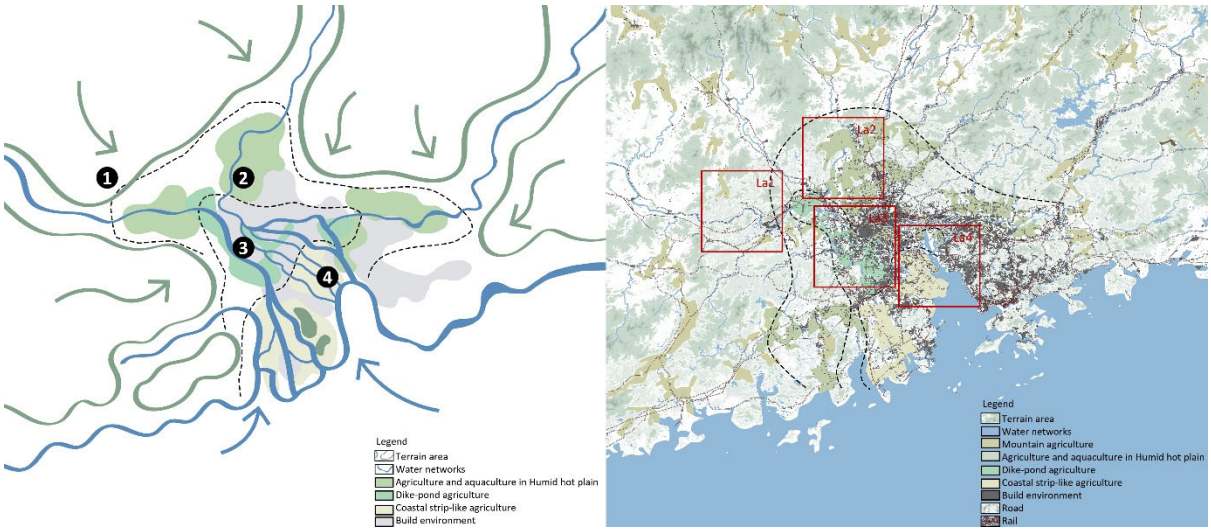

Figure 2. Four zones in PRD at the geographical pattern scale. photo credit: drawing by author.

Through the deconstruction and analysis of four selected blocks at the settlement cluster scale, the following characteristics of their layered structures and inter-layer relationships can be observed:

Within the natural substrate layer, the morphology of the water system emerges as the primary spatial determinant. Specifically, the natural water systems in La1 and La2 are relatively simple, dominated by the main streams of large rivers. La3 is more complex, characterized primarily by a dense network of water bodies. La4 presents the highest complexity, featuring two water morphologies - seawater and rivers - which form a relatively intricate topographical and geomorphological relationship on land.

In the agricultural network layer, La1 is predominantly mountainous, characterized by mountain agricultural landscapes. Plains of considerable scale form at river bends, giving rise to agricultural facilities such as ponds. Additionally, transportation and trade along the main river streams have become auxiliary industries in this region.

La2 exhibits larger plains on both sides of the main stream, forming large-scale enclosed field and pond agriculture. Due to the influence of urbanization, fragmented small-scale industrial facilities exist interspersed with agricultural areas.

La3 features a dense and complex water network, presenting a highly diverse agricultural field-pond landscape system. Near the confluence of the West and North Rivers, water is abundant, and the terrain is relatively high, resulting in lower flood pressure and stronger human control over water. This facilitates the formation of a more complete embankment system. Between the downstream West and North Rivers, influenced by topography and river dynamics, several tributaries interconnect. Numerous artificial canals have been excavated along these tributaries, dividing the relatively flat downstream area of the West-North River compound delta. Here, human control over water is relatively strong, and for production convenience, artificial fish ponds of appropriate scale and homogeneous form have been constructed.

La4 is influenced by both seawater and river water systems. Under the natural action of tides and artificial land reclamation, agricultural water conservancy facilities have emerged through human modification. These are primarily sandy fields, gradually transitioning into residential areas suitable for human production and living.

In the settlement occupation layer, there are significant differences in the density of settlement clusters, with La1 < La2 < La4 < La3. Regarding the distribution and spatial pattern of settlement clusters: for La1, settlements are distributed in a punctuated manner along rivers between mountainous areas. In the larger plains on the concave bank of the West River, large settlements have formed and developed into regional central cities. For La2, settlements are primarily distributed along the eastern bank of the North River. The settlements form a network-like distribution, jointly constituting a human habitation network with the intersecting fields and ponds. For La3, this area has the highest settlement density, with settlements connecting to form contiguous patches. For La4, the settlements exhibit significant variations, corresponding to changes in the geographical pattern.

Morphological analysis of PRDWS at the Settlement Cluster Scale

At the settlement cluster scale, the four selected sample areas exhibit distinct spatial structures. Moreover, the dynamic interplay between natural hydrological elements and anthropogenic production and living activities demonstrates varied characteristics across these regions (Figure 3).

La1 exhibits a landscape pattern characterized by mountainous terrain and hills, dominated by main streams, with artificially built areas scattered in mountains and concentrated in river valleys. This region is significantly influenced by natural topography and hydrological conditions. The difficulty in artificially modifying the mountainous and hilly terrain has resulted in a predominance of small-scale, dispersed agricultural settlements in the mountain areas, with limited settlement sizes. The spatial pattern primarily reflects human activities adapting to the natural environment.

However, in the larger plain areas along the West River, concentrated settlement activities have been facilitated through the construction of embankments and artificial land reclamation. These areas have gradually developed into the central city of Zhaoqing, which serves as the regional hub.

La2 presents a landscape pattern characterized by low-lying terrain, encircled by water networks, with settlements uniformly dispersed and interwoven. This region is located in the North River basin, with the eastern bank generally low-lying, forming a basic pattern of plains embraced by water networks. Within the enclosed area, relatively low-lying riverside plains have formed. To minimize potential losses from flood disasters, settlements are arranged in extremely small-scale, dispersed clusters, creating a sesame seed-like pattern of settlement groups.

This area is adjacent to core cities such as Guangzhou and Foshan, situated on the periphery of the PRD’s central urban agglomeration. Due to the outward diffusion of industrial activities from the core area, this region has been influenced to some extent, manifesting urban phenomena such as industrial parks. However, due to the lack of a comprehensive, large-scale regional planning approach, urbanized areas have developed in a fragmented manner, without exhibiting obvious systematic structural characteristics.

La3 exhibits a landscape pattern characterized by concentrated plains, interwoven rivers and canals, and diversified settlements connecting to form continuous areas. This pattern is distributed in the downstream confluence of the West and North Rivers (between the West and North Rivers). The region is situated at the hydrological hub of PRD, with Guangzhou and Foshan as its core cities.

In its early development stage, this area's elements of mountains, water, cities, and fields constituted an excellent feng shui pattern. Moreover, benefiting from both river ports and sea bays, convenient

transportation facilitated prosperous trade, thus exerting significant economic, political, and cultural influence.

In subsequent urban development, the region has implemented a spatial development strategy of 'advancing east, connecting west, expanding south, and optimizing north.' The continuous improvement of infrastructure networks has further expanded the urban framework. Consequently, in the flat hinterland, the urban built-up area has progressively integrated surrounding agricultural settlements, independent towns, and other scattered land uses into a cohesive whole, expanding outward from the core.

La4 presents a landscape pattern characterized by coastal sandy fields, river-sea interface, and settlements transitioning gradually from land to sea. This region is situated at the estuary of the Pearl River, with its coastline directly exposed to sea waves. The area is significantly impacted by typhoons and floods, thus in the early stages of development, urban built-up areas tended to be distributed in a punctuated manner closer to inland areas, under the shelter of hills and mountains.

Moreover, due to geological processes, the mixing and deposition of river and sea sediments at the estuary have resulted in shallow seabeds, making it difficult to form deep-water harbors similar to those near Hong Kong.

The punctuated urban built-up areas have developed along transportation routes or main streams, embedded among farmlands, water systems, and hilly green spaces, forming a spatial pattern of multiple elements collaged together.

CONCLUSIONS

In estuarine delta regions where complex water environments play a dominant role, the relationship between humans and water is one of the decisive factors determining the formation, growth, and change of human settlements. Since the beginning of the 21st century, coastal and delta regions have

faced numerous problems, such as imbalances in erosion and sedimentation caused by tidal surges. In the current context of global climate change and increasing water-related risks, in-depth research on human-water relationships in estuarine delta regions is of particular importance and practical significance.

PRD has a typical regional water system. Influenced by the unique interaction between runoff and tides in this region, different characteristics of human-water relationships have developed through the symbiosis between residents and the aforementioned environment. This study draws on the theory and methods of delta urbanism to conduct a dual-scale graphic analysis experiment from macro and meso perspectives (focusing on the West-North River compound delta area), yielding three main conclusions:

(1) The dynamic interplay between natural hydrological elements and anthropogenic production and living activities is the core process determining the development of PRD.

(2) PRDWS exhibits highly diverse and complex characteristics. At the geographic pattern scale, PRD can be divided into four types of water system areas: peripheral plateau and hilly areas, downstream delta enclosed field areas of various rivers, compound delta enclosed field areas, and alluvial plain sandy field areas. These areas respectively demonstrate four states: weak urbanization, urbanization margins, urbanization core, and dramatic changes.

(3) There exists a long-term dynamic balance between PRDWS and the urbanization process. At the settlement cluster scale, the differences of the four zones can be analyzed. The natural water system is initially the core dominant factor in urban and rural landscapes. Simultaneously, the rapid construction and evolution of infrastructure and industries drive the expansion of core built-up areas towards the periphery, forming new spatial patterns.

ABSTRACT

The extensive expansion of major Latin American cities represents a growing threat to the preservation of green spaces crucial for ecological balance and human well-being. Faced with the challenges of the environmental crisis and climate change, the relationship between urban expansion and environmental preservation needs to be addressed by urban planning instruments at different scales. The city of Medellín stands out in facing the challenge of containing its urban expansion while fostering sustainable development in the area of its Green Belt, dealing with complex relationships between access to housing and infrastructure, environmental preservation, and socioeconomic development. This article aims to present and discuss an innovative approach to dealing with urban expansion in Medellín's Green Belt, Colombia. The importance of the Partial Plan instrument through Land Readjustment as a fundamental strategy is highlighted. This instrument aims not only to contain the expansion but also to promote an equitable redistribution of land ownership, encouraging collaborative decisions among different actors. The proposed methodology is based on the analysis of the implementation of Partial Plans that use land readjustment as a means to reorganize the land ownership structure in the Green Belt. Practical cases such as the Pajarito Partial Plan will be analyzed, assessing the impacts of applying this strategy on urban dynamics, considering the active participation of the community and local authorities. The results include a more controlled urban expansion, with preserved green areas and a more equitable redistribution of ownership. The discussion addresses the challenges faced, the successes achieved, and the lessons learned, highlighting how the application of this instrument can contribute to a sustainable balance between urbanization and environmental preservation. Thus, the article aims to contribute to discussions of urban form and sustainable development, offering support for similar urban contexts.

Keywords: Expansion: Global South, Megamorphologies, Morphometrics, Tent Cities

INTRODUCTION

In a world with high urbanization rates, where the majority of the population lives in cities, urban challenges are intertwined with multiple contemporary crises, encompassing social, economic, and

environmental dimensions. In the context of Latin America, the intense and dispersed urbanization process, which accelerated throughout the 20th century, has led to high levels of urbanization and social inequality. Currently, about 80% of the Latin American population resides in urban areas, reflecting a scenario of profound transformations and challenges for sustainable development (Leite et al., 2020). The extensive expansion of large Latin American cities into green areas and environmental preservation zones poses a growing threat to the conservation of green spaces, which are crucial for ecological balance and human well-being. These areas provide vital ecosystem services such as climate regulation, water and food production, and air purification, among others.

Urban sprawl in Latin America has often been characterized by unplanned growth, frequently occurring outside the formal planning frameworks of cities. In large metropolitan areas like São Paulo and Mexico City, urban expansion and the reduction of green areas have increased surface runoff, subsequently raising the risk of flooding during the rainy season (de Lima et al., 2023). This phenomenon has led to irregular land occupation, lack of basic infrastructure, and inadequate public services, while also contributing to environmental degradation. In the face of the environmental crisis and climate change, the need to address the relationship between urban expansion and environmental preservation through urban planning tools at various scales has become increasingly evident (Marques, 2024).

In the Latin American context, the city of Medellín stands out for addressing the challenge of containing urban sprawl while promoting sustainable development in its Green Belt area, albeit in a limited way, as it navigates complex relationships between access to housing and infrastructure, environmental preservation, and socioeconomic development.

This article explores the case of Medellín, Colombia, as a reference case in the development and implementation of integrated urban expansion control tools. Medellín, once known for its high levels of violence and inequality, underwent an urban transformation process that included innovative planning and territorial management measures (Leite et al., 2020). The article is structured into four parts, beginning with the theoretical framework, followed by the Colombian context, the Green Belt, and the case study of the Pajarito Partial Plan.

Theoretical Framework

In the context of this article, Land Readjustment is highlighted as an important tool for urban reorganisation, especially in areas with precarious urbanisation. This instrument allows for the equitable redistribution of land with the aim of restructuring urban spaces and promoting the development of infrastructure. Within discussions on urban form, Manuel de Solà-Morales (1997) emphasises that urban form is directly linked to the organisation of public space and is essential for creating more inclusive and functional cities. The author advocates interventions that integrate fragmented areas, improving connectivity and social cohesion - a concept in line with Land Readjustment, which seeks to regularise spatial morphologies and promote a more cohesive and connected development.

On the other hand, Carlos Dias Coelho (2013) complements this analysis by addressing the relationship between urban form and the historical processes of land appropriation. According to him, urban morphology is the result of specific social and economic processes, and instruments such as Land

Readjustment need to respect these dynamics to avoid perpetuating inequalities. In the case of Medellín, the use of this tool cannot just be technical, but must take into account local characteristics and needs, promoting social and spatial integration.

For Solá-Morales (1997), urban form is directly linked to the structure and organisation of public space, which is essential for creating more inclusive and functional cities. The author emphasises the importance of intervening in the territory in order to integrate fragmented urban areas, which is in line with the logic of Land Readjustment, in which the redistribution of plots seeks to regularise spatial morphologies and improve urban connectivity. Solà-Morales' (1997) concept of urban acupuncture also reinforces the idea of targeted interventions that can catalyse the regeneration of entire areas, a principle that can be applied to land readjustment projects.

Coelho (2013) complements this analysis by focusing on the relationship between urban form and the historical processes of land appropriation and subdivision. According to him, urban morphology, especially in informal areas, is the result of multiple processes of adaptation and transformation that respond to specific social and economic logics. From this perspective, and reflecting especially on the Medellin context, Land Readjustment is not just a technical matter of land redistribution, but also a process of social negotiation that must take into account pre-existing dynamics and local needs, while respecting the social and spatial structure of the areas involved.

In this sense, the articulation between Land Readjustment and urban form involves not only the physical reorganisation of the territory, but also the incorporation of cultural and social elements that shape the space. This instrument must take into account the preservation of local identity and the strengthening of connections between public and private areas, promoting greater social and spatial cohesion. In this context, discussions about urban form linked to this instrument contribute to a critical vision of urban transformation, in which Land Readjustment, linked to other urban instruments, can be a tool for inclusion and requalification of cities.

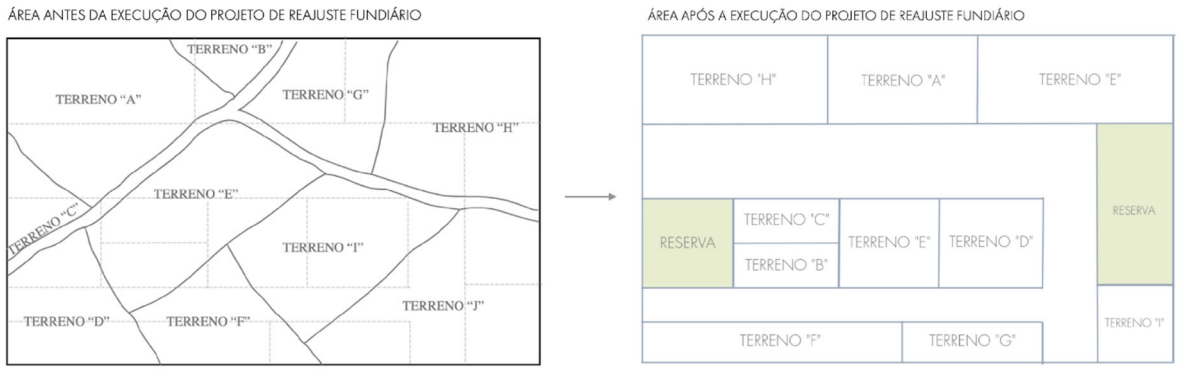

Figure 1 - Land Readjustment Concept. Source Pereira (2024)

Patterns of disordered and sprawling development generally characterise urban form and expansion in the peripheries of large Latin American cities. These trends are driven by a combination of factors, including inadequate land-use regulations, pressure for affordable housing, and the expansion of urban areas without proportional investment in infrastructure. The result is a fragmented urban fabric

with low population densities and insufficient infrastructure, which can exacerbate socioeconomic inequalities and environmental degradation.

In response to these challenges, there has been a growing emphasis on the need for more integrated and sustainable approaches to urban development in Latin America. This shift has been driven by concepts such as the compact city, urban regeneration, and the right to the city, which highlight the importance of densifying urban areas, revitalising existing neighbourhoods, and ensuring equitable access to urban resources and opportunities (Lefebvre, 1996).

The city of Medellín, Colombia, offers an example of how these approaches can be put into practice through the implementation of the Green Belt strategy, which aims not only to protect environmentally sensitive green areas on the city's periphery but also to serve as a platform for the development of public spaces and social housing, thereby integrating peripheral populations into the rest of the city. The Green Belt strategy departs from the traditional “plot-by-plot” urbanism, which tends to further fragment the urban fabric and exacerbate issues of mobility, infrastructure, and social exclusion.

Its implementation was facilitated by the use of innovative urban planning tools, such as Partial Plans and Land Readjustment. These instruments allowed the city to reorganise land ownership structures, promote collaborative decision-making among various stakeholders, and ensure the equitable distribution of the benefits and burdens of urban development.

The case of Pajarito demonstrates an effort to improve the quality of urbanisation in expansion areas while establishing respect for nature.

The Colombian Context

The current cycle of urban projects in Colombia began with the approval of Law 9 of 1989, known as the Urban Reform. In 1991, a new federal constitution was enacted, and later, in 1997, Law 388, the Urban Development Law, was promulgated. This law aimed to update Law 9, aligning it with the changes introduced by the 1991 Constitution. This process took place in a context of market liberalisation policies, where territorial planning decisions were decentralised to the municipal level. According to Bocanegra (2014), this resulted in two scales of power and influence: the National scale, responsible for regulating and managing certain resource sources, and the Municipal scale, in charge of planning, financing, and control.

Within this framework, one of the main urban planning instruments at the municipal level is the Land-Use Plan (POT), which defines the specific areas of the territory requiring urban interventions, projects, and specialised instruments. The POT also spatially distributes the municipality’s economic activities and determines major infrastructure projects to achieve its objectives (Ferro, 2010, p. 23).

The POT also designates Strategic Intervention Areas (AIE), which are programs and projects derived from the policies and strategies of the municipal POT. These actions must be approved and ensure a structural impact on the quality of life and spatial organisation of the city.

The execution of AIEs takes place through urban macro-projects, which are a set of technically defined and evaluated actions. These projects aim to carry out large-scale urban operations that impact the city's structure and guide its growth. Macro-projects must provide coordinated solutions to problems,

involve interested public and private entities, establish mechanisms for capturing land value appreciation, and ensure a fair distribution of costs and benefits among stakeholders.

Within this framework of transformations applied to the legal urban planning system, the role of the Partial Plan (PP) stands out. This tool, primarily technical but imbued with significant political and social implications, emerges as a paradigm in Colombia's new urban planning system. The Partial Plan is the instrument that develops and complements the POT's provisions in specific urban areas. It is mandatory for the development and transformation of expansion areas and urban renewal projects, linking land planning and management.

POTs establish guidelines and parameters for Partial Plans, determining the scale, complexity, and conditions for the projects. Each Partial Plan addresses specific urban programs and projects. There is no fixed definition of their magnitude, nor are they limited to small areas. The focus is on criteria, not specific areas. The key criteria refer to urban development and planning guidelines, which enable the creation of various Partial Plans aimed at implementing and financing the directives outlined in the POT, ensuring an equitable distribution of costs and benefits.

Law 388 of 1997 also mandates that PPs be developed through Urban Action Units (UAU). It is through this instrument that the rational use of land is achieved. The law defines UAUs as sectors of intervention within a Partial Plan. This scale of urban planning is precisely where Colombia's urban projects fit. Each UAU focuses on a set of plots, blocks, or groups of blocks, accounting for the need for public works and establishing rights and obligations for property owners (Montandon, 2009).

The Medellín Green Belt: Urban Expansion Control and Integrated Urban Revitalization

In the Colombian context and in line with the metropolitan planning established by the Metropolitan Area of Valle de Aburrá (AMVA), the city of Medellín has included the Jardín Circunvalar de Medellín in its strategic planning. The goal is to contain the urban sprawl towards green areas while also ensuring the urban redevelopment of already occupied areas from an integrated perspective. This approach not only addresses the urban design of these areas but also considers social, environmental, and economic dimensions.

The Jardín Circunvalar de Medellín, also known as Medellín's Green Belt, is a strategic urban project aimed at controlling the city's expansion and promoting environmental conservation while integrating marginalized communities into the broader urban fabric. This ambitious initiative aims to balance urban growth with ecological preservation and social inclusion by creating a green buffer zone around the city's perimeter. It not only curbs unplanned urban sprawl but also enhances the quality of life for the local population through integrated urban revitalization efforts.

Medellín's Green Belt project was conceived as a response to decades of disordered urban expansion, particularly in the city's peripheral and hillside areas. These zones, characterised by informal settlements and environmental degradation, were in dire need of infrastructure, public services, and environmental protection. The Jardín Circunvalar project aims to address these challenges by creating a continuous green corridor that serves both as a natural barrier to urban sprawl and a space for recreation, community engagement, and environmental education.

The project has two main objectives: controlling urban expansion and improving the quality of life in the city's peripheral areas. To achieve this, the Green Belt incorporates a range of interventions, including reforestation, the construction of parks and green spaces, and the development of social housing and public infrastructure. These efforts aim to integrate the peripheral communities into the city's urban dynamics while preserving the natural landscape.

Key elements of the Jardín Circunvalar include:

- Urban Expansion Control: The Green Belt acts as a physical and regulatory boundary, limiting further expansion into ecologically sensitive areas and protecting Medellín's surrounding hillsides from deforestation and environmental degradation. By creating a natural buffer zone, the project helps contain the city's growth within its existing urban footprint, preventing unplanned settlements in vulnerable areas.

- Environmental Conservation: The reforestation of degraded areas and the protection of existing natural spaces are central to the project. The Green Belt promotes the restoration of ecosystems, improving biodiversity and reducing the city's environmental footprint. It also contributes to climate regulation by preserving green spaces that help mitigate the urban heat island effect.

- Social Inclusion and Urban Revitalization: One of the project's core components is the integration of marginalised communities living in informal settlements. Through the construction of new infrastructure, public services, and social housing, the Green Belt project aims to provide these communities with better living conditions and greater access to the city's economic and social opportunities. The creation of parks, public spaces, and cultural facilities fosters social cohesion and encourages the active participation of residents in the development of their neighbourhoods.

- Public Spaces and Ecotourism: The project has also introduced a network of public spaces that offer recreational opportunities and promote ecotourism. Trails, parks, and viewing points are integrated into the Green Belt, providing residents and visitors alike with access to natural areas and creating new opportunities for economic development through tourism.

The Jardín Circunvalar of Medellín is an example of how urban planning can address both environmental and social challenges in a holistic manner. By integrating urban expansion control with community-driven revitalisation, the project not only curbs sprawl and protects natural spaces but also empowers local populations, fostering a more inclusive and sustainable city.

To achieve this, a series of urban instruments are coordinated, with the main one being the Territorial Ordering Plan (POT) of Medellín (2014-2027), which was updated in 2014. This plan establishes three Strategic Intervention Areas (AIE): AIE Centro River, AIE Edge, and AIE Transversals, as indicated in Figure 2. The Jardín Circunvalar de Medellín includes the AIE Edge, which is divided into five macro-projects: (1) Northwest Urban-Rural Edge (BUR), (2) Southwest BUR, (3) San Antonio BUR, (4)

Northeast BUR, and (5) South BUR, as well as part of the AIE Transversals, divided into two macro-projects: (1) La Iguana and (2) Santa Elena.

Figure 2 - Medellín's strategic intervention areas and macro-projects. Available at: https://www.medellin.gov.co/irj/portal/medellin?NavigationTarget=navurl://1835433ab6162f1d159791ea638561aa. Accessed on 15 September 2023.

Within the framework of the Jardin Circunvalar de Medellín, the macro-project areas were divided into 14 Master Plans and, on this more detailed scale, specific objectives and strategies were established for each sector. This article will discuss the case of Pajarito (12) (Figure 3).

.

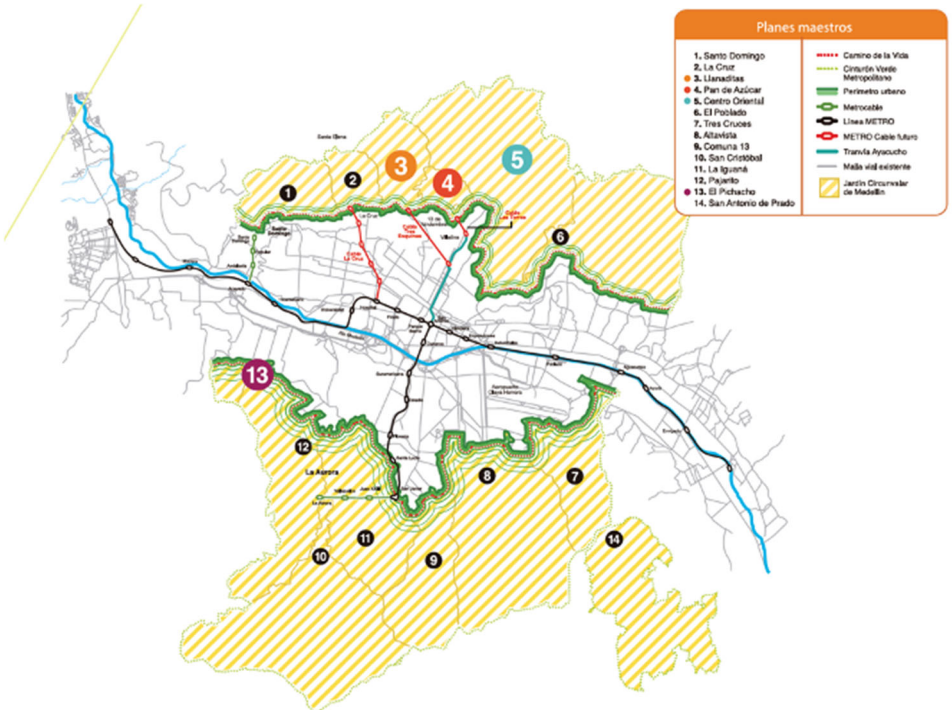

Figure 3 - Masterplan of the Medellín Circumpolar Garden. Source: Alcaldía de Medellín and EDU (2015)

The Jardín Circunvalar de Medellín has adopted a systemic intervention strategy in the territory, involving local communities through pedagogical models of consultation, dialogue, design, implementation, evaluation, and feedback. To achieve this, three strategic lines have been fundamental: (1) sustainability and environmental recovery, (2) comprehensive improvement of the habitat for life, equity, and social cohesion, and (3) pedagogical urbanism. Controlling urban expansion and enhancing environmental character and historical heritage are developed through ecological restoration, the establishment of public facilities, community gardens, recreational areas, and ecotourism; these uses are linked with activities that generate employment and income. Additionally, actions aimed at risk management are proposed, ensuring dignified and sustainable housing while improving local urban mobility and its connections with the Medellín Valley through sustainable public transportation.

These actions are coordinated to generate territorial transformation based on five attributes: (1) integral sustainability of the territory, (2) inclusive and structuring public space, (3) control of urban expansion with a holistic view of development, (4) quality connections within the territory, and (5) dignified, safe, sustainable, and affordable housing.

The Master Plans highlighted in Figure 3 provide the overall framework and strategic guidelines mentioned above, which must be followed by the Partial Plans. The Partial Plans, in turn, apply and detail these guidelines in the local context, ensuring that interventions are suitable for the specific characteristics of each area of the city. One way to develop a Partial Plan (PP) is through Land Readjustment. Although not every PP is derived from land readjustment, every land readjustment occurs within a PP. Land Readjustment is an instrument incorporated into the Colombian urban legal framework under Law 9 of 1989 and later regulated by Law 388 of 1997.

Land Readjustment is a method of urban development executed collaboratively, where property owners and tenants contribute to financing and executing the project, equitably sharing the costs and benefits of urban development. This practice is authorised by specific legislation, and its execution is managed by a multidisciplinary technical agency known as the implementation agency, which is responsible for the transformation process of the various land units within the project's boundaries (SOUZA, OCHI & HOSONO, 2018, p. 29).

Articles 45, 46, and 47 of Law 388 of 1997 define the bureaucratic process for carrying out a Land Readjustment project in Colombia. The project always occurs within an Urban Action Unit and must be approved based on the Partial Plan. Once presented, it must be approved by a minimum number of landowners representing at least 51% of the project's surface area. The project must include rules for valuing the lands and properties contributed to the project area and must consider the current urban regulations for the area. Restitutions will be made from the resulting land lots unless it is not possible, in which case an economic compensation will be provided. It is important to mention that there is also a regulation stipulating that 20% to 25% of privately owned lands in a Partial Plan are mandatorily allocated for Social Housing projects.

Pajarito

The Pajarito Partial Plan is the largest area designated for urban expansion as outlined in the Territorial Ordering Plan of 1999 and was later revised in 2012, accounting for nearly half of the areas allocated

for expansion in the same plan. Three main guidelines guided the project: the first proposed the creation of an urban edge, the second aimed to create social housing in a region lacking adequate housing, and the third focused on its environmental appeal, surrounded by rivers and mountains.

Determined by the Territorial Ordering Plan, it was established that the entire area would consist solely of a Partial Plan, which caused significant controversy since the area spans 230 hectares, whereas partial plans typically range between 10 and 20 hectares in size. Formulated between 2001 and 2002, this was the first Partial Plan with these characteristics approved in Colombia. The plan envisioned the construction of 1,258,684 m² for housing and 67,641 m² for complementary uses, divided into central zones for service provision and commerce. However, a large portion of the area is deemed unsuitable for construction due to environmental restrictions, resulting in a significant expanse dedicated to green spaces, linear parks, and river protection, totalling nearly 329,000 m² (Bocanegra 2010).

These characteristics make this urban edge a permeable territory that ensures the continuity of environmental systems and an abundance of open green areas, while also emphasising two essential urban conditions: low occupancy with buildings and housing complexes with heights ranging from four to eight stories, which is crucial for social housing. Additionally, the rugged topography facilitates access at intermediate building levels (Bocanegra 2010, p. 153).

The Pajarito Partial Plan, located in the expansion zone of Medellín, encompasses the incorporation of 38 plots of land from 36 owners. Of the total area, 43% will remain unoccupied due to environmental or geological conditions, while only 28% of the land is suitable for construction. Thus, only 63 hectares (27.3%) of the original 230 hectares are left for residential use and other new functions, after a final assessment of the other pre-designated areas. The project was conceived to provide high-density social housing in buildings of eight stories, containing between 100 and 238 housing units. The costs of urban infrastructure and services totalled $45 million. The municipality acquired 80% of the land through voluntary sales at prices that did not include expectations of future land value, and guaranteed the construction of infrastructure to ensure that the developments or sales of real estate products remained below the thresholds established by the Partial Plan. It is important to note that the constructed housing units are subsidised (Rojas Eberhard and Rave 2013).

The application of the ‘Land Readjustment’ tool in areas of urban expansion, especially in regions of social vulnerability, presents some differences from the use of this instrument in already consolidated areas. In these consolidated areas, each owner assigns part of their land, which is transferred to a trust. A complete redesign of the layout of the plots in the area is then carried out. In the case of Pajarito, the city council had to acquire some land, although the logic of development through urban action units was maintained.

This type of intervention in areas of expansion, especially in socially vulnerable areas, requires stronger government involvement, both in negotiation and in financing. It also involves greater sensitivity to social issues, since it is necessary to ensure that the original residents benefit and are not excluded from the urban transformation process. The ‘Land Readjustment’ tool, in this case, adapts to the need to reconcile urban development, land redistribution and social inclusion, while respecting the local reality and the demands of the residents. In the case of Pajarito, the instrument was also used as an important tool for relocating families living in risk areas.

Table 1 illustrates how the articulation between urban planning instruments is reflected in the urban form. To discuss the case of Pajarito, certain categories and elements of urban form established by Scheer (2016) were used. With regard to land and plots, it is important to note that this area specifically presents some challenges in terms of scale; the Partial Plan covers an area of 230 hectares, which is between 10 and 20 times larger than the partial plans established in the more central areas of Medellin. In addition, the area faced several environmental restrictions, such as complex and steep topography, as well as the presence of natural springs. As a result, 43% of the area could not be developed due to environmental or geological restrictions, and only 28% of the land is suitable for construction.

With regard to paths, there is a low road density resulting from environmental restrictions, combined with wide streets and irregular routes shaped by the natural morphology of the site. The limitation of roads hinders connectivity and impacts mobility within the area. This highlights the strong influence of geographical features on urban planning in the area, which has resulted in roads adapting to the irregular nature of the terrain.

The area has many open spaces and green areas, although there are relatively few trees. The built environment consists mainly of tall buildings, all with a uniform typology of eight storeys. The infrastructure is characterised by wide streets, which creates a more isolated environment dependent on the use of cars for transport, making it difficult to create a denser, more integrated urban fabric.

Table 1 - Analysis of key elements of urban form in the case of Pajarito. The categories are based on the elements of urban form established by Scheer (2016)

Built form	
Objects Paving, lawn, cultivated vegetation, signs, canopies, fountains, art, signals, and poles, planters, curbs.	**1. Many open areas/green spaces, but few trees**
Buildings Occupied buildings, topologically whole. Accessory buildings, sheds, kiosks, garage.	• **High rise buildings - 8 floors** • **The buildings have a homogeneous typology**
Infrastructure Large scale, occupied: bridges, stadium, canal, clock tower, city gate, city wall, triumphal arch, monuments.	• **Wide streets - isolated car-dependent area**
Boundary Matrix	
Plots Bounded, parcel or lot, signifying control	• **Challenges of scale (230 ha area)** • **Topographical and environmental challenges** • **Many open/green areas**

	The partial plan has an area of 230 hectares (between 10 and 20 x larger than usual partial plans)
Paths Continuous, the bounded space of the right of way of the street, rail, canal.	• **Low road density due to environmental restrictions** • **Wide streets** • **Irregular path due to morphology**
Land	
Land Watershed, natural vegetation, slope and aspect, river, harbours, topography.	• **Complex/rugged topography** • **Slopes** • **Springs** **43% will not be occupied due to environmental or geological restrictions, and only 28% of the land is suitable for buildings.**

Concluding remarks

In the context of debates on urban form, the discussion in this article has shown that the combination of different urban planning instruments, from strategic planning to partial plans and Land Readjustment, makes it possible to achieve a more organised urban form, overcoming the traditional "plot by plot" development approach. In the case of Medellín, this articulation aims for a more cohesive urbanisation, which despite its limitations, has allowed the reorganisation of a large area like Pajarito, respecting environmental and geological restrictions, which translates into more sustainable and controlled urban planning, guaranteeing development in a way that mitigates negative impacts.

As well as promoting a more organised urban form, this integration brings social and environmental benefits that are worth mentioning. In Pajarito, 43% of the area has been preserved due to environmental and geological restrictions, while only 28% of the land is earmarked for construction. This reflects a commitment to preserving the environment and promoting high-density social housing, especially benefiting resettled families who previously lived in risk areas. This approach balances the need to urbanise with the preservation of natural resources, promoting more inclusive urban development.

However, there are contradictions between the strategy and the executed plan. While the strategic planning defines the Green Belt as an area to contain urban sprawl, it also establishes new areas for urban growth, which raises questions. Is it possible to reorganise built spaces more efficiently? Is the verticalisation proposal really in line with the idea of a ‘compact’ and ‘polycentric’ city, as envisaged in the strategic plan? Such doubts raise discussions about the sustainability of this urban development model, especially considering the social and environmental impact of planning decisions.

Partial plans in central areas differ significantly from those applied in expansion areas such as Pajarito, where the scale of the project and environmental factors introduce various complexities. The need to integrate a series of urban planning tools in a large area, subject to environmental restrictions, demands specific solutions that are not always necessary in more centralised and consolidated areas. Despite the challenges, this integration of instruments seeks to avoid fragmented development and

promote more planned urbanisation, which represents an advance on traditional urban expansion practices.

The analysis of Medellín's Green Belt, based on Land Readjustment, reflects the attempt to reorganise fragmented urban areas with a view to social inclusion and environmental preservation. However, looking at it from the theoretical perspective of Manuel de Solà-Morales, who emphasises the importance of the relationship between urban form and public space, one can question the extent to which these interventions actually promote sustainable urban cohesion. Solà-Morales argues that connectivity and the integration of fragmented areas should be priorities, and the Pajarito Partial Plan, although it has preserved 43 per cent of the area for green spaces, still presents a dispersed urban form with low connectivity, especially due to topography and environmental restrictions. The use of uniform typologies of high-density buildings can also be criticised in the light of Solà-Morales' idea of the importance of interventions that respect the specific characteristics of each territory.

Furthermore, Carlos Dias Coelho emphasises that specific historical and social processes shape urban morphology, and that interventions such as Land Readjustment must take these dynamics into account to avoid reproducing inequalities. In the case of Pajarito, although the project seeks to integrate the vulnerable population and offer social housing, the centralisation of decision-making power in the hands of the municipality and the lack of typological diversity may raise questions about the initiative's real inclusive impact. In addition, the verticalisation proposed may be at odds with the notion of a compact, polycentric city, exacerbating socio-spatial segregation by creating isolated areas with little integrated urban infrastructure, which goes against the guidelines of a more balanced and sustainable urban development advocated by these theorists.

In the case of the Pajarito Partial Plan, the theoretical discussions reveal both the advances and the practical limitations of the application of Land Readjustment. Although the preservation of 43 per cent of the area for green spaces represents a commitment to sustainability, low connectivity and the use of uniform, high-density typologies can limit the inclusive impact of the intervention. By adopting a verticalisation solution, there is a risk of creating isolated areas, which could exacerbate socio-spatial segregation, contrary to Solà-Morales' recommendations on the importance of interventions that respect the specific context of each territory. Furthermore, Carlos Dias Coelho's criticism of the lack of typological diversity and the centralisation of decisions can be applied to Pajarito, where verticalisation does not necessarily promote the desired cohesion, raising questions about the long-term effectiveness of this approach.

Lost waterways of Country: A morphological approach to interpreting maps of hidden streams beneath Australian cities

Professor Paul Sanders[1], Professor Mirjana Lozanovska[2], Juan Alsina[3]
[1] School of Architecture and Built Environment, Faculty of Science Engineering and Built Environment, Deakin University, Australia, paul.sanders@deakin.edu.au, mirjana.lozanovska@deakin.edu.au.

ABSTRACT

The planning for colonial settlement in the 'new world' often originated with maps that accurately charted the topographical landscape features that were 'as found' by the colonial surveyors, upon which the first outlines of the proposed town plan of blocks and plots was drawn. While the intent of the maps was the blueprint for a future built manifestation, in the context of Australia the settlement drawings represent a contemporaneous record of the landscape that had been under the custodial care of the first nations peoples for millennia. These maps record the landscape features of immense cultural significance that were to be irrevocably disturbed, altered, or destroyed. The paper proposes to develop recent published research by the authors with the aim of this paper to develop a broad comparative study through the archival research and analysis of Geelong, Brisbane, and Sydney. The findings suggest a widespread phenomenon whereby the earliest colonial settlement surveys and maps can be understood as a representation of an end of a sequence of continual human habitation, rather than the conventional reading of the start of a morphological sequence. We conclude that colonial surveys maps are a valuable source for evidencing the form and location of important sites of lost cultural landscapes, in particular the lost waterways of Country, submerged beneath the modern city, that may be re-interpreted through design reparation for new urban design approaches, with implications for meaningful reconciliation of cultural heritage and identity.

Keywords: Urban morphology, Country, Lost waterways, Australian cities

INTRODUCTION

The notion of "Country" is fundamental to Australian Aboriginal understanding of spiritual, cultural, and social ties to the environment. Unlike the Western understanding of a geographic area, Country embodies the deep interconnected relationship between land, water and sky (Neale, 2020; Government Architect NSW, 2023). We begin by acknowledging the traditional owners of Country that are the subject areas of this paper, namely the Wadawurrung people of the Geelong, the Turrbal and Jagera people of Brisbane, and the Gadigal people of Sydney.

Generally speaking, every part of Country in Aboriginal Australia contains a set of travel paths crisscrossing the landscape, in which sacred places occur that were created by the ancestors. (Page and Memmott, 2021, 34)

Country is infinite where time and place are continuous, part of a seamless flow of life with no concept of a beginning or ending and is also known as the Dreaming. The Creator ancestors shaped Country (also referred to as Creation Stories). Songlines, connected to the Dreaming link sites of knowledge and are embodied in the features of the land (Neale, 2020). Every aspect of Country is interconnected and symbiotic, removing one element is detrimental to the whole system.

The terrestrial waterways of Country are dominated by existing large river systems such as the Murray Darling that drain vast continental basins, despite having been altered or manipulated. However, it is at the locations of city and towns, established over the last two centuries, where often the smaller streams, creeks and gullies have disappeared from view, confined into subterranean engineered drainage systems. Once an important fresh water source, these waterways have systematically been submerged and covered and are now lost as a tangible feature of the natural landscape.

Identifying significant landscape features that have been erased by colonial settlement and development can aid reconciliation by acknowledging and evidencing their histories towards restoring connections to important features of ancestral lands. This paper aims to identify former surface waterways as an example of lost landscape characteristics using archival maps, that provide evidence of pre-settlement natural environments.

The French theorist Michel de Certeau critically examines maps, arguing they are not mere objective representations of space. Instead, they are crafted by those in power to project political ideology and control over the inhabitants of a given area. Maps influence future outcomes and wield power through what they omit or deliberately exclude, distorting reality and reinforcing control (de Certeau, 1984). Maps also generate radical changes to existing conditions by their projective and future oriented imaginary. Mapping and territorial surveys are particularly spatial representations that both represented topographical conditions and produced a way of knowing, a system of knowledge that substituted and replaced other ways of knowing. Colonial land surveying was a means of claiming ownership. Mapping or planning envisioned a future imposed on the present land, reshaping its physical and socio-cultural characteristics. These maps gave speculative ideas a sense of reality, anticipating and facilitating future changes and transformations.

Various interpretations of a single document can often conflict, shaped by different historical perspectives as well as author positions. Survey maps, as tools of power, guided the development of cities by imposing colonial visions on the landscape. Indigenous communities navigated these imposed boundaries with strategic flexibility, described by de Certeau (1984) as a ‘turn’ of events. The lines of settlement—grids, fences, roads, and boundaries—ultimately became instruments of dispossession (Sanders et al. 2021).

The authors build on recent published research (Sanders et al. 2021, 2024) that establishes an alternative reading of the earliest colonial topographical features surveys and settlement maps, that they evidence the end of a sequence of continual human habitation, rather than the conventional reading of the start of a morphological sequence. The paper thereby proposes a ‘reverse gaze’ on colonial history, a look back in time, rather than a projective ‘forward’ looking gaze. This series of investigations have pursued this lens and frame of analysis towards developing a reparative approach to history, a historiography of revision and repair; and a reparative approach to urban design. This

paper aims to add to the ongoing discussion about urban landscapes and the importance of understanding the past as a complex and contested heritage.

Urban morphology, as a field of study, documents the physical structure and form of cities from their founding to their subsequent changes and developments. This method provides a solid foundation for compiling evidence of environmental changes using archival maps, photographs, and documents. Such data can prompt new questions that challenge the conventional Western historical narrative, which often overlooks negative and destructive human and environmental strategies integral to colonial settlement processes.

METHOD

Urban morphology, as a field of study, documents the physical structure and form of cities from their founding to their subsequent changes and developments. This method provides a solid foundation for compiling evidence of environmental changes using archival maps, photographs, and documents. Such data can prompt new questions that challenge the conventional Western historical narrative, which often overlooks negative and destructive human and environmental strategies integral to colonial settlement processes.

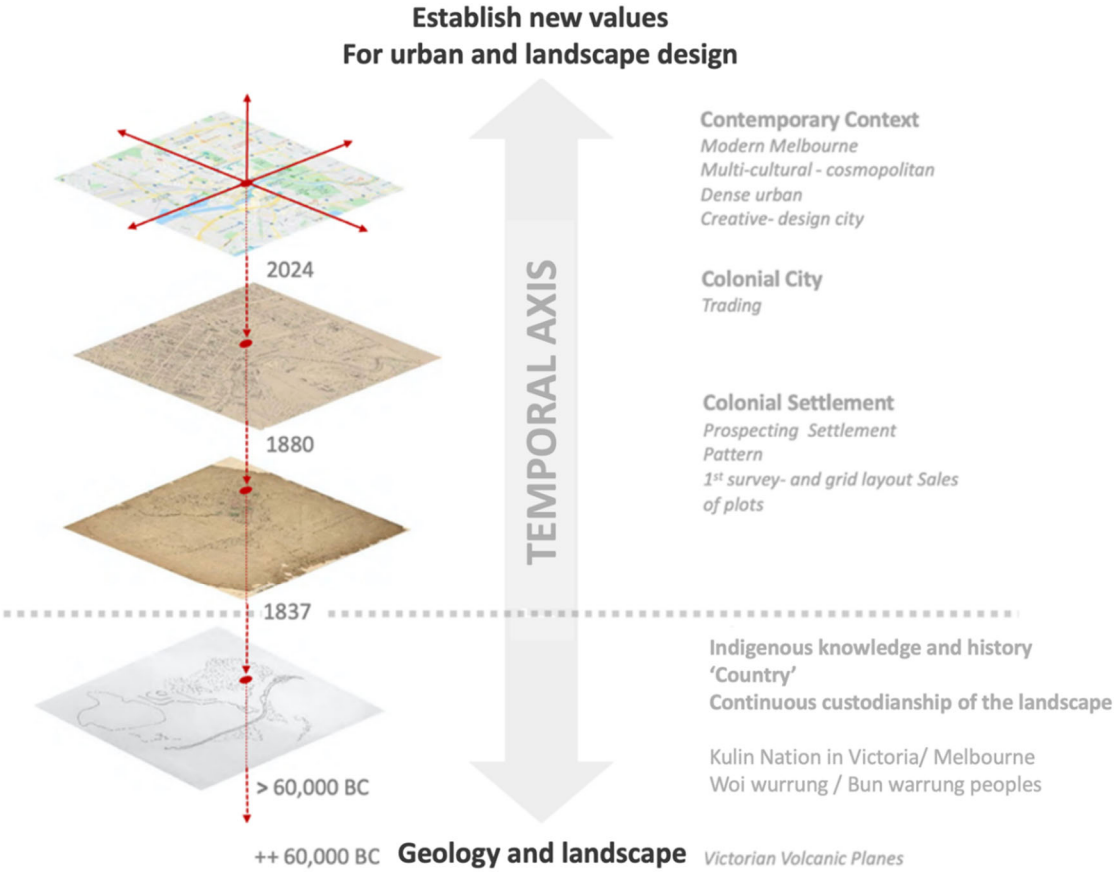

Figure 1. Temporal Axis from geological foundations of site to contemporary design values: Example of Melbourne, Australia. Source Authors.

The conceptual framework (Figure 1) establishes a temporal axis including the geological foundations that underpin the physical landscape through the various and multiple evolving morphological events to the present urban condition. The embodied connection of Country stretches across all these

temporal phases but remains unrepresented through such mapping. We suggest that the interpretation of the inherent dichotomies of pre and post-colonial dimensions of this temporal axis can establish new values for urban and landscape design.

According to Memmott et al. (2022) architects, urban designers, and landscape architects in Australia and other First Nations regions, are increasingly seeking specialised consultancy to integrate Indigenous cultural history and landscapes into their projects. This trend is driven by political movements emphasising Reconciliation Action Plans, decolonisation, Indigenous sovereignty, and intercultural ethics. However, these projects are concentrated in state capitals, where colonial forces were most destructive to Indigenous societies, resulting in fragmented and lost cultural knowledge.

In recognising that the historical geography of cities has been shaped by settler-colonial influences, Coyne et al. (2020) suggest that by examining urban infrastructures such as drainage, hydro-imperial knowledge must yield to culturally inclusive urban water designs.

Indeed, the restoration of rivers to former ecological and natural conditions, and the field of Water Sensitive Urban Design (WSUD) are becoming prevalent in the consideration of urban environments.

In this paper, we focus on a common phenomenon across three selected Australian cities of Geelong, Brisbane, and Sydney in which streams, creeks, or gullies that were important sources of water sustaining pre-colonial environments, have been confined within sub-terranean drains systems as urban development proceeded. To give substance the potential for design reparation, we feature a speculative student design project in Sydney, that provides clues to how lost landscape feature of Country can be re-imagined.

WESTERN GULLY: GEELONG, VICTORIA

The traditional name for Geelong is Djilang understood to mean ‘a tongue of land’. For the Wadawurrung people of the Kulin Nation the area of ‘coastal cliffs, wetlands, grassy and volcanic plains, and people were all formed by Bundjil and the Ancestor spirits who continue to live in the land, water and sky’ (Wadawurrung Traditional Owners Aboriginal Corporation, 2004). Bundjil, a Wedge Tailed Eagle, is the name of the great ancestral creator spirit.

Geology and topography

The physical aspects of Wadawurrung Country sits on the geological foundations of Pleistocene volcanics and Pliocene sediments known as Moorabool Viaduct Sands (MVS). Volcanic flows cross the central and southern parts of the reserve, creating an east-west ridge with views of Corio Bay to the north and the Barwon River to the south. The MVS forms soft sandstone cliffs along Corio Bay's southern and western shores, with a terrace sloping southward towards Geelong’s main ridge. The Barwon River, marking the southern boundary of the reserve, provided early settlers with fresh water but remained physically separate from Corio Bay. McKillop Street runs along the ridge, dividing the reserve into two halves. The southern half was drained by natural gullies formed through MVS erosion, as there were no tributaries or creeks (Brownhill, 1990; Marshall, 2020).

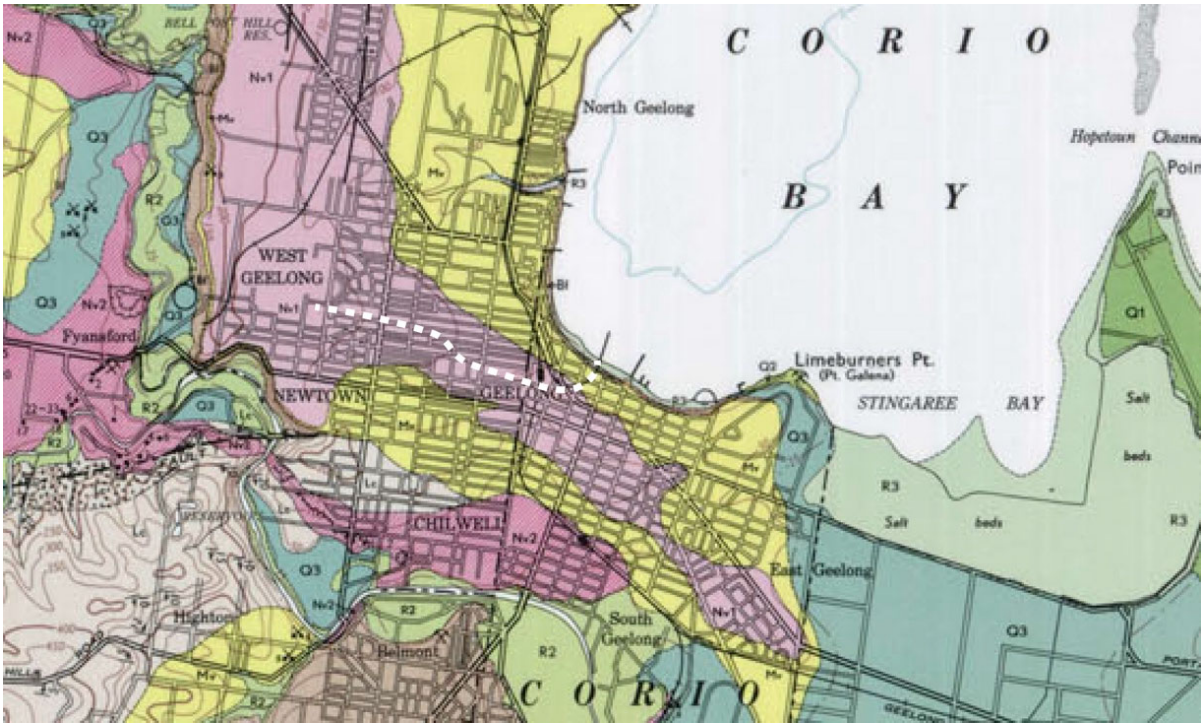

Figure 2. Geological Survey of Victoria, 1963. Geelong. 1 mile to 1 inch, geological map. Department of Mines, Victoria. . The course of The Western Gully is shown with a white dotted line. Accessed online August 19th at http://earthresources.efirst.com.au/product.asp?pID=370&cID=33.

The lateral ridgeline of Newer volcanics prevented the Barwon River from reaching Corio Bay, leading to several gullies that naturally drained the bayside districts mainly through the MVS. Among these, the Western Gully was particularly notable for its extended reach. Early maps trace the gully's path eastward to Corio Bay (Marshall, 2020). The Western Gully posed an obstruction to landward movement, and uncontrolled stormwater flow posed significant challenges for colonial settler mobility and travellers, especially on dark and stormy nights (Keavy, 1968).

Settlement maps and engineered drawings of waterway confinement

The Western Gully was first charted in its natural course on early settlement plans for Geelong. In Hoddle's map of 1850, it is shown flowing through a demarcated reserve of 59 acres for 'Ornamental Grounds Gardens', before discharging into Corio Bay through a smaller reserve allotment (see Figure 3). A reading of this alignment is that Hoddle anticipated the future preservation of the unhindered water course flowing through a landscaped reserve.

Figure 3. Hoddle, R. 1838, Plan of the Town of Geelong. Source: State Library of Victoria Maps Collection, M 821.411 A 1838.

However, in 1849 a first alternation occurred when a dam was built within the gully to manage water flow and prevent flooding, making it passable to the new colony. The dam, partly natural and partly artificial, served as a traffic route to and from La Trobe Terrace. It also aimed to provide water for horses and bullock teams, but the steep embankments and poor lighting made the location hazardous, leading to several drownings. By 1886, the dam contained little water but a large amount of mud due to seasonal fluctuations and drainage issues. As colonial Geelong developed, the business and traffic flow were significantly hindered by the gullies and elevated embankments, necessitating construction work. The most significant challenges and expenses were encountered during the filling of the Western Gully and the extension of the street to the bay front. In 1871, a determined effort led to a more level and cohesive streetscape, with soil from Victoria Terrace playing a crucial role (Brownhill, 1955; Rowe, 2021).

Figure 4. Johnstone Park Stormwater Sewer. 1912. Source: REF A33, Geelong Heritage Centre Collection, Public Records Office Victoria (PROV).

In 1912, a stormwater culvert was constructed between Johnstone Park and Corio Bay, incorporating a drain under Cunningham Street. During the 1930s depression, public funds were directed to civil engineering work to provide employment, leading to the construction of a brick-lined stormwater barrel drain along the Old Western Gully route.

The final major phase of confining the Western Gully occurred in 1964 with the construction of a light industrial zone between La Trobe Terrace and Pakington Street. The council executed eight schemes, with the most substantial involving Gordon Avenue above the old gully and its drain. Through various phases of construction, the Western Gully was permanently eliminated within a stormwater management system of brick culverts and underground sewers. These works aimed to improve sanitation and prevent flooding (Brownhill, 1955; Seaton, 1978; Rowe, 2021).

Creative reparation

In establishing new values for design reparation through urban and landscape design in Geelong, there are a few examples of interpretation and critical work related to paintings as historical documents, which provide crucial details and data for physical reparative measures. Creative strategies and performative events in Geelong offer glimpses of lost Country. One such event is Mountain to Mouth, conceptualized as a way to walk together in the footsteps of Aboriginal ancestors. The annual series of curated walks activated a way of remembering lost views in a changing environment (City of Greater Geelong, 2020). Johnstone Park has also been recognized as a site of cultural significance, highlighted by commemorative events like the NAIDOC (National Aboriginal and Islanders Day Observance Committee) Week trail and Reconciliation Day (Tournier et al. 2013).

In this context, ideas and recommendations to revive memories of lost waterways, such as the Western Gully in Geelong, can also be considered. There is potential for symbolic restorative urban landscape projects. By opening the buried culvert and re-landscaping Johnstone Park, remodelling the Geelong Waterfront, and revealing the exit of the culvert into Corio Bay, the presence of the Western Gully Creek could be revitalized (Sanders et al, 2024).

WHEAT CREEK: BRISBANE, QUEENSLAND.

The traditional name of Brisbane is Meanjin meaning the place of the blue water lilies (https://www.turrbal.com.au/our-story). The river "known as Maiwar, has been a meeting place, a highway and a source of food" (Murray, 2023) for the Turrbal and Jagera people, the original Aboriginal inhabitants of the area.

Geology and topography

The city area mainly consists of undulating to low hilly lands, generally below 80 meters in elevation, but rising to around 120 meters, with a few isolated higher hills like Mount Gravatt, which reaches 255 meters. This unit also includes very low-level plateaus, such as the Sunnybank area, which are small remnants of an ancient surface that sloped gently toward the coast. The low hilly areas typically have gentle to moderate slopes, while the middle to upper slopes of higher ridges, particularly in the western suburbs and on isolated prominent hills, are moderately to steeply sloped. This unit features a variety of rock types, including carbonaceous shales and lithic sandstones of the Tingalpa Formation, primarily exposed east of the city centre between Aspley and upper Tingalpa, extending to the coast in the Wynnum-Manly area. Additionally, a narrow, north-south band of rhyolitic tuff (ignimbrite) is found east of the city (Beckmann et al. 1987).

Figure 5. City of Brisbane Geological Map Sheet 3 [Extract]. The course of Wheat Creek is shown with a dark dotted line. Source:Geological Survey of Queensland Publication Number 323, 1965, Drawn by J.A.Wright, Department of Mines, Brisbane.

Settlement maps and engineered drawings of waterway confinement

When the Moreton Bay Penal Settlement moved to Brisbane from Redcliffe in 1824, it was established along the ridgeline beside the Brisbane River, chosen for its access to creeks, lagoons, and swamps (Brisbane City Council, 2008). Even during the period when the convict settlement was being dis-established, preparations for 'free-settlement' (albeit British colonial settlers) were already well underway. Starting in 1839, three surveyors had been sent to Moreton Bay to conduct trigonometrical surveys to determine topography as well as to report on the condition of soils, water and timber supply, with a view to recommending sites for towns, villages and other purposes (Johnson, 1988) (See Figure 5). As the settlement expanded, waterways cutting through what would become the Central Business District (CBD) were diverted and incorporated into new streets, named Creek, Tank, and Water Streets (Brisbane City Council, 2008).

Figure 6. Ham, T. & Co. 1863. Ham's Map of the City of Brisbane, Queensland, 1863. [Cartographical material]. 'Ham's map of the city of Brisbane, Queensland, compiled from official and private sources and lithographed by T. Ham & Co. Published by J. W. Buxton, Queen Street, Brisbane. Scale 4 chains to 1 inch.' Copied and digitised from an original map held by the John Oxley Library. Item is held by John Oxley Library, State Library of Queensland. Accessed online on September 8th 2024 at https://www.data.qld.gov.au/dataset/digitised-maps/resource/22bd64b9-1c7b-4a30-9dff-cc86227632a8/view/ec89b884-c017-464e-bef3-812c9eacdcdb.

Urban Morphologist Arnis Siksna identified that the settlement pattern of Brisbane was based on 200x90m 'medium rectangular blocks' with a street spacing mesh of 221x111m; internally divided with 20 equal back-to-back lots (Siksna, 1997, p.30). In Figure 5 the creek is existent but altered. Ham's 1863 Map of Brisbane (Figure 6) positioned reserves to accommodate the course of the main creek and the Roma Street Reservoir was constructed to manage the supply of water. Nonetheless, Ham's 1863 map (Figure 6) also shows the creek drawn as it meanders across the subdivision of blocks. It intersected and co-existed with the subdivisions, but this was a tenuous arrangement, as the construction of buildings between Queen and Adelaide Street would necessitate realignment of the creek.

Before 1866, Brisbane lacked a dependable and secure water supply. During the convict period, an earthen dam was constructed over Wheat Creek, in the area now occupied by Roma and Little Roma

Streets. Water was transported through a pipeline made up of connected hollow hardwood logs, which was powered by a convict-operated treadmill (Brisbane City Council, 2022).

In both Geelong and Brisbane, a dam was constructed across the stream to harness the supply of water, revealing this practice as integral to colonial strategies that altered the land and landscape. In the making of Geelong and Brisbane, open space was initially provided to accommodate the natural waterway, perhaps anticipating its future retention.

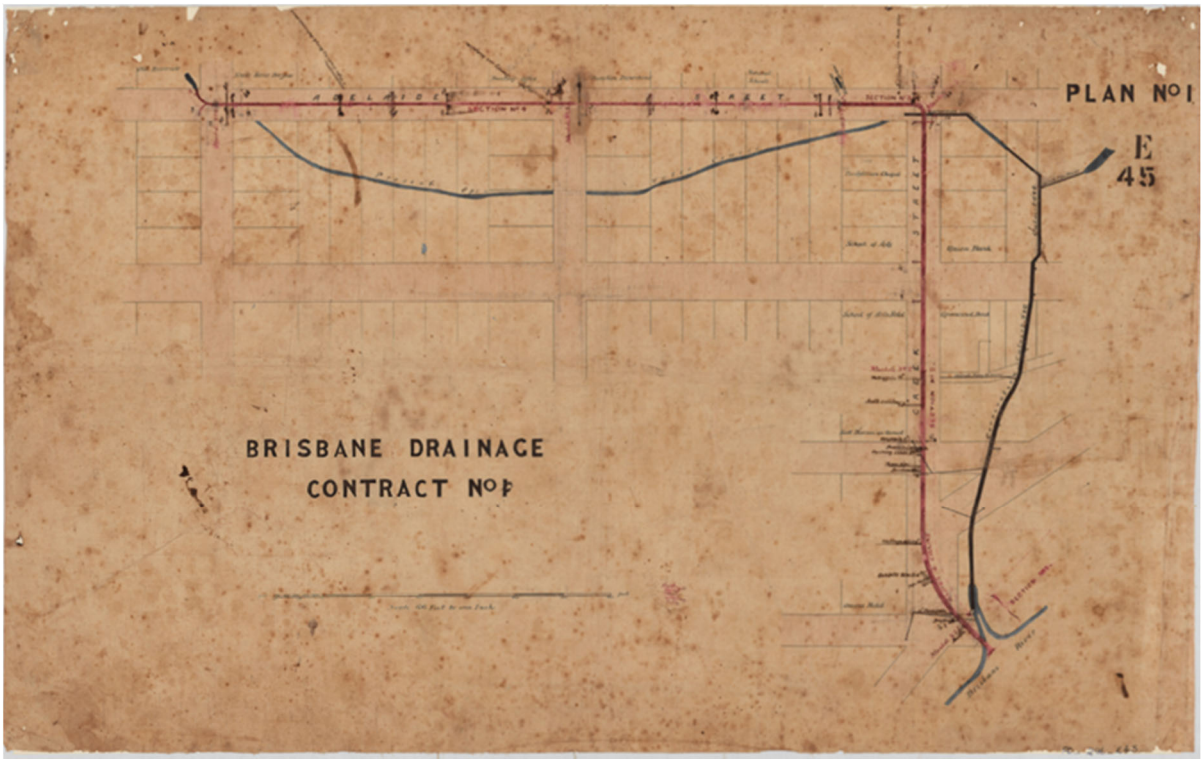

Figure 7. Brisbane Drainage Contract No 1. Source: Queensland State Archives, Item ID ITM3484685. Wheat Creek is redirected into a drain below Adelaide Street and Creek Street before discharging into the Brisbane River.

Brisbane's unpaved streets often became muddy in heavy rain. In 1860, the Municipal Council, incorporated a year earlier, built its first stormwater drain in Albert Street. However, inadequate stormwater drainage led to severe flooding in 1863. To address this, the Council constructed the Wheat Culvert at Adelaide and Albert Streets in 1863. Despite these efforts, most inner city drains were privately built to suit individual properties, and the Council's comprehensive drainage plans were delayed due to a lack of funds (Brisbane City Council, 2008).

In February 1875, a series of violent storms and floods brought the drainage issue to a crisis. Queen Street, the main shopping area, flooded three times, damaging basements and stock. Water from the swamp in Tank Street, which had become a cesspool, worsened the situation. Following pressure from building owners and Council representatives, the colonial government passed the Brisbane Drainage Act on 13 July 1875. William David Nisbet, the new Engineer of Harbours and Rivers, presented a drainage plan for Brisbane, proposing ten underground stormwater drains to manage natural water flows and discharge stormwater into the Brisbane River. The Brick Contract No. 1 Drain was completed in March 1877, serving as the main outfall for Brisbane's CBD. It collected flow from the 1863 Wheat

Creek Culvert, the "Corporation Culvert," and Robert Armour's private drain, running under Adelaide Street to Creek Street and then to the Brisbane River (Brisbane City Council, 2008).

Creative reparation

There are very few existing traces of the existing subterranean Wheat Creek apart from the physical stormwater drainage street grates. At a small park named Eagle Place, there is a plaque adjacent to an old fig tree that commemorates the water course from which Creek Street also takes its name. A fragment of the Wheat Creek culvert that was constructed in 1861 as part of the original drainage system was removed to make way for a bus tunnel and has been carefully reconstructed as a heritage display piece in the new underground King George Square Bus Station.

The opportunity for creative reparation of the lost creek has unfortunately been overlooked. For example, an obvious opportunity was for one of the numerous artworks commissioned for the public spaces at the new Brisbane Court precinct, situated on the former reservoir site, to have reflected the lost waterway. Nevertheless, some works do acknowledge Aboriginal history, particularly Fiona Foley's *Witnessing to Silence* (2005) in which the names of 94 massacre sites sandblasted into tiles are scattered around the area of the work (Cosic, 2005).

TANK STREAM: SYDNEY, NEW SOUTH WALES.

The original Aboriginal inhabitants of the City of Sydney local area are the Gadigal people of the Eora Nation, Eora meaning 'from this place' (City of Sydney 2017). The Boora Birra is one of the sacred Dreamings that details the creation of Sydney Harbour (NSW Government, 2024).

Geology and topography

Tank Stream was a source of water for the Gadigal people (Hinkson, 2001). Evidence that the stream was a location of importance was confirmed by archaeologist who discovered that the stream had been a burial site. Excavations in the late 1990s also uncovered 54 small stone artifacts, primarily waste material from tool-making, indicating that Aboriginal people once crafted stone tools near the stream (Irish and Goward 2024).

Figure 8. Sydney Geological Map. The course of Tank Stream is shown with a dark dotted line. Source: Commonwealth of Australia (Geoscience Australia) 2021, Sydney Geological Map - Australian Government Geoscience Australia Portal. Accessed online August 19th at https://portal.ga.gov.au/restore/3967feb2-d4e0-45f6-b994-c9601aea9663

The source of the stream was from swampy ground that was fed by water seeping from the underlying sandstone (Hinkson, 2001). The stream dropped about 30 metres through a series of waterfalls to Bridge Street, where it met the harbour. Draining about 82 hectares, it was supplemented by springs in what are now King and Spring Streets (Sydney Water 2010).

Settlement maps and engineered drawings of waterway confinement

Soon after the Sydney Cove settlement was established, the Tank Stream became polluted by waste and construction runoff. The stream's water supply was inconsistent, with nearby springs and wells quickly depleted during droughts. By 1796, a reservoir was built near the stream's mouth for water collection, reinforcing the same strategies of infrastructure that effected the most radical transformation of land and Country. The underlying sandstone was excavated to create three storage tanks, each tank held 20,000 litres of freshwater (Muecke, 2016), hence the stream derived its name. However, upstream contamination soon led to waste accumulation in the tanks (Casey and Lowe, 2016).

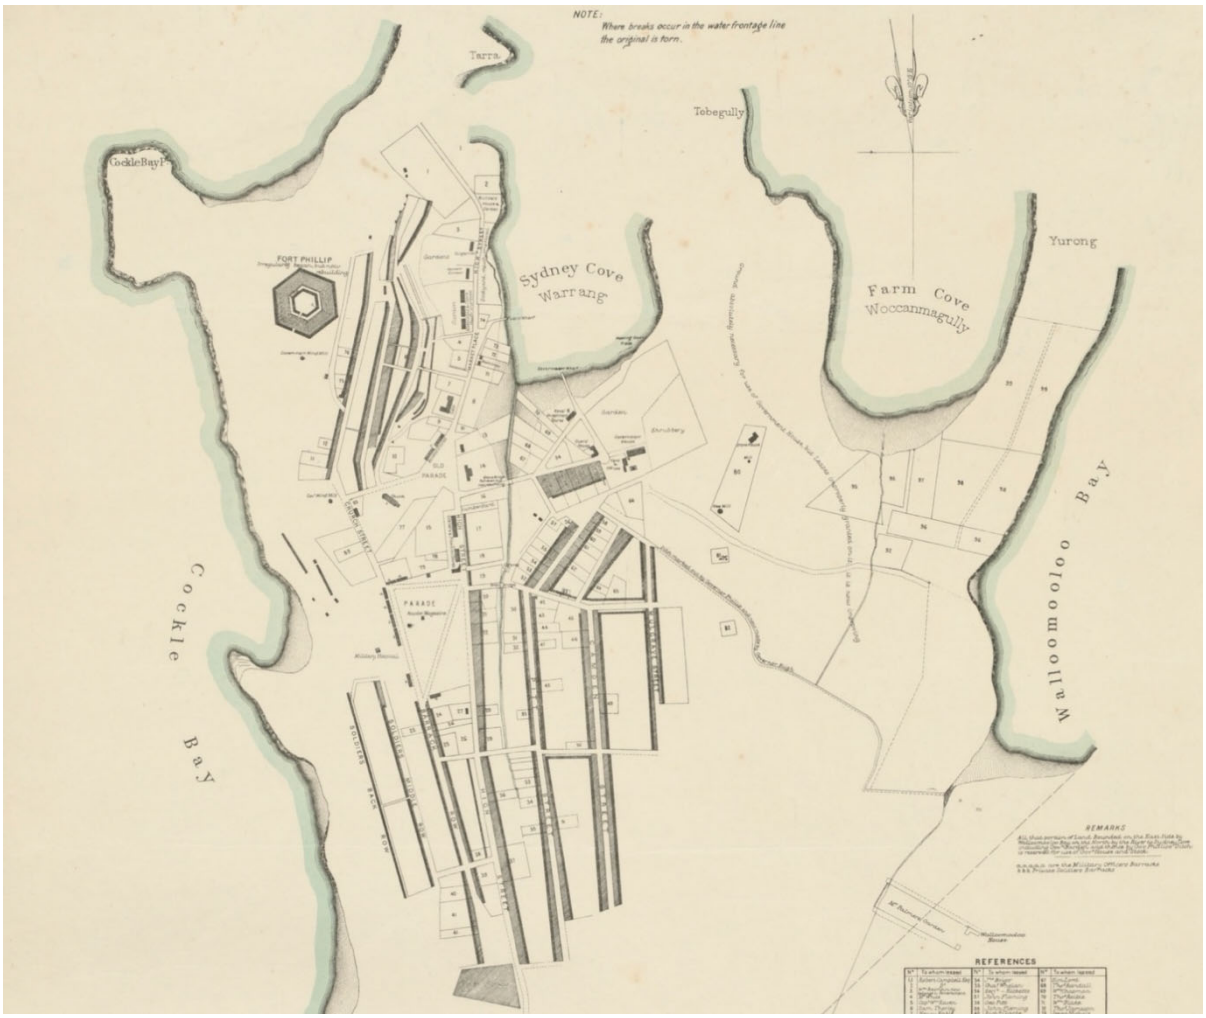

Figure 9. Meehan, J., and Bligh, W., 1754-1817. (1807). Plan of the town of Sydney in New South Wales [cartographic material] / by Jas. Meehan, assistant surveyor of Lands by order of His Excellency Governor Bligh, 31st October 1807. The Tank Stream flows through allotments between Pitt Street and High Street before discharging into Sydney Cove. Source: https://nla.gov.au/nla.obj-229911438.

Throughout the 19th century, efforts to regulate and improve the Tank Stream's condition failed. Prohibited activities near the stream included slaughterhouses, tanneries, and washing clothes (See Figure 9). By 1826, the stream was no longer used for drinking water, with the colony's administrative settlers relying on wells and rainwater instead. In 1833, the Tank Stream's condition and management were revisited, particularly regarding sewage disposal and silt accumulation in the harbour. By October 1856, the Tank Stream was enclosed, with significant drainage work completed by September 1857. Despite these efforts, problems persisted, especially after heavy rains (Casey and Lowe, 2016).

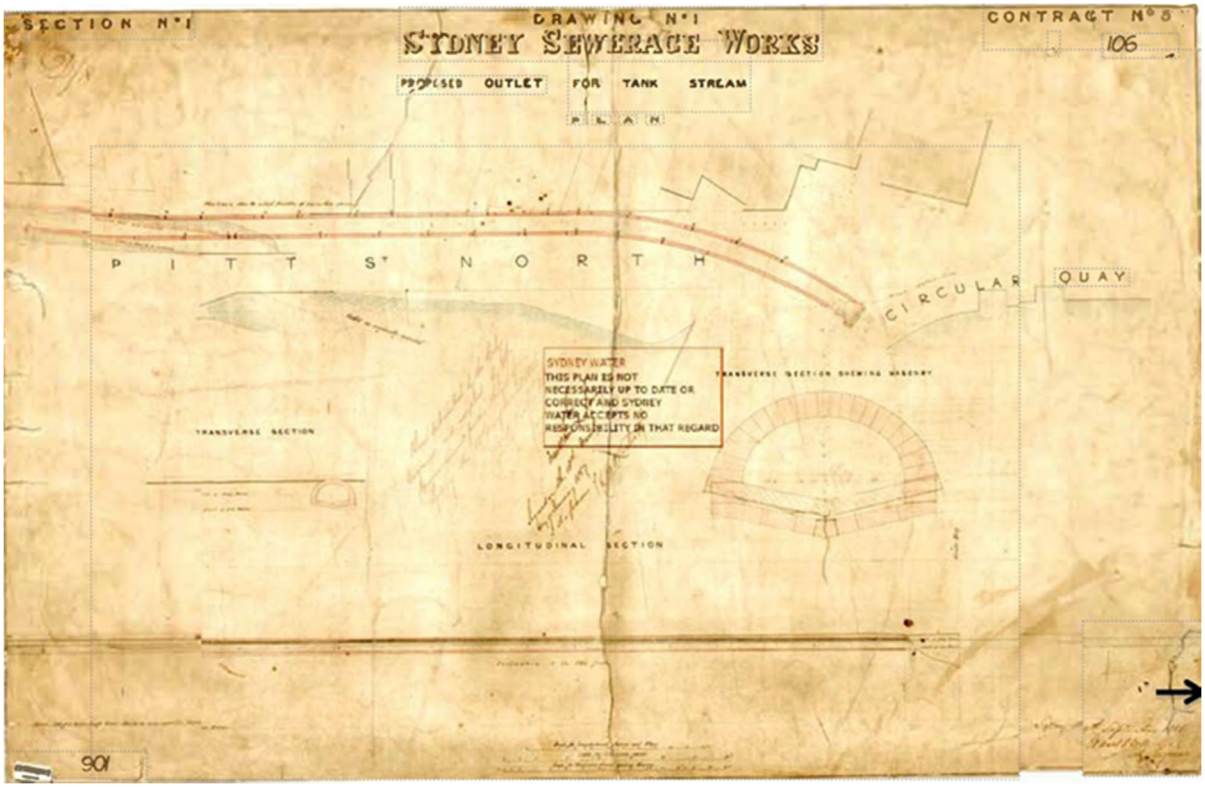

Figure 10. 'Drawing· No 1' of the Sydney Sewerage Works proposed new outlet for the Tank Stream. 1856. In Casey and Lowe (2016) Tank Stream Issues, City of Sydney Planning and Development Committee - 19 July 2016 - Item 6 - AttachmentB18 - Post Exhibition. Accessed online August 19th 2024 at https://meetings.cityofsydney.nsw.gov.au/Data/Planning%20and%20Development%20Committee/20160719140 3/Agenda/160719_PDC_ITEM06_ATTACHMENTB18.pdf.

In 1878, the Tank Stream Sewer was reconstructed, diverting its course under Pitt Street. Control over the sewerage system passed to the Water Supply and Sewerage Board in 1890. The Tank Stream continued to be used as a combined sewer, with measures to prevent sewage from entering the harbour. Over the past century, the Tank Stream has served as a stormwater channel, managed by Sydney Water. Changes in sewerage and drainage requirements, as well as construction activities, have affected its structure, with parts replaced or removed. Today, it remains an operational stormwater channel (Casey and Lowe, 2016).

Establish new values for creative reparation

Unlike the Western Gully and Wheat Creek, the Tank Stream in Sydney has received a lot of attention from historians that has resulted in its documentation through mapping and narration. Consequently, increased awareness has led to urban sculptures and artwork that memorialise its existence.

The Tank Stream Fountain, presented to Sydney by John Fairfax & Sons in 1981, commemorates the 150th anniversary of the Sydney Herald's first publication in 1831. Sculptor Stephen Walker aimed to associate water and bronze, linking the fountain to the Tank Stream, Sydney's first water supply. An inscription notes Walker's intention to connect the fountain with its historic location. Also known as the Children's Fountain, it is dedicated to "all the children who have played around the Tank Stream." An inscription on a plaque by the sculptor Stephen Walker revealed that The Tank Stream fountain recalls humanity's/people's past dependence on this flowing stream and our links with life around this region (City of Sydney, 2004a).

Tankstream – *Into the head of the cove*, installed between 1999 to 2019, is the title of five footpath installations created by Lynne Roberts Goodwin that were markers in the pavement to create a sense of the historic stream flowing beneath the surface of Sydney. Coloured glass modules were embedded in the pavement above the underground stream, angled away from stainless steel lines to mirror the flow of the Tank Stream in relation to Pitt Street. This installation draws a comparison between the city's natural and manufactured energy channels. At Alfred Street, the rods fan out, representing the stream's delta as it merges into Sydney Cove (City of Sydney, 2024b).

According to Coyne (2024) the Tank Stream is emblematic of settler colonial politics. Conventional stormwater designs stem from colonial strategies for waterscapes existing on the lands where Sydney was sited, imposed over First Nations water management systems. The Tank Stream holds potential for anti-colonial hydraulic urban co-design. Using colonial archives and field visits, Coyne is critical of the impact of settler-colonial urban design on contemporary views of watery spaces, concluding that hydro-imperial knowledge must give way to culturally inclusive urban water designs centred on First Nations perspectives.

To further the momentum to explore approaches for de-colonisation of urban infrastructure, we offer a detailed case study for design reparation by Deakin University Master of Architecture Student Juan Alsina. The speculative design project addressed restoring the memory of The Tank Stream, a lost ecosystem to urbanisation through reconnecting people with nature and place, creating environmental awareness, fostering a sense of belonging and a desire to protect. The design proposes a journey along the erased footprint of the Tank Stream that presents its natural and cultural landscape through time, featuring gathering spaces “reclaimed” by nature.

TANK STREAM DESIGN REPARATION - ECHOES A JOURNEY THROUGH TIME AND SENSES ***Student design project by Juan Alsina.***

The environmental debate inspired the concept of “Nature Taking Back Control” in our cities, shaping the project's main research question: How can we restore the memory of an ecosystem lost to urbanization by reconnecting people with nature and enhancing community engagement to foster a sense of belonging.

Analysis of the areas physical and non-physical characteristics suggested the location for a series of nodes highlighting the tension between the urban character and the Tank Stream’s footprint. The project’s design is a multi-layered response to historical, social, and environmental imperatives. Scrutiny of the Tank Stream Valley revealed key cultural, social, environmental, and heritage features. Strategically placed multifunctional nodes in historically significant areas evoke the stream’s history and ecological value while fostering community engagement. The project reintroduces elements of the original ecosystem. Each node enhances social and cultural functions, emphasizing shared spaces that foster community engagement. A sensory journey through five green nodes includes gathering spaces, educational areas, and exhibits featuring native plants and endangered species.

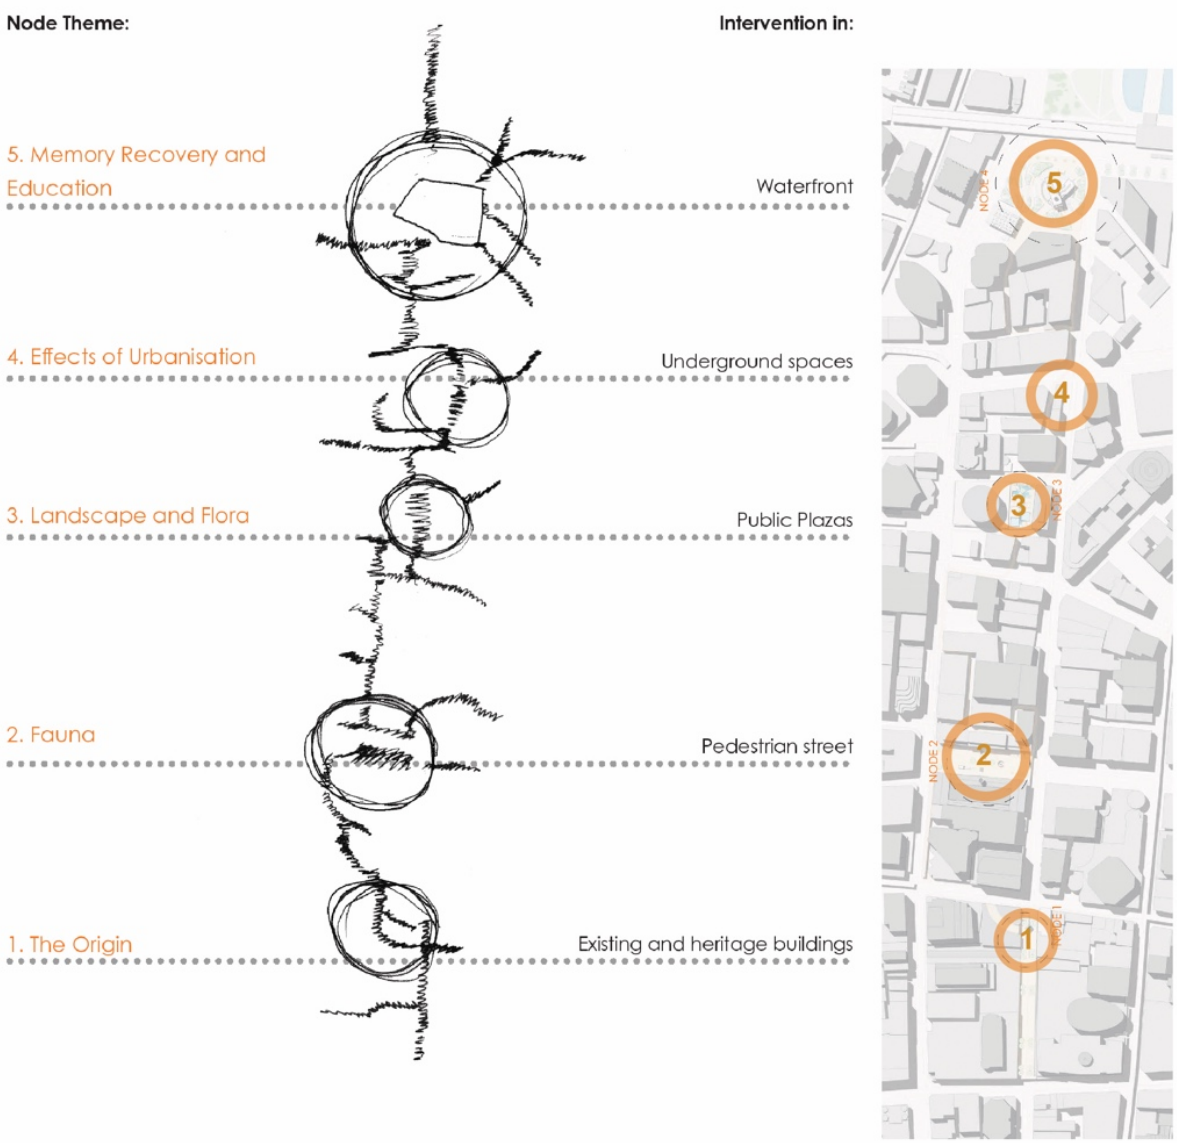

Figure 11. ECHOES A Journey Through Time and Senses. Source: Juan Alsina (2024).

The Journey - Serial Vision through five nodes.

Nodes 1-2 (Figure 12): The user enters the pavilion through a narrow, dark path, creating suspense and mystery. The internal garden is visible from outside through a layered façade but remains enclosed and inaccessible from within. There is no direct view of the outside, but the sounds of people passing by are still audible. The exit opens at the lower end, guiding the user's gaze to a stormwater grate with an organic pattern, referencing the Tank Stream below.

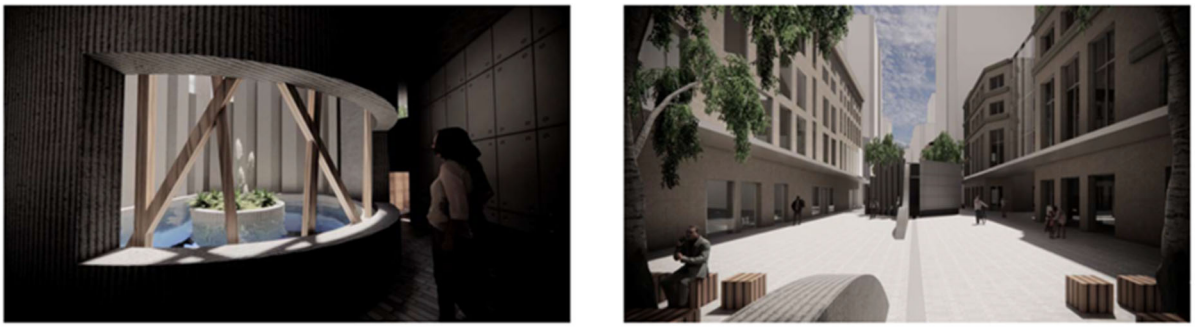

Figure 12. Juan Alsina (2024).

Nodes 2-3 (Figure 13): Approaching from the west end of Martin Place, the user encounters an elevated structure marking the entrance to an underground chamber, where the second node offers an experience of textures and shadows. In the first section, a linear water mirror reflects human shadows cast from above, with an informative wall at ground level. Moving to the second section, the user enters an underground gallery framed by two gardens that receive natural light through floor openings, covered by gathering spaces above. From here, the user can either explore the sewer system as part of the Tank Stream tour or exit via a circular staircase at the plaza's other end.

Figure 14. Juan Alsina (2024).

Nodes 4-5 (Figure 15): Walking down Pitt Street toward Circular Quay, the user encounters a dense green park with tall tree canopies. At its centre stands a lookout with two pavilion structures intertwined like trees. Positioned on a circular pond connected to the sea by a canal that floods at high tide, the lookout is accessed via a circular staircase around a central core, offering 360-degree views of native vegetation from the Tank Stream Valley. The pavilions serve as educational and exhibition spaces, sharing information about the Tank Stream's cultural and natural heritage.

Figure 15. Juan Alsina (2024).

DISCUSSION

In recent years the International Seminar on Urban Form has been striving to encourage a stronger relationship between research and practice (Samuels, 2013; Sanders, 2016) whereby the meticulous study of archival maps that describe past urban and environmental conditions provides documentary evidence upon which designers can interpret, explore and imagine alternative urban approaches and designs towards the re-inscription of and reference to lost waterways.

In this paper we have uncovered the documentation of the pre-colonial existence of three natural waterways that were firstly altered to control the water supply to the new settlements by either a dam or reservoir (Western Gully and Wheat Creek), or by creating tanks (Tank Stream). As each water system became overwhelmed due to the urbanising morphologies and pressures of the new colony, they were each confined into sub-surface drains to control water flows. The substitution of waterways for closed or open sewers indicates the severity of the transformation of the land in the construction of the colonial city. The research approach to focus on the waterways in colonial documentation – maps, surveys, charts – is a small step towards developing a reparative historiography. This method does not aim to alter the colonial documents but to read the documents against their intent, to identify in the documents the spatial, physical and morphological points of substitution of a land 'feature' – in this case waterways – for infrastructure that serves and supports the construction of colonial settlement. Exemplified in the analysis of maps and documentation of the three case studies are the stages of this process of substitution: firstly, the change of value of the waterway between its value from a resource and source of livelihood to an obstacle; secondly, due to increased quantity of colonial settler mobility, the disregard for the waterway as resource renders it an obstruction to the exercise of settlement – it is in the way of 'free settlement'; thirdly, direct investment by the colony to alleviate its 'obstructive' nature, and fourthly, to deploy the technologies of stormwater and sewerage and submit the waterway to an underground infrastructure. This series of exercises chart the process of colonisation as an appropriation of land 'features' /waterways from the custodian role of Indigenous peoples to the practices of colonial settlers.

In Sydney and Brisbane some visible commemorative markers (plaques/ sculptures) of the lost landscape features have been added, however no significant reparation through urban landscape design has occurred. Despite this apparent shortfall, establishing new values of landscape reparation and emerging design protocols for Indigenous led design for building on Country is gaining some urgency. We have shown through a strategic student design speculation project *Echoes: A journey through time and senses* by Juan Alsina how knowledge of site specificities can give visible and meaningful design reparation for lost landscape features, in this case The Tank Stream in Sydney.

However, connecting and designing with Country requires meaningful engagement with First Nations systems of being, knowing and practising. As the lessons embedded within our landscapes are being observed, the built environment is awakening and realizing the rich relationships, stories and ways of First Nations cultures (Gillmer, 2023).

The Australian Indigenous Design Charter guides the respectful and accurate representation of Aboriginal and Torres Strait Islander culture in design and media. It assists both Indigenous and non-

Indigenous designers and helps promote understanding among clients, including governments, businesses, and organizations (Indigenous Architecture and Design Victoria et al 2016). The ten principles of the Charter are as follows:

1. Indigenous led. Ensure Indigenous representation creation in design practice is Indigenous led.

2. Self-determined. Respect for the rights of Indigenous peoples to oversee representation creation of their culture in design practice.

3. Community specific. Ensure respect for the diversity of Aboriginal and Torres Strait Islander culture by following community specific cultural protocols.

4. Deep listening. Ensure respectful, culturally specific, personal engagement behaviors for effective communication and courteous interaction are practiced.

5. Impact of design. Always consider the reception and implications of all designs so that they are respectful to Indigenous culture.

6. Indigenous knowledge. Respectfully ask the client if there is an aspect to the project, in relation to any design brief, that may be improved with Indigenous knowledge.

7. Shared knowledge (collaboration, co-creation, procurement). Develop and implement respectful methods for all levels of engagement and sharing of Indigenous knowledge (collaboration, co-creation, procurement).

8. Legal and moral. Demonstrate respect and honour cultural ownership and intellectual property rights, including moral rights, and obtain appropriate permissions where required.

9. Reconciliation Action Plan (RAP). Develop a RAP incorporating the AIDC:CD.

10. Charter implementation. Ensure the implementation of the AIDC:CD to safeguard Indigenous design integrity.

Indigenous Architecture and Design Victoria et al. (2016)

New projects for the built environment in Australia need to adopt the guidelines of the Australian Indigenous Design Charter to align with protocols for authentic design outcomes.

CONCLUSION

Australia, like other post-settler societies, is grappling with the challenges and consequences of its history. The colonisation of Australia occurred as a military and settler strategy. While one significant strategy was to obtain knowledge of the ‘lie of the land’ and this was executed through mapping, its aim was towards identifying the best sites for colonial settlement. The aim was not to understand or appreciate the natural features of the land or its environmental context. As revealed by the Terra Nullius status – that the land was uninhabited - assigned to Australia, territorial colonisation proceeded alongside practices to eradicate its Aboriginal inhabitants.

Recent efforts towards reconciliation have included political apologies, but the design professions and education sector have been slow to embrace significant change. Nevertheless, advancements by First Nations designers, planners, and architects are leading efforts towards establishing principles and frameworks for the design of cities based on ecological balance and socio-environmental justice (Coyne, 2022).

Acknowledgement

The authors would like to acknowledge the input of design research supervisor Dr. John Rollo for his valuable input in guiding the direction of Juan Alsina's Masters Studio Project.

ABSTRACT

The article analyzes the transformation of Galeria Olido, in downtown São Paulo, from an interstitial corridor into a cultural center. This change has redefined its role in the city, connecting different moments and offering an educational-cultural program. The text discusses the processes of des-territorialization proposed by Deleuze and Guattari, highlighting how places can be modified over time. It also explores the differences between reterritorialization promoted by the State through public policies and that initiated by the population or the market. Thus, it investigates whether the remodelled gallery suggests the creation of a new common public space or a renewal of the urban space's collectivization.

Keywords: Commercial Galleries, Relationship Between Public and Private Space, Public Administration, Reterritorialization and Resignification of Galleries

INTRODUCTION

For a few decades now, there has been talk of overcoming binaries, with profound reverberations and repercussions in the social, political, and urban spheres. On the one hand, we witness undesirable processes of privatization of public spaces, but on the other hand, some situations reveal horizons of hospitable thresholds in the city. In this context, our interest lies in transition territories, an unavoidable topic. However, for at least two centuries, the covered galleries of Paris, the famous "passages," precursors of Modernity for Walter Benjamin, had already introduced the question of a certain blurring between public and private in the metropolis. Thus, we are interested in studying the occurrence in the city of a rather unique territory: the inner block passage galleries, particularly the renewed Olido Gallery and its programmatic and social interactions within the fast-paced transit environment. We are talking about a gallery that has been transformed by the State into a center for cultural production and reception. This aesthetic change has significantly altered the role of this gallery in the urban center, especially considering its existence (and near erasure) in recent decades. We can say it has started to play a connecting role associated with other temporalities of permanence, linked to an intense educational and cultural program. This will raise the issue of processes of de- and

reterritorialization of a territory, a key pair of concepts proposed by Deleuze and Guattari in one of their major works, A Thousand Plateaus: Capitalism and Schizophrenia, or the idea that a place undergoes profound changes in its functioning logic and purposes, its meaning transmuted by the loss and addition of layers of re-signification over time. Such a process can occur spontaneously or be promoted and encouraged by public policies. The question then arises whether, in these places, especially the gallery that has been reterritorialized and gained new urban significance, it indicates a path toward constructing a new common or a renewed process of collectivizing public space through its interstices. Furthermore, we question the differences in the reterritorialization process when triggered by the State, associated with public policies, by actions initiated by the population, or by market interests. The Olido Gallery, located in the center of São Paulo, was chosen as the object of study, conducting a critical analysis of the spatial and programmatic transformation process of this historic interstitial urban corridor.

METHOD

The methodology employed is both empirical and theoretical. Based on theoretical concepts, we sought to interpret reality through an analysis grounded in these concepts, without restricting ourselves solely to theory. Theoretical concepts provide a fundamental framework for a critical reading of reality. However, we acknowledge the importance of confronting them with observed reality. Thus, we conducted surveys and on-site analyses to validate, challenge, and enrich the theoretical positions. This approach offers a complex understanding of the phenomena studied, avoiding overly subjective analysis. With the aim of fostering a discussion about these spaces, particularly the galleries that have been reterritorialized and acquired new urban significance, we ask ourselves: can these interstitial micro territories represent a horizon for the construction of a new commons, or a new process of collectivizing space?

DISCUSSIONS

The territorialization and deterritorialization of the passage galleries of São Paulo

The inner block galleries in São Paulo assume multiple roles, offering a variety of shops and services. Some serve as passages and connections, while others specialize in certain products, attracting customers who linger. However, there is no general rule, as the heavy foot traffic is not necessarily related to the types of products sold. Over time, these galleries have had to adapt their purposes according to new local realities, remaining spaces of diverse commerce, comparable to shopping malls, while also preserving their function as urban passages and connections. These galleries establish unique relationships between public and private, emphasizing the permeability between these two domains. The blurred boundary between these domains, provided by these territories, stimulates and emulates minority agencies that contrast with the binary logic of the city that contains them, becoming micro-territorialities that signal other alliances between public authorities, the market, and the local population—whether they live, work, or simply pass through. Territories with almost no sovereignty, fragile sovereignties in consonant dissonance, a condition of hospitality.

"Based on the idea of agency, the territory comes closer to another possible interpretation of its meaning: the place of conflict, of the struggle for the right to something that gives it existence, of the enunciation of that something which exceeds the codification and stratification imposed by sovereign

power. Territories territorialized by contents and rules linked to sovereign power, State, and Capital can be crossed by deterritorializing lines and forces." (Guatelli, 2022, p.56).

These interstitial architectures play a significant role in the transformation of public and private spaces, influencing the dynamics of street usage as public areas. The degree of access allowed, and the ease of this access are directly related to the level of privacy in these spaces, offering different experiences to visitors. To smooth the transition between public and private spaces, galleries often integrate elements at their entrances, creating a "grey zone" that makes the transition between spaces almost imperceptible. The presence of bars and restaurants in the galleries increases permeability and congestion, offering a sense of access and enjoyment to all. While some galleries are primarily characterized as passageways, offering a variety of shops and services, others stand out for the specialization of services, attracting a specific audience.

However, it is important to note that this pattern can vary between galleries, as the predominant use as a passageway is not necessarily related to the types of products available. Circulation and communication are directed by organizational strategies and serve them. Circulation and communication networks play an essential role in shaping the space-time throughout the territory. These networks are constantly evolving, adapting to the scale determined by the strategies, whether at a broad or local level. The transformation and establishment of this new territory inevitably alter what is considered common in that area. However, even in an ambiguous space between being public and being private, where subtle changes in the environment occur, when examined considering the notion of the commons, boundaries and limits become evident, as this is how the reterritorialization of space is established.

"The commons must have clearly defined limits, as it is important to identify the community to which it pertains; the rules must be well adapted to local needs and conditions and in alignment with its objectives; the individuals to whom these rules apply must regularly participate in the responsible bodies; [...] The commons does not gather market consumers or users of an administration external to production, but co-producers who together establish collective rules for themselves." (Dardot, 2017, p.160)

The processes of deterritorialization and reterritorialization of these places, along with their political and cultural dimensions, are closely intertwined. Deterritorialization can occur symbolically, involving the destruction of symbols, historical landmarks, and identities, or concretely, affecting political and economic aspects, such as the rupture of old ties and population boundaries. Furthermore, individuals, classes, and social groups always absorb, to varying degrees and scales, deterritorialized or deterritorializing perspectives. These processes reflect the complex interactions between power, culture, and identity in the construction and transformation of territories. When addressing these concepts, it is important to highlight the influence of philosophers Deleuze and Guattari, considered pioneers in this field. The galleries deterritorialize and reterritorialize the public-private relationship in urban space. The "gray" becomes a potent third deterritorialized-reterritorialized territory.

"We constructed a concept that I like very much, that of deterritorialization. [...] Sometimes we need to invent a barbaric word to capture a notion with a new ambition. The new notion is that there is no territory without a vector of exit from that territory, and there is no exit from the territory, that is,

deterritorialization, without, at the same time, an effort to reterritorialize elsewhere." (Deleuze, apud. Haesbaert, 2002, p.01)

The case of Galeria Olido

The place known as Galeria Olido originated during the golden age of São Paulo's galleries, in 1957, when it was inaugurated as Cine Olido, the first cinema located inside a gallery. The name "Olido" was created from the fusion of the names Domingos and Olivia, its founder and his wife, respectively. Located at Largo do Paissandu, near major passageways such as the Galeria Comercial (now known as Galeria do Rock), the area was known as São Paulo's Cinelândia, standing out as a privileged space for leisure and cultural gatherings. In the following decades, a significant shift occurred in this region due to the relocation of the city's center to the southeast and the rise of shopping malls. During the 1980s, major financial institutions moved to other parts of São Paulo, while shopping malls began to emerge, offering large parking lots to accommodate the growing use of automobiles by the population. This combination of factors led to the decline of the city center, resulting in the abandonment of movie theaters, which were once frequented by the elite. In response to this economic shift, the company responsible for Cine Olido divided the main auditorium, which previously held 800 spectators, into three smaller theaters. In 1980, the space was renovated to adapt to this new configuration. Cine Olido ceased operations in the late 1990s but was later restored and reopened by the city administration in 2004. (Pereira, 2008)

Ilustrada

Cine Olido volta com mais salas

O cine Olido retorna às origens neste sábado, com o luxo e a pompa que a circunstância exige. Afinal, trata-se de uma tríplice inauguração deste cinema, considerado, no final da década de 50, "o mais luxuoso de São Paulo", agora, dividido em três pequenas salas de projeção: Olido 1 (470 lugares), Olido 2 (300 lugares) e Olido 3 (300 lugares), equipadas com modernos equipamentos — projetores Philips e lâmpadas Xenon.

A clássica casa de espetáculos transformou-se, através de um arrojado projeto do arquiteto alemão Hermann Guettches, há 22 anos construindo cinemas no Brasil, num sofisticado e confortável centro cinematográfico com piso de mármore e paredes espelhadas.

A construção dos três cinemas — a palavra "reforma" seria inadequada, já que tudo é novo no Olido — custou à Empresa Sul Paulista, proprietária de outras 20 salas na cidade, mais de Cr$ 200 milhões, uma fortuna, se se considera o investimento feito pela Gasmont — Cr$ 800 milhões — na compra dos 22 cinemas da Companhia Serrador. Mas o gerente do Departamento de Publicidade da Sul Paulista, Caetano Abruzzini Neto, acha que o dinheiro foi bem aplicado: "O Olido vai concorrer, em luxo, com os cinemas dos Jardins e, como eles, será lançador de grandes produções."

Para ter uma idéia, o primeiro filme a entrar em cartaz no Olido 1 será a superprodução francesa "A Guerra do Fogo" (Quest for Fire), dirigida por Jean-Jacques Arnaud, com duas horas e quarenta minutos de projeção, sobre o período paleolítico, e que custou mais de 15 milhões de dólares. Uma obra para marcar época, exatamente como o filme de estréia, em 1957, do antigo Olido, "Tarde Demais para Esquecer" (An Affair to Remember), do cineasta irlandês Leo McCarey, onde Cary Grant morria de amores por Deborah Kerr, esperando sua amada no topo do Empire States.

Tudo indica que a modernização do Olido, de acordo com o modelo europeu de dividir grandes cinemas em pequenas salas, venha a ser um exemplo seguido pelas outras empresas do mercado em relação às salas centrais. Com a dilatação dos horários — as três salas começam a funcionar às 11 horas e, aos sábados e vésperas de feriados, com sessão extra, às 24 horas — e o agrupamento de salas no mesmo local, as opções dos espectadores crescem e as intermináveis filas tendem a acabar. Uma característica de quase cinquenta cinemas dos Jardins, hoje.

Há, entretanto, alguns detalhes que tornam o Olido diferente dessas salas gêmeas fora do centro. O luxo começa nos luminosos, de neon, e se estende para o interior dos três novos cinemas, todos construídos no mesmo nível do piso do antigo: cores harmoniosas (carpete cinzento e poltronas vermelhas, no Olido 1), escadas de acesso em laído, paredes em Murolflex e telas flutuantes. Os três seguem um projeto arquitetônico bastante semelhante, com pequenas alterações nas cores das paredes e no carpete. Outro detalhe fundamental: o sistema de ar condicionado Lowa, considerado excelente para amplos espaços, é garantido contra eventuais falhas e, desde já, o gerente da empresa adianta que funcionará ininterruptamente.

Única falha do Olido: as três salas não estão equipadas como nos "dolby", a exemplo de dois outros cinemas da Sul Paulista (Paulistano e Iguatemi), porque o sistema exige cópia original do filme e, em alguns casos, isso se torna impossível. Porém o representante da empresa adianta que a instalação do "dolby" está nos planos futuros da Sul Paulista.

Assim, as novas produções prometidas para o Olido — "E.T.", o grande sucesso de Steven Spielberg, entre outras — serão exibidas com cópias processadas em laboratórios nacionais, conforme exigência legal. Para os próximos meses já estão programados outros filmes de igual nível, destacando-se a produção italiana, dirigida por Fulvio Grilli, "Possa Que Ela Seja uma F...", baseada na peça homônima de John Ford, sobre um caso de incesto, com a atriz Charlotte Rampling.

As três salas do cine Olido serão pré-inauguradas com sessão especial para convidados, às 20 horas de hoje. São os seguintes os filmes de estréia: "A Guerra do Fogo" (Olido 1); "Aconteceu no Mar Egeu" (Olido 2); e "Loucamente Apaixonados" (Olido 3).

Uma das salas do novo Olido, a ser pré-inaugurado hoje, para convidados.

Public policies were implemented to revitalize the downtown area and improve the conditions of the space. One such project, launched by the city administration in 2004, was the reopening of the site, now called Galeria Olido, with the goal of restoring its role as a meeting point in the region. An important aspect of this project was that it aimed not only to reopen the cinema and gallery, but also to create a new hub for culture and leisure in conjunction with public engagement. The location introduced a café, a telecentre, and three rooms dedicated to cinema, music, and dance, the latter of which allowed performances to be viewed from the sidewalk as an invitation for social interaction and participation. This was referred to as the "Dance Showcase." (Soares, 2004).

Through an agreement with the private sector located on the ground floor, the State implemented public policies aimed at transforming the dynamics and culture of the space's use, occupying the previously vacant building with the installation of three municipal departments to increase occupancy. This approach invites criticism, as an analysis of the resource management by São Paulo's city hall reveals a tendency to create spaces and dynamics through these public policies without investing in the long-term maintenance of these spaces or considering their long-term use to legitimize and expand them as common spaces. An example of this occurred in 2018, when the headquarters of the Department of Culture was moved to a new location in the city center, following the same strategy used at Galeria Olido, without considering the possible consequences for the space after the departure of the public cultural administration from Olido (Prefeitura da Cidade de São Paulo, 2018). This undermines the previous investment and hampers the process of legitimizing the space over time. This situation illustrates the theory of the commons, which emphasizes the importance of collective participation in creating rules for themselves, rather than external administration, since a vertically managed space does not foster plural cultures of appropriation—essential elements for the reterritorialization of the space.

Today, the Olido Cultural Center plays the role of co-producer, managed by individuals closely connected to the project, focusing on stimulating new activities and projects that generate everyday life, constantly expanding the gallery's horizons as a cultural center aligned with social interests.

In 2019, a new project was implemented to attract an activity already present in the central region, but with a keen approach from the administration, attentive to local dynamics. A space was created within Galeria Olido dedicated to exhibitions, workshops, and permanent activities related to electronic music, which is central to much of contemporary musical production. This space includes electroacoustic experiments, performances exploring the intersection between technology and music, as well as gatherings between DJs and urban dances such as House, Passinho, and Vogue. There is also an intention to transform Galeria Olido into a center of convergence for new media, where the public can access the latest developments in the world of VJs and audiovisual installations. The goal of this center is to give proper recognition to an entire culture that has developed around DJs and electronic music, without making gender distinctions, valuing its importance. After the implementation of this project, the gallery became known as the "DJ Gallery." (Assef, 2019).

Thus, from a theoretical perspective, the territory is perceived as a delimited and controlled space where the exercise of power is manifested, often related to the political power of the State. Haesbaert (2002) explores the cultural or symbolic-cultural perspective, which emphasizes the symbolic and subjective dimension of the territory, where it is understood as the result of the appropriation and symbolic valuation by a group in relation to its lived space. This creation arises from the daily activities of social appropriation, contributing to the formation of unexpected and unique social interactions in the space. The territory of Galeria Olido is understood as a set of programmatic and social agencies. These agencies are not limited to geographical space, making the authors' concept of territory very broad.

The pandemic triggered a period of intense effort to preserve the culture of use rooted in the space, as the absence of gathering places hindered the desired interactions, demanding extra effort from people to keep alive the hospitable, welcoming, and popular spirit of the location. During this challenging time, the proposed agencies were put to the test, transforming Galeria Olido into a fundamental space for the expression of cultural multiplicity—a true magnet for various groups, especially racial and regional, who used the space to promote their cultural traits. Maintaining this territory beyond the physical space became a significant challenge.

"It is not exactly the space that forms an identity, but the political and cultural strength of the social groups that reproduce within it and their ability to produce a certain scale of identity, territorially mediated." (Haesbaert, 2002, p.01)

After going through a period of closure due to the pandemic and facing the challenges of economic crises, the gallery experienced a reopening marked by significant changes. The Municipal Department of Culture announced the beginning of a new phase for the Olido Cultural Center in 2022 with the inauguration of the Multimedia Showcase, becoming the first public cultural center with an emphasis on digital culture in the city. This space was dedicated to various forms of artistic expression, such as multimedia artistic interventions, video art, interactivity, virtual reality, research, and digital inclusion, valuing diversity and all artistic languages. (Durval, 2022) The intention was to establish the Olido Cultural Center as a public space for the creation and experimentation of innovative projects that not only promote local culture but also explore new possibilities offered by digital culture. In this context, the OLIDO HUB emerged, proposed by the current manager of the space, Luciana Ramin, inspired by the concepts of innovation hubs, aiming to promote and form networks between digital culture and

local cultural practices. This was a multidisciplinary space that addressed the intersection between the arts and new media, encouraging a hybrid and interdisciplinary approach as a catalyst for innovative practices. (São Paulo, 2022)

Figure 15: Passage of Galeria Olido, photo credit: Autoral, 2023.

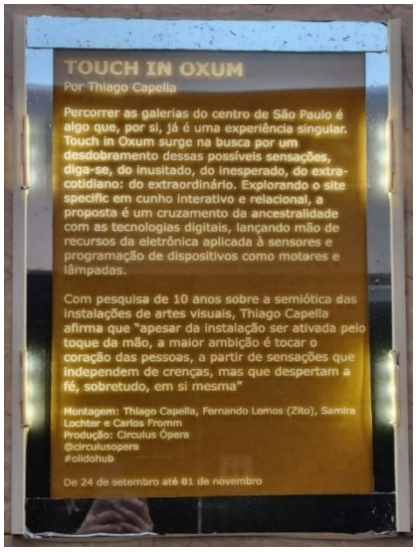

Figure 16: Newsletter introducing the Touch Oxum project, photo credit: Autoral, 2023.

Additionally, the gallery expanded its exhibition spaces to include circus culture, and a room equipped with multimedia resources, the result of a collaboration between the Circulus Ópera and Coletivo Substancial collectives, who worked together in a type of artistic residency. Furthermore, initiatives such as "Forró na Olido" brought together artists, collectives, and traditional forró enthusiasts, attracting a new audience and further reinforcing the cultural role of the space. These were examples of collaborative partnerships, where both sides mutually influenced each other, fostering a connection of thoughts and desires that drove the revitalization of the space, creating a sense of shared belonging. An urban rift of artistic and cultural convergence and radiations, by incorporating these elements of multiculturalism, Galeria Olido reaffirmed its commitment to being a social catalyst and condenser, seeking to expand its role in this regard. (Siqueira, 2023)

"The language of the commons is not only 'descriptive and performative,' but above all inclusive. It enables us to think, under the same framework, about forms of activities, mobilization, and relationships that at first glance seem to have little in common with one another." (Dardot, 2017, p.167)

CONCLUSIONS

The reterritorialization of urban galleries, as exemplified by Galeria Olido, demonstrates that these interstitial microterritories can indeed transform into significant collective spaces. The galleries studied are different in nature, but by identifying the transformations that have occurred within their spaces, it becomes clear that a new common is being created for these interstitial spaces, one that goes beyond the original commercial space, transforming into cultural spaces with the intention of expanding this culture beyond the walls of their passageways. These movements, which seek to form a new common within these spaces, are what connect these galleries.

Galeria Olido found its path through its cultural center, supported both by state legitimization and, most importantly, by the active participation of the people. The continuous interaction of visitors keeps the project dynamic and alive. This phenomenon is also evident in other galleries in downtown São Paulo, such as Galeria do Rock and, especially, Galeria do Reggae. These galleries represent a model for the longevity and vitality of urban spaces, where Black culture has spontaneously found places to gather and express its identity. (Dias, 2020)

Figure 17: Stalls sell fabrics, masks, shirts, and accessories, photo credit: Dias, 2020.

Figure 18: Muslim ceremony with African drums, where men dance and sing to Allah, incorporating elements of the continent's culture, photo credit: Dias, 2020.

Galeria do Reggae, despite its evolution away from its original focus on reggae music, remains an important site of reterritorialization for Black culture in São Paulo. Once home to numerous stores selling records, equipment, and CDs related to reggae, today only a handful of these shops survive. The gallery has transformed into a multicultural space, where immigrants from African countries such as Nigeria, Angola, and Congo have brought new vibrancy and cultural exchange to the location. Although some tension exists between different groups, the gallery remains a meeting point where African and Brazilian communities coexist. (Pacilio, 2023)

This process of reterritorialization in Galeria do Reggae reflects the broader trend seen in other downtown galleries, where spaces once defined by commercial activities have shifted towards becoming centers of cultural expression and social interaction (Pacilio, 2023). Throughout its history, Galeria do Reggae has served as a significant hub for the Black community, hosting gatherings that foster identity and belonging. Even as the physical space evolves, the gallery's cultural significance endures, providing a platform for the expression of African and Afro-Brazilian identities, despite the challenges posed by economic shifts and urban changes.

Much like Galeria Olido, which hosts events and gatherings that celebrate African cultures, Galeria do Reggae has adapted to serve the needs of its visitors. While it no longer serves primarily as a space only for black music, its reterritorialization as a center for cultural exchange—where Black culture continues to thrive—is a testament to its resilience and importance. The spontaneous occupation of this space by African immigrants and the subsequent creation of a new common within its walls have cemented the gallery’s role as a cultural landmark in the city.

The reterritorialization of Galeria do Reggae, as well as Galeria Olido, demonstrates how these urban spaces evolve beyond their original purposes, becoming vital cultural hubs that preserve and foster diverse identities. These galleries not only represent the dynamic processes of cultural adaptation and appropriation, but also highlight the importance of creating inclusive spaces where communities can form new commons and continue to thrive, both culturally and socially.

ABSTRACT

The definition of morphological region, since its first appearance in Conzen's work on Alnwick, has always aroused controversy. The fact that the author presented maps of morphological regions in research on Ludlow, Newcastle and British historical centres and urban landscapes, without defining his methodological procedures, has resulted in numerous interpretations. Various contemporary researchers have investigated the concept and its correct delimitation, applying it to several cities around the world. However, such studies have only served to confirm the ill-defined nature of the term, with one questioning the methods associated with the concept. We researchers at the Landscape Laboratory, (LAP) EAUFMG, consider that Conzen demonstrates how to delimit morphological regions by using the four maps that make up his 1984 work on Ludlow. With the aim of contributing to more precise theoretical and practical definitions, our research has encompassed conceptual discussion and the application of methodological experimentation in contrasting historical-geographical contexts. In order to fulfil the study's core objective, namely the application of the concept in urban planning, Conzen's work on Alnwick (1960) and Ludlow (1975, 1984), together with more recent work are examined. As such, this article concludes that redressing the conceptual imprecision and definition associated with the term could greatly enhance contemporary research, given that the expansion of cities is generating ever larger dimensions of built spaces, in relation to plots and blocks. It is believed that these developments will require new forms of morphological analysis, that may assist in understanding contemporary phenomena across the urban landscape.

Keywords:

INTRODUCTION

Conzen, when disseminating his ideas regarding morphological regions in his work on Alnwick (1960) and in the subsequent articles on Newcastle (1962) and Ludlow (1975, 1988), used his geographical training, acquired in Germany, to theoretically substantiate his application of regionalization in urban morphology. The origin of these studies, according to Whitehand (1981, 2009) were a result of discussions amongst German geographers on the theory of regionalization, from which Conzen

elaborates a retrospective on the concepts and their application. He also notes that the first research, mainly in German-speaking Europe, tended to be based on historical-geographical investigations, carried out in the first half of the 20th century and concludes that throughout the history of the field, the German focus was often referred to as urban landscape or Stadtlandschaft (Passarge, 1930). However, it is contended that these investigations were based more on broader regional sub-divisions carried out by Granö (1929), than on the internal divisions of cities.

Reference to the development of the hierarchy of morphological sub-divisions and the degree of coincidence in the limits between the tri-partite complex of the urban landscape stand out. Thus, Whitehand states that Conzen innovates by studying these regional aspects in internal urban areas. When analysing the similarities between the studies carried out by the German geographer in 1929 and those developed by Conzen in 1960, Whitehand identifies contrasting results, as these early studies culminated in the formulation of more or less uniform and reduced morphological regions, in some cases delineated by non-linear and wide boundaries. He concludes that whilst identifying insignificant similarities, the proposal does not allow expressive hierarchical classification, adding that Conzen establishes the basis for the morphological region adopted by the English school when reflecting on, analysing and mapping several English cities.

The dissemination of the concept and its applications

In his book and articles, Conzen has aroused the interest of researchers in various parts of the world who have sought to use them as inspiration for their own work over the last 60 years. We highlight Whitehand JWR (1981); Slater, T. R. (1990); Baker, N. J. and Slater, T. R. (1992); Kropf K S,(1996) Larkham PJ, Whitehand JWR (1996); Gibson, (2000), Morton N (2002); Barke, M. (2003); Larkham, P. J. and Mmion, N. (2011); Slater, T. R (2018); K. Gu (2019), Pereira Costa et al (2019); Oliveira and Mm: affer Ali Yaygin (2020); Muzaffer Ali Arat,(2022).

The first article that references and discusses morphological region was published by Whitehand in 1981 and entitled The Urban Landscape: historical development and management Papers by M R G Conzen. Chapter 3 contains several explanations about the method used by Conzen in the definition of planning units and morphological regions. Regarding the former, Whitehand explains that these are products of morphological processes and are useful for understanding the urban plan, whilst also contending that methodology should depend on detailed examination of the formation and development of the settlement, subdivision of blocks and plots and analysis of land use and occupation.

Chapter 3 also presents a set of maps created by Conzen in Ludlow and perhaps provides the most enlightening elucidation on the definition of morphological region by explaining that the process may be carried out through overlapping and crossing the three delimitations: the typical area of the urban plan and the typical historical and land use areas. These 3 overlapping maps generate the morphological region. The hierarchy of orders, however, is not mentioned.

In Slater's 1990 The Built Form of Western Cities Essays for M R G Conzen on the occasion of his 80th birthday, two articles contained in section VI, Townscape Conservation, present the morphological regions and discuss their practical purpose in both the field of cultural preservation and urban planning. The first of these (taking as a reference the order of publication in the book) is by Peter J Larkham entitled: Conzen, conservation and management of historical townscapes. He notes that

Conzen's ideas on urban preservation form an important part of his broad approach to urban landscape preservation based on the concept of historicity. Larkham attests as to the tri-partite factors that constitute the historicity of an urban landscape, namely the town plan, urban fabric and use and occupation of the land. The quality of historic urban landscapes and their historicity largely depend on the survival of town plans and the stock of traditional buildings, according to Conzen (1984) - land use being viewed as a minor and indirect aspect of historicity.

In the chapter entitled Townscape management: ideal and reality, Whitehand emphasises the importance of applying the concept in order to preserve an area's historicity, through the definition of morphological regions based on a combination of the above listed components. These constitute a direct reflection of the historicity of the city, whose elusive quality is not distributed uniformly throughout the city, hence the hierarchy of regions. The author questions if the three elements of the tripartite vision: the city plan, the urban fabric and the use and occupation of land are the components of the historicity of the urban landscape and surmises as to what method could be employed when carrying out a systematic examination of these elements.

Whitehand refers to Conzen's article in which he lists possible analyses for defining the same regions and their hierarchy, which are firstly the time interval, and the morphological periods produced by the urban landscape. The spatial distribution of the historical form in each component, including consideration of concentration and mix, used to exemplify the degree of mutual compatibility between the three temporal components, and their adaption, are also observed. Historicity may be affected by obsolescence, building decay, inappropriate "restoration" and local circumstances, such as the use of adjacent areas and landscape settings and the presence of archaeological deposits. (Conzen, 1975, 82-3). Whitehand explains that, despite the importance of this concept of morphological region there is no clear published explanation of how these regions are constructed and no attempt has been made to replicate this detailed study elsewhere to date. This early work summarizes the recurring themes related to morphological regions, the difficulty in defining them, the lack of a common terminology and their applications for public policies both in zoning and the listing of conservation areas necessary for determining land use and occupation laws.

Baker and Slater (1992) addressed the problem of definition when stating that the term morphogenetic regions, originating from Conzen's 1962 study of Newcastle Upon Tyne which, while containing extremely detailed maps, failed to present a methodology for identifying a morphological region. In the article entitled The structure of urban landscapes: strengthening research and practice (2009) Whitehand incorporates into this new text the observations he had already presented in chapter 03 of the book he edited in 1981. Based on the definitions previously presented, he states that the text aims mainly to correct deficiencies and reflect on studies published by other authors noting that the main concern is with Conzen's method of regionalization and its development over the last 20 years. According to Whitehand, this reflection focuses on how structure and space are projected by the landscape, combined with the role that spatial variations play in delimiting areas in order to define the limits of morphological regions. He defines the urban landscape as the product of the combination of geographic units that are articulated in their historical-geographical character and in the temporal process of their formation. He refers to the use of the term urban landscape units and the process to identify them as morphological regionalization. Character and delimitation of such units or regions are considered not only central to urban geographic morphology, but also important in

their application in planning. It is clear that for Whitehand, the importance of the concept lies in its application to urban planning, being that he emphasises that care should be taken in the correct preparation of maps and figures when used in the field.

METHODOLOGY

This text analyses the application of the concept in urban planning and, in order to fulfil the proposed objective, draws on studies undertaken by Conzen in Alnwick (1960) and Ludlow (1975, 1984) as well as other more recent work. A case in point is Barrett's 1992 study on Birmingham city centre which details units of constructed forms and land use that were tabulated, assembled and combined to produce the three maps of the morphological regions (or Townscape) - the method employed by Conzen in Ludlow providing the author's inspiration. However, since Barret fails to explain the process, the reader is prevented from having a full understanding and will perhaps incur problems when delimiting morphological regions.

Whitehand, for his part, further extends the analysis of urban to suburban areas and presents a study carried out by Jones (1987) on urban morphological regions in various Birmingham and London suburbs. It was noted that the three complexes of urban morphological analysis were repeated in suburban areas, the study of which was commissioned to be presented at a public hearing called to draw up a local plan. Items related to this included the presence of suburban roads, adapted rural lanes and the subdivision of plots of private residences and detached houses of greater density. In this suburban regionalization vegetation was taken into consideration in addition to the three components of urban form identified by Conzen in his work on urban centres.

Jeremy and Susan Whitehand's 2005 theoretical comparative study, carried out on two areas whose boundaries were characterized by the same level of resolution, was also cited by the author himself in the 2009 publication. The two essentially suburban areas are both largely products of the 20th century - a part of Lantzville, Vancouver Island, Canada, and Upplands Väsby, north of Stockholm, Sweden. Although the article provides information on the densification process of the two areas, the author himself acknowledges that these are initial studies requiring further research.

Another work cited in the article is the thesis developed by Bienstman (2007) in the Dutch city of Alkmaar and Bromsgrove in Birmingham. Here the author acknowledges the difficulty municipal managers have when defining policies designed for the preservation of historical centres due to their limited conceptual knowledge – the result being inadequate management and preservation of the local character. The innovation of this study lies in the proposal of orders to be used when defining degrees of preservation and also the inclusion of fringe belts and residential areas which are considered to be the main units of the urban plan (the morphological regions).

Other contributions are listed and refer to studies carried out in Asia, principally the study of the Chinese city of Pingyao, where it was possible to measure the triad of elements (streets, plots and block plans) linked to the main development characteristics of the urban plan (Whitehand and Gu, 2007a). A further study carried out by the same authors in a small area near the Forbidden City in Beijing confirmed the capacity for complete morphological regionalization (Whitehand and Gu, 2007b) and its effectiveness in articulating the current urban landscape as a product of centuries of development. In the last section, Whitehand reflects on the applicability of different aspects of

conservation and urban planning, highlighting studies for zoning and citing examples of applications in urban planning and preservation. These include zoning plans and regulations within the Plans d'Occupation des Sols (Land Use Plans) in France (Kropf, 1996b), in the Planes Especiales (Special Plans) in Spain (Barke, 2003) and in the delimitation of 'design areas' in the United Kingdom (Hall, 1997). Muzaffer Ali Arat returned to the topic in his thesis entitled Strengthening the Conzenian Method of Morphological Regionalization (2022) and included other work on morphological regions carried out after Whitehand's article in 2009. In his research, he considers all work on the topic including those previously defined by Whitehand for which he prepared a table listing the author's name, the city where the study was carried out and the time. In addition, the table contains aspects such as the term used to define the region in which the formal complex may be analysed and the number of hierarchies considered, together with the morphological elements that constitute the regions and how these contribute to the definition of hierarchy. The table objectively assists scholars who dedicate themselves to the analysis of the studies elaborated and benefits from the simplification and quality of the themes explored. Regarding morphological regions and their definitions, the thesis, by listing these subsequent works, reinforces the impression that the topic is still characterized by the inconsistencies previously listed by Whitehand (2009), Kai Gu (2019) and Pereira Costa et al (2020)

Pereira Costa et al, drawing on these authors, clarified that when referring to morphogenetic regions, planned units and geographic order, Conzen used examples rather than offering explanation, this in contrast to his approach to the tripartite concepts, burgage plots or fringe belts, in which a full conceptual explanation is provided. In the 1st case there is the possibility of incorrect individual interpretation, statements and conclusions which are deficiencies related to the fact that the concepts, until recently, have not yet been condensed into a single term. As Gu (2019) observes, they are complex and clarification has not contributed to the variety of morphological terminology. This author identifies the use of several terms, such as urban morphological regions that can also be defined as 'urban landscape regions', 'urban landscape', 'urban landscape units', 'morphological units' and 'character areas', concluding that the problem deserves greater systematization.

More recently, Muzaffer Ali Arat (2022) presented a review, identifying the concept's main weaknesses, including the poor relationship between each regionalization and the body of historical-geographical knowledge. He also points out the deficiency in terminology and the lack of definition of options and procedural steps (including the preparation of intermediate and final regional maps). An analysis of the work carried out by the researchers cited further confirms this observation and this aspect will be the next topic of our article.

THE RESULTS OF RESEARCH STUDIES AND THEIR CORRELATION WITH CONZEN

To prepare this analysis, the items listed in table 2.5 of Conzen's article on Ludlow (1984) were used. These outline the following parameters: researchers, date and place where the studies were applied, the terms used to define the area under study, which formal complexes were considered, how many hierarchies were raised in the morphological regions, identification of their morphological components and their contribution to the hierarchy. These items were also listed by Muzaffer Ali Arat (2022) in the table containing a chronology of all work carried out between 1960 and 2022.

Research from 1960 onwards includes Conzen's 1975 and 1984 work on Alnwick and Ludlow and Whitehand's analysis of Amersham after 1997, followed by studies carried out in partnership with Kai

Gu, on the cities of Pingyao and Beijing in 2007. In 2009 the article entitled The Structure of Urban Landscapes: Strengthening Research and Practice was published in which he presented several pieces of work by other scholars, including studies by Jones (1987) on urban morphological regions in the Birmingham and London suburbs, as well as those carried out by Barrett (1996) in Birmingham. In addition to these he cites work on the city of Sibiu, Romania, in 1999, the morphological regions of Barnt Green, near Birmingham, England, in 2005, two other sites in the north-western cities of Lantzville, Vancouver Island, Canada in 2005 and northeastern Upplands Väsby in Sweden in 2008. The article also lists research developed by Bienstman (2007) in the Dutch city of Alkmaar and Bromsgrove in England. Also noteworthy is his 2011 research in Guangzhou, China, carried out jointly with Birkhamshaw and finally the 2012 work on Stratford Upon-Avon. Barke (2003), for his part, applies the concept of morphological regions in the city of Antequera, Spain where two criteria are used to define homogeneous areas. In the first, the analysis focuses on morphological and in the second, on functional aspects related to land use and occupation. No regional hierarchy is observed or studied.

In 2011, Larkham & Morton, developed studies in Edgware and Docklands (London), using the term morphological regions and formal complexes. They consider as morphological constituents the various characteristics of the components of the urban plan, the layout, the division of roads, blocks and plots and land occupation, as well as the occupation rates. Further work includes Vitor Oliveira (2015) in Porto and Alsadaty (2022) in Cairo, whilst Muzaffer Ali Arat lists those developed by Zhang in Shanghai in 2003 and in 2015 in Guangzhou. The studies carried out by Kai Gu in Auckland in 2010 and Chen in the city of Zuoying (Taiwan) in 2018 are also cited. Finally, there is Arat's 2002 thesis entitled Strengthening the Conzenian Method of Morphological Regionalization, in which he explores the concept of morphological region in Antequera and Istanbul. Analysis demonstrates clearly that Whitehand was the most prolific researcher, being that he developed studies on morphological regions in several places around the world, including England, China, Canada, Sweden amongst others.

Although many of the scholars cited refer to Conzen's concepts, interpretation and application are arguably rather vague, and the use of terminology is diverse and therefore fails to provide a unified, standardised or agreed set of definitions. The presentation of solely maps, without an explanation of the results presented also serves to highlight that Conzen's concepts were only partially applied. In line with the many studies, the terms used to designate the object of study also vary and include plan units (twice), urban landscape (once), urban landscape units (twice) and characteristic areas (once).

Regarding the definition of morphological components, the following terms are also used: urban plan (03), urban plan and urban fabric (02) and the tripartite analysis based on Conzen's concepts: urban plan and fabric, land use and occupation (03). In this definition, the author justifies, in some cases, the use of the urban plan in homogeneous areas resulting from planned development that does not present significant morphological variation. The terms, therefore, expand as studies find more developed and defined formal complexes.

In relation to the orders that define the hierarchies, areas analysed only in urban plans naturally do not exist. Moreover, the morphological constituents are subdivided into the orthogonality of the urban plan, the layout of the plots and the types of building and block construction, adjusted according to their function. This characterization of formal complexes (urban plan) is repeated in the study by Zhang, in Shanghai (2003) and Guangzhou (2015). The procedure was also used by Larkham and

Morton (2011) in their studies on Edgware and Docklands in London and their justifications are similar to those provided by Whitehand et al.

With regards to the formal complexes that contain the urban plan and the urban fabric, Whitehand et al (dates) define the number of 03 hierarchies of morphological regions in the study of Upplands Wäsby, Sweden, which are repeated in the work carried out in Lantzville, Canada. To define the morphological constituents, variations in the urban plan were selected, particularly subdivision patterns and housing types in the city centre, residential areas and marginal belts, which contribute directly to the hierarchy as first and second orders. Differences in the implementation of blocks and facades, in relation to their cladding materials, constitute the third order of the hierarchy and are defined in the work on both cities.

For studies that use formal complexes based on Conzen's study in Ludlow, comprising the urban plan and fabric and land use and occupation, it is observed that they were also used by Whitehand and Gu, in Beijing (2007), Whitehand, et al, in Guangzhou, (2011) and in the work carried out by Birkhamshaw and Whitehand in Stratford Upon-Avon (2012), despite the difference in the terms used to define the type of analysis. In the Beijing study, 02 hierarchies of morphological regions are composed of the constituents established by the residential types, original housing complexes, semi-detached and housing transformations and their institutional support amenities. In Guangzhou, Whitehand, et all define a hierarchy of 3 regions, in which the morphological constituents fit only 02 regions in the urban plan containing the layout and the implantation of buildings on the plot over time. These 2 regions are classified as first order, while spatial variations in plot pattern (shape, size and notably plot depth) and their correlation with the building structure and land use may be classified as second order. Buildings, type evolution, land use and occupation contribute to the definition of the first and third order hierarchy.

In Stratford Upon-Avon (2012) two hierarchies of morphological regions were also considered. Their first order constitution is characterized by large residences composed of extensive gardens, suburbs intended for the upper middle class and housing transformation across urban expansion. The second order refers to the transformation of residential models.

Kai Gu's (2010) analysis of morphological regions in Auckland defined three hierarchies. The urban plan containing the subdivision of roads, blocks and plots as morphological constituents are listed and considered to be the first order in the hierarchy. The second-order hierarchy includes the types of buildings and their transformations from their origins to contemporary models, whist the third order includes the elements that are part of the land use and occupation.

For Oliveira (2015) the morphological regions in Porto have four hierarchies. To analyse them he used Conzen's concepts and listed the urban plan and its components as first-order morphological constituents. The buildings, their characteristics, plot occupation and uses contribute to the second and third orders, whilst the transformations of the buildings and their environmental perception are deemed to be fourth-order elements.

Chen's 2018 work in Zuoying (Taiwan), although not highlighting the terms and formal complexes associated with Conzen's concept of hierarchies of morphological regions, does mention the

morphological constitution of the areas and the subdivision of the land, construction typology, land use and occupation over time. The latter items are however not associated with the hierarchy.

Alsadaty (2021) in his work on Cairo uses Conzenian concepts for both the term and the formal complexes to classify two hierarchies of morphological region. He considers the projects implemented before 1920 as first-order hierarchy and the periods between 1920 and 1948 as second-order. The built forms between these periods and the use and occupation of the land are not considered.

Arat´s thesis (2022) argues for a more applicable and explicit method of morphological regionalization and proposes a new approach. His set of criteria which aim to clarify the application of the step-by-step method is, however, reminiscent of the table developed by Conzen in Ludlow. He further develops criteria designed to answer the questions contained in the table and lists the following ten items.

i. the age of the streets/expansion phase of the city, geometry of the streets, layout of the plot (area, width, depth), types of building block plans, building coverage and position of the buildings - based on the urban plan.

ii. architectural style, construction material and building height - based on the structure of the building;

iii. land use. This set of criteria establishes a fundamental basis for the foundation of a more systematic and robust methodology for the identification and delimitation of the morphological region.

Although the author defines it as a more systematic and robust methodology for the identification and delimitation of the morphological region, these seem to us to be merely developments of the aspects contained in Conzenian theory´s tripartite vision

The innovative approach that stands out is the development of the morphological constituents which he distributes according to the criteria listed in the table and the classification to describe them. Explanations for each of the criteria listed and their application to the cities of Antequera and Istanbul are also presented.

CONSIDERATIONS

For Whitehand (1981), despite the conceptual importance of morphological regions, the absence of a clear explanation of how these are constructed may be a cause of numerous misinterpretations. Kai Gu (2019) corroborates these observations by commenting that the terms are complex and clarification has not contributed to the variety of morphological terminology. He identifies the use of several terms, such as ‘urban morphological regions’ that can also be defined as 'urban landscape regions', 'urban landscape', 'urban landscape units', 'morphological units' and 'character areas', concluding that the problem deserves greater systematization (Pereira Costa et al, 2020). In fact, when listing all the work produced and their nomenclature, it is clear that Conzen himself used the term types of plan units in Alnwick, which only evolved into morphological regions in his study on Ludlow. The same procedure may be observed in Whitehand, who uses the term plan units twice. (This terminology was also adopted by Kai Gu and Zhang. The other terms used include urban landscape (once), urban landscape units (03) and characteristic areas (once). On the other hand, Chen, Oliveira,

Larkham, Morton and Alsadaty, adopt the Conzenian concept, in other words the morphological region, related to the following formal complexes: urban plan, urban fabric, land use and occupation.

A summary of the Hierarchy of morphological regions provides the following numbers: 02 orders are found in three studies; 03 orders in 02, 04 orders in 04 and 05 orders in Conzen's with most studies thus considering the regions to be composed of four orders.

However, the definition or classification of each order varies greatly and it is clear that the urban plan, containing the project for subdividing roads, blocks and plots, is considered to be of the first order in its contribution to the hierarchy.

The types of buildings and their transformations from their original to contemporary state can be considered second order.

Third order contribution to the hierarchy includes temporal variations in the land subdivision use and occupation and their impact on the original building format.

For Oliveira (2015), the fourth order resides more in the user's perception of the transformations he or she observes when walking along the street. However, for the other three researchers (including Conzen), the fourth order is characterized by small modifications in the plot dimensions and in the appropriation of the buildings for new uses.

CONCLUSION

In conclusion, it is possible to analyse the same regions and their hierarchy in terms of firstly, the length of time and morphological periods which in turn define the urban landscape (Whitehand). The tri- partite model includes a combination of historical components to exemplify the degree of mutual compatibility between different periods and their adaptation. Historicity can be affected by obsolescence, building decay, inadequate "restoration" and local circumstances, such as the use of adjacent areas and landscape and the presence of archaeological deposits. (Conzen, 1975, 82-3). In fact, when we analyse the process of identifying morphological regions, ranked by the character of the tri- partite model, their usefulness in the application of urban planning proposals can be observed, both in the creation of possible regulations for land use and occupation laws and the management of cultural heritage. In Borges Filho’s thesis Urbs Adamantina (2023) the identification of morphological regions and their characterization through the hierarchical organization of similarities can be used to define the listed polygons according to the degree of importance of the assets to be preserved. He justifies this approach by referring to the 2010 IPHAN standards, which allow for the inclusion of several non-continuous polygons which may contain specific standards in relation to character. According to the author, instead of having a single instrument to regulate all assets, there are therefore morphological regions. Such a strategy allows for greater acuity and better use of the tools necessary for defining character and specificities.

Likewise, the use of morphological regions is useful when defining regulations for land use and occupation according to the specificities of the elements that make up the respective regions. Another relevant aspect is the savings in both time and money, since instead of a case-by-case registration survey, the elements and similarities of each region allow for precise and expeditious 3-dimensional modelling.

The evidence collected from the various scholars cited suggests that their analyses can be considered, in Whitehand's words, unfinished business, underlining that concept and definition may be considered over flexible and open to numerous interpretations, which through dissemination and discussion can and perhaps should be condensed into a more common and agreed conceptual terminology.

ABSTRACT

The paper proposed here comes from the discussions had at Laboratório de Poéticas Fronteiriças [LabFront - http://labfront.weebly.com], a research, development, and innovation group that aims to investigate further the relationship and possibilities between the fields of art, science, and technology. The exponential technological developments happening in the 21st century, at a pace never seen before in human history, make it so that every sphere of life is permanently affected, needing an adaptation in how things were traditionally perceived. From our day-to-day life to an industrial level, reality as it was has been reshaped to allow for the multiple possibilities presented by technological and scientific advancements. We are currently faced with a paradoxical hidden environment being constructed in front of our very eyes in a digital sphere that can be accessed with the help of mobile cameras, haptics, and stereoscopic devices that are mingling and transforming our understanding of urban spaces. This expansion, created in a space where geographical barriers are easily overcome, makes it easy for highly known cultural environments — such as UNESCO heritage sites across the globe — to be invaded and, therefore, have their existence and meaning altered. We know, from Françoise Choay, how the urban, historical environment works as a mirror to reflect how we construct society. When adding a digital/virtual layer that dialogues and directly alters the structure of existence (life), we face a paradox when dealing with our historical heritage in a post-digital cultural environment. This paper, therefore, aims to discuss how the existence and overcoming of complex objects that are bleeding into every space on Earth through digital means helps to reconfigure our cultural landscape.

Keywords: Digital heritage; digital arts; artificial landscape; digital landscape

INTRODUCTION

In late September 2023, Meta (previously the Facebook company) announced a partnership with Ray-Ban to launch their new generation of smart glasses, Meta Smart Glasses, to be sold in early October of the same year. With a starting selling point of $299, the glasses are filled with many digital features, most noticeable being the glasses' built-in camera, speaker, microphone, and, in particular their Artificial Intelligence (AI) assistant. Although still lacking in many functions, we can understand the Meta Smart Glasses and other smart glasses being launched in the market as a new generation of wearable haptics: technological devices used to access digital layers of our reality.

Lately, especially since the 2010s, we have seen a massive increase in both technologically assisted realities and haptics created to access them. Although the concept of such types of reality was first presented in the 1980s with the creation of the term Virtual Reality (VR) (Netto; Machado; Oliveira; 2002, p. 4), it was only in recent years, from the turn of the 20th to the 21st century, that we had the technological development needed, alongside the significant decrease of their price to allow such dimensions to "escape" industrial and academic contexts and bleed into our daily lives, forever changing the construction and understanding of our landscapes. One of the spheres recently transformed by such transformative technology is the UNESCO heritage sites around the globe. On the premise that such technology allows us to overcome things such as geographical barriers alone, we understand that the digital layer invasion in such places has an effect that needs to be studied as to how and what changes are done to their meaning and existence in itself.

Such discussions are state-of-the-art in regards to the configuration of environments and the creation of mixed landscapes and thus enter the focus of Laboratório de Poéticas Fronteiriças [LabFront - https://linktr.ee/labfront], a research, development, and innovation group based in the Guignard School of Fine Arts in Minas Gerais, Brazil. The group aims to problematize the borders of art, science, and technology and their reverberation. With previous work on how life is being interfaced by technology in various ways, it is of great interest for us to delve further into how the perception of millennial historical sites is faced with challenges and changes due to how life as we know it is in constant change due to fast, constant technological developments.

With such an idea in mind, we present this paper to be divided into two sections, besides this brief introduction and our final considerations. Firstly we will dive into the history and transformation of culturally known landscapes and how our understanding of them and their existence has been altered by the digital technologies we are focusing on to, in the second section, dissect the idea of how cultural heritage is disengaged from life thus creating a paradox when one thinks of living heritage when faces with current technological and scientific developments. Ultimately this paper aims to discuss how a new post-digital cultural landscape is being created and altered in front of our eyes outside of previously delimited spaces.

SMART DIGITAL CITIES

As it is known, cities have been developed, grown, and rearranged accordingly, not only to their population, but to the technology available at the time. Although some things like streets and avenues have seen somewhat relatively few adaptations throughout centuries, especially in European cities, the way we perceive how we utilise the space around us has, undoubtedly, shifted as the population was introduced to new ways in which to perceive reality, interfaced by technological advancements. We understand that:

[...] in the city of the 19th-century field workers already took their places as citizens and congregated socially in spaces where daily life was oriented by industrial logic. That meant an explosive growth in the number of people concentrated in the city had taken place and consequently, new ways to use such space were developed (Benevolo, 1981). [...] The changes in the city [...] are due to the intention of rationalising the relationship between city, citizen and production (Gobira; Silva; Andrade, 2020, p. 3. Our translation).

How technology developed the work is essentially linked to the way the surge for development in our environments shifted.

Not only was it now needed for us to adapt socially to the changes created by technology, here in specific digital technologies, but we also were forced into reshaping our understanding and relationship with our surroundings due to how industries primarily started to accommodate the new developments. Not only that, but the new possibilities in multiple areas, such as agriculture, medicine, biology, etc., due to new technology-aided discoveries have increasingly heightened human life expectancy as well as made for a safer world that now houses more than 7 billion individuals, with some countries such as India and China holding populations of over 1 billion people each. As it is, "Today, more than half of the world's population lives in cities, leading to a lot of problems linked to the explosion of the urban population in towns; to solve these problems, countries are progressively improving the use of new technologies to make cities smart" (Scorpio et al., 2020, p. 1). Those smart cities, although with different specificities to their definition, can be overall understood as:

[...] constellations of instruments across many scales that are connected through multiple networks which provide continuous data regarding the movements of people and materials in terms of the flow of decisions about the physical and social form of the city. Cities, however, can only be smart if there are intelligence functions that are able to integrate and synthesise this data to some purpose, ways of improving the efficiency, equity, sustainability and quality of life in cities (Batty et al., 2012, p. 481).

We can thus understand smart cities as another step in the urbanisation of cities, especially the large ones where we have a concentration of population and an industrial/technological hub. Coined firstly in the 1990s (Söderstrom, 2014, p. 7), it is a:

[...] concept that is created with the demand of making use of technologies through communication networks and the internet for the transformation and use of the urban environment (being a part of urbanisation processes) in an efficient manner, searching, in its essence, to bring equilibrium amongst competition and sustainability. The stimuli to digital development aim to create more [liveable] attractive cities, thus gathering private capital investments (Gobira; Silva; Andrade, 2020, p. 8. Our translation).

We can easily imply then how there would be an industrial push regarding the development (and redevelopment) of urban areas into smart cities, seeing that, as stated here, they are the culmination of technological and financial needs of the post-digital[43] world. As new technologies are created, they can be applied both to our day-to-day lives and on a larger construction scale in the streets, buildings, signs, and other makers of urban spaces. Such use has created a strong movement of capital, in an interconnected way, across the globe, allowing also for better populational control thanks to the use of state-of-the-art technologies aimed to be used in smart cities, such as the Internet of Things (IoT); image processing; Artificial Intelligence (AI); technologically assisted realities, like virtual reality (VR),

[43] We understand post-digital as a moment in time, we are currently living in, where "we can consider that computation has brought new possibilities to society, including for art and technology. With that in mind, [...] [we have] the configuration of a landscape that merges analogue and digital elements" (Gobira, 2018, p. 85. Our translation).

augmented reality (AR) and mixed reality (MR/MX); brain-computer interfaces (BCI); nano-bio-info-cogno-technologies (NBICs).

As stated, such developments, in their use in smart cities, are still somewhat experimental, and that is due not only to the still costly and difficult application but also to the need for a change in the understanding and infrastructure that permeates such environments. That is because smart cities need to be projected by a multidisciplinary team to use technologies to solve urban, social, and economic problems that are created by the growth of the cities and of technology itself. We understand then that smart cities create not only an extrapolation of traditional environments but develop a complete, multidimensional landscape by using software and hardware, and the need for a direct approach to both empirical and digital realities. As of the 2020s, researchers have somewhat agreed that, when it comes to developing smart cities, "challenges include, but are not limited to, environmental issues, air pollution, the heat island effect, the lack of natural resources, and deteriorating infrastructure. Implementing effective policies and strategies for smarter urban growth has received further interest under such scenario" (Jamei et al., 2017, p. 1). One way in which developments are being catered towards, with environmental and cost efficiency questions in mind that is permeating the world around us without being necessarily seen or understood by people other than researchers, developers, or the industry as a whole, is through "invisible" technologies.

While complete reconstructions of cities and ways to interact with our environment are impossible, since the turn of the 21st century, people have been growing accustomed to the use and contact with the digital world. A much more significant, faster, and expanding landscape is being created in laboratories, industries, and research centres, and in the very palm of our hands, though many might need to be made aware. That is because such an environment is somewhat obscured by the difficulty in access and difficulty in the knowledge of how to access. Still, it is, regardless, being steadfastly fed through by millions of people worldwide, especially due to the use of the internet. Although now ubiquitous, some technologies, like our smartphones, tablets, and laptops, are, in reality, haptic devices that connect us to the digital layer of our socially constructed reality (Berger; Luckmann, 1991). The possibilities there, although invisible to the naked eye, are lying in wait for interactions to be developed and put into action, updating our vast landscape. We can see such interactions, for example, in how we use our smartphones as maps, interconnecting the city streets, buildings, urban transport, etc. That is one possibility of mixed reality that is easily accessible to the general population for one. On a deeper, more technologically complex level, we have various research on the use of technologically assisted realities of BCI applications for smart cities for navigation, entertainment, and mobility reasons (Kohli et al., 2022), as well as the use of 3D modelling and VR for research and development of sustainable practices and applications in urban areas (Jamei et al., 2017).

In specific areas of urban life, we have seen more daring uses for the general public: in cultural spaces like museums, we have seen more applied cases of diverse technology and how it can be used and interacted with (Gobira, Silva, 2019; Gobira, Mozelli, 2018). Such discussion is essential for us here seeing that,

[...] at the same time that it preserves, an archive can distance its content from the world around it. To think of an archive in a public institution is to think of it as a needed opening to the world around it, seeing that it can enable the diminishing of the distances that the archived objects tend to keep. The archive can also safeguard and create cultural knowledge of a people and its identity and, with

that, it is open to various interventions, allowing for new configurations and creating new questions (Gobira; Corrêa; Almeida, 2017, p. 270).

As we have proposed here in this paper, the landscape is not simply created by the physical world around us but by its multiple layers, its people, the way it interacts within itself, and, evidently, its social, cultural, and historical context. Thus we cannot overlook heritage sites, be it in the form of cultural institutions or actual historical sites, like, for instance, the ones recognized by UNESCO. Therefore, technological developments will also directly and indirectly affect those places and how we understand and interact with them.

As such, we have seen a surge in research in regards to how we can actively interact and understand cultural heritage sites through the lens and interfaced by technology in this new, still in exploration, obscure landscape. “The growing prevalence of digitization efforts on cultural heritage has elicited widespread international interests regarding their potential implications for the preservation, presentation, and management of cultural heritage assets” (Dang et al., 2023, p. 228). China has appeared as a strong proponent of new techniques and the use of technologies to preserve its cultural heritage sites. As shown by Dang et al., inside its 14th Five-Year Plan, the Chinese government and its researchers are using the notion of digital twin44 to expand its landscape and tap into the digital layer of its environments.

Cultural heritage, subjected to environmental risks, material decay, natural disasters and disturbance of visitors, needs to be comprehensively documented and understood. Simple and “linear” information from manuscript recordings and manual measurements can hardly collect full-scale construction details and performance with high complexity and variability and interpret its invisible interactions with the environment. In addition, the correctness and accuracy of the information are highly dependent on the expertise and responsibility of practitioners. In contrast, digital twin techniques seem to be more reliable. Virtual (p)re-construction is always linked to building information modeling (BIM), that the 3D model reproduces the material characteristics, component types and construction phases of the physical structure with detailed and standardized attribute libraries (Dang et al., 2023, p. 229-230).

However, as we have previously stated, such developments are somewhat recent and still need to be more thoroughly studied and published, with only a few instances out there, as of the writing of this paper, of research in the area of the possibility of digital expansion in cultural heritage sites. Regardless, as we propose, it is merely a question of time before such discussions have a large influx into the academic sphere seeing that they are, undoubtedly and unavoidably being made. What rests for us here, in this paper, as our goal is not to be a case study, is to understand better the literature that makes us able to comprehend how such things can exist and expand.

A LIVING HERITAGE

Just like with the environment around us, as we touched upon in the previous section, we understand that “the layers that make up the museum are created through the work of researchers and

[44] “Typically described as consisting of a physical entity, a virtual counterpart, and the data connections in between, the Digital Twin is increasingly being explored as a means of improving the performance of physical entities through leveraging computational techniques, themselves enabled through the virtual counterpart” (Jones *at al.*, 2020, p. 36)

collaborators throughout time" (Gobira; Rezende, 2022, p. 23). One would not be able to detach a section of reality from its context. Still, it is relevant for us here, faced with the discussion we are proposing in this paper, that we make clear the specificities that make up what constitutes our understanding of reality and, consequently, of heritage. That is because with such markers in mind, we can comprehend the world around us regardless of the way it may (and often does) radically change. As it is, "The remnants of experience still lived in the warmth of tradition, in the silence of custom, in the repetition of the ancestral, have been displaced under the pressure of a fundamentally historical sensibility. Self-consciousness emerges under the sign of that which has already happened as the fulfillment of something that has always already begun. We speak so much of memory because there is so little of it left" (Nora, 1989, p. 7), and technology is one of the leading players in this ever-constant extrapolation and possible replacement of the commonplace.

We have approached and understood the changes that cities have undergone in a practical stance in the previous section. Still, it is vital to us to understand how it allows for the archivist spaces to help in constructing a new cultural landscape in the post-digital context. According to Françoise Choay, it was after 1837 that the understanding of something as heritage changed to accommodate not only constructions but the larger environment as a whole (Choay, 2001, p. 12-13), and that, despite many debates in regards to the specificities of its definitions, it leads to questions in what constitutes as a threat to urban heritages, the field and its researchers have a consensus that it is incredibly pertinent for us to preserve them (Choay, 2001, p. 17). Still based on Choay, "the old formations only reached their heritage identity by obstructing the reorganization of the urban space, transforming the material city into an object of knowledge. The relationship between preservation, heritage, and city incorporates the idea of landscape" (Gobira; Corrêa; Almeida, 2019, p. 272. Our translation). Thus, we can comprehend that despite being a part of the makeup of landscapes, we cannot take the definition of urban heritage and extrapolate it without considering its part and the context as a whole and its need to be preserved. When considering the cultural institutions, we need to change our perspective. That is because,

[...] these hieux de memoire are fundamentally remains, the ultimate embodiments of a memorial consciousness that has barely survived in a historical age that calls out for memory because it has abandoned it. They make their appearance by virtue of the deritualization of our world-producing, manifesting, establishing, constructing, decreeing, and maintaining by artifice and by will a society deeply absorbed in its own transformation and renewal, one that inherently values the new over the ancient, the young over the old, the future over the past. Museums, archives, cemeteries, festivals, anniversaries, treaties, depositions, monuments, sanctuaries, fraternal orders-these are the boundary stones of another age, illusions of eternity. [...] We buttress our identities upon such bastions, but if what they defended were not threatened, there would be no need to build them. Conversely, if the memories that they enclosed were to be set free they would be useless; if history did not besiege memory, deforming and transforming it, penetrating and petrifying it, there would be no lieux de memoire (Nora, 1989, p. 10. Author's emphasis).

Therefore, we can imply the need for such institutions as a part of the landscape created for their enclaved instance that allows for the objects and non-objects to be preserved and role in memory when faced with an ever-constant changing reality and the remains of our memories. Such pertinence can be perceived more clearly when we understand that:

[...] the museum is a legitimation instrument and it, constantly, suffers with changes in reality, but never leaving such reality and its progressive flux. All the events that create the museum do it as part of an illumination instrument of reality. The museum constitutes - and is part of the constitution of - reality between a past shown in the objects (and non-objects) that it is safe keeps, allowing, through the production of knowledge, through its promotion and access, the maintaining of all of its heritage as something contemporary (Gobira; Portugal, 2022, p. 24).

We can thus understand, based on the quote presented and on Choay's descriptions, that despite being held inside the understanding of urban heritage, those institutions do not act according to the dictations of urban heritages as places of memory. That is because the idea of cultural heritage is disarticulated from life and urban heritage, existing in a space removed from time, acting as its preserver.

That is not a discovery. It is known that "in the 19th century [...], the institutional consecration of historical heritage gives it a different temporal status. On one side, it gains the intensity of a concrete presence. On the other, it is installed in a definitive and unequivocal past, built by the collective work of historiography and the (understanding of) historical consciousness of the mutations imposed by the industrial revolution to the abilities of the human beings" (Choay, 2001, p. 206. Our translation. Author's emphasis). What we are facing currently is merely a continuation of how the different understandings of existence come together in the creation of the landscape. An interconnected, constantly evolving landscape. While the discussions and adaptations before took centuries to be able to be perceived in any precise manner, the aid of digital technology has forever transformed our perception by allowing us to understand the reality in which we live and creating a paradox in regards to the sphere in which the cultural heritage, that is the focus of this paper, exists. That is because while existing in a place outside of time in an attempt to be able to preserve a fleeting existence of memory, such places are now being invaded by current, generative technologies, thus creating a direct link that evokes the need for an analysis of living heritage, one that is being constantly updated due to the expansion and bleeding of the digital world into our empirical one. It is in such status that the obscure digital landscape is being formed.

FINAL CONSIDERATIONS

As we have seen throughout this paper and more clearly through our day-to-day lives, ubiquitous and state-of-the-art technology has forever reshaped our socially constructed reality. We are dependent on the digital expansion of our existence in many different degrees to be able to be an active participant in society. From the moment we are born, we are registered into databases, no longer being able to escape having an extension of our bodies that exist online. When analysing it by such close examples, we can perceive that the digital space, which has existed for decades now, is slowly being filled and used and expanded according to our abilities and needs to do so. Seeing the use of digital technologies in constructions, buildings, and the environment around us, we can better understand how the reconfiguration of our post-digital landscape is being formed and why.

Smart cities are the more clearly defined possibilities when severe research and studies have gone into what the changes in technologies might mean to us as a society. Still, they are not the only manner in which we can see and access the different dimensions that make up our landscape. The ease of access and cheap manners in which we can be interconnected with each other, with our homes, with

the world around us, has reshaped the world we live in and our way of occupying it. Looking at a more extensive scope, it is clear that such changes extend to every corner of our existence, including the focus of this paper, which is the cultural heritage sites. The paradox created, and here previously discussed, will be further analysed as more and more intentional advances are made into controlling and safeguarding the digital layer bleeding into those objects and non-objects; We are already seeing the first movements towards such research being done, for example,, in China, a country that has been in recent years very advanced in state-of-the-art discussions. More and more countries are soon to follow in their footsteps, both for cultural and economic purposes, making it so we can, hopefully, shed more of a light on the currently obscure landscape we are just now being able to access and discover.

Paulo Mendes da Rocha and the ships: morphological analyzes between ideas and metrics

Flavia Botechia[1]
[1] Department of Architecture and Urbanism, University Federal of Espírito Santo, Brazil, flavia.botechia@ufes.br

ABSTRACT

In the Cais das Artes architectural project, could Paulo Mendes da Rocha have designed an architecture as a ship? Added to the influence of industrial and tectonic issues, the proportionality system could be used in a way referenced in the architect's port memories? Published in the reference literature, this project with cultural use is composed of an architectural ensemble formed by three volumes - theater, museum, and administration - organized on a horizontal plane, moored, on the banks of Vitória´s bay (Espirito Santo, Brazil). References to port and nautical structures are frequent in the architect's speech as well more specifically when he talked about projects developed (built or unbuilt) for his hometown Vitória. The objective of this article is to present the results of a morphological analysis to explain the metrics of the Cais das Artes architectural project. To this end, documentary collections were necessary - cartographic, iconographic, and textual -, as well one redesign drawing protocol and the adoption of an “analysis system” composed of three sets: contributing with data from the work and document collection; System #1 aiming to decompose the work into constituent elements, and System #2 with speculations on the architectural composition at constituent levels, namely: spatial, material, and urban surroundings. During the studies, it was possible to register that one of the identified ship proportions is equivalent to the proportion 1/6, and that this same proportion is identified on the architectural composition. The conclusion seems to reflect that the procedures to analysis architectural allows us to appreciate the obvious rules of composition such as rhythms, materials, etc, to the less obvious and more subtle ones such as typological variations, comparative articulations, speculating how much of the discourse is capable of being materialized.

Keywords: Paulo Mendes da Rocha; urban morphology; architecture

INTRODUCTION

All over his career, Paulo Mendes da Rocha talked about the ships as a passion. References to port and nautical structures are frequent in the architect's discourse, as well as the idea that the "[...] nature is not that of a nature purely to be contemplated" (Rocha, In: Wisnik, 2012: 60). On other several occasions, in the readings carried out on the work of Mendes da Rocha, more specifically on those projects developed (built or not) for his hometown Vitória, there are mentions of engineering works on the territory, such as those about "dredged and drained" areas (Wisnik, 2012: 61); or uninterrupted port routines related to "[...] ships, for technical reasons of navigation, sometimes unload at three in the morning or set sail at half past midnight [...]" (Rocha, Wisnik, 2018: 33); or even

about geography and opportunities "I was born in the port of Vitória, State of Espírito Santo [...]. When I think about models for objective things, projects, Vitória's enclosure often appears in my mind. An energetic city that, while you work, can be heard over the noise of the docks. The port is an illuminated powerhouse that refers to the idea of the Universe, the world, schedules and adventure in occupying its spaces. The spatial arrangement appears in memory with the floating part of its territory"[45] (Rocha, In: Wisnik 2012: 38), among others. Could the influence of nautical metrics have entered the metric of architectural design?

The objective of this paper is to present the results of a morphological analysis to explain the metrics of the architectural project Cais das Artes (Vitória, 2007-2011) due to the adoption of an "analysis system" based on the authors Ching (1999), Borie et al. (2008) and Unwin (2013) composed of three sets. Published in the reference literature on the architect, that architectural project with cultural use is composed of an ensemble formed by a theater, museum and administration organized on a horizontal plane, moored on the shores of Vitória´s bay. This paper is structured in two sections. First there are the presentation of the methodological procedures and then the results obtained by the interpretation of this architectural masterpiece.

METHOD

The first adopted procedure in this study, still in the morphological pre-analysis phase, was the formulation of the theoretical framework and bibliographic review from the published works about Mendes da Rocha. Not necessarily focused on the knowledge of Cais das Artes, the activities were focus on reading the texts, listening to interviews and watching films to understand the main ideas of the architect. Subsequently, scientific articles, theses, dissertations, periodicals, and newspaper articles were also selected, and it was possible to quantify: 19 books, 07 scientific articles, 15 articles in journals, 05 theses/dissertations and 05 newspaper articles published between 1996 and 2022 to identify mentions or representations. In this context, and specifically about the Cais das Artes, the first mention that could be identified was in a regional publication called Imagem urbana magazine, from 1998.

Zein (2023: 55) warns that to interpret architecture, "[...] it must be admitted that these works were, in turn, elaborated through customary design methods of the professional field of architects". For the author, "non-textual tools" (drawings, sketches) and "textual tools" meet to compose the reading of a project or the design process for "at least two reasons". The first tools are relevant because the act of projecting involves speech and thoughts; and the second one, disseminate what was researched as well as the drawing. With this notion as a guiding line, there was time to write an analysis protocol composed from the reading of three works selected based on experiences of previous research, namely, Ching (1998), Borie et al. (2008) and Unwin (2013).

From Ching (1998) issues related to the composition, order and decomposition of architecture were worked on, recognizing how to identify the parts of the whole, practicing elementarization, naming the elements and creating vocabulary, as well as addressing principles of composition such as axis, hierarchy, surroundings, and construction system. For the author, there are four systems divided into: space, structure, delimitation, and circulation. By spatial system we intend to understand spaces and

[45] Citations translated by the author.

their programmatic functions; By structure system, columns, beams, slabs and cantilever are searched, observing sizing and positioning; in the delimitation system, compositional elements are registered, such as the vertical planes that contain the external and internal volumes; With the circulation system (of people or vehicles) the connection and connection axes, vertical and horizontal, in the building can be noticed. For Ching (1998) the context component must be analyzed because views, topography, sun, dialogues with forms. In architectural analysis, proportion (systems of proportionality and proportions, for example, of materials), scale (visual and human) and principles of order such as axis, symmetry, hierarchy, repetition, rhythm, etc., can also be observed.

By reading Alain Borie, Pierre Micheloni and Pierre Pinon (2008: 33) it was possible to discuss some issues about the geometry of forms and a particular notion of transformation of architectural and urban objects seeking to "[...] to understand the architectural object as the project or the resulting from its surroundings and not as something with value in ism [...]". When addressing the notion of “deformation”, the authors proposed a System of Analysis of Architectural and Urban Forms composed of three principles: the corpus of analysis, the system or systems of analysis, and the vocabulary employed. Specifically, about the systems, the authors describe two procedures. In the first there are stages: decomposition of the elements, qualification of the nature of the relationships between those elements, quality of the modification or not of the elements. In the second system, the constitutive levels, about architectural forms, are the spatial and the material characterizing surroundings, internal subdivisions, dynamic spaces, static spaces.

It also seemed very opportune to us to observe the methods of studies and how the analysis of buildings could be carried out. Unwin (2013: 5) warns about the need to proceed with one's own analyses, consulting what has been published, but never "blindly" repeating past analyses: "Working from published sources, it is very likely, if not certain, that the analyst will come across inaccuracies in the drawings and may be disoriented by the occasional cases in which the photographs were printed backwards". In doing so, the author defends the consultation of published materials (including textual and non-textual ones), but at the same time advocates the practice of redrawing.

In this article presents the results of the studies are presented according to System #1 and System #2. This interpretation first sought to decompose the object by elementarizing its parts and, subsequently, to observe the logics of composition of the parts with the whole, from the inside out and vice versa.

RESULTS AND DISCUSSIONS

About the architecture and the plot

Cais das Artes, an executive architectural project from 2007, developed by the architect Paulo Mendes da Rocha in partnership with the Metro Arquitetura, is located on the shores of Vitória’s bay, in Enseada do Suá neighborhood (Vitória, Espírito Santo, Brazil). The architectural ensemble facing a cultural center is programmatically diluted and consists of three solids, independent but united by a horizontal plane. Such a design strategy, according to J+S (Wisnik, 2018: 176-177), is "[...] a constant in his work since the gymnasium of the Clube Atlético Paulistano: a certain dissolution of the object, with levels and scales to dominate the volumetry, and allow the open space, the public function".

The composition consists of three main solids. The first and largest housing the facilities of a theater, where artists and visitors can immerse themselves among sets, costumes, and music, in a total of 14,000m² and can house up to 1.300 seats divided into two levels. The second solid, 8,500 m², has the

function of a museum with exhibition rooms, auditorium, and library. This does not sit directly on the ground, being seated on 6 reinforced concrete pillars, spaced 54 meters apart, making the ground, as is characteristic of the architect's work, public and the block elevated and traversable by visitors. In this solid, the visitor will be able to discover worlds and "other seas" without leaving the port. The smallest of the solids, almost a perfect cube, has the function of conducting the complex housing employees related to management and the collection. In addition to this function, it also houses the plumb of public toilets, thus allowing the architect's initial desire to suspend the museum from the ground, integrating it into the landscape. After all, what would a ship be without a tugboat?

During an interview with Wisnik (2012), Mendes da Rocha exposes design decisions in the case of this project and, specifically, how he deals with the different solutions adopted for the solids that houses the functions of museum and theater. More than a mere justification, the architect's speech allows us to explore the historical layers of the territory and the actions of engineering in the transformation of the place over time.

In this non-linear timeline of the territory´s history from the cove of calm waters that attracted foreigners to the materiality of the rectangular plot of 300 by 70 meters, it is possible to register formal intermediate stages of the plot that influences the architect's thoughts. It is thus understood to identify 4 formal periods: water between islands, land in islands, striation between islands and solids.

The first stage has primitive characteristics of the site known as Vitória´s bay or a geographical enclosure of seawater that advances through the interior of the continent. Generally, concave in shape, the bay referred here currently has a linear shape resulting from several engineering actions that dredged, rectified, grounded its contour, artificialized its edge over four hundred years. With 120 meters wide and 7,500 meters long, this bay has to the north the city of Vitória, to the south, Vila Velha, to the east the infinite horizon the Atlantic Ocean and Africa, to the west the Port of Vitória, an enclosure that receives ships from different parts of the planet.

The ships, that came from all over and enter this enclosure day and night, has maximum size rules, such as the Cosco-Shipping cargo ships, with their 189 x 32.25 meters, and Log-in, with 218.45 x 29.8 meters, and oil tankers, such as the Robert Maersk, measuring 171.2 x 27.4 meters. Accompanying the ship from the attraction on the high seas to the port are smaller vessels called tugboats, with 34.2 x 12.6 meters, with the function of guiding and avoiding impediments or obstacles along the way (Figure 1). In addition to the oil explored off the coast of the state, the other cargoes arrive stored in containers with a standard of 6.1 x 2.44 x 2.6 meters.

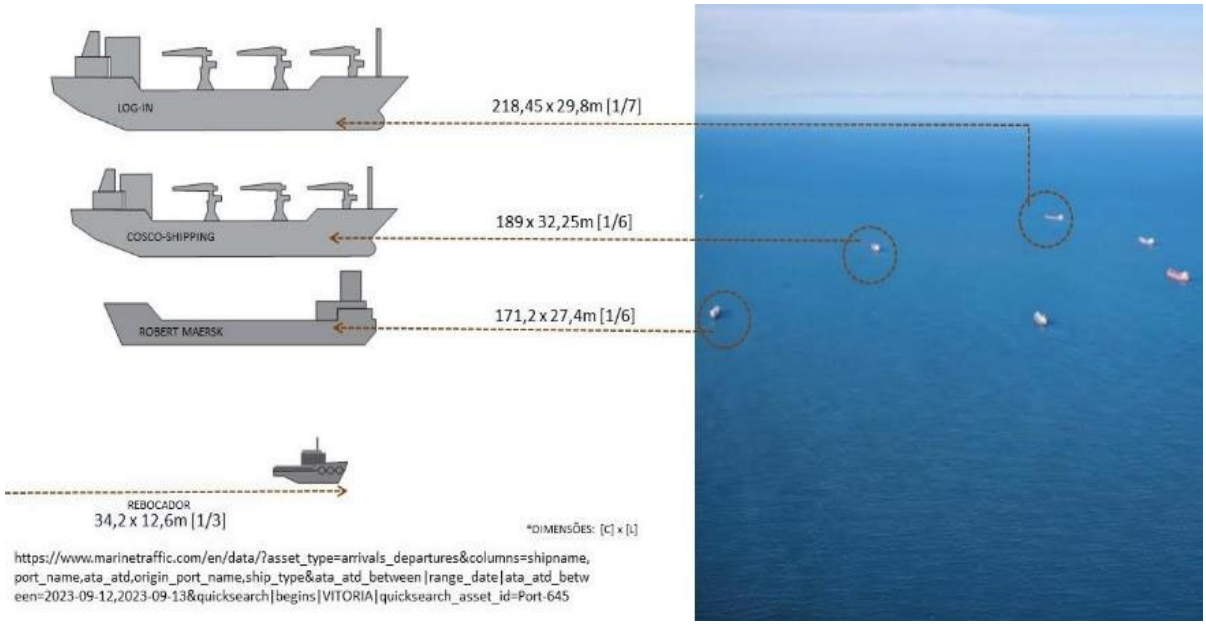

Figure 1 - Metrics of tugboat vessels transiting the bay of Vitória (Source: marinetraffic, adapted by the author, 2023).

In the second formal stage, during the 1960s, for multiple reasons that involved actors from the public and private initiative, the bay was dredged, and its natural concave shape was definitively changed to a linear shape given by a riprap. About 1.2 km² is equivalent to the created soil that unites few islands; both the larger islands, already occupied by neighborhoods, and the smaller islands occupied by animals and vegetation.

In the next stage – third – the urban plan was designed when the smooth soil is changed to a striated soil with demarcation of properties in a two-dimensional composition. It is proposed a set of blocks in different trapezoidal and rectangular formats, from 60 by 120 meters to 240 by 420 meters, and an urban tissue in scales formed by local streets with 7 meters large and main streets of 21 meters, promoting interconnection between the central area and the seafront.

In the fourth formal stage, the layer of the three-dimensional is added. The soil is used and occupied by buildings and increasingly by human beings in a replacement of non-human inhabitants: stones, vegetation, birds, reptiles, amphibians, and fishes. The buildings have prismatic shapes from 10x15x4 meters in one of their smallest formats to the other ones configuring profiles of 100 meters and bases with a tendency to rectangles around 20 by 80 meters.

There is also a height configuration given by the construction of the Deputado Darcy Castello de Mendonça Bridge, "Third Bridge", started in the late 1970s with 70 meters high in the central span, and 3.3 km long connecting two neighboring municipalities separated by the bay. When it comes to talking about landscape of Vitória´s bay, one cannot fail to mention the presence of the chapel Convento da Penha, from 1568, located on a hill 154 meters high. Although located at a distance from Vitória´s limits, the presence of this monument promotes debates and influences the creation of public policies at the local level. According to Otondo (2013: 174) during the development of the architecture project and "As part of the model, Paulo Mendes da Rocha made some cargo ships, exquisitely made of colored paper, in different sizes, from different origins of the globe, the Greek and Russian ships".

System #1

The building form of the probable "anchored ship" Cais das Artes can be read in four sets - spatial, structural, delimitation, circulation - based on the principle that a whole can be subdivided into parts and if this is done it is an abstraction for the purposes of studies (Ching, 1998). In System #1, elements that make up the project are identified. So the graphic analysis and the action of redesigning the architectural projects are taken as an instrument of interpretation (Figure 2).

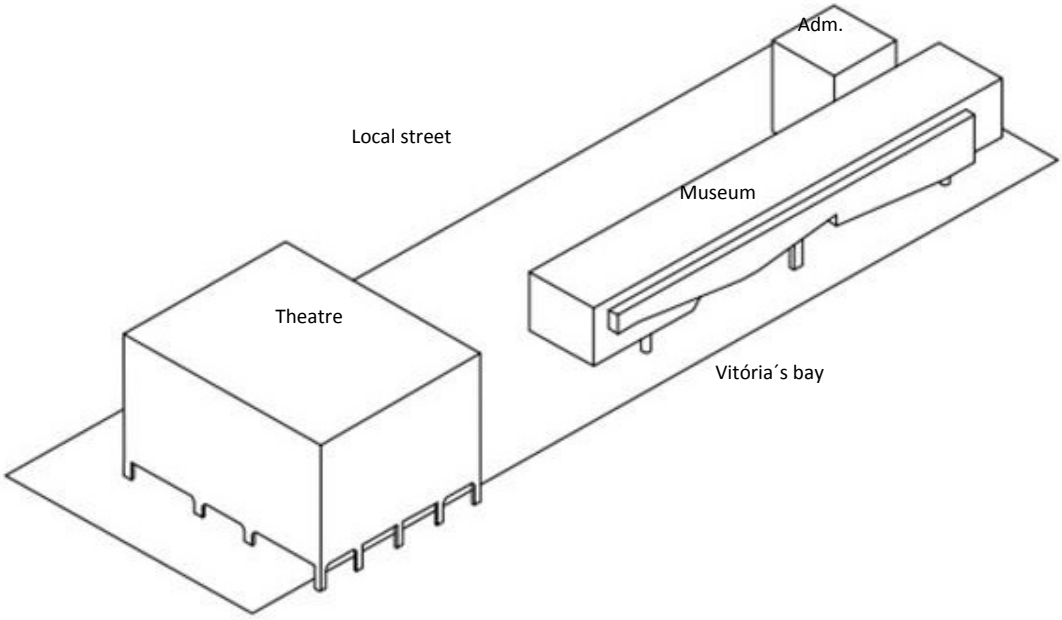

Figure 2 – Cais das Artes: architectonic composition (Source: author based on modeling developed by Uliana, 2023)[46].

The first set of System #1 contemplates spatial aspects. It is "a set of bodies" (Pisani, 2013) composed of three independent solids that approach each other without touching, "[...] pure solids, loose from the ground, which are articulated by aerial passages" (Otondo, 2013: 173). Two of the solids tends to the cube and a third to a parallelepiped with the base cut out. The first and smallest "almost cube" has bases equivalent to 22x22 meters, the second is larger with bases of 70x58 meters. Between these two there is the third solid 6 times as deep as it is wide, 50 meters away from the 32-meter-high solid and 3 meters from the 24-meter solid. Its dimensions are 26x144 meters at the base and a height of 15 meters, being elevated 3 meters from the ground. This third solid of the composition is central and by format hierarchy stands out from the others. On the side facing the ground, it has cutouts and diagonals cutting the linearity of the edge of the solid.

As protagonist as the solids, the surface on which they are arranged is a prominent compositional horizontal element, gaining the strategy of connecting the solids giving a sense of the whole (while keeping them independent). This surface can be related to: "At ground level, the freed space is configured as a square, also the result of an embankment, which opens up over that representative place of human ingenuity that is the port" (Pisani, 2017: 167). In the second set, the structural aspects

[46] These architecture modeling were made by Antônio Uliana (graduated student in architecture and urbanism, Ufes).

of the architectural work are highlighted, such as pillars, beams, slabs, and construction system (Figure 3).

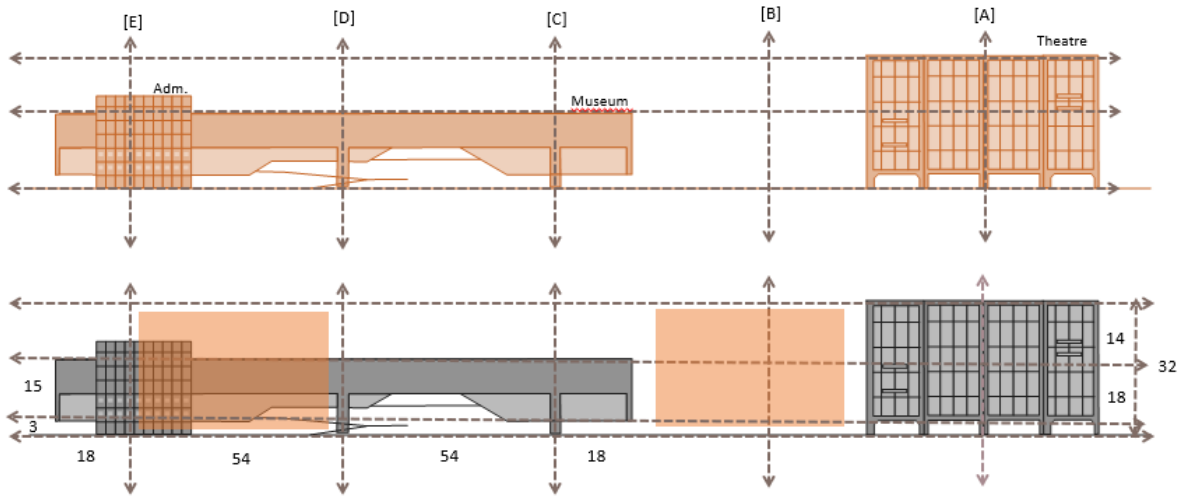

Figure 3. Structural elements of architectural composition (Source: author, 2023).

The smaller solid is made up of metal pillars and beams. The pillars in profile “I” are 8 in number, and are next to the perimeter walls, except for one of them. The slabs, in steel deck structure composed of galvanized steel panel in trapezoidal shape covered by reinforced concrete, are occupied by a set of administrative rooms and public bathrooms having between these two programs the vertical circulation system formed by elevator and stairs.

About 3 meters away is, in parallel, the solid supported by 6 concrete pillars in the horizontal plane. Such reinforced concrete pillars are 54 meters apart from each other in span. In the composition of the elevated solid, the ends are cantilevered of 18 meters. The constancy of the metric equivalent to the number 6. It is impossible not to notice the presence of the 7-meter-high beam supported by the six pillars. On the support of the steel deck slabs there are 1-meter-high transverse metal beams and the slabs in turn are mismatched at level and half level, making the possibility of rooms with double height ceilings a reality.

The larger solid, in turn, is composed of 32 reinforced concrete pillars, with the 4 pillars at the edges in trapezoidal shape, 6 in circular shape and the others in rectangular shape. Of these, 20 pillars are aligned to the face of the outer and peripheral box. Reinforced concrete slabs and beams complete the structure of this speaker because for Mendes da Rocha (Rocha; Wisnik, 2018: 211-212) "[...] It is impractical to imagine the suspended theater, we did it on the floor. However, under the audience, which necessarily must rise from the stage to a background, we precisely imagine the theater's living room opening to the sea, to the same parade of ships, but already with its tectonic installations, that is, its pillars entirely in the water, à la Venice. After all, it must be considered that in that place there is no difference between building directly in the water or in the landfill [...]".

The third set includes aspects related to delimitation. Such aspect, in what specifically configures here the external limits, is carried out by concrete slabs. In the smaller one, it takes on a width of 1.2 meters and 15 cm thick. Each face of the cube has modulation for 70 plates. The 144 meters long are subdivided into 6-meter modules contemplating 3 precast concrete plates.

The larger solid will receive as external delimitation precast concrete plates in the modulation of 1.50 x 3 meters and thickness of 10 cm, in addition to frames in aluminum and tempered glass. As it is a “music box” there are specifications related to the delimitation with acoustic properties such as structural masonry, rock wool, mechanical protection, and acoustic masonry. The question about the foundation of these buildings on landfill from the 1970s once identified by Pisani (2017: 167) were not reported here (Figure 4).

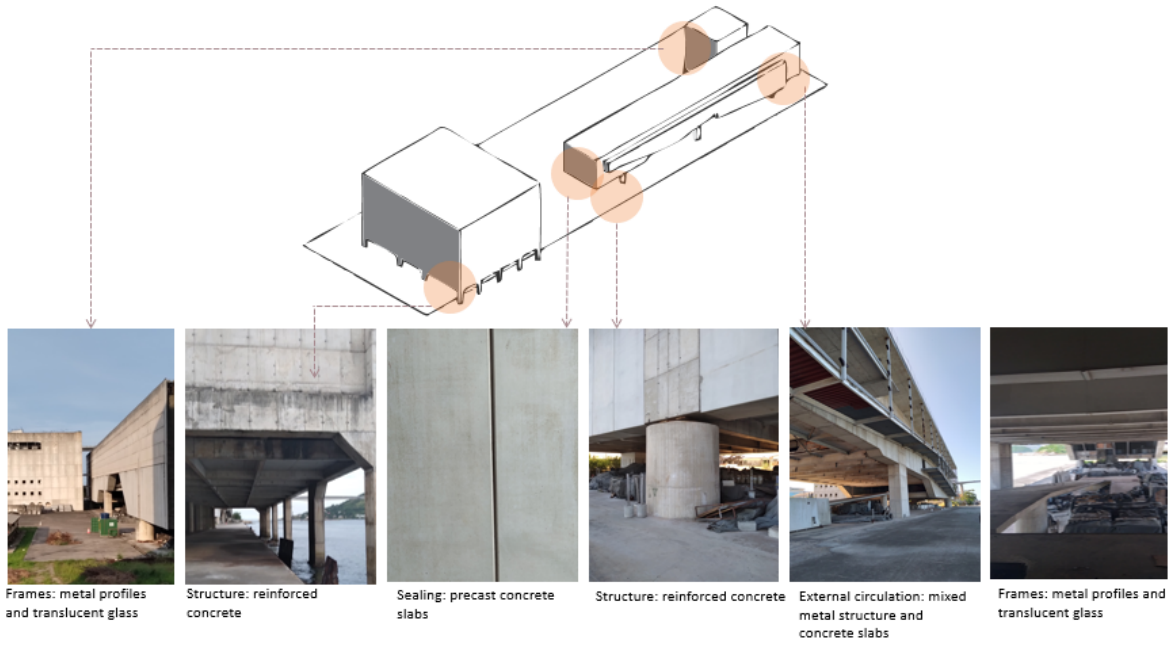

Figure 4. Materiality of architectural composition (Source: author, 2023).

Circulation is a theme of decomposition along with the last set proposed in this System. All solids, with ground floor at the plaza level, have elevators and stairs. The smaller solid has a set formed by a cargo elevator and stairs, the larger solid by 2 sets of elevators, stairs and other 2 sets of elevators and stairs arranged in the northern portion of the solid facing the circulation of artists and technical backstage. Between the north and south portions is arranged, in the center of the composition, the foyer provokes the access of the public at level and necessarily through the horizontal plane.

In particular, the museum's project, for having been "conceived loose from the ground" (Otondo, 2013: 177), 8 meters from the limit of the bay of Vitória and 20 meters from the road curb, requires a specific design to reach the main access meters high in relation to the ground: "[...] The architect designs the circulation with great care: the entrance to the museum is made by a large ramp whose intermediate landing is almost a square (8x8 meters) [...]" (Otondo, 2013: 179). The horizontal and internal circulation of the museum promotes the inevitable displacement so that the visitor can interact with the future collection. In addition to the main access ramp, this solid has 2 sets of elevators and stairs arranged to the east and west, also having an external ramp in metal structure, reinforced concrete and coating in concrete slabs measuring three meters wide. This ramp allows connection between the three levels of the internal slabs, in the internal solid of 14 meters high, without reaching the ground and stands out for the volumetry in the composition of the south elevation (Figure 5).

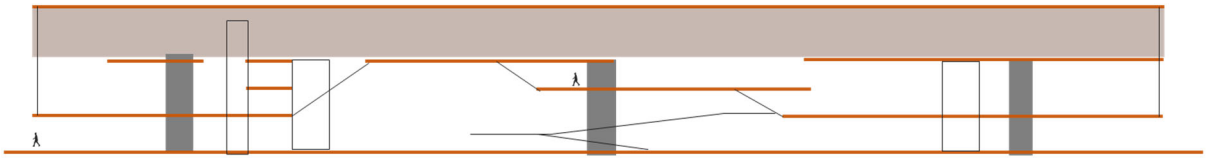

Figure 5. Sectional levels of the solid that houses the museum function (Source: author, 2023).

System #2

In system 2 the rules of composition were studied, speculating intrinsic parameters, and related to the documentary analysis of the executive architectural project. In this system, it is important to say that there is a lot of interpretation, which means, in turn, that the rules observed are not those that the architect uses or used to design, but those that the observer was able to identify.

To this end, the analysis was carried out, the redesign of the floor plan, sections, and elevations, also considering the three-dimensional modeling using digital tools, and then proceeded with the description of the architectural object from 3 constitutive levels - spatial, material, and urban surroundings - previously observed in the literature. So, spatial parameters were observed as the axis; symmetry; hierarchy; given [organizational resource]; rhythm and repetition (Figure 6).

The first two north-south and east-west axes can be noted, subdividing the lot into four quadrants. The east-west connects the square and the urban tissue, interconnecting the vertical circulation axis of the theater with a hypothetical circulation channel formed by the approximation between the solids of the museum and administration. Then, enhancing the north-south axis, it is possible to replicate it in 54-meter modules, forming 5 transversal axes to the lot [A, B, C, D, E], connecting street and water: 2 axes and that cause symmetry in the theater and administration; 1 axis connects directly with a set of pillars in the museum; 1 axis divides the museum to the center, but does not cause symmetry. The metric of 54 meters is a multiples of the unit 6 meters.

In the east-west direction there are 4 longitudinal axes to the lot connecting square and street: 1 axis divides the solid of the museum to the center and whose extension extends to the elements of vertical circulation of the theater. There seems to be a 2-1-2 compositional logic here. This same sequence provokes a reading of the project in reference to the sectorization of uses in compositional band administrative use, horizontal and vertical circulations and, in parallel to water, the main use of the architectural complex (in this case housing theater and museum).

In the identification of the compositional axes in the east-west direction from the south elevation and the street, it is possible to record the metric of 54 meters by 32 meters in height, including the spacing between museum and theater, a kind of invisible rectangle recorded by Otondo (2013: 177) (Figure 3).

As for the hierarchy of the set, the solid of the museum for its hierarchy of implantation (in the center) and format (in horizontal bar). In hierarchy one can also verify what Ching (1999) calls "form within form" with the two boxes of the theater, two (imperfect) cubes one inside the other. The same occurs in the museum's solid, which also contains a trapezoidal-based prism.

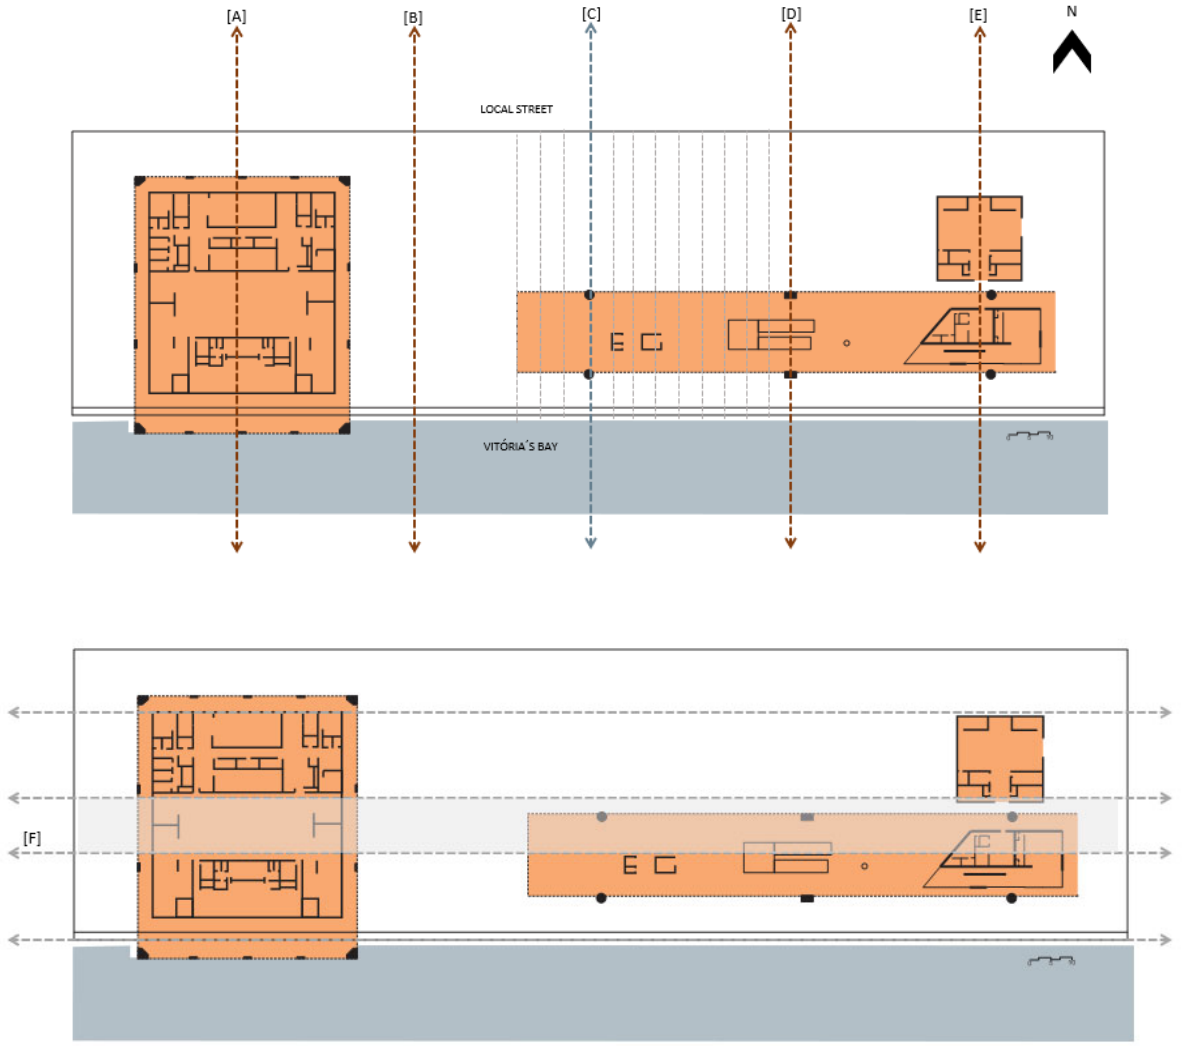

Figure 6. Composition system and spatial parameters transversal to the plot (Source: author, 2023).

By organizational resource was taken the identification of the horizontal plane. It is this rectangle that gives meaning to the whole, enhances the public function, makes the transition between city and water, in addition to promoting a support for observation of the landscape. In addition to these issues, other resources were noted: [1] space within space; [2] space connected by common element; [3] linear organization with a sequence of repetitive spaces; [4] Mesh as an organizing principle. The composition with the mesh and the "space within the space" immediately leads to visualizing "project within the project" in an overlap that goes beyond time and space, the built and the unbuilt.

Parameters related to rhythm and repetition were also noted. From the decomposition of the floor plan, two exercises were carried out. At this level, materiality parameters were observed to understand the proportion system and materials (structure, fence, and frames) (Figure 7). Before describing the observed proportions, it is important to return to the metrics of solids. The solid of the theater observes 32 meters of height, the solid of the museum 18 meters of height (being raised 3 meters from the ground), the solid of the administrative was thus designed with 23 meters of height.

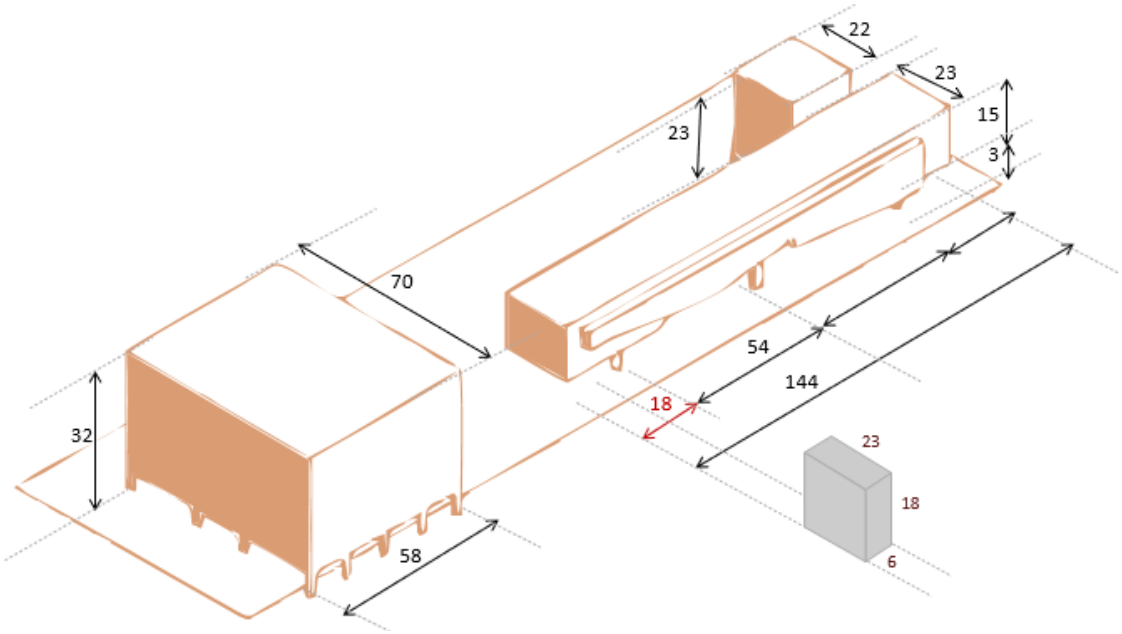

Figure 7. Composition system and the parameters of materiality and proportion (Source: author based on modeling developed by Uliana, 2023).

Among the proportions in architecture enumerated – Fibonacci sequence, golden section, regulating lines, Ken, modulor, anthropometry, visual scale, human scale – its possible to argue that the Cais das Artes project is at the intersection of the proportions of visual scale and regulating lines, the latter defined as: "If the diagonals of two triangles are parallel or perpendicular to each other, They indicate that the two rectangles have similar proportions. These diagonals, as well as the lines that indicate the common alignment of the elements, are called regulating lines" (Ching, 1999: 290).

Added to the influence of industrial and tectonic issues, the system of proportionality used in a way could be referenced in the architect's port memories? Permission is requested here to record merely speculative impressions, seeking to place side by side the nautical proportions of the ships and the architecture. It is thus noted that one of the ship proportions identified is 1/6, as well as that of the solid that houses the museum function in its metric 23/144 or approximately 1/6.

In addition to the possible ways of seeing the proportion of a container, an element extremely associated with the world's cargo ships. From this metric of 2.44 by 6.1 by 2.6 in height, it can be said that the total volume of the museum's solid (except for the issue that there are cutouts in the base) corresponds to 1,680 containers; The solid of the theater corresponds to 3,306 containers and the solid of the administration to approximately 285 containers (although in the latter case the equivalence is not integer and the resulting numbers are fractional). The ships can hold from 5,000 to 20,000 containers. To close this reasoning: 1,680 divided by 285 results in 6 (or 1/6), and 1,680 divided by 3,306 in 0.5 (or 1/2).

CONCLUSIONS

The decomposition of the architectural work allows us to appreciate from the obvious rules of composition such as rhythms, materials, full, empty, to the less obvious and more subtle as typological variations, comparative articulations, speculating how much of the discourse is capable of being materialized. This is so, as Zein (2023: 57) reflects, because the "[...] a work of critical and referenced

recognition of a work of architecture will certainly deal, at every moment of its steps, with forms of representation and non-verbal/non-textual studies (drawings, diagrams, sketches, schemes, etc.); just as it will necessarily deal with verbal or textual forms". It is understood that with the studies developed, many other research perspectives were opened about the design process in architecture.

Permanence and transience in the Florianópolis Urban Agglomeration, Brazil: a configurational analysis in the neighbourhoods of Pedra Branca and Jurerê

ABSTRACT

In the Florianópolis Urban Agglomeration, tourism-driven urbanization has led to neighbourhoods with a high concentration of occasional residences, while traditional urban growth persists. This dual process accelerates urban sprawling, creates social boundaries, and reshapes the urban fabric. Pedra Branca, characterized as a permanent neighbourhood, contrasts with Jurerê, considered a transient one. Both neighbourhoods have become highly valued within the settlement. This study surveys and compares the socio-spatial features of these neighbourhoods, focusing on how urban form, permanent and transient spaces and income levels can influence urban development. The study then analyses the spatial attributes of both neighbourhoods mainly using the "integration value", from Spatial Syntax Theory, which evaluates the integration of the road system within the global and local context. Building typologies were also considered for the spatial analysis. To characterize the neighbourhoods as permanent or transient spaces, census data (IBGE, 2022) on housing were analysed, focusing on the proportion of occasional and permanent residences. That information was crossed with income distribution to understand the socio-spatial attributes of both neighbourhoods. The results allow a comparison of growth processes, the qualities of permanent and transient spaces in Florianópolis Urban Agglomeration, besides the interactions between these neighbourhoods and their surrounding areas.

Keywords: growth process, permanent spaces, transient spaces, socio-spatial configuration.

INTRODUCTION

Florianópolis Urban Agglomeration is the largest urbanized area in Santa Catarina state, with a population of 1.193.507 inhabitants (IBGE, 2022) and is located on the coast of Santa Catarina state, Brazil. Its urban fabric is organized by a continental and an island portion, where in the continental one prevails conventional urban fabric and in the island the tourist urbanization has an expressive role in the urban sprawl process.

Mainly from the 1970s onwards, the spatial reorganization of the settlement was characterized by what Solà-Morales (1997) identifies as a combination of new morphological arrangements and their locational implications regarding uses and socio-economic aspects. This urban dynamic was led by two main vectors of development: the intensification of tourist activities in the coastal areas of the island, at the same time in which growth originated from a higher accessibility - due to the road investments promoted by the state - was guaranteed in the continental portion (Sugai, 2002). Meanwhile the coastal areas the tourist urbanization occasioned, in terms of use, a high concentration of hotels establishments and summer residences, characterizing this space as a transience space, in other areas the conventional urbanization promoted residential occupancy and the emergence of subcentralities, concentrating job activities and permanent residences.

In spatial terms, distinctly from the recurrent pattern of the urban fabric growth, consolidated based on the progressive division and urbanization of agricultural land – under a layout known as the "fishbone model", where local streets are connected perpendicularly through a main road – and by expansion of the foundational grid (Reis, 2002), the new urban growth vectors had as their main premises the fragmented grid pattern, where land subdivision and urban infrastructure are consolidated at the same time. This form of urban sprawl, however, has been resulting in an increase of urban segregation, both by road disconnections with the surrounding area such as geographic isolation, especially when regard to urban tourist spaces.

The segregation of the new areas has been increasing pockets of poverty while leading to occupation by the high-income population in monitored strongholds, often accessible only by car. Two emblematic examples are the case of Pedra Branca, a neighbourhood belonging to the city of Palhoça, and Jurerê, a coastal neighbourhood located on the north portion of Santa Catarina Island, in the city of Florianópolis. The interaction between these spaces with the surroundings is mainly due to economic dynamics, as they concentrate a large supply of jobs. Regarding morphology, they rarely engage with their surroundings, exacerbating social and economic issues through a silent segregation orchestrated by dominant groups (Sugai, 2002), process also known as commodification, where there is a transformation of space urban in commodities, with public power taken over by the private sector (Romero, Mendes, 2023).

How are these two neighbourhoods configured, considering their functional and the urban form characteristics? What impacts do they generate in the (re)structuration of the surroundings and in the urban growth process?

Metropolisation, tourist urbanization and new dynamics of urban growth: an approach in Florianopolis Urban Agglomeration

The search for innovation constitutes the essence of metropolitan dynamics, becoming a dimension subject to analysis and observation under the constant pressure of uninterrupted growth induced by industrial capitalism. This process leads to the transformation of the modern metropolis, which adopts a new configuration through emerging patterns of modernization (Meyer, 2000).

However, it is important to highlight that the contemporary metropolis – a product of post-modernity – does not arise solely from the unfolding of the industrial metropolis, but is also the result of an urban restructuring that explodes, implodes, establishes or re-establishes new spaces; the contemporary

metropolis is, in general, polycentric, fragmented, discontinuous and kaleidoscopic, in which its limits become practically undefined (Soja, 2008). In this context, it tends to break traditional urban continuities, creating diffuse and isolated centres of activities (Meyer, 2000).

In terms of function, the contemporary metropolis does not replace, for example, the industrial activities by service activities; on the contrary, it expands “its attributions within the new stage at all levels and aspects of the productive stage called post-industrial” (Meyer, 2000, p. 7, our translation). Consequently, the contemporary metropolis tends to present greater functional dynamism. This dynamism partly arises from the expansion of pre-existing configurational conditions and partly from urbanization efforts to accommodate the demand for urban sprawl. The spatial-functional reorganization is fuelled by class dispute and based on the locational advantages afforded to high-income groups, which tend to create segregation within urban spaces (Villaça, 2001).

Accessibility is one of the most important locational values which guarantee a high valuation of a place (Hillier, 1999, Villaça, 2001). In the urban sprawl process, the improvement of accessibility is conditioned by high-income people's needs and specific economic interests. In the process, more valued become certain areas and routes in the urban fabric, while others lose value over time (Santos, 1993).

In addition to accessibility, other factors have become significant for urban sprawl in the contemporary metropolis, one of which is the economic exploitation of the landscape. Within this context, tourism plays a key role in configuring new urban spaces. Tourism is not defined merely as an economic activity, but a spatial one that induces and generates various economic activities (Vera et al., 1997). The sun-and-sea segment of tourism is particularly vital in this urban development model.

Macedo (1998) identifies two recurring patterns in urban-tourist occupation in Brazil, naming classic subdivisions the ones with a main street along the sand strip, and contemporary subdivisions the configuration based on streets that promote access only to residential areas, perpendicular to the sand strip. The patterns he identified, however, are not inherent to tourist urbanization. They also occur in other parts of the city, with adaptations being made depending on the maritime limits and the scenic potential of the tourist areas. On the other hand, an important observation made by the author refers to the lack of connection between the owner and the city in which his properties are located. In general, they occupy these residences only during the seasons, reinforcing the seasonal character of tourist urbanization.

For Pereira (2014), in addition to factors related to economic and land use, the creation of urban tourist space is characterized by the integration of leisure activities associated with the sea into daily life. The author points out a behavioural change, as the maritime area, previously only focused on fishing and port activities, with the bad smell of waste thrown into the sea constantly present, becomes attractive for walks on the beach and sunbathing. Consequently, they also become attractive for urbanization, functioning as new hubs of centrality.

Most cities are not prepared to deal with the spatial, social, economic and cultural effects generated by tourist urbanization. We can mention, among the various consequences generated, the lack of infrastructure and urban planning, the overcrowding of public spaces and, even more damaging, the transformation of residential neighbourhoods, causing residents to be expelled and replaced by new

and more affluent inhabitants (generally high-income tourists), in a process known as gentrification (Bobic, Akhavan, 2002).

Gentrification is an urban phenomenon that materializes class dispute in contemporary urban space. The socio-spatial dynamics arising from gentrification are related to the structures of capitalism, which operate to strengthen and perpetuate the wealth and power of the dominant class, being this process achieved through accumulation, dispossession, expropriation, displacement and expulsion of the less favoured social classes (Mendes, 2015). The gentrification process often happens in places where tourism urbanization is present, involving selling properties and replacing them by higher-standard residences.

On the other hand, segregation is a phenomenon that happens in new urban tourist areas and also in spaces originated from the "conventional" processes of sprawl, that is, from the demographic growth with high real estate speculation. In those cases, there is the emergence of new barrios spatially segregated from the pre-existent urban fabric, most of the time primarily accessed by car. These areas are also known as fortified enclaves, that is, "privatized, enclosed, and monitored spaces for residence, consumption, leisure, and work" (Caldeira, 1996, p. 303, our translation).

METHOD

To identify the permanent and transient spaces of the Urban Agglomeration of Florianópolis, we surveyed the proportion of vacant and occasional-use residences in the settlement, that is, those that do not have inhabitants or that have residents for a period regardless of the purpose (holidays, work, season, etc.), and the proportion of permanent residences. Transient spaces were those that have more than 50% of vacant housing and for occasional use. These data were obtained from IBGE census sectors (2022). They were spatialized on the urban agglomeration map, in a procedure carried out throughout QGIS software, version 3.12.22.

Transient spaces do not necessarily happen only in urban tourist areas. However, urban tourist spaces - considered here the urban fabric directly connected to bath areas and with a high predominance of occasional residences - corresponds to the most relevant portion of transient spaces, as conceptually pointed out by Macedo (1998).

In the second stage, we considered two neighbourhoods for analysis (figure 1), the first one is Pedra Branca, located at the continental portion of Florianópolis Urban Agglomeration, and classified as a permanent space. The second one is Jurerê, a neighbourhood located on the island portion, classified as a transient space. Both neighbourhoods originated from the process of metropolisation and intense urban sprawl that occurred from the 1970s onwards, differing significantly from the growth process originating from traditional subdivision.

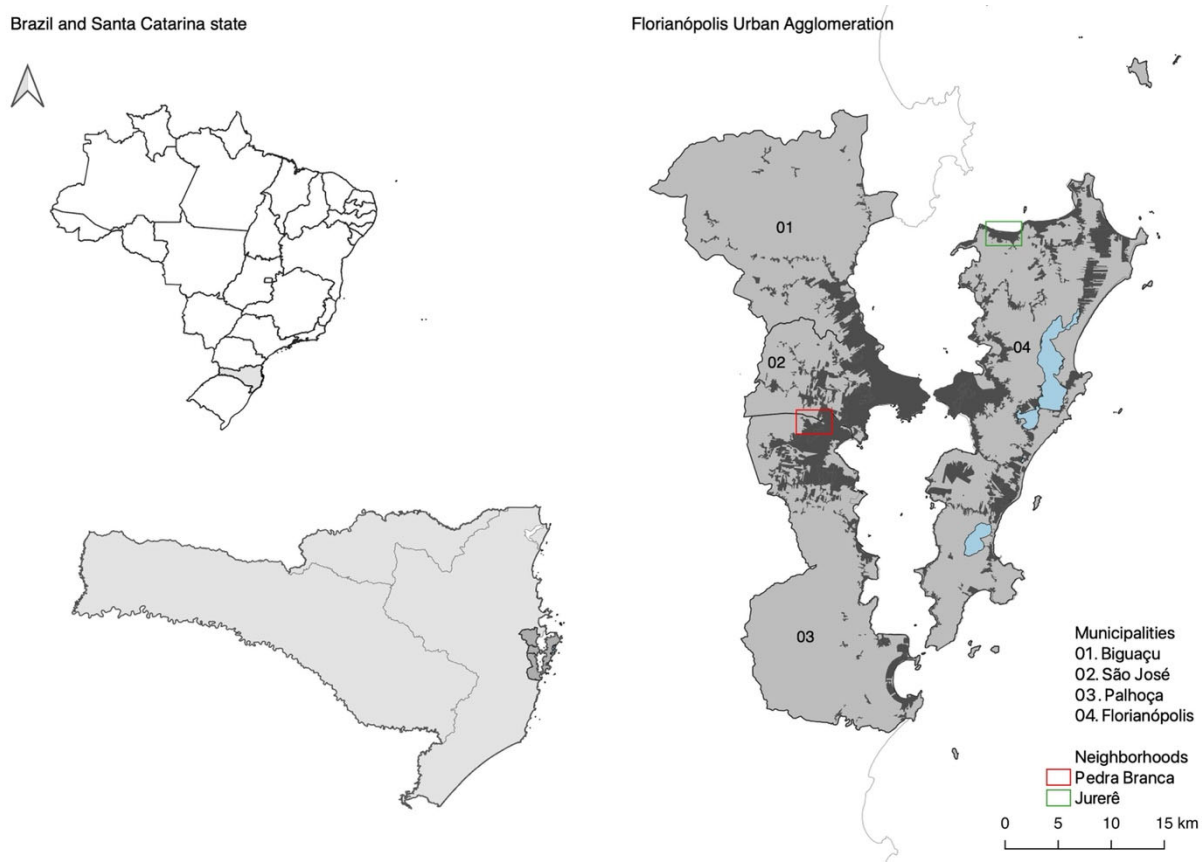

Figure 1. Jurerê and Pedra Branca neighborhoods in the context of Florianópolis Urban Agglomeration. Source: prepared by the authors based on the IBGE cartographic base (2022).

For the configurational analysis, the urban forma characteristics were correlated with functional and social aspects, among which were considered: a) the relation between accessibility, based on layout, and land use, finding how central in the neighborhood for the surroundings; b) the characteristics of the neighborhood and the surrounding buildings correlated with income levels, understanding if there is a trend towards gentrification or segregation; c) the connectivity between the road system and the surroundings, surveying the level of segregation present in both neighbourhoods.

For the first aspect, we linked Space Syntax Theory, specifically the global and local integration value, with the concentration of commerce and services. We measured local integration within an 800-meter radius, representing a 10-20-minute walking distance (Bueno, Reis, Saboya, 2017), and analysed the concentration of commercial and service establishments based on Areas of Interest identified in Google Maps, following the approach of Reis and Almeida (2023). To create the maps and define centrality areas, we used tools like the DepthMap plugin and the Google Terrain complement, both available in QGIS.

For the second procedure, we used Mapbox and Google Earth to identify the predominant building types in the neighbourhoods and in their surroundings. Additionally, we mapped income rates using census data from IBGE (2010) and spatialized this information on a QGIS map. By analysing the obtained information, we could assess the current levels of gentrification or segregation in Pedra Branca and Jurerê.

The last aspect we evaluated the connectivity level between both neighbourhoods to their surroundings. We surveyed the number of connections to Pedra Branca and Jurerê, through the connectivity index obtained using Space Syntax Theory, together with the walkability of these accesses, through photographic surveys. With this information we could understand how fragmented neighbourhoods are.

The purpose of this set of analyses is to verify how the permanent and transient spaces in the Florianópolis Urban Agglomeration, especially those of great relevance in the process of contemporary urban sprawl, interact with the building forms and the pre-existing urban fabric, observing and understanding configurational aspects inherent to the new context of urban sprawl. It is important to highlight that the qualitative analysis on the levels of centrality, the presence or absence of gentrification and segregation and how fragmented they have as a parameter the comparison between both locations.

RESULTS AND DISCUSSIONS

The Pedra Branca neighbourhood and its consolidation process

The Cidade Pedra Branca project, implemented in Palhoça, a municipality in the Florianópolis Urban Agglomeration, Santa Catarina, situated in the continental portion of the Agglomeration, as observed in the figure 2. Its consolidation became at the end of the nineties (1999), with the transformation of a family farm into a subdivision aimed at high-income classes out of the main upper-class axes of the metropolitan area.

Figure 2. The urban ambience (on left) and the urban fabric (on right) of Pedra Branca neighbourhood. Source: photo from authors and map prepared from cartographic bases from Prefeitura Municipal de Palhoça and satellite images from Google Earth (2022).

The monofunctional zoning with well-defined urban functions for work, housing, leisure and circulation prevailed in the first years of existence of the neighbourhood. Within the project, small and medium-sized industrial zones were also defined, thus meeting the high demand for this type of activity throughout the metropolitan region. Mixed use will only appear from 2013, in the so-called last stage (the biggest one), with the development of the central sector. The neighbourhood, planned

under the premises of multifunctional zoning, was inaugurated under a development aligned with the principles of New Urbanism (Reis, Menezes, 2015).

The Cidade Pedra Branca project was designed with the primary goal of utilizing human-scale principles to seamlessly connect public and private spaces, fostering a high quality of life that encourages the full use of public areas. Its form is composed of a radial grid, which starts from a square where the building blocks are clustered around it, thus configuring the road system. Regarding the occupation and land use, each block was designed to house buildings with up to 12 floors, where commercial units are distributed on the first floor, while the upper ones are destined for residential use. According to Reis and Menezes (2015), the designed public spaces have defined and continuous boundaries, with dimensions that match the intended activities. The boundaries of the streets and squares create a clear separation between public and private areas, connecting indoor activities, such as commerce, services, housing, with exterior collective spaces.

With the great real estate expectations generated, the neighbourhood presented, after its consolidation, as a centrality structure for the surroundings, as well as in the settlement. Aimed to guide urban sprawling, the neighbourhood improvement process relies on numerous contributions and compatibility of principles, with renowned consultants such as the urban planners Jaime Lerner and Jan Gehl.

Intense advertising promoted the sale of the neighbourhood, being mainly governed by the ideas of an alternative urbanism to the pre-established structures in the dispersed and fragmented surrounding territory. According to its creators, the space's configurational pillars include: a) walkable structure, where the number of blocks were designed to serve high-standard real estate developments, including housing, educational structures, services and essential businesses, b) sustainable city, with most of the buildings presenting ecological systems in their infrastructure, attracting investors and residents who are interested in this performance, c) neighbourhood for people, aimed to integrate the scale system between person and car, d) mixed uses and safe public spaces, offering shopping and leisure services at all times.

The Jurerê neighborhood and its consolidation process

Jurerê is a neighbourhood in the north of Santa Catarina Island, region where most part of the Florianópolis tourist urban space is situated. The communal lands that existed in the island, not useful for agriculture, gradually acquired economic importance and were privatized, with tourism having an important role in the appreciation of these lands (Reis, 2002).

The Jurerê urbanization project had as its main goal the consolidation of a region that is essentially aimed at the high-income population, with high-standard properties and a private offer of commerce and services (Siqueira, 2021). Its distinct urbanization model regarding other regions of the Santa Catarina`s island – where growth predominates based on the foundational grid and local roads with a herringbone layout (Reis, 2002) – can be considered one of the first resorts with planned urbanization in Santa Catarina.

Regarding the subdivisions, it refers to a configuration of "garden cities", composed of rectangular and large lots that are permeated by green areas among the buildings, as shown in figure 3. For Henrique (2005), some streets are located on a flat site (a marine terrace), causing problems of

drainage during rainy periods, which is incompatible with the project's propaganda, based on the combination between nature, infrastructure and several options and entertainment.

Figure 3. The urban ambience (on left) and the urban fabric (on right) of the Jurerê neighborhood. Source: photo from authors and map prepared from cartographic bases from Prefeitura Municipal de Florianópolis and satellite images from Google Earth (2022).

According to Mezzomo (2009), the urbanization process of the neighbourhood began with the division of its land into lots along the sand strip (east-west direction) and up to the Ratones river (north-south direction). Jurerê's urban fabric is structured into two portions. On the east side, the region is known as Jurerê Tradicional. The orthogonal grid urban layout was designed by the architect Oscar Niemeyer in the 1950s. The area is limited to the east by a hill (morro de Canajurê) and by a winding road from the colonial rural subdivision. On the west side, Jurerê Tradicional is currently integrated with the more recent portion, known as Jurerê Internacional. The subdivision of the urban fabric, also in a grid, occurred in the 1980s and was carried out by Grupo Habitasul.

The land use is predominantly residential, with a high concentration of commerce and services in two main regions: the first is in Jurerê Internacional, in Avenida das Raias (located in the north-south direction), which was specifically designed to be an open Mall, being accessed only by pedestrian. The second commercial area is in Jurerê Tradicional, where commerce is distributed along a set of streets and emerged in a more organic way compared to the first case.

The permanent and transient spaces in the neighborhoods of Pedra Branca and Jurerê

In the Urban Agglomeration of Florianópolis, areas with a high concentration of permanent residences are primarily situated on the mainland and parts of the island near the historic centre of Florianópolis, extending into its surroundings between the north and south bays of Santa Catarina Island and further inland. In contrast, coastal bathing areas are marked by a significant presence of occasional residences, predominantly located on the northern coast of the island, with the Jurerê neighbourhood standing out as a key area for these types of properties.

Figure 4 illustrates that, according to IBGE (2022), the 16 census sectors within the Jurerê neighbourhood have an average of 55.4% occasional residences. This percentage peaks at 78.3% in the central census sector, particularly in the area known as Jurerê Internacional. This seasonal

population pattern results in substantial fluctuations in the use of public spaces throughout the year, with a large influx of people during the summer and a significant decline in the winter. Seasonality causes a turnover of commercial establishments, as some are unable to maintain themselves during low season periods. Some establishments remain closed and only open in the summer which, on the other hand, means that the demand from people eventually exceeds the services offered in the region.

Pedra Branca exhibits a more permanent residential condition. Its six census sectors (figure 4) have an average rate of occasional residences of 12.3%, with the highest rate at 28.9%, in the residential portion, and the lowest at 6% (IBGE, 2022). The lowest concentration of occasional residences corresponds to the "heart" of the neighbourhood, where mixed use can be found, with a variety of commerce and services. Unlike Jurerê, in the Pedra Branca neighbourhood, commerce remains at an intense pace throughout the year, with a high flow of people, especially on weekends. Commerce has less turnover, highlighting the constant expansion of the neighbourhood's centrality.

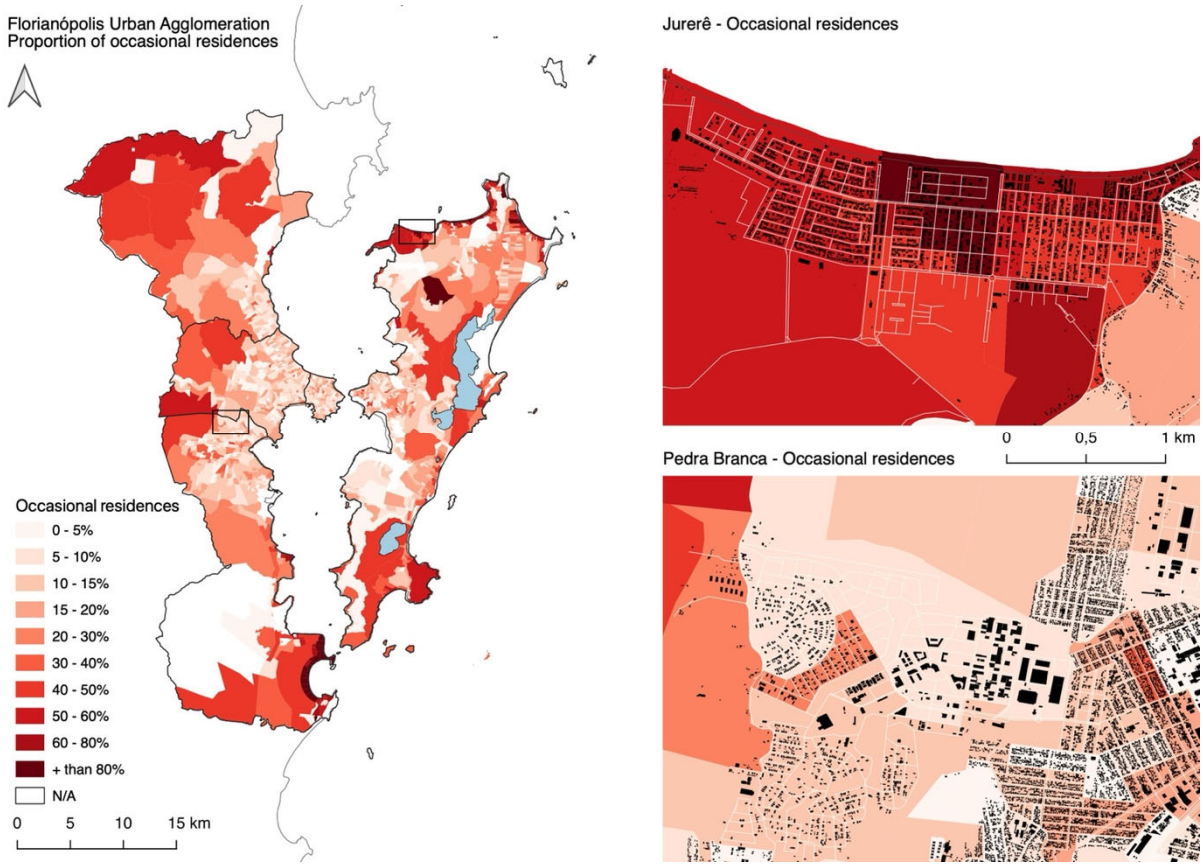

Figure 4. Proportion of permanent and occasional residences in Florianópolis Urban Agglomeration (on left), in Jurerê (on right-above) and in Pedra Branca (on right-below). Source: map prepared from cartographic bases from municipal records (Florianópolis, São José, Palhoça and Biguaçu) and from IBGE (2022).

The accessibility in the neighbourhoods of Pedra Branca and Jurerê

As shown in the map of figure 5 (on left), the integrating nucleus of the Florianópolis Urban Agglomeration, representing the 10% most accessible axial lines in the settlement - based on global integration value - is strategically located at the intersection of the BR-101 and BR-282 highways. This area extends the adjacent urban fabric on the continental portion of the settlement, characterized by a grid-like structure. However, when examining areas with high local integration value, within an 800m radius, shown on figure 5 (on right), high accessibility is not conditioned only to this region. Instead, it

appears in a dispersed manner across the island and other parts of the continental portion, in various dimensions, highlighting the process of polycentric development (Almeida, Reis, 2023).

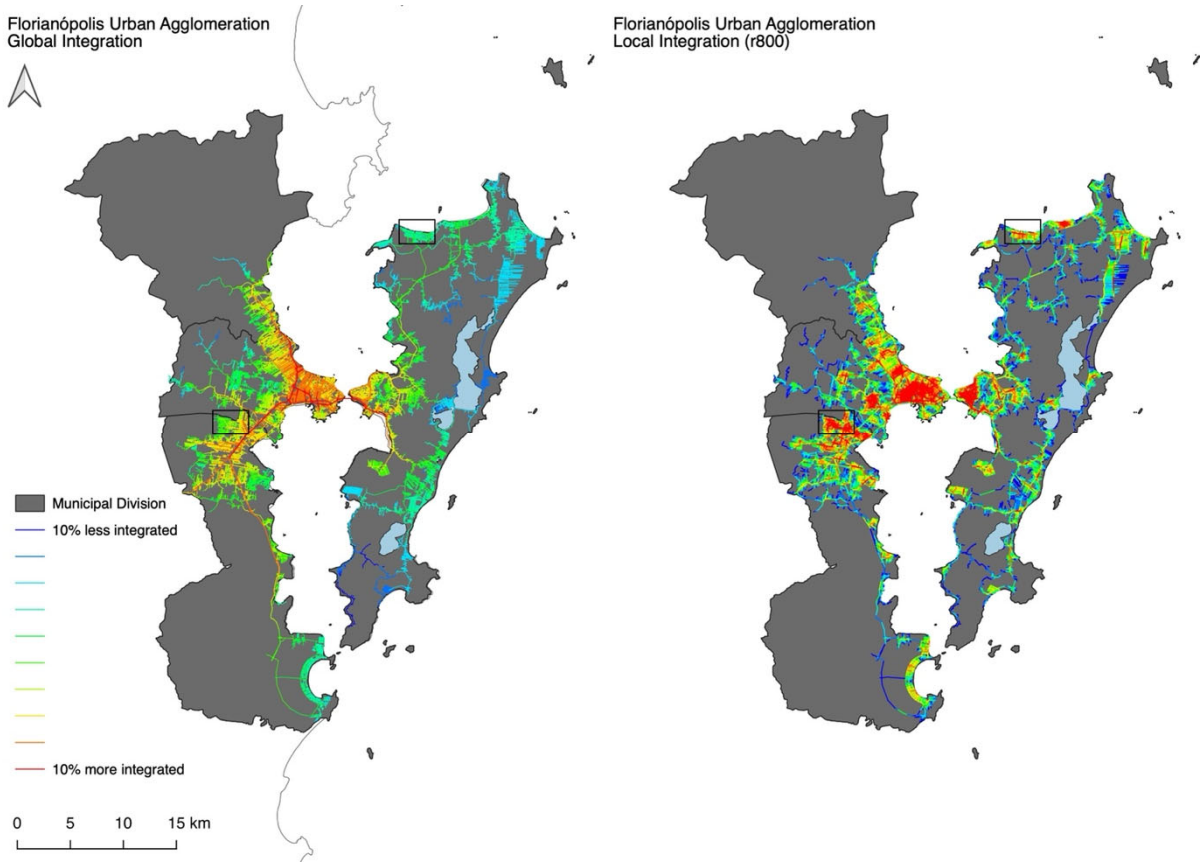

Figure 5. Global integration map (on left) and local integration map using an 800 meter-radius (on right). Source: map prepared from cartographic bases from municipal records (Florianópolis, São José, Palhoça and Biguaçu).

Both Pedra Branca and Jurerê, though not situated in the integrating nucleus of the Florianópolis Urban Agglomeration, feature an axial system that largely falls within the top 30% of locally integrated structures, based on an 800-meter radius. The axial lines in these neighbourhoods typically range between 66 and 131 on a scale of 0 to 255, where lines closer to 0 are the least integrated and those near 255 are the most integrated.

This spatial configuration indicates that Pedra Branca and Jurerê neighbourhoods have a strong potential to develop local centralities, as evidenced by the high concentration of commerce and services observed in Google Earth's Areas of Interest, indicated in figure 6. Unlike other parts of the city, where centrality evolved gradually, these purposefully designed neighbourhoods stand out in terms of layout, building volumetry, and income levels, making them more conducive to economic dynamism.

In Pedra Branca, while the surrounding areas also exhibit high local integration, the concentration of commercial establishments is particularly notable in the neighbourhood's core, where it also presents institutional use, with the presence of a private university. The surrounding regions are primarily residential, with some industrial zones. Here, accessibility is on par with other socio-spatial factors, such as income levels, population density, and the design of the core buildings, which feature

commercial spaces on the ground floor and residential units above. In contrast, Jurerê's geographic isolation makes accessibility the key factor for the concentration of commerce in its central area, despite its "central region" being designed with a similar building layout and mixed-use distribution as in Pedra Branca.

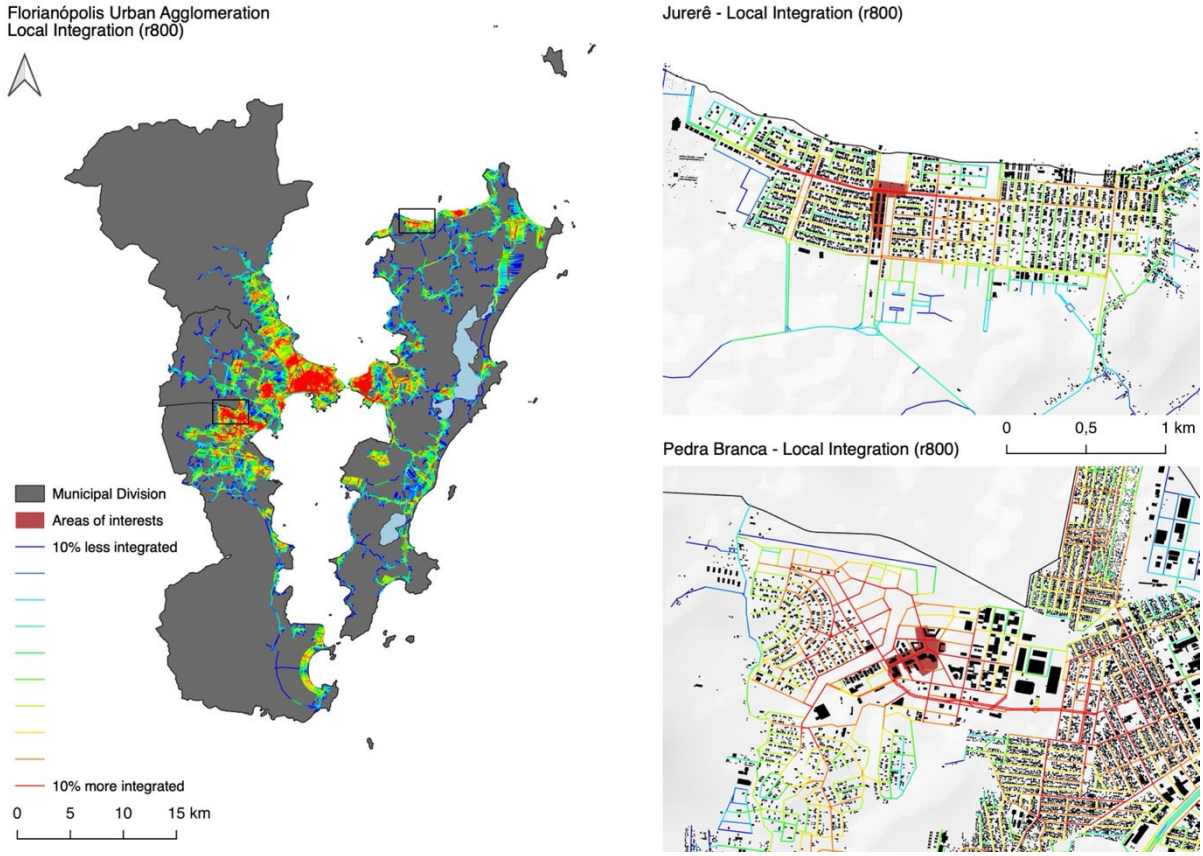

Figure 6. Local integration map (on left) and local integration map in Jurerê and Pedra Branca(on right). Source: map prepared from cartographic bases from municipal records (Florianópolis, São José, Palhoça and Biguaçu).

Urban form and income in the neighborhoods of Pedra Branca and Jurerê

The income map (Figure 7), based on IBGE census sectors (2010), shows that in the Florianópolis Urban Agglomeration, the highest concentration of high-income groups is found on the island portion. While the island's urban area has an average income of R$ 10,818, the mainland portion has an average income of R$7,042. Florianópolis has the highest incomes due to a large portion of its territory being concentrated on Santa Catarina Island, combined with its status as the state capital – factors that attract high-income groups to choose this location for permanent residence and/or real estate investments.

However, this "locational advantage" of Florianópolis does not impede high-income populations from being concentrated in the continental portion. According to the income map of the Florianópolis Urban Agglomeration (IBGE, 2010), the census sectors that make up the Pedra Branca neighbourhood have an average household income of R$20,452, while the average in Jurerê is R$10,256. Despite Pedra Branca having an average income twice as high as Jurerê, both neighborhoods are among the wealthiest regions of the Florianópolis Urban Agglomeration, which, in turn, has a household income range that varies between R$848 to R$46,233 across the urban census sectors.

The concentration of high socioeconomic strata in these neighbourhoods creates a clear socioeconomic barrier between them and their surrounding areas. This phenomenon is particularly pronounced in Pedra Branca, where low-income regions are found nearby. For instance, the Frei Damião community, located just 200 meters away from the centre of Pedra Branca, is one of the poorest areas in the Florianópolis Urban Agglomeration, with an average income of only R$1,985 in its poorest census sector (IBGE, 2010). Jurerê, geographically isolated, borders areas primarily consisting of fishermen's residences. In both cases, there is minimal interaction between social classes, a division that is further deepened by the transient nature of the higher-income population in Jurerê.

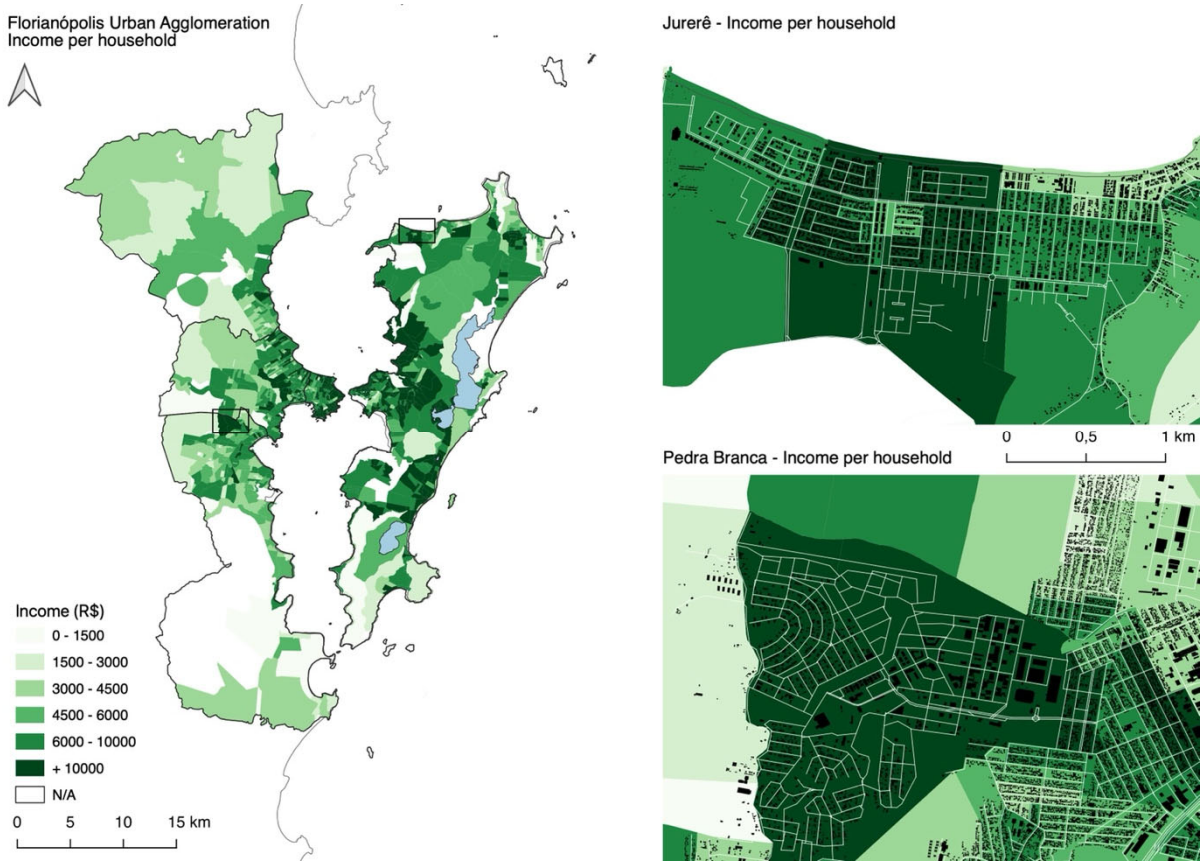

Figure 7. Income distribution map in Florianópolis Urban Agglomeration (on left), in Jurerê (on right-above) and in Pedra Branca (on right-below). Source: map prepared from cartographic bases from municipal records (Florianópolis, São José, Palhoça and Biguaçu) and from IBGE (2022).

The configurational attributes in Pedra Branca and Jurerê neighborhoods: synthesis of the analysis

When considering the characteristics of the urban form, permanence and transience, and income conditions in Pedra Branca and Jurerê, we can observe some similarities and differences in the socio-spatial configuration of these neighbourhoods. Table 1 outlines the main conditions related to the analysed attributes:

Table 1. Main socio-spatial attributes of the neighbourhoods of Pedra Branca and Jurerê. Source: prepared by the authors.

Neighbourhoods	Urban form	Land use	Permanent and transient spaces	Income profile
Pedra Branca	High local integration and low global integration, urban layout in a radial grid (from its centre) and volumetry composed of high-standard residences and multifamily and mixed-use buildings in the neighbourhood centre.	Predominantly residential neighbourhood, with the presence of mixed and institutional use in its centre.	Neighbourhood composed predominantly of permanent-use residences, representing 88.7% of the residences. The neighbourhood has low seasonality.	High-income neighbourhood, with an average income of R$20,452 per residence. It is almost twice the average of Jurerê.
Jurerê	High local integration and low global integration, layout in an orthogonal grid, volumetry composed of high-standard residences and multifamily and mixed-use buildings in the neighbourhood centre.	Predominantly residential neighbourhood, with the presence of mixed-use in its centre.	Neighbourhood composed predominantly of occasional-use residences, representing 55.4% of the residences. The neighbourhood has high seasonality.	High-income neighbourhood, with an average income of R$10,256 per residence. It is comparable to the average of the Island of Santa Catarina.

CONCLUSIONS

In the context of the Florianópolis Urban Agglomeration, Pedra Branca and Jurerê are neighbourhoods with low global integration. Both are high-income areas but differ in some characteristics: Pedra Branca is oriented towards local activities with many permanent residences, while Jurerê is primarily transient and focused on tourism activities.

Their configurational structures result in well-succeeded functional performance, with concentration of commerce and services, creating important local hubs. However, they also have high socio-spatial segregation, Pedra Branca due to its minimal road connections with surrounding areas, and Jurerê because of its geographic isolation.

The layout and initial plans for Pedra Branca and Jurerê reflect the preferences of the dominant classes, who seek high-quality housing, leisure, services and security. This dynamic highlight the socio-spatial division: high-income areas have high local integration with good services and amenities, while their surroundings often face infrastructure issues, intensifying urban segregation.

Although the Pedra Branca neighbourhood sells the proposal of integration between the different uses by several social classes, there are factors that must be presented as contrary: such as the disconnection of the surroundings, especially the urban mobility, giving scope to urban voids, which are being valued by real estate speculation. Jurerê, on the other hand, was deliberately designed as an “oasis” within the urban environment, where its seclusion and commercial establishments focused on high-income strata restrict, somewhat, the access to the beach, a space considered public under Brazilian law.

It is essential to consider integrating these neighbourhoods with their surroundings, as they have favourable configurational characteristics compared to other city areas. Public policies that incorporate less privileged groups both in terms of housing and the use of their public spaces could enhance urban diversity and reduce inequalities driven by the real estate market.

ABSTRACT

This article broadens the discussion on the relationship between nomenclature and urban form in precarious occupations in Brazilian cities. The aim is to analyses whether the terms "Favelas" and "Urban Communities," recently adopted by the Brazilian Institute of Geography and Statistics, can be applied generically considering the diversity of these areas. The study conducts a comparative analysis between an "Área Livre" in Osasco, São Paulo, and a "Ressaca" in Macapá, Amapá. The methodology involves mapping data such as location, occupation duration, built environment characteristics, housing typologies, and urban infrastructure into an analytical matrix to assess their alignment with the locally used nomenclature. The findings suggest that a specific nomenclature, recognized by both residents and municipal administration, can improve the identification and quantification of these areas, aiding in the development of public policies aimed at enhancing living conditions in precarious occupations.

Keywords:

INTRODUCTION

Precarious and informal occupation in urban areas, often referred to as "favela", is a phenomenon rooted in Brazil's history, reflecting the social and urban complexities that have developed over more than a century. From the end of the 19th century, favelas began to form in large Brazilian cities, such as Rio de Janeiro, highlighting both the lack of urban planning and the persistent social exclusion that affected a large part of the population. Over time, the terminology for these areas has evolved, significantly influencing how these occupations are perceived and treated both by society in general and by public policies.

This study critically analyses the different names used to describe precarious occupations in Brazilian cities, examining how the terms "favelas" and "urban communities", recently adopted by the Brazilian Institute of Geography and Statistics (IBGE), do or do not capture the diversity and complexity of these territories. The three-dimensional analysis methodology proposed by Tessari (2016) is used to

demonstrate that the generalization of the term "favela" can obscure the regional and cultural particularities of these occupations, making it difficult to formulate appropriate public policies.

Through the case study of two different areas - Jardim Vicentina, an occupation of public areas in eight allotments in the Jardim Roberto district in Osasco, SP, in the Southeast region, and *Ressaca* Chico Dias, an occupation of public areas in the Amazon, made up of stilt houses in Macapá, AP, in the North region - the aim is to establish a deeper understanding of the socio-spatial dynamics that characterize precarious occupations in different regional contexts in Brazil, contributing to the formulation of public policies that are more aligned with the needs of the resident populations.

The article is structured in several sections. Firstly, it presents a summary of the evolution of the term "favela" in Brazil; then it analyses the specificities of precarious areas in the cities studied, addressing aspects such as location, time of occupation, structure of the built environment, housing typologies, urban infrastructure and origin of the population. In the third part, an analytical matrix is used to compare the divergences and convergences between the nomenclatures used by the population and the municipal authorities, relating them to the terms adopted by the IBGE.

The comparative analysis of the two cases suggests that the nomenclature, when established by the municipal administration and adopted by the population, directly reflects the territory occupied, facilitating the formulation of public policies and the development of projects aimed at improving the lives of the population of these settlements.

FAVELAS IN BRAZIL: Terminologies and relationships with urban form

Precarious occupation in urban areas, commonly known as "favela", is a complex and historically rooted phenomenon in Brazil. Since the end of the 19th century, these occupations have been consolidated in large cities such as Rio de Janeiro, reflecting the lack of urban planning and the social exclusion of a large majority of the population.

The term "favela" originated in the context of the accelerated urbanization of Rio de Janeiro, and was initially associated with Morro da Favela, where ex-combatants from the Canudos War settled. As detailed by Backheuser (1906), the housing conditions of the poor in Rio de Janeiro in 1906 were extremely precarious, with many living in overcrowded tenements in the city centre. Modernization policies, such as the Pereira Passos Plan (1902-1906), resulted in the demolition of tenements and the forced migration of the poor, encouraging the occupation of the hillsides that formed the physical structure of the city, and thus the creation of the first favelas.

Although the term "favela" originated in Rio de Janeiro, this form of occupation spread to several Brazilian cities, such as Salvador, Recife, Belo Horizonte and, later, São Paulo and Brasília. The IBGE (2011) adds that these occupations are called in various ways in different municipalities, including terms such as "invasão", "grota", "baixada", "comunidade", "palafita", among others, becoming synonymous with precarious housing for the poor, perpetuating stigmas that have directly influenced public policies.

In the 1950 Demographic Census, the Brazilian Institute of Geography and Statistics (IBGE) proposed the official definition of favelas, a term used to describe irregular settlements in urban areas, characterized by unauthorized occupation of the land, lack of basic infrastructure and precarious housing (Valladares, 2012). During this same period, engineer Passos Guimarães played a key role in

defining the favela and associating it, for the first time, with the idea of irregular land ownership. Guimarães described favelas as areas of popular housing on illegally occupied land, without proper land regularization, and with improvised constructions, without access to essential urban services such as water, sewage and electricity. This direct link between favelas and irregular ownership reinforced the social and institutional stigma that came to accompany these areas, consolidating the view that favelas were an urban 'anomaly' to be combated.

Based on this definition, consolidated in the 1950s, land irregularity became one of the main criteria for characterizing slums, in addition to precarious physical and infrastructural conditions. In the 1991 Census, the IBGE continued to use the term 'subnormal agglomerations', classifying them as areas with at least 51 housing units that simultaneously lacked essential public services and had irregular land occupation. This concept continued to be used in the 2010 Census, but new debates arose about the appropriateness of the term, as different regions and municipalities adopted alternative names, seeking to avoid the stigma associated with favelas. Pasternak (2008) argues that despite the evolution of nomenclatures, the term "favela" continued to be widely used, perpetuating prejudices and negatively influencing the formulation of public policies. As research progressed, the specificities of precarious occupations were recognized and, depending on the location and the physical and legal characteristics of each area, occupations were given different names by public bodies.

The terminology has evolved, and many municipalities have opted to use other names to avoid the stigma associated with the term "favela". Costa and Nascimento (2005) documented the various nomenclatures adopted in the main Brazilian capitals, which vary according to local policies and the characteristics of the areas.

In 2007, the Ministry of Cities (Marques, 2007) adopted the generic term "precarious settlement", highlighting the spatial peculiarities and precariousness of these occupations. Regardless of the methodology adopted, based on the way in which the municipalities and resident populations called the occupations, the adjective alluding to precariousness remained, denoting the need to act on the physical, social and land needs of each one.

Despite the publication of this document and the debate on it, which served as a reference for the creation of this type of action within the Programa de Aceleração do Crescimento (BRAZIL, 2007), the IBGE continued to use the term Subnormal Agglomerations and the same methodology for surveying and quantifying the population and living conditions in precarious occupations in Brazil.

In 2022, the Ministry of Cities' Peripheral Territories Secretariat organized a working group to review the conceptualization of precarious occupations in cities. The aim was to recognize these areas as an integral part of the city and to differentiate between the autonomous and collective strategies of the population to meet their housing needs in the face of insufficient public policies.

The results of the study confirmed the diversity of names for precarious occupations, such as "favelas", "comunidades", "quebradas", "vilas", among others, reflecting geographical, historical and cultural differences. The IBGE therefore revised the nomenclature of these areas, proposing "favelas" and "urban communities" as broader and more inclusive terms (IBGE, 2022). However, the ability of these terms to capture the complexity of Brazilian urban realities, especially considering regional and cultural variations, remains a matter of open debate.

The spatial diversity of Brazil's precarious occupations and their different urban forms demand continuous reflection on how nomenclatures can help or hinder the formulation of policies that truly respond to the needs of their residents.

Consolidating the terms "favelas" and "urban communities" as broad concepts that incorporate the multiplicity of names given to territories seems to us to be a standardization that does not consider the form and regional and cultural characteristics of each location.

According to IBGE data from 2019, Brazil had 13,151 subnormal settlements, housing 5,127,747 households, currently known as favelas. The Northern region, where Amapá is located, showed the greatest proportional growth in the number of households in favelas compared to 2010, with an increase of 48.6%. In 2019, the region was home to 299,262 households in subnormal settlements. Macapá, for example, registers a peculiarity in its informal occupations, known as "*ressacas*", made up of dwellings on stilts in flooded areas, which differ significantly from the traditional favelas found in the Southeast region, where the absolute number of households in favelas is the highest in the country, with 3,093,760 units. The Southeast, despite having registered a lower growth in percentage terms (12.2 per cent), is still the region with the highest number of slum dwellings in Brazil. These regional differences reflect the different adaptations to the environment and the cultural and economic specificities of each area.

Understanding urban form and how the nomenclature used to describe it influences social perception and the formulation of public policies is one of the aims of this research. Tessari (2016) proposes that the urban form of favelas can be analyzed based mainly on three dimensions: public space, plot and building. Each of these dimensions offers a unique perspective for understanding how favelas are structured and function, as well as how the different nomenclatures used to describe them influence perception and intervention. How can analyzing these three dimensions contribute to a more appropriate nomenclature that captures the complexities and specificities of favelas? How can the definition of terms affect urban development and public policies aimed at these areas?

Despite this attempt at unification, the debate about the suitability of these terms to capture the complexity of Brazilian urban realities continues, especially in the face of regional variations, such as the "*ressacas*" in Macapá and the "palafitas" in the Amazon. It is argued that the use of two terms can return to the difficulty of definition and quantification, negatively impacting the formulation of public policies. A single term, established through an in-depth study that considers the specificities of each municipality, could avoid generalization and promote more effective interventions aligned with local needs.

These variations in terminology not only reflect Brazil's geographical and cultural diversity, but also have implications for the urban form of these occupations. Do the different names influence the perception of the spatial organization of favelas? How do these nomenclatures impact on the way public spaces, plots and buildings are viewed and treated by public policies? To what extent do these terminological changes reflect a reconfiguration of the urban form of these areas? And by changing the name of a settlement, do we also change its spatial perception and the solutions proposed for its regularization?

It is understood that the nomenclature used to describe precarious occupations is not just a technical issue, but also reflects the power relations that structure urban space. As Pasternak (2008) observes,

the choice of terms such as "favelas", "subnormal agglomerations" and "precarious settlements" directly influences public policies and the social perception of these areas. The language used to describe these urban phenomena has the power to shape social realities, legitimizing or delegitimizing ways of life and, consequently, impacting urban intervention and inclusion in the urban fabric. So how does the urban form of these favelas influence and is influenced by the terminology used? How does the spatial organization of favelas impact urbanization and land regularization policies?

Jardim Vicentina: One of the cases of precarious occupation in Osasco, SP

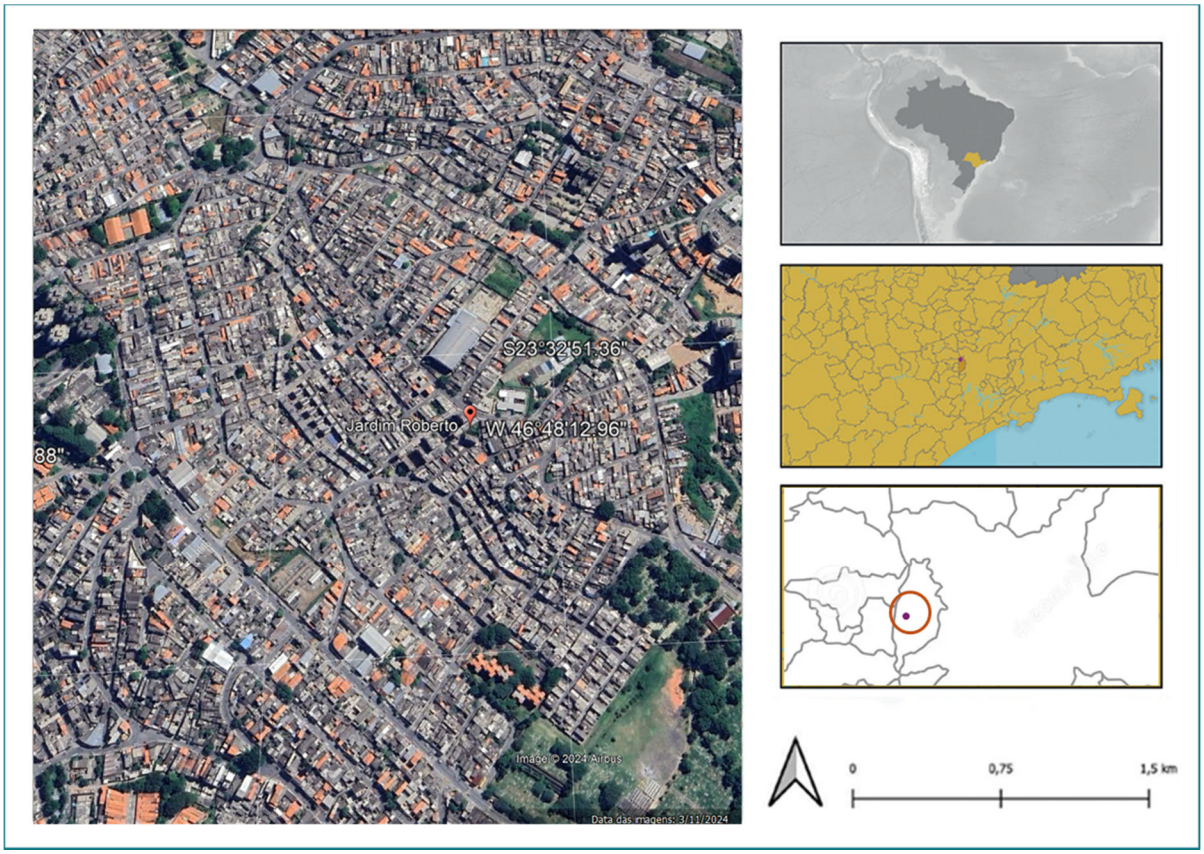

Figure 1: Location of Osasco in the São Paulo Metropolitan Region. Image credit: Prepared by Ivan Alves Pereira from BC 250 IBGE (2019) on Google photo (2020) in Alvim and Rubio, 2022

Located in Osasco, Jardim Vicentina is an emblematic example of the challenges faced by the municipality in terms of precarious occupation and housing policies. Osasco, which was emancipated from São Paulo in 1962 and quickly became an industrial hub in the São Paulo Metropolitan Region (RMSP), inherited uneven development patterns and significant shortcomings. The city's rapid growth, driven by industrialization and internal migration, resulted in disordered urbanization, especially in areas unsuitable for formal urbanization.

The occupation arose in the midst of the city's accelerated growth and urbanization. Classified as a "free area", it has occupied the public areas of eight allotments in the Jardim Roberto district since the 1970s (SEHDU/PMO, 2012).

The "free areas", as defined by the municipality of Osasco, are public lands intended for common use, but which, due to a lack of supervision and pressure for housing, were gradually occupied by low-

income populations. The lack of urban infrastructure, combined with the location on a valley floor and proximity to watercourses, created a highly vulnerable scenario for residents, who faced constant risks of landslides and flooding.

Urban Form of Jardim Vicentina

The urban form of Jardim Vicentina is marked by disorderly occupation and the absence of formal urban planning, consisting of a fragmented structure where plots are irregular and often located on risky land. Access roads are narrow and poorly defined, with alleys that make it difficult for vehicles to circulate, including emergency vehicles. The lack of paving and proper drainage contributes to the degradation of urban conditions, especially during the rainy season, when there is frequent flooding. The urban form of Jardim Vicentina has a direct impact on residents' quality of life.

Figure 2: Shape of occupation in Sections 1 and 3 of Jardim Vicentina, Osasco in 2006. Image credit: RUBIO, 2017

The occupation along the valley floor and on the banks of the stream defines the morphology of the occupation, which is segmented into three main sectors:

Section 01: located in a more elevated and less vulnerable area, it has relatively regular spatial organization, with plots of varying size, but with some regularity in the layout of the houses. The buildings are predominantly masonry, but despite being the most consolidated in the district, they still face challenges such as insufficient sanitation infrastructure and a lack of adequate public spaces.

Section 02: located in an area of steep slopes, this sector has a chaotic spatial organization, with houses built without following a defined pattern or orientation. The steepness of the terrain

aggravates the problems of instability, resulting in frequent landslides. Most of the houses are built with precarious materials and without adequate foundations, which compromises structural safety.

Section 03: located at the bottom of the valley and close to the stream, it has the most critical urban form. The chaotic layout of the housing, especially in the most vulnerable sectors, contributes to unhealthy conditions and makes it difficult to provide essential public services such as rubbish collection and medical care. Improvised dwellings, built with scraps of wood and fiber cement roof tiles, occupy narrow alleyways, often encroaching on areas that should be set aside for environmental preservation. The unhealthiness was exacerbated by the direct discharge of sewage into the stream and the accumulation of rubbish, which was often deposited in the watercourse by the residents themselves (RUBIO, 2017).

In 2005, the Área Livre was home to approximately 865 households, with an estimated population of 3,148 residents, most of whom were migrants from the Northeast. Of the total number of residents, 31 per cent had bought the land and built their homes, while another 17 per cent had bought homes that had already been built. The disorderly occupation resulted in a occupation with a high population density, poor infrastructure and significant environmental risks (SEHDU/DTS, 2007).

In addition, the lack of public spaces and communal areas reduced opportunities for social interaction and community development. The lack of green areas and the disorderly occupation of the valley floor compromise the environmental sustainability of the occupation, exacerbating the problems of pollution and soil degradation.

The Comprehensive Urbanization Project

In response to the challenges posed by the urban form of Jardim Vicentina, the Osasco city council drew up and implemented a comprehensive urbanization project in 2007. This project included the canalization of the stream with the installation of a road, organizing the occupation along it, the installation of basic sanitation infrastructure, such as water supply, sewage and electricity supply networks, and the construction of housing units to resettle the families who lived in the risk areas and the creation of leisure and living areas.

The urbanization work and the entire process of removing and resettling families was carried out with funds from the Federal Government's Growth Acceleration Programme (PAC), supplemented by municipal funds between 2010 and 2015, with the aim of not only improving the occupation’s infrastructure, but also mitigating environmental risks and promoting the social integration of residents.

Despite the progress made with the comprehensive urbanization project, numerous challenges remain, such as the extremely complex land regularization process, which is hampered by the historical disorderly occupation and the lack of proper land documentation. In addition, the maintenance of the infrastructures put in place requires continuous investment and the active participation of the community to guarantee the sustainability of the improvements made.

As such, Jardim Vicentina remains a symbol of the challenges faced by Osasco in its housing policy, and although the living conditions of many residents have improved significantly, the need to complete the land regularization process, as well as the need for additional urban interventions,

remains crucial to the effective transformation of this and other precarious settlements in the city (RUBIO, 2017).

Ressaca Chico Dias: A Portrait of Precarious Occupation in Macapá, AP

Located in the city of Macapá, the capital of the state of Amapá, the *Ressaca* Chico Dias is a clear example of the urban challenges faced in the Brazilian Amazon. The occupation of the Amazon has been shaped by a series of economic and governmental factors over time, from the first contacts with external societies to major natural resource exploitation projects. These processes have often overlooked traditional populations and resulted in urban areas deeply marked by social exclusion and a lack of planning. Macapá, like many other Amazonian cities, emerged from this context of exploitation and colonization, and the *ressacas* represent a peculiar form of precarious occupation in this region (CARVALHO, 2020).

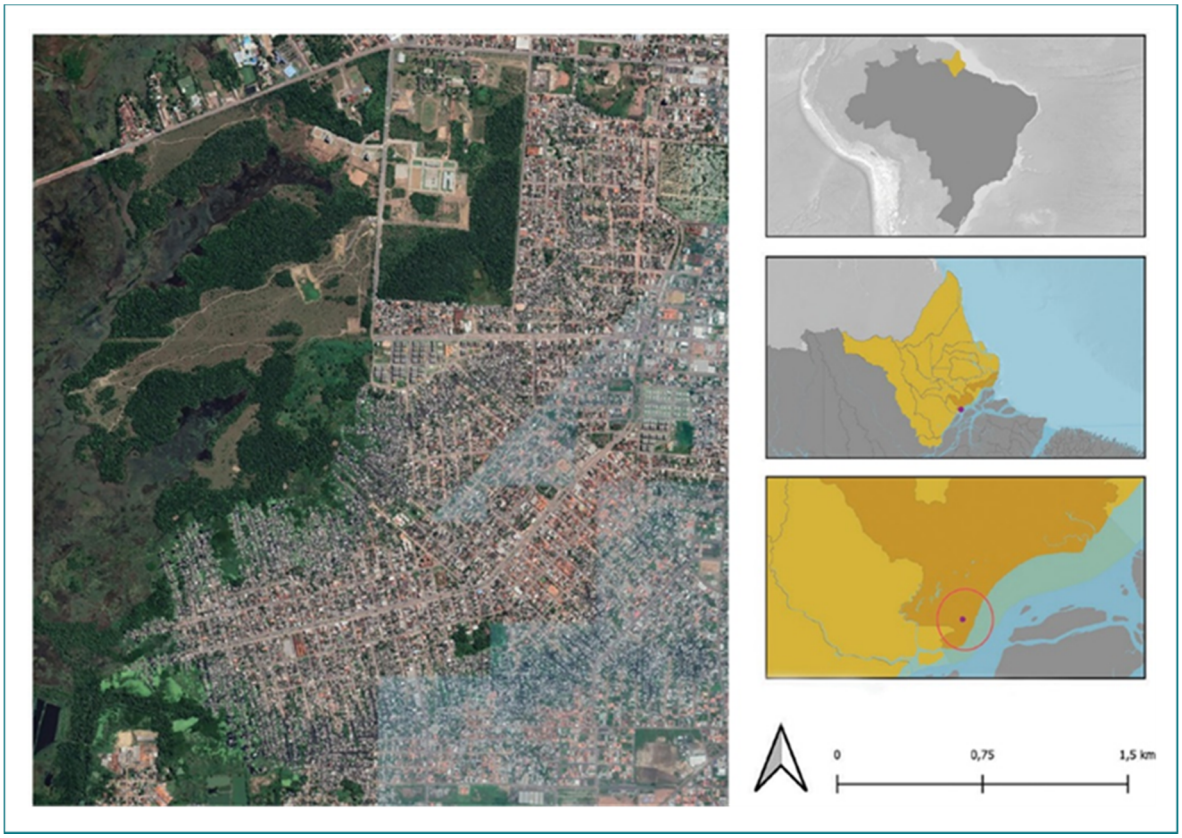

Figure 3: Location of the Chico Dias ressaca from BC 250 IBGE (2019) on Google photo (2020). Image credit: Prepared by Ivan Alves Pereira from BC 250 IBGE (2019) on Google photo (2020) in Alvim e Rubio, 2022.

Macapá's Context and Development

Macapá, located at the mouth of the Amazon River and part of the Legal Amazon, is one of the few Brazilian capitals without a direct road link to other capitals, accessible only by air and water (DRUMMOND; PEREIRA, 2007). This unique geographical location, combined with rapid population growth since the 1990s, has brought significant challenges for the city's urbanization. Disorganized expansion and the irregular occupation of land, especially in *ressaca* areas - naturally flooded zones close to the best urban infrastructure - became commonplace as immigrants from various parts of

Brazil, especially the Northeast and Pará, arrived in search of better living conditions (ANDRADE, 2005).

Urban Form of the Ressaca Chico Dias

Chico Dias, located in an environmental protection area, represents a microcosm of the complex social, economic and environmental interactions that permeate the lives of its inhabitants. Situated in the districts of *Novo Buritizal* and *Congós*, next to the Fortaleza Igarapé, it exemplifies the peculiar urban form of *ressacas* in Macapá. These areas are characterized by stilt houses, built on flooded land and connected by wooden bridges. The lack of basic infrastructure, such as sanitation and water supply, contributes to the proliferation of diseases such as dengue fever and malaria, as well as high rates of hepatitis. The urban form of Chico Dias is defined by a linear spatial organization, where the houses, mostly made of wood, line up transversally from the access bridges, occupying a flooded area (AGUIAR, SILVA, 2003).

This spatial arrangement reflects the need to adapt to the flooded environment, but also exacerbates the conditions of insalubrity and social isolation. According to data from, around 82.2 per cent of residents access their homes via bridges, while 12.3 per cent arrive by dry roads, and a small percentage (2.7 per cent) have to cross flooded paths. The prevalence of stilts and the lack of proper urban planning result in a high population density in vulnerable areas, where buildings are often made of improvised materials such as wood and fiber cement tiles.

The Chico Dias *ressaca* is home of a population that depends mostly on informal activities for its livelihood. With a high unemployment rate, 63 per cent of families have at least one unemployed member, and most residents earn no more than a minimum wage. This precarious economic reality is reflected in the infrastructure of homes, which are often built with cheap materials and lack the minimum conditions for habitability. Around 79.5 per cent of homes are made entirely of wood and are in flooded areas, which contributes to the deterioration of living conditions (CARVALHO, 2020).

Figure 4: The urban form of Ressaca Chico Dias. Images credit: CARVALHO, 2020 in ALVIM and RUBIO, 2022

In addition to precarious housing, the urban form of the *Ressaca* Chico Dias also negatively affects access to essential public services. Rubbish collection, although considered satisfactory by 64.4 per cent of residents, contrasts with the critical situation of sanitation and water supply. With 74 per cent of households having no access to sewage treatment and water quality often considered poor, residents are forced to seek alternative and often unsanitary solutions for their basic needs.

Education and health in Chico Dias also face significant challenges. While 57.5 per cent of residents consider local schools to be of reasonable quality, the situation regarding health services is more worrying, with 45.2 per cent of citizens evaluating their quality as regular. Inadequate access to medical care and limited educational infrastructure aggravates already precarious living conditions, perpetuating a cycle of poverty and social exclusion (CARVALHO, 2020).

Although there are isolated efforts to improve living conditions in Chico Dias, such as the construction of some basic infrastructure and the limited provision of government assistance programmes, the need for a comprehensive urbanization project is urgent. This project should include land regularization, the restructuring of the urban form to reduce the vulnerability of housing to flooding and the implementation of essential public services such as sanitation, water supply and rubbish collection, as well as actions that address the precariousness of housing in order to improve living conditions. Without planned and continuous intervention, the disorganized urban form and living conditions in the Chico Dias lagoon will continue to perpetuate the social and environmental vulnerability of its population.

URBAN FORM AND NOMENCLATURES: a discussion of case studies

By analyzing the data for the Jardim Vicentina occupations in Osasco and the *Ressaca* Chico Dias occupations in Macapá shown in tableau 1, we can identify both points of similarity and specificities

that reflect the geographical, social and cultural conditions of each region. These elements are crucial to understanding local dynamics and urban form.

Tableau 1: Aspects of the settlements. Data credits: Rubio, Alvim and Carvalho, 2024

ASPECTS	SETTLEMENT	
	JARDIM VICENTINA	CHICO DIAS
Country Region	Southeast Brazil	Norte do Brasil
Localization	Urban area	Urban area
Climate	subtropical	equatorial
Resident Population	3,148 residents	De 400 a 500 residents
Population origin	Northeastern migrants	Migrants of Belém do Pará
Time of occupation	30 years	40 years
Form of occupation	Valley bottom inserted in the formal city grid	Flooded areas within the urban grid
Housing Type	Self-built housing, predominantly in masonry	Self-built dwellings, predominantly made of wood
	in many cases overlapping.	on stilts (palafitas)
Public Space	Fragmented, with narrow paved streets and alleys and staircases	Bridges connecting the accesses to the houses. There are no public facilities. The difference between public and private spaces is made possible by a portal installed at the entrance to the houses.
Land Situation	Occupation of public areas in 8 allotments	Occupation of an environmentally protected public wetland area
Block/Lot	The blocks and lots are not defined and are irregularly installed on slopes and valley bottoms, with dense and disorderly occupation.	Lots adapted to flooded areas, with linear layout within the Igarapés
Urban infrastructure	Precarious and insufficient	Precarious and insufficient
Environmental Risk	Areas at risk of landslides and flooding	Risk of flooding and proliferation of water-borne and endemic diseases diseases such as malaria and dengue fever
Social Conditions	Population with an average income of 1 to 2 minimum wages and low level of education	Population with an average income of 1 minimum wage and low level of education
Public Intervention	Comprehensive urbanisation works	One-off works to pave the main access roads
		and improving the bridges that provide access to the houses.
Nomenclature Used by the City Hall	Precarious slum settlements of the favela type	Ressaca (subnormal settlement))

Approximations between the settlements

Although both occupations are considered precarious and present difficulties in terms of infrastructure and living conditions, the similarities between them are limited due to their regional and environmental specificities.

1. **precariousness and vulnerability** (public space, block/lot, building):

Both Jardim Vicentina and *Ressaca* Chico Dias are marked by significant precariousness, but nature differs according to regional characteristics. In Jardim Vicentina, the disorderly occupation of valley bottom areas subject to landslides and flooding creates an environment of high vulnerability. In *Ressaca* Chico Dias, vulnerability is linked to the occupation of wetlands, where houses on stilts are a response to periodic flooding, but remain vulnerable to the lack of adequate infrastructure and unsanitary conditions and the risk of water-borne diseases due to water contamination.

2. **Geographical and Social Isolation** (Public Space, Block/Plot):

There is no physical isolation in Jardim Vicentina, since it is part of an occupation and thus integrated into the formal urban fabric, despite the geography of the valley floor and the fragmentation of public space. Exclusion there is a social issue, given that the majority of residents are on low incomes. In *Ressaca* Chico Dias, isolation is caused by the fact that it is located in flooded areas, accessible only by wooden bridges, which creates both physical and social barriers for residents. This isolation is a

common factor that contributes to social exclusion and limits opportunities for economic and social development.

Settlement specificities *- based on Tessari (2016)*

1. Adaptation to the Environment (Public Space, Block/Lot, Building):

The specificities of the two settlements are strongly influenced by local environmental conditions. In Jardim Vicentina, adaptation to the slopes and valley bottoms occurs in an improvised way, with self-built houses on irregular land and often in risk areas. This adaptation is limited and aggravates the structural problems of the houses. In *Ressaca* Chico Dias, adaptation to the flooded environment is visible in the construction of houses on stilts, a traditional solution in the Amazon region. However, this form of occupation also brings specific challenges, such as the difficulty of integrating these areas with the rest of the city and continuous exposure to unhealthy living conditions.

2. Public Intervention and Impact on Urban Form (Public Space, Building):

The impact of public interventions varies significantly between the two locations. In Jardim Vicentina, there was a process of urbanization that included investments in infrastructure, the construction of housing units and the reconfiguration of the road system. These interventions have resulted in improvements in living conditions, but many structural problems persist due to the complexity of the land and the irregularity of property ownership. In *Ressaca* Chico Dias, the absence of adequate public interventions perpetuates the precariousness of the settlement. The houses continue to be built in an improvised way, with low-quality materials, and the basic infrastructure is practically non-existent, which drastically limits the possibilities of improving the residents' quality of life.

Reflection on Nomenclature and Implications for Public Policy

1. Nomenclature and Social Perception (Public Space, Block/Lot, Building):

The nomenclature used to describe settlements plays a crucial role in how these places are perceived and addressed by public policies. Jardim Vicentina, initially known as Área Livre, is a type of "favela" that carries with it a series of stigmas associated with precariousness and social exclusion. This nomenclature, although appropriate for describing the reality of this dense and irregular occupation, may not capture the nuances of the origin of the occupation and the population's perception of the urban interventions that have already been carried out. In *Ressaca* Chico Dias, the term *ressaca* is used to describe a very specific precarious occupation in the Amazon region, where houses are built on stilts in wetlands areas. This nomenclature is more appropriate for reflecting the local environmental and cultural conditions; however, being classified as a "subnormal settlement" carries a connotation of precariousness that does not accurately reflect the specific characteristics of the region

2 Implications for Public Policies:

The nomenclature used to describe settlements plays a crucial role in how these places are perceived and addressed by public policies. Jardim Vicentina, initially known as Área Livre, is a type of "favela" that carries with it a series of stigmas associated with precariousness and social exclusion. This nomenclature, although appropriate for describing the reality of this dense and irregular occupation,

may not capture the nuances of the origin of the occupation and the population's perception of the urban interventions that have already been carried out. In *Ressaca* Chico Dias, the term "*ressaca"* is used to describe a very specific precarious occupation in the Amazon region, where houses are built on stilts in wetlands areas. This nomenclature is more appropriate for reflecting the local environmental and cultural conditions; however, being classified as a "subnormal settlement" carries a connotation of precariousness that does not accurately reflect the specific characteristics of the region.

FINAL CONSIDERATIONS

The urban form of the Jardim Vicentina and *Ressaca* Chico Dias occupations exemplifies how urban precariousness can manifest itself in different ways in different regional contexts in Brazil. Although they share common aspects of vulnerability and marginalization, the geographical, climatic and cultural specificities of each location determine unique urban forms that require different approaches to both public policies and urban interventions. The nomenclature adopted by city halls has a significant influence on the perception and the way in which public authorities intervene in these areas. Generalizing the term "Favela" is not an ideal solution, as this neglects regional particularities, which are essential for formulating effective public policies. Nomenclatures that reflect the specificities of each location, such as the term *Ressaca* in Macapá, provide a more accurate and richer view, facilitating more appropriate and inclusive interventions. It is therefore essential that the choice of nomenclature is made carefully, in order to accurately reflect the reality of each community and to promote policies that respect and respond to the unique needs of each urban context.

Looking at the information presented, it is possible to identify several points of similarity between the two settlements, despite the diversity in the form of occupation and the characteristics of the housing. The similarities stand out especially in the social characteristics, such as the length of occupation, the origin of the population, the level of education and income, elements that are closely linked to urban precariousness and social vulnerability in both contexts.

The land situation of the two settlements is also similar: in Jardim Vicentina, occupation takes place in public areas along a watercourse (APP) that crosses eight allotments; in *Ressaca* Chico Dias, occupation takes place in a public wetland area of environmental protection. However, the characteristics of the houses differ considerably: in *Ressaca* Chico Dias, the houses are mostly built of wood, with larger internal dimensions; in Jardim Vicentina, the houses are predominantly made of masonry, with smaller rooms and greater density.

Both typologies studied represent precarious occupations of urban areas that are unsuitable for families to live in, and without the action of public authorities to mitigate precariousness, guaranteeing decent housing conditions is practically impossible. Labelling and generically grouping them as "favelas" or "urban communities" doesn't change the way families identify with their place of residence and life. Max Weber (1973), quoted by Peruzzo (2009), defines community as a broad concept that covers heterogeneous situations, but which is based on affective, emotional and traditional foundations. In both cases, the population identifies strongly with their place of residence and the form of occupation, making any attempt at simplistic categorization that disregards the complexity and specificity of each area ineffective.

Recognizing the specificities of the Jardim Vicentina and Chico Dias settlements is essential for formulating effective public policies adapted to local realities. Analyzing the urban form, considering public space, plots and buildings, reveals that although both face significant challenges, solutions to improve living conditions must be specific to each context. The nomenclature used to describe these settlements must accurately reflect regional and cultural particularities, avoiding generalizations that could result in inappropriate public policies. The ultimate goal should be to promote inclusive and sustainable urbanization that respects the particularities of each region and effectively improves the quality of life of residents.

Finally, it's important to recognize that a "favela" can be an urban community, but not every urban community is a favela. It can be an *Área Livre*, a *Ressaca*, a *Mocambo*, a *Cortiço*, or any other type of occupation, if the people who live there identify with the place. Therefore, instead of focusing on labels, the bodies responsible for delimitation and quantification, by the IBGE or the municipal government, should concentrate on developing methodologies that get closer to the specific realities of each occupation, in order to help shape public policies that address the precariousness and vulnerability present in all forms of precarious occupation in the city, respecting the particularities and promoting the inclusion and dignity of the inhabitants**.**

Radical Reframing: Modern Transformations of the Rio de Janeiro City Center Morphology

Carlos Feferman[1]
[1] Urban Project Lab (LAPU), Graduate Program in Urbanism (PROURB), Faculty of Architecture and Urbanism (FAU), Federal University of Rio de Janeiro (UFRJ), Brazil. cfeferman@fau.ufrj.br

ABSTRACT

These guidelines provide instructions to format your paper. It is advised to write directly into the template and use the formatting styles, indicated in light grey that should be deleted before final submission. The full paper must be between 12 and 14 pages, including figures, tables and references. The abstract should be a single paragraph and should follow the style of structured abstracts, but without headings: 1) Background: Place the question addressed in a broad context, present the research problem, and highlight the purpose of the study; 2) Aims and objectives of the study, 3) Methods: Describe briefly the main methods applied. 4) Findings: Summarize the article's main findings; and 5) Conclusion and implications: Indicate the main conclusions or interpretations.

The contemporary morphology of Rio de Janeiro's city center is a many-layered system. Its current form was decisively shaped by radical transformations in the first half of the twentieth century. Modern urbanism aimed at a gradual substitution and broad restructuring of the inherited colonial and nineteenth-century fabrics. The new framework relied on tools such as increased density, functional restrictions, autonomous objects, a new role for the street system and large-scale arrangements of the urban block. In contrast to the autonomous plans often associated with modern urbanism, these transformations took place at the heart of the historic morphology. While the piecemeal implementation often resulted in a fragmented, incongruent whole, the partial reframing also established new directions for development. This paper examines the different historic strategies of modern urbanism in the central area of Rio de Janeiro, their impact on the preexisting fabric and the persisting issues related to the contrasting morphologies. Modern strategies are categorized by type and better understood through comparative analysis within the modern repertoire. Recent attempts to transform the inherited contradictions shed light on the nature of the city center's hybrid morphology. An assessment of future possibilities is discussed through the contemporary interpretations of the city block and through the restructuring of interstitial space.

Keywords: Modern Urbanism, Rio de Janeiro Morphology, Alfred Agache, Pereira Passos, Eduardo Reidy

INTRODUCTION

A series of modernizing initiatives in the first half of the twentieth century extensively transformed the colonial and nineteenth-century urban fabric of Rio de Janeiro's city center. These transformations

responded to the demands of urban expansion and the symbolic consolidation of the city as the capital of the Republic. Modeled primarily after French urban planning experiences, the initiatives ultimately sought to rationalize the city's streets and blocks, creating overarching frameworks to unify the dispersed historic developments.

Four pivotal moments define the urban transformations within the examined historical arc. First, an initiative modeled after Haussmann's Parisian interventions was carried out in the early 1900s under Mayor Pereira Passos and the Federal Government. Second, French architect and urbanist Alfred Agache's extensive plan for the city center aimed to consolidate the changes initiated by the Passos Reform and introduced new structuring elements, from the urban block to the metropolitan scale. The third phase, strongly influenced by Le Corbusier in the 1930s, marked a fundamental shift toward canonical CIAM modernism, proposing a new role for the architectural object. Lastly, a post-war plan by architect Eduardo Reidy for a large-scale Civic Center on a newly leveled area sought to radically transform the central city with its emphasis on infrastructure and monumental characteristics.

Each of these moments, which have been studied individually, represents a complex set of urban tools and concepts, often experimental in their time. Developed in the context of European cities, their application was complicated by Rio de Janeiro's colonial morphology and its peculiar geography between mountain and sea.

The present work thus proposes to examine the above sequence of historic urban interventions as a layered system, through its conflicts and continuities. The inherited colonial morphology, often schematically characterized both historically and historiographically, will be reappraised through its structural significance and permanence throughout the modern period. Furthermore, the city's geographical characteristics will be analyzed in light of the challenges they posed to the application of European urban planning tools. Their interrelationship is examined through comparative analysis of tools and concepts.

METHODOLOGICAL DISCUSSION

To understand the layering process in Rio de Janeiro and the relationship between its successive morphologies the present works employs the comparative analysis of historical planning strategies.

The utopian image of "Enlightenment space," which Anthony Vidler describes as "geometrical, rational, gridded, and above all transparent, universal and seamless, equally illuminated and illuminating" (Vidler, 2011: 131), translates into more mundane realities in the nineteenth century. The Enlightenment's notion of "clearly defined entities, separate from each other, taxonomically organized in series and hierarchies, as known and knowable as the space that surrounds them" persists as a horizon of identifiable parts waiting to be built, understood, and transformed. This concept perhaps forms the historical basis of the idea of types within an increasingly complex system of rearranged elements.

This is also the basis of the modern project of transparency. The urban block, for example, as a recognizable entity within a larger framework and, within the block, the mechanics of its internal parts. Gradually, the system will acquire new elements: functional, spatial and technical, as well as different densities. The clear reading of its parts will give way to a process of differentiation, as observes Panerai, Castex and Depaule.

Vidler's reading is thus both a description of physical objects and a reflection on the foundational practices within the field of urbanism. The utopian horizon he describes becomes a symptom of the search for a commanding framework, where urban components are presented as recognizable units, accessible to both the planner and the public.

According to Panerai, Castex, and DePaul, the primary objective of their study on the urban block was to describe spatial models, aiming to go beyond the empirical developments of physical objects. Their work engages with historical discussions and theoretical insights related to the formation of urban models, contributing to broader efforts to stabilize and unify the field of urban morphology.

Our work thus examines the gradual process of rearranging urban elements in search of a coherent framework. It also seeks to uncover less evident structures in developments often portrayed as uncoordinated, such as the colonial fabric of Rio de Janeiro. As we will see, the urban block played an uneven role in the early stages of the city center's development. Its prominence emerges for a relatively brief period, before being questioned again by the modern canon.

EARLY MODERN TRANSFORMATIONS

Modeled after the Haussmann reforms, the early twentieth-century transformations carried out by Mayor Pereira Passos (1902-1906) and the Brazilian federal government aimed to modernize Rio de Janeiro's central area. The plan included a broad range of interventions: 1) opening major connective thoroughfares such as Avenida Central boulevard; 2) leveling of two prominent hills (Castello and Santo Antonio); 3) expanding the central area into the sea; 4) expanding and regularizing the street system; and 5) transforming the center's functional profile from a heavily residential area into one focused on business, commerce and administrative buildings, with increased density. These extensive reforms, both symbolic and economic, as historian Mauricio de Abreu observes, spanned the next decades and responded to Rio de Janeiro's new role as the capital of the Republic, industrial center, and major shipping port (Abreu, 1987).

The pronounced topography played a fundamental role in the morphological development of Rio de Janeiro, particularly the two large hills in the central area, each occupying around 30 hectares. Paulo Santos describes how the city grew on and around these and other geographic features, gradually spreading into the available lowlands (Santos, 1968). Santos notes that, in its early stages, 'there was no difference between military architecture and town planning' (Santos, 1968: 88). The high ground remained a crucial element of the city's defense strategy during the colonial period, as envisioned by the Portuguese, and held strong structural and symbolic significance in its spatial planning.

The colonial city, over which early modern reforms were overlaid, is often described in terms of its restrictive qualities by both historians and contemporary figures. Mayor Carlos Sampaio (1920-1922), as cited by historian Sonia Gomes Pereira, claimed that 'the city center was suffocating between the hills and the sea.' (Pereira, 1996). Similarly, Abreu describes a 'cramped city, limited by the hills of Castelo, São Bento, Santo Antônio, and Conceição' and highlights the inadequacy of its street system, with 'narrow and dark streets.' He considers that 'the Passos Reform represents a moment of fundamental break in the relationship between State and Urban' (Abreu, 1987: 73). The historian thus sees a major shift characterized by concerted actions aimed at unifying the dispersed colonial fragments.

There is, nevertheless, an ordered framework within the colonial city, one that continues to manifest itself within the superimposed developments of the twentieth century. This framework involves the concept of local clusters, shaped by the fragmented geography. These clusters have their own internal logic, organized around the structuring role of public space. Santos emphasizes the importance of the public square in Portuguese urbanism as 'the meeting center of urban life' (Santos, 1968: 64), while Gomes Pereira, drawing on Kevin Lynch, views the Largo do Carmo, the city's main founding colonial square, as a special type of node, one that 'radiates its influence' and functions as a symbolic core for its surrounding area (Pereira, 1996: 74).

Thus, a more complex relationship between colonial and modern frameworks emerges beyond the idea of substitution or simple superposition. Paulo Santos speaks of the 'organicity' of colonial development – in contrast to the term 'organic' – (Santos, 1968). There is, here, an implied systemic framework that orders the somewhat dispersed development of local clusters in response to the contingencies of the geography. This theme recurs throughout the twentieth century, as the city expands, occupying the available patches between mountain and sea, connected through an increasingly autonomous network of infrastructural lines – an idea that would be later recognized by Agache, Le Corbusier and Reidy, as will be discussed further on.

Within this framework, the restrictive qualities of the colonial street system often played a secondary role. While the narrow streets did present problems for the city's development at specific points, their influence remained confined to the ambit of the local cluster. The colonial grid was largely preserved in many areas throughout both early and late modern developments, despite a major increase in density brought about by the gradual replacement of its historic buildings.

The permanence of parts of the colonial streets and the continued logic of cluster areas called into question the role of the grid and the urban block as dominant tools in early modern remodeling. Santos observes that the street system was relatively regular, though not as geometrically precise as the Pombaline grid in Lisbon (Santos, 1968: 95). The colonial block, with its heavily fragmented parceling, was gradually adapted through the widening of streets and the merging of its narrow, elongated plots, which allowed for an increase in density with new, higher buildings.

An entirely rectified grid system would await the leveling of Castelo Hill and the expansion of the center into the newly opened area in the 1920s. This laid the groundwork for a more significant role of the urban block, as would be proposed by Alfred Agache. The problem then became one of compatibility between the nineteenth century clusters and the rectified expansion areas.

During Pereira Passos's term, the main accomplishment remains the opening of the Central Avenue boulevard. Its infrastructural role, connecting the newly built seaside avenue to the port area, has been noted by Abreu (Abreu, 1987), while Gomes Pereira highlights the intention to create a modern, civilized, and cosmopolitan space, following the model of the great European capitals (Pereira, 1996). The avenue begins at a large open plaza where the republic's most important government and cultural buildings were located, conforming a new focal point that would structure the city's expansion toward the sea and into the area opened by the leveling of the Castelo hill. (Figure 1) The plan thus aligns itself with the logic of the radiating local cluster.

ALFRED AGACHE: TOWARDS A COMPOSITIONAL FRAMEWORK

In late 1927, architect and urbanist Donat Alfred Agache, then General Secretary of the 'Société Française des Urbanistes,' was hired by Antonio Prado Junior, mayor of the Federal District, to develop an extensive plan for the city of Rio de Janeiro, coordinating it with the ongoing projects initiated under Pereira Passos. Agache's comprehensive proposal, titled City of Rio de Janeiro: Remodelling, Extension and Embellishment, aimed to address the city's complexity and employed a wide range of tools to provide a unified plan.

The proposal, which came to be known as the Plan Agache, acknowledges the key features of the preexisting colonial framework. An introductory chapter titled Anthropo-Geographic Factors presents the city's historic development through high-ground panoramas, depicted in paintings and drawings, revealing the importance of public squares, street spaces, and the relationship between the stretches of flatland, where the city had expanded, and the surrounding hills.

Agache also acknowledges the city's 'particularly special topography,' which he states 'imposes undisputed solutions' (Agache, 1930: 135). He seeks to understand its physical nature and impact on the contemporary urban situation through a cartographic sequence that illustrates the evolution of the city center and its relationship to the surrounding topography, including the recent changes to the central hills. (Figure 2) The gradual urban growth depicted in these images reinforces the idea of extension lines connecting local clusters, while also reiterates the local role of the street grid in addressing the city's fragmented complexity.

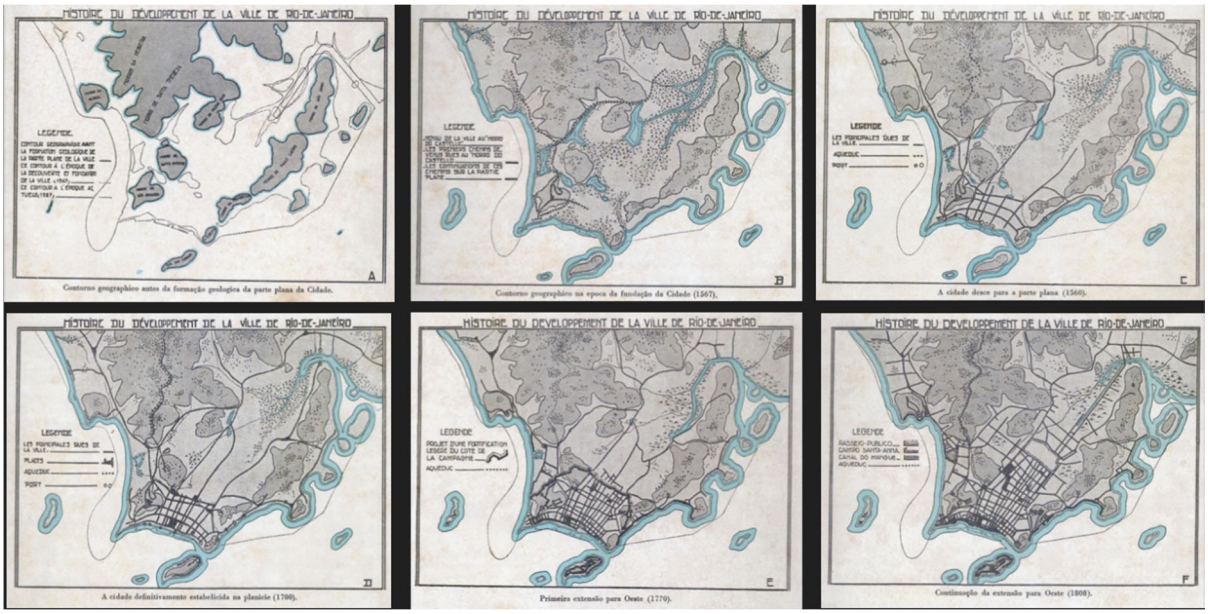

Figure 2. Sequence of maps presented by Agache showing the historical development of Rio de Janeiro in relationship to the geography. Agache. Plan.1930.

The plan's title encapsulates the various tools introduced by Agache. The concept of extension applies to scenarios such as the leveling of hills and the reclamation of land from the sea. It also relates to the grid system: the structuring capacity of the street grid, the increasing importance of transportation in urban planning, and the role of the block within the grid. The concept of remodeling, in turn, pertains to the ongoing transformations of existing clusters, including the reform of the colonial street grid and the adaptation of historic blocks through increased density, new alignments, and the reconfiguration of plots, as we have seen. Remodeling also involves reinterpreting already-established structural lines and incorporating them into a coherent plan. Lastly, the idea of embellishment addresses the symbolic significance of the structuring boulevards and, more broadly, the new governmental and business functions of the central area, including the modern expression of its architecture.

His previous work with Eugène Hénard consolidated two fundamental ideas. First, the importance of a rational circulation system, subdivided into distinct categories based on their nature (such as pedestrian, economic, or professional movement) and their relationship to centrality (convergent/divergent) (Hénard, 1982). This approach led to a better understanding of planning instruments according to their scale and purpose. Agache, in his proposal for Rio de Janeiro, writes: 'The broad lines and characteristic points required by the project must be considered. The remodeling project is, in effect, contained within a framework whose generating coordinates we will quickly analyze, and which responds to the needs of urban traffic' (Figure. 3) (Agache, 1930: 135).

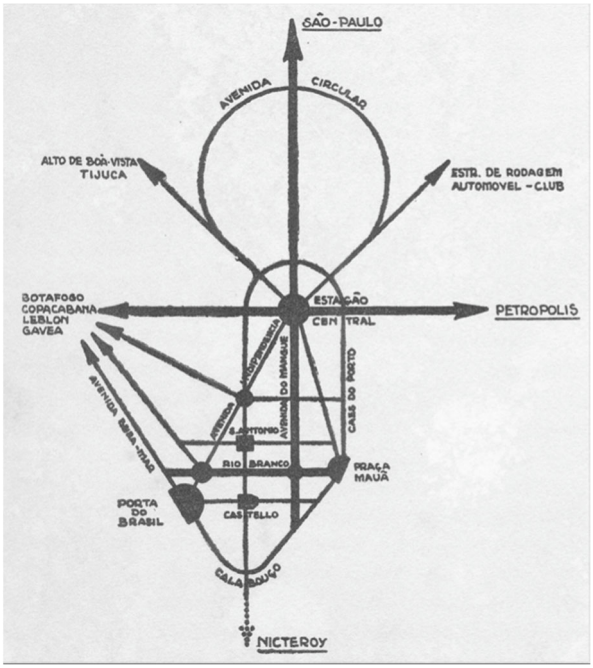

Figure 3. Metropolitan Structure, termed Ossature (Bone Structure) constituting a system of infrastructural lines. Agache. Plan.1930.

A second idea, expressed in Projet d'Ensemble des Parcs et Jardins à Établir dans Paris (Hénard, 1982), posits that parks and squares can serve a structuring function for the city as a whole. This idea resonates with the role of the public square within the historic fabric of Rio de Janeiro, as we have seen. It also counterbalances the role of the street as a structuring element, favoring the compositional strategy that characterizes Agache's Beaux Arts approach and its alignment with the development of Rio de Janeiro's central area. Agache included a map of 'parks, squares, and playing fields' within the proposal, detailing their respective radii of influence. (Agache 1930: 206)

Perhaps the central focus of Agache's proposal is his extensive study of a new role for the urban block as a coordinating element within the plan. He approaches this on two fronts: first, by systematizing the block as an instrument to occupy the newly opened expanse where Castelo Hill once stood; and second, through the gradual adaptation of blocks within the historic fabric. (Figure 4) In both cases, the urban block is conceived as a complex system incorporating various spatial and functional elements developed since the mid-nineteenth century. This includes internal courtyards, a pilotis-arcade system mediating between urban life and the building, the gradual tapering of overall volume to allow light to reach the city ground, increased density, and legislative instruments that lend a sense of unity to the overall block form. (Figure 5). The effort marks a gradual shift away from the cluster morphology of the colonial period, although it retains some of its spatial aspects, particularly the role of public space.

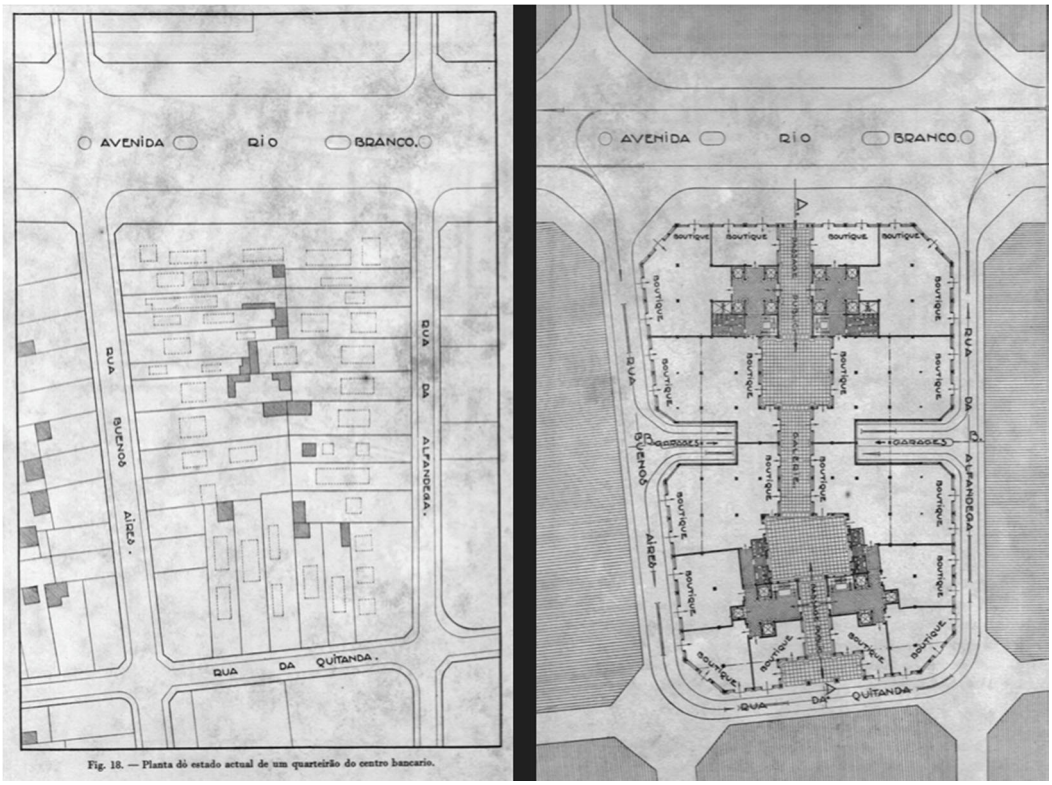

Figure 4. Proposal for the gradual transformation of the existing colonial block, including widening of the street and substitution of its historica buildings. Agache Plan.1930.

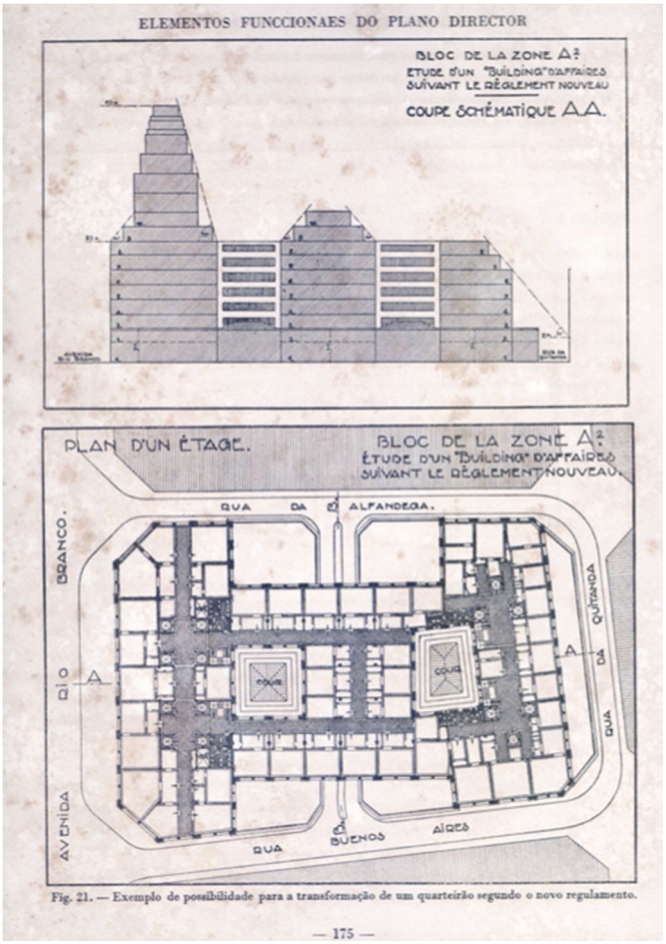

Figure 5. Plan and Section for new block in the the newly developed Castelo Esplanade, showing new density, tapering and internal courts. Agache Plan.1930.

The effort marks a gradual shift away from the clustered morphology of the colonial period toward a more continuous fabric and sense of unity. It nevertheless retains some of the spatial qualities of the historic development, particularly the role of public space in shaping local differentiation within the city center. This approach facilitates the transition between historical layers and newly planned extensions. Though the grid system is now clearly in play, Agache does not pursue a Cartesian regularity. The result is a series of negotiated spatial interactions.

THE URBAN BLOCK AND ARCHITECTURAL AUTONOMY

A new site for the Ministry of Education and Health was planned in the newly opened area of Castelo Hill, which had already been partially occupied during the late 1920s and early 1930s. The building was intended to play a symbolic role in the development of this area, marking its significance in relation to the nearby square which was already home to key governmental buildings. As is well-known, the Brazilian team, composed of soon-to-become prominent figures in Brazilian modernism, including Lucio Costa, Oscar Niemeyer, and Affonso Eduardo Reidy, among others, was joined by Le Corbusier in 1936, on his second visit to Rio de Janeiro.

The effort resulted in what is considered the first realization of the Cartesian high-rise, a landmark in modern architectural development (Segre, 2013). The final version comprised a main vertical block containing office spaces and a horizontal block housing an auditorium, foyer, galleries, and a terrace.

The building would be almost entirely detached from the ground through pilotis, forming an open square that could be traversed by the public. Although it would be free-standing, the building was set within the Agachian block system that characterized the extension plan, thus surrounded by a continuous wall of buildings that would eventually line the borders of their blocks.

Despite Le Corbusier's insistence on relocating the building near the waterfront to emphasize its panoramic view of the bay and mountainous landscape, the project remained within the originally planned extension area, as shown by the historic correspondence between the Swiss architect and the Ministry of Education and Health, organized by historian Maurício Lissovsky (Lissovsky, 1996: 108-114). The unbuilt version would have reaffirmed the modern building's role as an autonomous object, underscoring its relationship to the idea of a continuous ground and to the surrounding landscape. The initial version for the open terrain was published alongside the design that would ultimately be built, done in collaboration with the Brazilian team. (Le Corbusier, 1939)

Significantly, the circumstances of Le Corbusier's insistence reveal his personal feud with the traditional block system, to which the project would ultimately have to adapt. In the same edition where he publishes the plans for the Ministry of Education building, a comparative figure-ground diagram contrasts his proposed residential area for the Ville Radieuse with the dense block patterns of Paris, New York, and Buenos Aires, which he termed Villes Pêle-Mêle (jumbled cities). 'These four city diagrams, on the same scale,' Le Corbusier writes, 'reveal the true revolution in urban land use' (Le Corbusier 1939: 30).

A schematic diagram also accompanies the documents for the Ministry of Education building in the same edition (the 1934-38 works). It compares the contiguous blocks, titled 'traditional use of land in Rio,' with the 'new method realized'—the free-standing building, now in its definitive plot within the Agachian grid. (Figure 5) The idea of a liberated ground and the autonomy of the object remained intact (Le Corbusier, 1939: 81). The result was a partial victory.

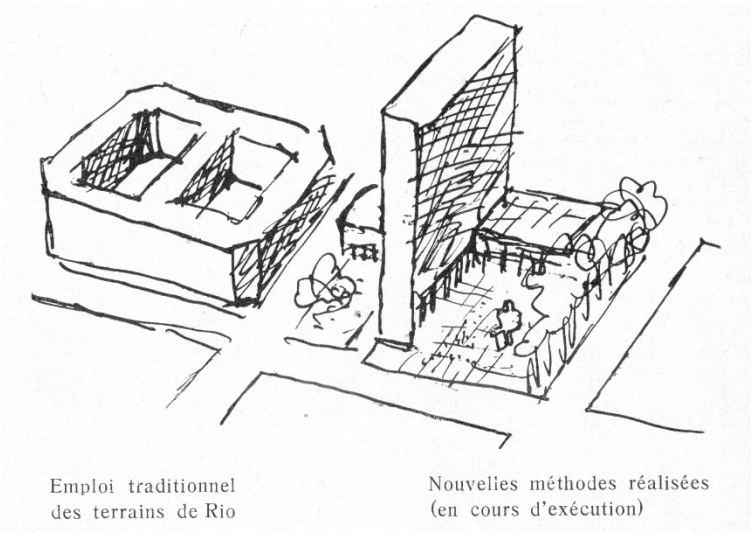

Figure 5 Comparative diagram of proposal for the Ministry of Education and existing urban block in the Castelo Esplanade, photo credit: Le Corbusier.

Le Corbusier's argument illustrates a shift in focus from the rue corridor, with its narrow, meandering path, to a broader opposition to the gridded system of the urban block and its repetitive framework.

This shift not only envisions an increasingly central role for the autonomous architectural object but also introduces a new spatial perspective that defies the planar qualities of the grid. This stance had a particular impact on Reidy, who recognized a paradigm shift from the block as the fundamental unit of the city to an open system – perhaps with implied block-scale subdivisions, or rather, rhythms – but framed by an external infrastructure, an idea similar to Agache's metropolitan ossature.

Interestingly, the Ministry of Education reaffirms the concept of the local cluster, as the open space on which it is situated functions as a core square, redefining the surrounding blocks. It thus signals a new role for the architectural object within the block system.

RADICAL DISSOLUTION OF THE URBAN BLOCK

In the late 1930s, Eduardo Reidy, who had worked as an assistant to Agache, evaluated the role of the block system as a fundamental framework for the development of the city center: "Although this system had already been abandoned in more advanced countries, it undoubtedly represented a significant step forward for us, compared to the precarious conditions in which our capital had been built until then" (Bonduki, 2000: 63). For Reidy, the system represented a necessary intermediate phase transitioning from the dense and fragmented colonial fabric toward the full expression of a contemporary modern urbanism.

His unrealized plan for the Castelo esplanade (1938), adjacent to the recently completed plans for the Ministry of Education – then under construction – serves as a precursor to the future plan for a downtown Civic Center (1948). These proposals follow Le Corbusier's urban principles, some of which had been discussed in relation to the Ministry building and its relationship to the surrounding blocks, particularly the fundamental modern concepts of continuous ground and autonomy of the detached architectural object.

Other characteristics of the 1938 plan included the "separation of local access and high-speed traffic," the "reduction of the number of streets," the design of "green open spaces," and the implementation of "level crossings" for pedestrians. The area was envisioned as an "urban nucleus planned to provide collective well-being." Furthermore, the plan aimed to infiltrate the old city at its borders, where "it presented insufficient scale" or a "disorganized structure". (Bonduki, 2000: 64)

These characteristics reappeared in the 1948 design for a Civic Center, planned to occupy the large central space left open by the leveling of Saint Antônio Hill, an area of nearly forty hectares. Reidy describes this operation as "the last chance to introduce a completely new element into [the Capital's] center of gravity" (Bonduki, 2000: 118).

ABSTRACT

This paper addresses a phenomenon increasingly discussed in China, referred to as 'thousand cities one face'. There exist worries that as social-media-driven economies influence cities, they will become more similar to one another. To test whether such a phenomenon exists and develop a comprehensive understanding, this paper takes a quantitative approach, identifying cities' Internet-Celebrity Spots (ICS) – top-ranked hotspots on social media, compiling data on their type and morphology, and using statistical tests to answer the following questions: i) Concerning the types and spatial configurations of ICSs, are Chinese cities becoming similar or not? ii) Which cities are more similar or unique? What is the degree of similarity between them?

A total of 413 scenic spots and 1800 restaurants are identified as ICSs for a total of 9 cities from 3 of China's geographical regions. ICS types are labeled, and 16 indicators describe the morphology of each, regarding physical form, cultural services, and consumer activity. Cosine similarity is used to test the similarity of ICS type, while the Kruskal-Wallis test and Mann-Whitney U-test are used for evaluating ICS morphology similarity.

Similarity is obtained for the overall group, all city pairs, as well as each city, and results are analyzed with reference to real-world phenomena. Results show that regarding both ICS type and ICS morphology, similarity of cities exists, but only for a portion of cities sampled here. This confirms the 'thousand cities one face' phenomenon can be reflected in data, but also shows that the phenomenon is not as widespread as commonly described. Driving factors for similarity including geographical location, economic development, etc. are also analyzed. It is hoped that this study will not only address public discussion, but also help policy makers better understand the public's perspective, and lead to better development of cities overall.

Keywords: Internet Celebrity Spots, similarity, urban morphology, data mining

INTRODUCTION

As urbanization proliferates within a country, and as modernization progresses within cities, it is speculated that urban morphologies will converge into more homogenized forms. In recent years, with the rapid development of social media and the emergence of the internet-celebrity-economy

(ICE), the so-called 'thousand cities one face' phenomenon is an increasingly discussed topic online. This can be recognized as studying the same phenomenon as topics of homogenization and similarity commonly discussed in fields of urban planning, landscape ecology, geography, etc. In this paper, the effect of ICE on similarity between cities is studied through a quantitative approach.

Current urban morphology research has covered similarity for aspects including urban expansion and urban environment etc. Studies have been conducted for the cross-city comparison of urban morphology expansion (Jia et al., 2020; Lemoine-Rodríguez et al., 2020; Cai et al., 2022), as well as the correlation between urban morphology and sustainable development (Cao et al., 2021; Stuhlmacher et al., 2022). Under its rapid urbanization and the regulation of its unique municipality administrative structure, China is subject to controversy regarding its urban form becoming increasingly similar, and this similarity has been verified at the city-level and block-level (Song et al., 2018; Ding et al., 2022).

Although the overall trend of increased urban morphology similarity has been verified in multiple aspects, it can be argued that cities are multifaceted. Thus, different perspectives may lead to different conclusions. For the topic of 'thousand cities one face', a city's policymakers tend to focus more on the macro-scale phenomena in their cities, such as urban expansion(Pili et al., 2017), urban function distribution(Tian et al., 2010), etc. However, as the internet becomes an increasingly integral part of society and life, information flow, including those about cities, is increasingly affected by social media (Zhou et al., 2023). By shaping the flow of information, social media implicitly determines which areas in a city are searched for and visited by more people, thus constraining the public's perception of cities within these areas. Such areas can be perceived as emerging hotspots of increased activity birthed by internet influence and are studied in this paper under the term "internet celebrity spots" (ICS). Studying urban morphologies through the perspective of ICSs to give more accurate insight into the public's ICE-driven perception of cities is the primary goal and novelty of this paper.

ICSs are a product of the ICE, thus as a derivative of the 'thousand cities one face' argument, it can be hypothesized that policies and natural developments following ICS growth will cause cities to lose their cultural features and experience excessive commercialization of hotspots, leading to increased similarity of cities. Studies have discussed how the ICE builds cities' ICSs through social media and in turn builds internet-celebrity-cities, and how this brings both significant opportunities and challenges for city development (Che et al., 2022). This also shows how ICSs are currently a prominent component of city development. ICSs act as the main site at which cities are connected with both tourists and residents and the surrounding spatial configuration in their vicinity plays a key role in shaping cities' image and reputation (Nolasco-Cirugeda et al., 2020; Iranmanesh and Abokhamis Mousavi, 2023). Most studies have used two-dimensional metrics for describing spatial configuration, but several studies using three-dimensional approaches have also been introduced in recent years (Cao et al., 2021; Yang et al., 2022). In addition, ICSs not only carry basic physical morphology characterizes, but are also closely tied with human commercial activity as well as cultural services and facilities (Ye et al., 2018; Zhang et al., 2022). Therefore, this study augments fundamental morphology indicators with additional indicators on three-dimensional information and urban function when characterizing urban areas.

In this paper, 2213 ICSs from 9 provincial capitals are characterized using type and morphology data, in order to test the hypothesis that within the perspective of ICE, cities in China display significant similarity. On one hand, we use cosine similarity to quantify the similarity between ICS types between

cities, and on the other hand, we use 16 indicators characterizing the physical, cultural, and consumer activity aspects of ICSs to quantify urban morphology, using the Kruskal-Wallis Test and Mann-Whitney U Test as mathematical tools to test the similarity of cities' ICSs. This study strives to answer the following two questions: i) With respect to the types and spatial configurations of ICS, are Chinese cities becoming homogeneous or not? ii) Which cities are more similar or unique? What is the degree of similarity between them?

METHOD

The overall methodology used in this paper is summarized in Figure 1. This includes selection of cities, selection of internet celebrity spots including scenic spots and restaurants, collection of type and morphological data, indicator selection, as well as analysis of results.

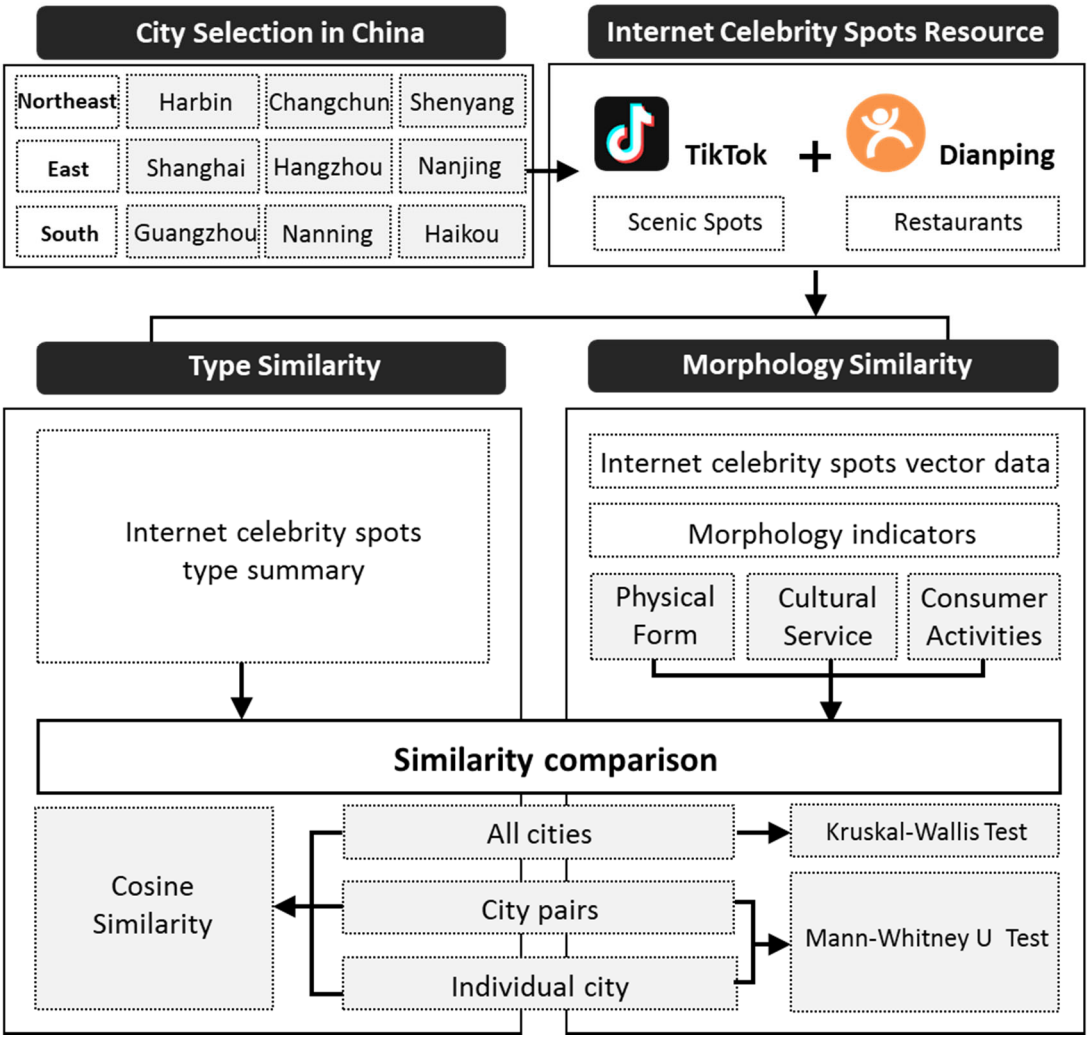

Figure 1. Overview of the methodology adopted in this study.

Selection of case cities

The 9 cities in this study were selected according to geographical location and climate, as well as population and socio-economic development etc. They are 9 provincial capitals from 3 primary Chinese geographical regions: East China (Shanghai, Nanjing, Hangzhou), South China, (Guangzhou, Haikou, Nanning) and Northeast China (Harbin, Changchun, Shenyang). In East China, summer months

are humid and hot, while winter months are moderately humid and moderately cold. The general economic development of East China is relatively high. South China is warm all year round, with no snowfall and high humidity. Guangzhou is one of the economic and commerce centres of the region. Northeast China has long winter months with harsh cold, and rainfall is concentrated in the short summer months. It is the traditional centre of heavy industry in China.

Selection of Internet Celebrity Spots

Two types of ICSs are considered here: scenic spots and restaurants. These are selected according to TikTok and Dianping data respectively. ByteDance's TikTok is one of the major social media platforms which shape the public's perception of cities. Its content as well as corresponding geotagging have been shown to be valuable for understanding the geography (Lin et al., 2023), public image (Wang and Feng, 2023), and tourist visit activity (Zhang et al., 2022) of China's cities. Dianping (https://www.dianping.com/) is the largest Chinese-language third-party online platform for customer reviews (equivalent to Yelp), and its content has been widely used for relevant studies on cities (Guo et al., 2018).

Regarding the selection of scenic spot ICSs, this study takes into account the fact that public preference shifts with season change. Data is obtained from Ocean Engine's list of the most popular scenic spots on TikTok between April 2023 and March 2024. The top 20 attractions of each month are selected, and information includes attraction names. Preprocessing of attraction data includes removing duplicate entries with identical geographical boundaries, non-tourist-attraction entries (stations, hospitals, residential areas, etc.), entries with ambiguous non-specific addresses, and large rivers (e.g. Songhua River). In total, 413 scenic spot ICSs were chosen for the 9 cities.

Restaurant ICSs were selected from the restaurant ranking list extracted from Dianping's website API, retrieved 23rd February 2024. The top 200 restaurants which satisfy qualifiers including being open, having more than 50 comments, and rated higher than 4.0 points were selected. Collected information includes name and type, as well as longitude and latitude. In total, 1800 restaurant ICSs were chosen for the cities.

Type data source

As the Ocean Engine platform does not include specific type data on every scenic spot, this information is supplemented by data retrieved from corresponding entries on Dianping's website. Type data for restaurants are according to classification displayed online by Dianping. However, as redundant categories exist, merging of categories must be carried out, e.g. merging 'wildlife zoo' and 'zoo', merging 'leisure district' and 'recreational district', or merging 'Japanese food' and 'Japanese cuisine'. After processing, 32 scenic spot types and 41 restaurant types are adopted.

Morphological data source and preprocessing

This study uses morphological data collected from multiple sources. The name, source, year and preprocessing of each data is listed in Table 1.

Table 1. Morphological data type, source, year and preprocessing.

Data type	Data source	Year	Data description and processing
Boundaries of the administrative	Chinese Academy of Sciences Resource and	2022	Extract urban boundary.

divisions of cities in China	Environmental Science Data Platform (https://www.resdc.cn/) (Xu, 2023)		
Building footprint	Zenodo (https://zenodo.org/) (Shi et al., 2023)	2024	Filter out building footprints larger than 20 square-meters in each city.
Building height	Zenodo (https://zenodo.org/) (Wu, 2022)	2020	Rasterized data for building height at 10-meter resolution.
Road network	OpenStreetMap (https://www.openstreetmap.org)	2024	Select motorway, trunk, primary, secondary, tertiary, residential, unclassified layer, all for city roads, set up 40 m, 20 m or 10 m buffer according to road type and extract the centre line of the buffer as a road network data.
Point of interest	Amap (https://www.amap.com/)	2022	Point data with attached name, type as well as longitude and latitude. Extract points for food and beverages, shopping, accommodation service, along with recreation as points for consumer activities. Extract points for tourist attractions as well as science, education and culture (only consider subcategories relevant for ICE, including museums, expositions, science museums, art exhibits, planetariums, cultural centres etc.) as points relevant to cultural activities. All point data are converted to the GCS_WGS_1984 geographic coordinate system.
Area of Interest	Baidu Map (https://www.baidu.com/)	2024	Extract ICS boundary according to name. ICSs with missing boundary data are supplemented using information from other map website and satellite imagery (Amap, National Platform for Common GeoSpatial Information Services etc.) and merged using ArcGIS Pro 3.0.1. software. All area data are converted to the GCS_WGS_1984 geographic coordinate system.

The calculation areas for ICS morphological data are obtained using a methodology described in Figure 2. First, raw data for ICSs include two vector data types: point data with single geographical coordinates for restaurant ICSs, and polygonal boundary data for scenic spot ICSs from Baidu maps. For both data types, a 300-meter buffer zone is created using ArcGIS Pro 3.0.1 under the justification that 300 meters is the average 5-minute walking distance within which people visiting ICSs are likely to also traverse. The buffer zone area is added to point and area data and considered as part of the ICS area when calculating morphological data. Furthermore, when ICS areas encounter city boundaries, it is cropped using the city boundary by Boolean operation between the two areas, i.e. any ICS areas beyond city boundaries are removed. City boundaries are according to data from the Chinese Academy of Sciences Resource and Environmental Science Data Platform.

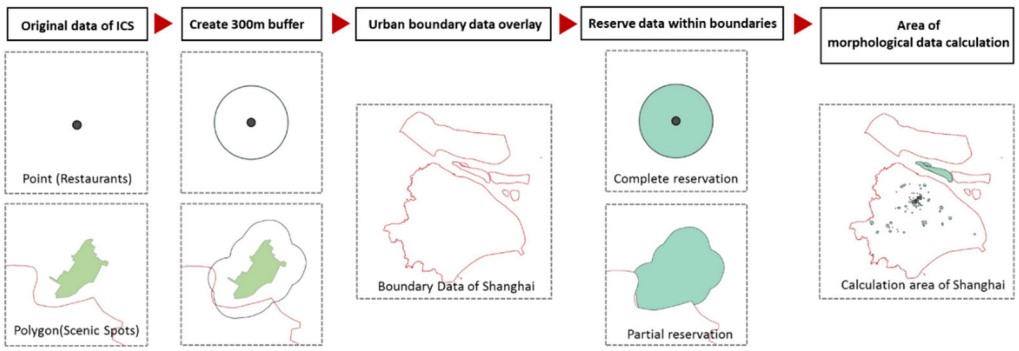

Figure 3. The calculation area of ICSs.

Indicator selection

According to a report jointly published in August 2022 by Ipsos Ltd. and multiple platforms (Oceanengine， 2022), uniqueness of cities is the primary attractor for Chinese tourists, and specific destinations include boutique commercial areas, natural scenic areas, cultural and historical sites, local cuisine, large shopping centres, and landmark buildings. From this it can be seen that compared to traditional theories such as Kevin Lynch's work on the perceptual form of urban environments, and M. R. G. Conzen's theories on urban morphology, tourists' cognition of city features are much more limited, and that the architectural form, consumer environment and cultural features are what tourists place focus on. Therefore, this study describes the configuration surrounding ICSs, using three perspectives: physical form, cultural services and consumer activities. Table 2 defines the 16 indicators used for quantifying the different aspects of urban morphology and generating a comprehensive overall description. The detailed mathematical formulation for each indicator is given in Appendix A.

Table 2. Morphological indicators.

Indicator	Dimension	Abbreviation	Description
Road network density	Physical Form	RND	Traffic accessibility
Building density		BD	Surrounding development intensity
Building footprint ratio		BFR	Surrounding development intensity
Average building height		MEAN	3D architectural feature
Maximum building height		MAX	3D architectural feature
Standard deviation of building height		STD	3D architectural feature
POI proportion of science ,education & culture service	Cultural Service	P_SEC	Cultural space composition
POI proportion of tourist attraction		P_TOURISM	Cultural space composition
Cultural service POI density		D_CU	Density of cultural spatial distribution
Cultural Service POI diversity		SHDI_CU	Complexity of cultural space types
POI proportion of food & beverages	Consumer Activities	P_FOOD	Consumption space composition
POI proportion of shopping		P_SHOPPING	Consumption space composition
POI proportion of accommodation service		P_HOTEL	Consumption space composition
POI proportion of recreation		P_RECREATION	Consumption space composition
Consumer activities POI density		D_CS	Density of consumption spatial distribution
Consumer activities POI diversity		SHDI_CS	Complexity of consumption space types

RESULTS AND DISCUSSIONS

Type similarity

Type similarity is quantified using cosine similarity. A total of 36 similarity results are created for pairs between the 9 cities selected here and are listed in Table 3. It should be note that, data for scenic spot and restaurant are of different nature and size, so should not be compared to each other. Comparison is only made within scenic spot data and restaurant data. The most similar city pair for scenic spots is Harbin and Shenyang (0.897), and the most dissimilar is Nanjing and Shanghai (0.290). The city pair with highest similarity for restaurant is Changchun and Shenyang (0.953), while the lowest is Guangzhou and Harbin (0.106). Overall, there is a significant disparity in the similarity between cities,

meaning when the public views cities from the perspective of ICSs, similarity exists for a portion of cities within the sample here.

Table 3. The overall average, maximum, and minimum of the pair values

Type	Mean	Max	Min
Scenic Spots Type Similarity	0.679	0.897	0.290
Restaurant Type Similarity	0.372	0.954	0.107

Figures 4 and 5 illustrate the cosine similarity results between city pairs for scenic spot and restaurant data respectively. Figures 6 and 7 display the average similarity ranking for each city, where the average similarity of a city refers to the average of cosine similarity values between it and all other cities. Corresponding radar plots are also included in Figures 6 and 7 to visualize the proportion of each type of scenic spot or restaurant within each city and reveal the type compositions of each city.

Regarding the comparison of city pairs, the maximum similarity pair of both scenic spot and restaurant data are between cities of the same geographical area. This means the ICS type of cities studied here is still most prominently influenced by geographical location, and corresponding climate conditions. For example, Harbin and Shenyang have highest scenic area similarity as Figure 4 shows, and they are both from Northeast China. Figure 6 indicates that City Parks (A07) and Theme Parks (A27) are the two highest proportion ICS types in both cities. This is presumed to be due to cities Northeast China putting emphasis on developing winter tourism in recent years, making winter-themed parks a hot destination for the public. Examples include Harbin's Ice Snow World and Polarland, as well as Shenyang's In Box Container Village and Peace Bay Ice Snow World. The correlation between restaurant type similarity and geographical location is observed to be even greater, especially for the three cities in Northeast China and East China, where the minimum similarity within the two geographical areas are 0.716 (Changchun and Harbin) and 0.625 (Nanjing and Shanghai) respectively, both far higher than the overall average of 0.372. This can be explained through the cuisines in Northeast China and East China being more unified throughout history. Meanwhile, dissimilarity of restaurant types between the north and south of China is also reflected by the data.

It is notable that, the minimum value for scenic area type similarity is generated within Nanjing and Shanghai (Figure 4), which are both from East China. Nanjing possesses abundant natural scenery resources, along with a rich history and cultural heritage. It is known for and advertised with such features, thus popular tourist destinations mostly include Natural Scenery(A23), Historical Sites(A14) and City Parks(A07). On the other hand, Shanghai is situated on the Huangpu River and has developed numerous site-seeing spots and routs within the city. In addition, Shanghai has the advantage of being one of China's largest economic and commerce centres, thus has attracted theme parks and themed districts from multiple leading IPs. These attractions have all grown to be Shanghai's representative ICSs. From the real-world situation of these two cities, it can be seen that when analyzing cities from an ICE perspective, the causes for similarity can be more complex, and each city's resources, economics and development strategy are all important factors in addition to geographical location.

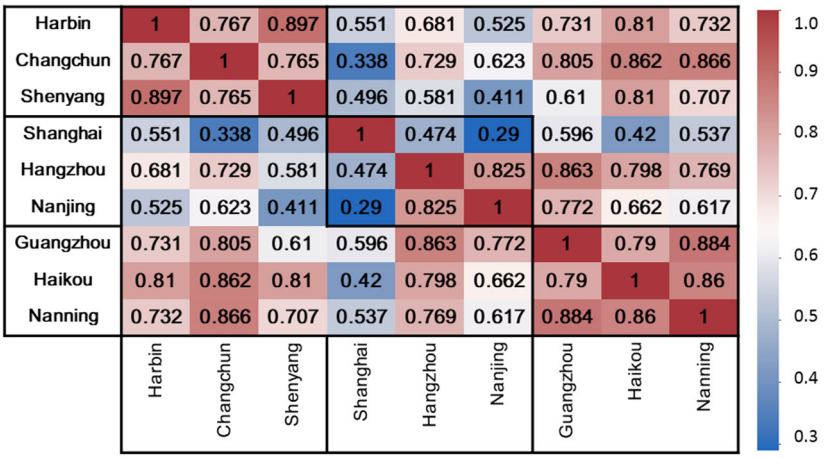

Figure 4. Similarity matrix of scenic spot types.

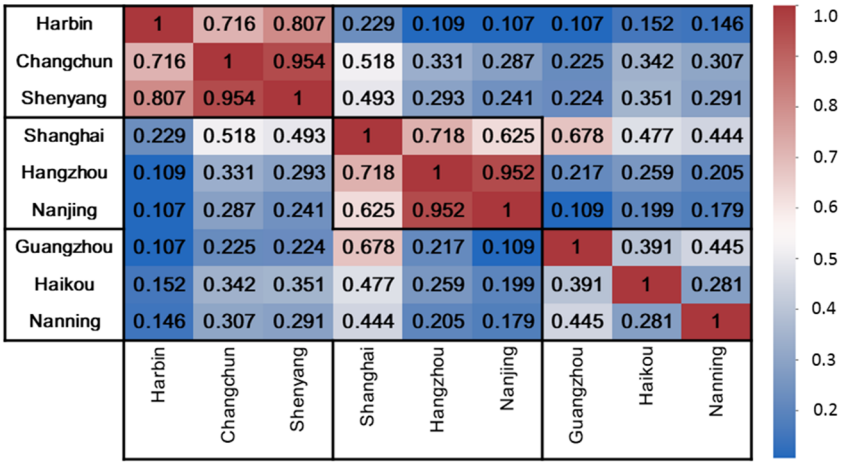

Figure 5. Similarity matrix of restaurant types.

Regarding the average similarity of individual cities, Figure 6 shows that Guangzhou is the most similar for scenic spot types. As illustrated in Figure 6, Natural Scenery (A23) and City Park (A07) are the majority types popular in most cities. Guangzhou follows this trend, and along with its other minor scenic spot types, it is at a position of highest average cosine similarity with other cities.

Meanwhile, it can also be seen in Figure 6 that Shanghai has the most unique scenic spot types. Half its ICSs are composed of City Sightseeing(A08), Ancient Villages(A02), Leisure District(A08), Theme Park(A27) and Landmark Building(A18). People often perceive Shanghai as a big city which lacks its own uniqueness, but from the data results it can be seen that Shanghai in actuality displays a more diverse range of ICS types, making it unique from other cities. This is an example of ICE-driven cognition showing deviation from reality. In terms of data, Shanghai is at a direction away from the majority of cities, thus has lowest cosine similarity.

On the other hand, Figure 7 shows that Shanghai has the highest similarity in restaurant ICS types, showing Shanghai's popular restaurants overlap with many restaurants in other cities. This suggests that consumers visiting internet celebrity restaurants in Shanghai are more likely to find a similar experience with that of other cities, and means that compared to scenic spots, restaurant and food

are easier to replicate between cities. Restaurant ICS type data shows most cities have several unique majority types, while Shanghai has a wider range of types, thus its middle position leads to higher average similarity. The data here corroborates the common intuition that Shanghai is an open, diverse and inclusive metropolis, while explaining the duality of Shanghai's scenic spot type uniqueness and restaurant type similarity.

Also in Figure 7, Nanning has the lowest average restaurant similarity. It has very unique cuisine, consisting mostly of Guangxi Cuisine (B16) and Cantonese Cuisine (B08). Other cities rarely possess Guangxi Cuisine, making it unique. Again, note that data for scenic spot types and restaurant types should not be cross-compared.

Ranking	City	Average Similarity (Scenic Spots)
1	Guangzhou	0.756
2	Haikou	0.752
3	Nanning	0.746
4	Changchun	0.720
5	Hangzhou	0.715
6	Harbin	0.712
7	Shenyang	0.660
8	Nanjing	0.591
9	Shanghai	0.463

Urban Morphology Similarity

Similarity of morphology for the 9 selected cities is discussed in three levels: the overall group, all city pairs, and individual cities. The ArcGIS Pro 3.0.1 software is used for geo-spatial data manipulation while tools including the SciPy library and SPSS 26 were used for statistical analysis. Regarding data form, all ICSs in cities are characterized using the 16 indicators for physical form, cultural services and commercial activity, giving each city 16 data distributions. All indicators have non-negative values, which is important for understanding analysis results. Normality of all distributions are tested using the Kolmogorov-Smirnov test, and found to not be satisfied, thus non-parametric tests are used instead of parametric tests such as ANOVA and T-tests.

First, the overall similarity of the 9 cities is analyzed using the Kruskal–Wallis test, a non-parametric counterpart of one-way ANOVA which considers the ranks of numerical values to accommodate distributions which cannot be assumed to be normal (Sá and P, 2007). Specifically, a single ranking is assigned to data across all distributions, and significant difference in the median ranking of all distributions is analyzed. This is implemented in Statistical Package SPSS 26 software, testing whether similarity exists respectively for each of the 16 morphological indicators. The null hypothesis H0 is the distributions corresponding to each city all originate from the same distribution. The Kruskal–Wallis test returned significance levels (P-values) of 0.000 for all 16 indicators, thus the null hypothesis is rejected. This result shows that for all morphological indicators, at least one city shows significant differences with other cities in the group, and from a ICE perspective, an overall similarity does not exist for the morphology of these 9 cities.

Second, similarity between each city is analyzed. This study uses the Mann-Whitney U-test, which is the equivalent of the Kruskal-Wallis test for individual pairs. It uses the ranking approach for two data distributions, and tests whether there is a significant difference in median (Mann and Whitney, 1947;

Okoye and Hosseini, 2024). This is implemented using Python 3.9 and the SciPy library's default Mann-Whitney test function. P-values produced by the U-test are equivalent to conventional T-tests, and refer to the probability that two samples are of the same distribution (PEARSON, 1914). In the context here, it indicates the probability that two cities are considered similar.

Figure 8 displays the P-values for all 16 indicators in descending order, revealing the overall trend for each indicator. It can be observed that only less than half of cities display significant similarity (non-negligible P-value), and most cities are dissimilar (P-value approximately zero). This means that the 'thousand cities one face' phenomenon only exists within a subset of cities, and corroborates findings from type similarity analysis, i.e. There does exist highly similar city pairs within the cities selected in this study, but this is far from all city pairs. Regarding specific indicators, the descending trend for P-values of BD, BFR, D_CS, MEAN, P_FOOD, P_HOTEL, P_RECREATION, P_SEC, P_SHOPPING, P_TOURISM, RND and SHDI_CS are relatively consistent, but for 3 specific indicators, D_CU, MAX and STD, P-value descends significantly more rapidly. This indicates that for these 3 indicators, only very few city pairs show similarity. The indicators MAX and STD are driven by building height, thus its dissimilarity can be attributed to cities' natural random disparities in building height, as well as inevitable random errors such as resolution-driven rounding errors introduced in the satellite telemetry data used here. The indicator D_CU is driven by cultural POIs (see Appendix A.), thus compared to other indicators, such as D_CS which is driven by consumer POIs, the total number of POIs driving D_CU is significantly smaller, and more prone to random disparity between cities, leading to dissimilarity. For D_CU, only Guangzhou and Hangzhou, Hangzhou and Nanjing, as well as Guangzhou and Nanjing have a P-value larger than 0.7. This shows that in the context of ICE, compared to other cities, these 3 cities are more likely to give visitors similar experiences with regard to cultural service POI configuration, such as the density of scenic areas, museums and memorials. These three cities are all relatively economically developed eastern and southern cities where natural and cultural tourist attraction resources are more abundant, thus similar economic development and environment will lead to similar cultural POI density within ICS hotspots within the cities.

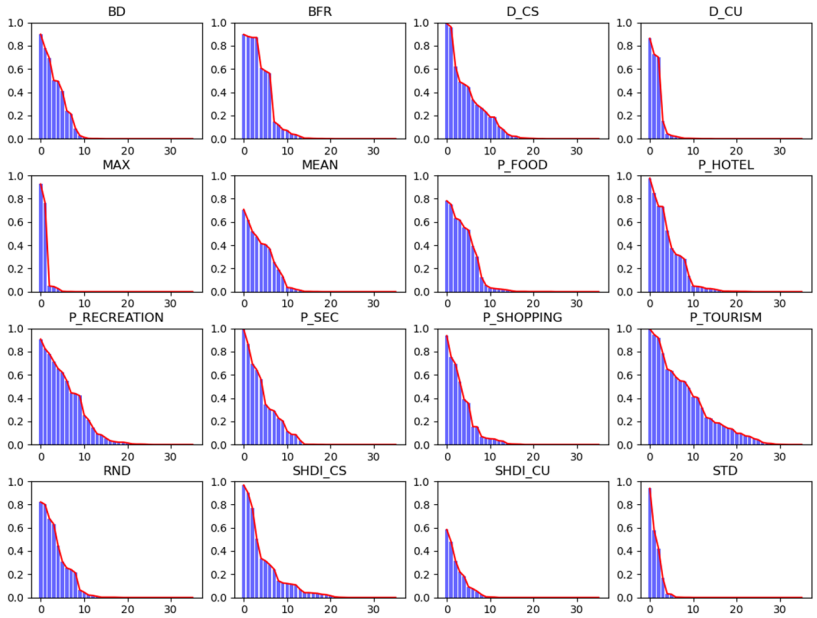

Figure 8. P value trend generated by Mann-Whitney U Test.

This study averages the P-values of each city to characterize its similarity with other cities, i.e. adding the P-values between it and each other city and dividing the number of other cities. The addition of P-values carries meaning here, which could be explained through expected value. Consider city i, which is compared to other cities j≠i . Each outcome of similarity for city j leads to 1 more similar city, with probability Pj, while dissimilarity leads to 0 more cities, with probability (1-Pj). Thus, the expected total number of cities similar with city i is

$$EX_{total,i} = \sum_{j \neq i} 1 \times P_j + 0 \times (1 - P_j) = \sum_{j \neq i} P_j$$

where Pj is the P-value between city j and city i. Furthermore, averaging P-values can be interpreted as the expected increase of cities similar with city i with each additional city, or in other words, the probability that the next city will be similar with city i, based on knowledge from current cities. This is considered as

$$EX_{average,i} = \frac{\sum_{j \neq i} 1 \times P_j + 0 \times (1 - P_j)}{N - 1} = \frac{\sum_{j \neq i} P_j}{N - 1}$$

where N is the total number of cities (including city i). Note how $EX_{average}$ is a measure of similarity which is independent of total city number.

Figure 7 displays the average expected similarity for all 9 cities and all 16 indicators. When considering geographical location, no significant correlation is observed with overall maximum and minimum values of average similarity. On the other hand, Shanghai, Nanjing and Guangzhou are the three cities with higher economic development. Shanghai shows uniqueness, i.e. dissimilarity in many aspects, while Nanjing and Guangzhou show similarity in many indicators. For Shanghai, its MEAN and STD, the three-dimensional building characteristic indicators, show significant difference with other cities. This can be understood through the original data, Shanghai has a higher coverage of taller buildings, raising the mean and standard deviation values of its building height data. This also fits the common perception that Shanghai is a highly urbanized city with many skyscrapers and unique city skyline. The other unique city is Haikou, which holds the lowest similarity in 6 indicators, especially concentrated in cultural services. From the original data it can be observed that Haikou has sparse cultural POIs around its ICSs, and also lacks in the diversity of such POIs, falling far behind other cities. This is speculated to be due to Hainan province having Sanya, another more prominent city for tourism. Also, Hainan is a geographically isolated island with a less extensive history. These facts combined may contribute to Haikou not having developed similar levels of cultural services as other cities.

Looking at all three groups of indicators, Nanjing stands out with its high average expected similarity. By principle of the U-test, as well as the form of the original data, it can be seen that Nanjing's data is most evenly distributed on either side of the overall median for each indicator, leading to its data distribution being closest on average to other distributions. Guangzhou similarly shows a significant level of similarity. In contrast, regarding the groups of indicators, Changchun and Shenyang show most significant dissimilarity in physical form indicators, Haikou and Harbin are most unique in cultural service indicators, and Changchun and Shenyang are again the least similar in consumer activity indicators. Analyzing the data from a real-world perspective, Nanjing is geographically centered in

latitude within China, and its economic development is also at a medium level within the 9 cities here, leading to its high average similarity. Conversely, Northeast China, where Changchun, Harbin and Shenyang are from, is the northernmost area in China. In fact, Changchun, Harbin and Shenyang are the 3 northernmost provincial capitals in China. Furthermore, the economic development of Northeast China is a commonly observed phenomenon in recent years, and this also drives the significant difference in city morphology.

Figure 9. Average expected value of individual cities.

CONCLUSIONS

This study discusses the hotly debated topic of 'thousand cities one face' from the novel perspective of Internet-Celebrity-Economy, conducting similarity quantification and tests for the type and morphology characteristics of Internet-Celebrity-Spots in 9 provincial capital cities in China.

Based on data for the 9 cities selected in this study, and separately approaching the two branches of type similarity and morphological similarity, the similarity between cities is discussed for cities overall, city pairs, and individual cities. The conclusions which could be drawn include: 1) Regarding all cities and city pairs, significant similarity between the characteristic indicators of cities can be observed, but exist between a portion of the samples here. 2) Regarding individual cities, Shanghai shows noteworthy difference in its type similarity. As a typical internationalized metropolis, when compared to other cities, it simultaneously possesses more dissimilar scenic area ICS types, and more similar restaurant ICS types. This points to the significant advantage which large cities hold in tourism development, i.e. they have more diverse tourist destinations not available elsewhere, as well as more diverse restaurants which cover cuisines of other cities. Meanwhile, Nanjing is a city with a medium placement in geographical location and economic development, thus displays corresponding similarity

in many indicators. In contrast, Harbin, Changchun and Shenyang have more marginalized placement in both geography and economics, displaying corresponding dissimilarity in certain indicators.

The results from this quantitative analysis can bring insights for city policy makers, aiding them in raising cities' uniqueness or benchmarking and replicating other cities. It is hoped that the approach taken here, collecting and analysing urban morphology data with the perspective of ICE and ICS, can allow a better understanding of the public's interests as well as their cognition of city images. As a topic of debate, the 'thousand cities one face' phenomenon is verified in the quantitative results, showing its importance. Meanwhile however, it has also been shown that numerous cities are able to retain their uniqueness. As the Internet-Celebrity-Economy continues to grow, how to correctly understand its effects and incorporating it into urban design studies and policy making will be an important direction of research.

Reimagining urban fabric: formal analogies between informal settlements and ottoman mahalle

Ezgi Nur Güngör[1]
[1] PhD Candidate Department of Architecture and Design (Transitional Morphologies Research Unit, Department of Architecture and Design, Politecnico di Torino), Italy, ezgi.guengoer@polito.it

ABSTRACT

An intriguing formal analogy emerges when comparing the urban fabric of late Ottoman mahalle (residential neighborhood) with the contemporary informal settlements of 21st-century Ankara on urban scale. Despite both embodying a form of organic development, they diverge significantly in terms of urban continuity. While the former is esteemed as a foundational element worthy of conservation, the latter often faces condemnation and imminent transformation. This research posits the existence of a controlled and systematized organicity inherent in the evolutionary trajectory of 19th-century Ottoman mahalle as an archetype, stemming from their regulatory framework. Employing a comparative methodology, this study seeks to offer a novel lens through which to perceive the concept of "informal." Proposing an analogy through morphological analysis between late Ottoman mahalle and contemporary informal settlements, while bypassing considerations of legality, prompts critical inquiry into urban transformation and regeneration processes. To substantiate the analogy between the two urban fabrics, this study endeavors to synthesize the Typology as Themes of O.M Ungers with Caniggia and Maffei's process-based approach to morphological study. Its objective is to generate a three-column matrix comparing the urban fabric typologies of 19th-century Ottoman settlements with contemporary informal settlements and to show typological compatibility between them as well as thematic relation between them. Ultimately, this study reinterprets the building clusters of Ottoman mahalle as urban block typologies as well as the mixed clusters of gecekondu (informal units). Despite their deviation from pure geometric principles, these clusters offer a pathway for transformative processes. Embracing them as urban block typologies presents an opportunity for thematic urbanization rooted in formative analogy, steering away from wholesale destruction. Such formative comparison of urban form holds promise in shifting local transformation strategies towards more sustainable and inclusive urban regeneration through the generative side of thematic typology.

Keywords: Ottoman mahalle, informal settlements, typology as theme, urban fabric, urban block

INTRODUCTION: READING ORGANIC SETTLEMENTS

Despite extensive demolitions and urban transformations, a formal connection between distinct urban tissues persists, offering significant insights for future urban design interventions. Existing morphological studies of informal settlements often overlook how these areas adapt to and penetrate existing urban fabrics. Understanding the morphology of informal settlements is crucial for ensuring a sustainable continuity of urban form. This research posits that there is a meaningful analogy and

interconnection between the organic urban fabric of the Ottoman mahalle and the gecekondus that emerged adjacent to mahalles in Ankara's Altındağ district. By examining these relationships through the frameworks of "organism" (Caniggia and Maffei, 1979) and "Grossform" (Hattasch, 2016), this study aims to demonstrate how informal settlements and historical urban forms can constitute a cohesive whole through their morphological adaptations. This approach raises critical questions about how informal settlements can be integrated into urban design without resorting to total demolition or drastic transformations. The research seeks to address the following questions: How can we enhance our understanding of the urban morphology of informal settlements to anticipate their contributions to urban development and identify sustainable continuity strategies? To what extent can informal settlements be considered adaptable to existing urban tissues? How can informal settlements be conceptualized in relation to different urban fabrics-historical fabric in this case-irrespective of their legal status? Can a morphological analysis of informal settlements within historical urban contexts offer new perspectives on informality and state-led transformations? To explore these questions, this study first reviews relevant literature on informal settlements, urban morphology, and the urban history of Ankara. It then conducts a detailed morphological analysis to elucidate the findings.

The Literature on Informal Settlements

The term "informal" refers to settlements that develop outside the formal regulations of a state concerning land tenure, urban planning, design, and construction (Dovey and Kamalipour, 2017). This term also encompasses various labels such as slum and squatter (Dovey, 2012), shanty towns (Rodwin, 2022), popular settlements (Hernandez, 2009) and self-help settlements (Ward, 2015), unifying them under one heading to avoid overlapping meanings (Dovey and Kamalipour, 2017). In summary, informal settlements can be broadly defined as urban areas that have arisen independently of governmental oversight regarding urban design, planning, and construction (Kamalipour and Dovey, 2019: 63).

Numerous scholars have investigated the urbanity of informal settlements through diverse research questions (Roy and AlSayyad, 2004; Neuwirth, 2005; Davis, 2006; Dovey, 2012; Tonkiss, 2013). Despite the advancement of methodologies for examining urban form (Hillier, 1984; Moudon, 1994; Gauthier & Gilliland, 2006; Marshall, 2009; Sima & Zang, 2009; Whitehand, 2009), the morphology of informal settlements has remained largely underexplored.

As Kamalipour (2016) notes, Davis (2006) conducted a typological study focusing on the proximity of job opportunities, which led to the development of a taxonomy of informal settlements. In order to move the gaze from formal to informal in morphoplogical studies, Dovey and King (2011) aimed to define and categorize the typology of informal settlements based on growth processes, including settling, inserting, or attaching. Kamalipour (2016) also investigated the urban interfaces of informal settlements, focusing on their spatial relationships and connectivity to nearby public spaces. McCartney and Krishnamurthy (2018) sought to bridge the terminological divide in the literature between formal and informal settlements by categorizing the morphological structures of slums based on site factors, building typologies, and configurations of circulation space.

These studies show that informal settlements contribute to the sustainability of most developing cities despite their lack of formal regulations (Dovey, 2012). Regarding this, informal settlements show great

potential of incremental adaptation within the mixture of different urban fabrics (Kamalipour, 2016). Self-organization is the key and dominant typological mode (Kamalipour and Dovey, 2019) contributing to this adaptation. Furthermore, because of their spontaneous development, they have been considered as “modern vernacular environments” (Lapping, 1973). On the other hand, there is a need of process for the cities to achieve the sustainable mix (Jacobs, 1961), while these settlements develop in the city. Van den Hoek (2008) defines this process as “cyclical transformation”. However, existing depictions of informal settlements are inadequate in capturing the complexity of their morphology, which is necessary to justify and facilitate their cyclical transformation (McCartney and Krishnamurthy, 2018).

Towards a Comprehensive Morphological Characterization of Informal Settlements

A healthy cyclical transformation for a city requires well-organized design interventions. Marshall and Çalışkan (2011) emphasize that poorly described urban morphology can lead to inadequate design interventions. Despite the existence of studies on the urban morphology of informal settlements, the current findings contribute minimally to design interventions, calling into question the methodologies used in these studies. Therefore, this study posits that a morphological characterization synthesizing two different approaches in urban morphology—process-based typology and typological theme—is necessary for a comprehensive understanding of informal settlements.

The development of morphological characterization has been maintained through different approaches (Kropf, 2011). Yet, the roots date back to the study of architectural typology. The idea of the categorization of typologies extends back to Durand, who first, introduced the concept of “model” which is equal to “type”, while systematizing a methodology: cataloging types, classification of formative constraints, and recomposition of constraints (Petruccioli, 1998). Cataloging types, in Durand’s manner, was the categorization of buildings first according to their function (church, temple, theatre), then their geometric and compositional constraints (footprint on: round shape, rectangular shape, horizontals). Following the works of Saverio Muratori, process-based typology (Caniggia and Maffei, 1979) has developed a substantial discourse in morphological characterization that adheres to the concept of urban form as a series of aggregations (Kropf, 2014). Caniggian approach analyzes urban form by representing hierarchical relationships (from part to whole on building footprints, the system of routes/streets, and topography) between and within different districts/towns (Kropf, 2009).

On the other hand, Aldo Rossi (1966) took a step further of Durand’s approach, prioritizing geometric and compositional constraints over function while putting forward the “autonomy” and “persistence” of form through the term “urban artifact” (Marzot, 2014). Rowe and Koetter (1978), furthermore, brought a new perspective through Collage City, which categorizes autonomous urban entities instead of independent buildings, based on their stimulative character in the city (such as memorable streets, stabilizers, the garden, and nostalgia-producing elements). The typological theme (Schrijver, 2021), which Ungers initially suggested and developed under the influence of Rowe (Hertweck and Marot, 2013), has the ability to bring together these concepts under a single heading: "theme". The term "theme" is an abstract concept used to encapsulate all initial ideas, illustrations, and content related to an architectural form—whether it be a building, a building ensemble, or an entire city—under a single analogous figurative object, irrespective of its scale (Güngör, 2022). Although the idea first appeared to categorize architectural elements (buildings) through the term Grossform (megaform), it then began to show up in a kind of morphological characterization of cities (Dialectic City, 1999; City Metaphors, 1982; The City in The City: Berlin as an Archipelago, 1977). To better understand the

interaction and typological relationship between Ottoman mahalle and informal settlements in Ankara, a synthesis of typological theme and process-based typology is necessary.

Urban history of Ankara: The Ottoman *mahalle* and informal settlements

As it was already mentioned, this research analyses the interaction between the urban fabrics of Ottoman mahalle and informal settlements, both situated adjacent to each other in the city center, atop two hills separated by the Bent stream (Figure 1).

The Ottoman mahalle plays a crucial role in defining urban form, functioning historically as both a physical and political unit. Cerasi (2001) describes the mahalle as a cluster of row garden-houses organized around a central public building or monument, such as a mosque, fountain, or medrese, with houses aligned along organic, winding streets. The 1924 military plan of Ankara depicts these clusters as distinct urban islands, each corresponding to a mahalle (Figure 1). This representation reinforces the idea that the mahalle can be viewed as a typological unit akin to an organic urban block in Ottoman settlements, underscoring its significance in understanding the urban fabric of historical Ankara.

Although the mahalle's evolution dates to the fifteenth century, the earliest document on Ottoman settlements in Ankara is from 1924, produced for military purposes (Cengizkan, 2004). Despite transformations since the early twentieth century, the urban fabric of mahalle remains recognizable due to planning decisions and conservation policies in Ankara's history. The first modern master plan of Ankara, Jansen Plan, maintained a deliberate separation between traditional and modern urban fabrics, aiding in preserving the Ottoman mahalle's form (Tankut, 1988). In the 1980s, documentation of Ulus's historical districts and the Ulus Historical Center Conservation Planning Competition (Çakır, Altınöz and Özüduru, 2019) reinforced this separation and heightened awareness of Ottoman mahalle typologies. Although post-2000 regulations have been controversial (Çakır, Altınöz and Özüduru, 2019), the urban fabric of Ottoman settlements has largely retained its historical characteristics, evidenced by street networks, building footprints, urban islands, and plot patterns.

Özdemirli (2019) notes that squatters or "gecekondus" in Turkish, on the other hand, began to emerge in Ankara primarily after World War II, during a period of rapid urbanization and migration. These makeshift settlements, lacking formal planning and infrastructure, were constructed so quickly they were referred to as "gecekondu," meaning "built overnight" (Özdemirli, 2019). Although many have been demolished, gecekondus represent a significant part of Ankara's housing history. Over time, gecekondus in Ankara have undergone various stages of transformation through informal upgrading, government interventions, and policy changes. These stages include the authorization of demolition, pardoning of existing gecekondus, recognition of their political power and formalization, and eventually the criminalization and demolition of gecekondus as part of urban transformation initiatives (Özdemirli, 2019) (Figure 2). Unconventionally, there was a period when gecekondus in Turkey were formally recognized and granted construction rights, significantly influencing the current urban form, including building footprints, urban islands, and plot patterns. However, since the 2000s, government policies have re-informalized and demolished many gecekondus, replacing them with high-rise apartment blocks through controversial urban transformation projects.

Regarding the aforementioned information, this research argues that despite the demolition and replacement of informal settlements, there is a clear formal connection between the urban tissues of the Ottoman mahalle and the gecekondus. This connection can inform future design interventions, providing potential insights towards urban transformation strategies.

METHODOLOGY : THE SYNTHESIS OF MORPHOLOGICAL APPROACH

To elucidate the formal analogy between informal and historical settlements, this paper posits that a morphological characterization of both informal and historical urban fabrics is essential. Given the variations and ambiguities in morphological characterization within urban form literature (Kropf, 2014), this research aims to synthesize process-based typology and typological theme to achieve a specific objective: thematic and compositional characterization.

The typological theme approach can be observed in a series of Ungers' works, including "Grossform," "Dialectic City," "Architecture as Theme," "The City in the City: Berlin as a Green Archipelago," and

"City Metaphors" (Schrijver, 2021). Among these, "Grossform" and "The City in the City: Berlin as a Green Archipelago" provide a clear set of definitions and methodologies, which this study interprets for synthesis. These works refer to “megaforms” not in a literal sense, but metaphorically, as mature forms that have achieved self-sufficient complexity in their geometry and form, regardless of scale (whether a building, an urban block, or an urban district). To achieve thematic characterization, this study adopts Ungers' four criteria of self-sufficient complexity as described via Grossforms: the presence of an over-accentuated element, a connecting element, the existence of figure and theme, and an ordered principle (Schrijver, 2021).

The process-based typological approach is employed initially to reveal the ordered principles of informal and historical settlements in Ankara. Furthermore, Ungers' definition of ordered principles is insufficiently clear and can be better described through the hierarchical relations delineated by Caniggia. Consequently, this research adopts Caniggia's compositional terminology and analytical system, focusing on building and street layers: unit, structure, system, organism, and route; matrix route, planned building route, and break-through route.

Although Caniggia's system is inherently applied to gridded settlements, this study extends its application to organic settlements to uncover analogies between the figure and theme of informal and formal settlements. Unlike Ungers' approach-which does not apply scalar hierarchy-, this study synthesizes typological themes and process-based typological methods by thematizing the hierarchical components described by Caniggia (1979) (unit, structure, system, and organism).

The analysis involves the diagrammatic representation of Ottoman settlements and informal settlements in the Altındağ district of Ankara. The morphological characterization is carried out by analyzing six distinct periods using a range of historical data, including the 1924 military map, the Jansen Plan, the 1944 map, the 1953 map, as well as GIS data from 2015 and 2024. Unlike other historical studies of Ankara's urban form, this research does not focus specifically on each planning period. Instead, it emphasizes selected periods that reflect significant changes in laws and regulations concerning gecekondus, aiming to provide clear depictions of the figure-ground data of Ottoman settlements across different periods since founding of Turkish Republic. First, the analysis compares the differences between each period. It then conducts a morphological characterization on various scales (organism, system, and structure) using thematic analysis. To establish an analogy between the formative components on different layers (building footprints and street systems), this study creates a typological sequence matrix, inspired by "The City in the City: Berlin as a Green Archipelago."

RESULTS AND DISCUSSIONS

Results

The initial development of Ottoman settlements exhibits an organic progression in structural scale. However, the typology of these structures cannot be determined due to the lack of information or maps documenting building development from that period. The Ottoman mahalle, influenced by the steep topography, displays a distribution characterized by a homogeneous structure that shows an unfolding distribution. Although the Jansen Plan proposed converting a significant portion of Ottoman settlements into elongated urban blocks, which would have compromised the unfolding nature of these historical settlements as an organism, these plans were not executed. This is evidenced by the

1944 map, which clearly shows the expansion of the settlement, maintaining its original boundaries (Figure 3).

The 1953 map marks the initial emergence of informal settlements on the other side of the hill, which is divided by Bent Stream (Bentderesi). This area had remained undeveloped, likely due to its steep slope. The distinct topography of the small hill and the gradual establishment of gecekondus resulted in the formation of an organism constituted by the meeting of the two halves of the divided hill. While it may seem tenuous to describe this as an encounter solely based on the cellular development of informal and historical settlements, the 1953 map also allows for the observation of the structural and unit development of buildings. The buildings' scales, as elementary units, are remarkably similar in both the informal and Ottoman settlements, which justifies the notion of defining this development as an encounter (Figure 3).

The urban data acquired in 2015 indicates that the interaction between the two urban halves reached its own spatial boundaries, which were defined by the lowest sidehill isohips. The topography shaped this urban organism into a distinct encirclement, clearly illustrated in the organism diagram. At this juncture, the southwest half of the hill was predominantly occupied by Ottoman mahalle, while the north half consisted exclusively of informal settlements. The transformation of the southern part into macro-scale dispersed building campuses significantly altered the urban fabric from smaller cells to larger ones, reinforcing the encircling. This change is evident in the street diagram, where the street pattern's evolution from the 1953 map to the 2015 data is distinctly observable. The development of informal settlements based on the 1953 map suggested a potential second tangential encirclement. However, this potential was nullified by urban transformation projects initiated in the 2000s.

While the streets emerging in 1953 displayed an organic layout parallel to both Ottoman and informal settlements, a part of (northeast) 2015 street layout revealed a markedly different urban fabric. The building footprints and the large point blocks from 2015 do not exhibit any logical or parallel alignment with the previous urban fabric, indicating a significant shift. By 2024, urban data reveals the complete erasure of the north half of the hill, as buildings were demolished in accordance with urban transformation regulations. Nevertheless, original street layout remains intact. Together with the new street layout on the northeast for the point blocks and demolished north halve, the urban fabric evolve into a state of confusion (Figure 3).

Due to the absence of maps showing building footprints from the periods of 1924 and the Jansen plan, a comparative analysis of the structural systems with subsequent periods is not feasible. However, data from later periods provides significant insights into the typologies of mahalle-gecekondu urban fabric. Based on the 1944 map, the Ottoman mahalle was the predominant urban form, whereas a systematic presence of gecekondus was not evident at that time. The urban systems displayed an organic layout, with the elementary units—historical Ottoman housing—exhibiting a recurring pattern. This repetition creates what Pettruccioli (2007) describes as an "occasional seriality," where the organic layout of each mahalle is interspersed with repeated units, forming a serial system. In

contrast, the gecekondus did not conform to either an organic or serial group layout. Instead, they were sparsely scattered along the isohips on the hillside, lacking any cohesive pattern (Figure 4).

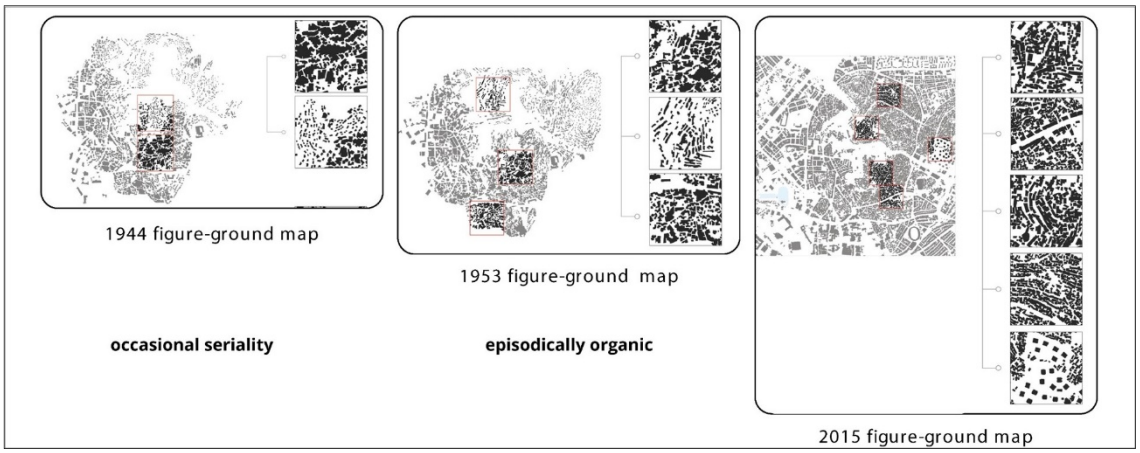

Figure 4. Structural systems of mahalle and gecekondu over time

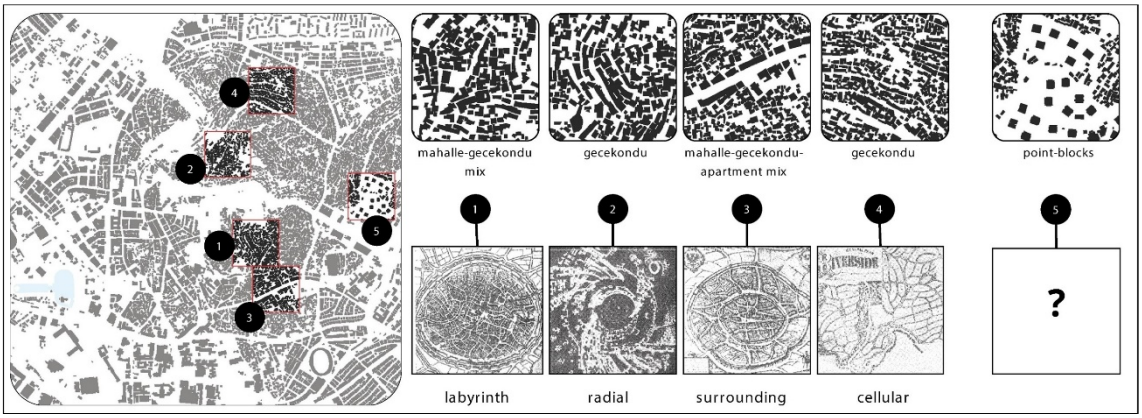

Figure 5. Morphological comparison of the structural systems of the mahalle and gecekondu in 2015

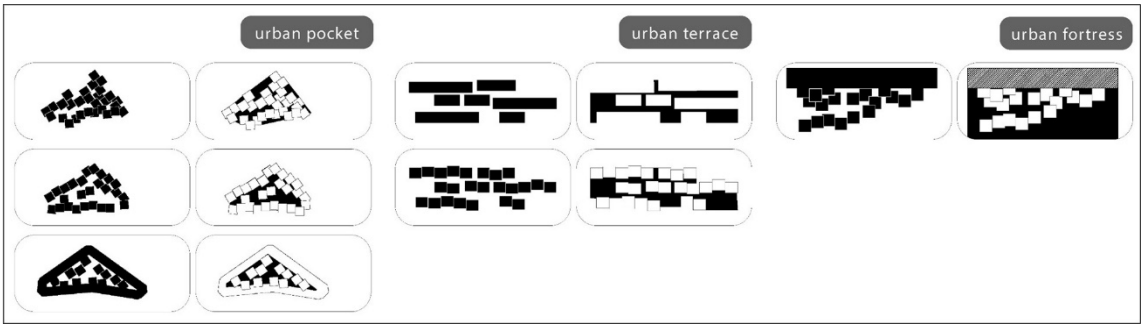

Figure 6. Potential transformative themes of elementary structures derived from the morphological combinations of mahalle and gecekondu units

The 1953 map reveals that the Ottoman mahalle maintained its characteristic occasional seriality, while the gecekondu units began to penetrate the organic layout of mahalle cells on the southwest half of the hill. Initially scattered on the north half, the gecekondu units started forming a serial repetition by attaching to each other linearly along the isohips. This development suggests the emergence of a new structural typology, which Pettruccioli (2017) refers to as "*episodically organic*." In this context, the elements themselves reflects organic growth patterns but occurs in distinct episodes rather than as a continuous process. This hybrid form represents a significant shift from the purely organic or scattered layouts observed in earlier periods (Figure 4).

The 2015 data indicates that the density of gecekondus and their structural system reached a level where the two halves of the hill could be perceived as a unified organism, characterized by similar unit and structure scales in the urban fabric. However, there are nuanced differences between the systemic composition of gecekondus and Ottoman mahalle.

The linear aggregation of gecekondus on the northern hillside resulted in the emergence of a *cellular* structure. In contrast, on the southern hillside, the aggregation of gecekondu units produced a *radial* structure. The Ottoman mahalle meanwhile, maintained its occasionally serial structure with the encroachment of gecekondu units, leading into a mixed structure which can be interpreted as a *labyrinth* form. The modern linear apartment blocks constructed since the 1957 Yücel Uybadin Master Plan of Ankara thickened the boundaries of Ottoman mahalles along the lowest isohips of the southern half of the hill (now Ulucanlar Avenue). This thickening can be interpreted as a *surrounding* form, reinforcing the concept of encirclement and emphasizing the reading of the hill as a single organism composed of Ottoman and informal settlements (Figure 5).

High-rise point apartment blocks, constructed adjacent to the hillside border, on the other hand, do not generate a consistent typology with either the Ottoman or informal settlements, nor with the rest of the city (Figure 5). These high-rises were intended to relocate gecekondu residents from the northern half of the hill, but their vague typology caused significant ambiguity after 2015, effectively resetting the urban fabric of the organism to its initial state when half of the hill was empty. This regression is clearly shown in the 2024 urban data.

On the other hand, the elementary structures of the aforementioned forms—namely the mix of gecekondu-mahalle, apartment-mahalle, and gecekondu structures—exhibit variations in spatial identities that can inform future urban transformations. They also highlight the significance of the spatial themes created by these structures within the urban context. The combination of gecekondu-mahalle can be interpreted as an urban pocket, offering potential access points to an organic block that can accommodate urban activities in spatially dynamic ways for future transformations. The elementary structures composed solely of gecekondus reveal a terrace configuration, which can be seen as urban terraces ripe for future interventions. Moreover, the combination of mahalle, gecekondu, and apartment structures generates a theme reminiscent of a fortress, where gecekondu-mahalle units are integrated with thick substantial apartment buildings. This arrangement conceals the organic open spaces between the gecekondu-mahalle units that lie behind the apartments. Thus, this configuration can be interpreted as an urban fortress that opens up to open-air activity spaces, providing opportunities for future interventions (Figure 6).

Discussion

The synthesis of typological theme and process typological approach while analysing the informal and ottoman settlements reveal several facts in organism scale. Regardless of their legality and the occurrence of demolitions, the aggregation of gecekondus generates a distinct urban tissue. This urban tissue shares significant similarities with Ottoman settlements, with minor differences at the structural scale, resulting from historical preservation implementations. According to Petruccioli (2007, p.184), different urban typologies can be integrated into a cohesive whole if they respect and adapt to each other's spatial logic, leading to typological compatibility. This compatibility is evident at both macro and micro scales when comparing Ottoman and informal settlements.

The analysis reveals five distinct typological themes concerning the reciprocal formation of Ottoman mahalle and gecekondu urban fabric on a macro scale: unfolding, encounter, encirclement, and confusion. Up until the theme of confusion, the temporal transformation of these typological themes shows how the interconnection between Ottoman mahalle and gecekondus adapts over time, culminating in an encirclement. This adaptation is also evident in the encroachment of gecekondus into the inner courtyards of Ottoman mahalle urban blocks. Thus, gecekondus not only dominate the northeast half of the hill but also penetrate the structural system of the Ottoman mahalle. Comparison of conservation timeline and urban fabric analysis reveals this fact clearly.

The analysis of both mahalle and gecekondu reveals notable similarities and differences. On an urban scale, the elementary units and their structural systems share similarities, while the structures of these elements exhibit slight differences. Both Ottoman houses and gecekondus are nearly identical in proportion, contributing to their similar appearance. However, the aggregation patterns of elementary units to constitute a structure differ: gecekondus align linearly along the isohips without providing interior courtyards between buildings, whereas Ottoman houses follow a trapezoidal arrangement along the street edges, adhering to the primary property distribution layout established during Ottoman times. This consistency in following plot edges is likely rooted in Ottoman regulations regarding house construction.

Despite differences in structural organization, both systems exhibit an organic pattern. This research posits that the steep slope of the hill significantly influences this similarity. From this perspective, the research suggests that the spontaneous consciousness emerging during the Ottoman period and after the 1950s, when gecekondus were constructed, shares a similarity. Both periods emphasize topography through the organic system, highlighting the impact of the hill's topography on the settlement patterns. However, there is a key distinction: in the evolution of Ottoman mahalle, the street and plot patterns were established first, whereas in the evolution of informal settlements, construction of gecekondus played a primary role with street patterns developing subsequently. This causes an essential difference in structural formation within the two halves of the hill.

Regarding these observations, the primary difference between Ottoman and informal settlements lies in the emergence of their elementary structures. The elementary structure of an Ottoman mahalle adheres to a set of rules that create defined street edges and internal courtyards, contributing to consistent spatial qualities. In contrast, gecekondus do not follow a prescribed pattern but instead develop organically in response to natural conditions, resulting in a lack of consistent spatial quality. Yet, since they follow the isohips in different levels, there is a recognizable radiality that offers a potential spatial quality for future urban transformation. From this perspective, this research asserts that, despite its organic nature, the occasionally organic structure of the Ottoman mahalle creates a type of organic urban block with distinct spatial qualities, which is not clearly visible/differentiable in informal settlements.

Another vital fact concerning the difference between occasional seriality of mahalle and episodically organic structure of gecekondu is related to the consistency of the elementary unit types: the Ottoman house and the gecekondu. Despite the similarity in unit scale, gecekondus lack a repeating unit type at the architectural level because they were constructed independently and without mastery. Conversely, the Ottoman house has consistent types—with features such as cumba/loggia, avlu/internal courtyard, and two-storey construction—that exhibit synchronic variations across the

southwest half of the hill. Regarding these findings, this research asserts following points that could be important to understand formative relations between Ottoman and informal settlements:

1. There is a typological compatibility between ottoman and informal settlements despite the differences arising from the system of evolution.

2. The informal urban tissue composed of gecekondu generates an encroachment tissue, which generates a mix of gecekondu-mahalle units with thematic potentials for urban transformation strategies.

3. Gecekondus create a distinct urban fabric alongside mahalles, which helps define the combined characteristics of Ottoman and informal settlements. This composition reflects four principles of Ungers' Grossforms: a) the presence of an over-accentuated element, represented by organic urban blocks formed by a mix of gecekondu and mahalle units; b) a connecting element, such as the isohips of the topography; c) the existence of both figure and theme, characterized by encircling and interlocking elements; and d) an ordered principle as organic serial development. In this context, the interconnection of mahalle and gecekondu structures on either side of a hill can be seen as a unique Grossform. The typological compatibility and overlap of informal urban fabrics further support the concept of Grossform by weaving together Ottoman mahalle and gecekondu urban elements.

4. Typological thematization of urban tissues offers new compatible urban transformation strategies for future implications on different scales (organism, system, structure), which brings a new perspective to the continuity process of informal settlements through a formative approach.

CONCLUSIONS

In conclusion, this research elucidates the morphological parallels between Ottoman mahalle and gecekondus in Ankara, revealing a typological compatibility that transcends their legal and historical differences. Despite the challenges posed by urban transformation initiatives, the study shows that both settlement types share a consistent spatial logic influenced by the topography of the hills they occupy. The synthesis of process-based typology and typological themes provides a nuanced understanding of these urban fabrics, offering a framework for future urban interventions that respect and integrate the spatial qualities of both formal and informal settlements.

By identifying five distinct typological themes—unfolding, encounter, encirclement, and confusion—this research underscores the dynamic interaction between Ottoman and informal urban forms. These themes highlight the potential for creating a cohesive Grossform, referred to as the Encircling-Interlock form, integrating different urban typologies into a harmonious whole. This compatibility suggests new avenues for urban transformation strategies that can enhance the continuity and sustainability of informal settlements, leveraging their inherent adaptability and spatial coherence.

Due to the scale and detail of accessible data, the morphological characterization is limited to the organism, system, and structural scales, omitting the elementary scale, which requires detailed floor plans. Additionally, the plot patterns are not clearly visible in the maps used, leading to an oversight of this aspect. Future analyses should aim to integrate plot patterns for a more comprehensive

morphological characterization. The findings of this study suggest that understanding the Grossform of informal and historical settlements can be beneficial for future urban transformation projects, especially in areas like Altındağ where remnants of street layouts and some gecekondus are still recognizable. Moreover, reading informal settlements through their typological compatibility could contribute to a global understanding of informal settlements, potentially redefining the term "informal" in morphological studies and emphasizing its value in design developments and interventions. Ultimately, recognizing and preserving the formal connections between historical and informal urban tissues is vital for developing more inclusive and sustainable urban environments. This study advocates for design interventions that build on the identified typological themes, promoting a more holistic and integrated approach to urban transformation in Ankara and similar contexts.

Research on Evaluation Factors of Traditional Commercial Streets Pedestrian Comfort: A Comparative View between Experts and Travelers

Yutong Ma[1], Tongyu Sun[2] Mengyue Mei[3]

ABSTRACT

The perceived pedestrian system is not equivalent to the objective physical built environment due to multifaceted reasons, such as instantaneous traffic conditions and personal travel habits. Evaluating the comfort of a pedestrian system proves challenging when relying solely on a top-down expert perspective, as it may struggle to encompass the nuanced perceptions of individuals within the immersive environment. Conversely, adopting a bottom-up pedestrian viewpoint presents difficulties in comprehensively examining the interplay between neighbourhood spaces and traffic from a more generalized standpoint. Consequently, the actual comfort of the built environment often exhibits a gap from design expectations in diverse situations. The research employed the semi-structured interviews to gather evaluation factors of pedestrian comfort on a traditional commercial street. Factors were considered respectively from the perspectives of urban design experts and ordinary residents engaged in everyday travel. Interviewees and the evaluated street were selected from a typical 15-minute neighbourhood in Shanghai, China. Compared to the two perspectives on the evaluation factors of pedestrian comfort, the findings suggested that physiological responses, emotional perceptions and travel characteristics significantly influence on travellers' perceived comfort. In contrast to the experts' concentration on the objectivity of cause and effect of the travel, residents prioritized experiential facets, giving greater consideration to emotional perceptions such as perceived safety and convenience conveyed by physical elements. The study established a comprehensive framework for the elements and criteria of pedestrian comfort evaluation. A multifaceted perspective is advantageous in addressing the process of urban space gentrification and enhancing the neighbourhood's performance in urban transportation and travel.

Keywords: Pedestrian Comfort, Evaluation Factors, Comparative View

INTRODUCTION

Since 2023, Shanghai has adopted the 15-minute community life circle as the core concept for organizing residential spaces throughout the city. This approach seeks to reorganize urban spaces based on walking time and distance. As the physical embodiment of the 15-minute community life circle, the community pedestrian system is closely connected to daily urban life and the public

transportation network. Pedestrian comfort in traditional commercial streets is a critical factor that significantly influences urban vitality, economic sustainability, and social interaction. These streets, often rich in historical and cultural significance, serve not only as commercial hubs but also as important public spaces where people engage in a variety of activities. Increasing evidence reveals that the improvements in the built environment can facilitate pedestrians by providing more convenient transportation (Ball et al., 2001), accessible destinations (Owen et al., 2007), and well-maintained footpaths (McCormack et al., 2010), etc.

The comfort experienced by pedestrians in these environments is shaped by a complex interplay of factors, including the physical elements of the community pedestrian system (Ewing, 2009), personal characteristics of residents (Bean et al., 2008), walking behaviours and habits (Alfonzo, 2005), physiological perceptions (Wankhede et al., 2016), and psychological perceptions (Singh,2016). While the importance and relevance of different influencing factors are combined into evaluation indexes such as Walkability Index (Frank, 2009), Pedestrian Environment Index (Peiravian, 2014), and Neighbourhood Environment Walkability Scale (Cerin, 2009), there remains a gap in the comparative evaluation of these factors from the perspectives of both experts and travellers. This divergence in perspectives can lead to differing priorities and outcomes in designing and managing traditional commercial streets.

Additionally, several recent studies have linked walking with the diverse demands, activities, and purposes of residents during their travels. Individual characteristics and travel behaviours of pedestrians are closely related to the study of walking comfort. The field of architecture often focuses on the social or physiological characteristics of pedestrians, such as the elderly (Tournier et al., 2016), and children (Rothman et al., 2014). These studies typically explore the walking behaviours of specific groups and corresponding built environment design strategies. As travellers, pedestrians' travel purposes (Bohte and Maat, 2009), time of travel (Moiseeva et al., 2010), duration of travel (Ding et al., 2016), and modes of travel (Rasmussen et al., 2015) significantly influence their behaviours and perceptions while walking. Integrating walking as part of the overall travel process allows for a more systematic understanding and integration of urban public spaces, ultimately enhancing the efficiency and quality of community pedestrian systems.

This paper seeks to bridge these gaps by conducting a comprehensive analysis of the evaluation factors that influence pedestrian comfort in traditional commercial streets, comparing the views of experts and travellers. The study selected the commercial streets of the Kongjiang sub-district in Shanghai, China, as the focus for researching pedestrian comfort. By systematically reviewing previous studies on pedestrian comfort and conducting field research and design analysis, the study constructed semi-structured interviews with residents and experts who live in or near the neighborhood. The findings enabled the collection of detailed explanations and descriptions of factors affecting pedestrian comfort within the neighborhood, and provided valuable insights for the development of more inclusive and user-centered urban design strategies.

LITERATURE REVIEW

Elements of Chinese 15-min neighbourhood pedestrian system

The modern community pedestrian system is an integral part of both the road and public space networks within a community. Since 2018, China's Planning and Design Standards of Urban Residential

Area (Ministry of Housing and Urban-Rural Development of the People's Republic of China, 2018) have adopted the 15-min, 10-min, and 5-min pedestrian-scale neighbourhoods as the basis for organizing residential area. Cities such as Beijing, Shanghai, Jinan, Changsha, and Zhengzhou have incorporated 15-minute community life circle into their master plans as the fundamental unit for urban and rural resident area. In Shanghai, most 15-minute community life circles are delineated according to the administrative boundaries of sub-districts.

The community pedestrian system serves dual functions of pedestrian transportation and recreational walking. It includes roads suitable for walking and non-motorized travel, as well as pedestrian zones, paths, and public space nodes such as plazas, green spaces, and enclosed or open interaction spaces. Natural, artificial, and cultural landscape elements, along with transportation and recreational facilities and other amenities, cater to the aesthetic needs of pedestrians and support walking activities. The interaction and coordination of these networks, environments, and facilities are often reflected in the quality of pedestrian paths, road landscapes, and public spaces, thereby creating a sense of place, belonging, and participation for community residents and forming a complete community pedestrian system (Sun, 2011). Based on 15-minute community life circle, a slow traffic network comprising urban roads, greenways, and public passages needs to be constructed, to enhance the safety and comfort of pedestrian movement (Ministry of Natural Resources of the People's Republic of China, 2021).

Pedestrian comfort and its determinants

Walking, as a mode of travel in any part of a journey, is significantly influenced by factors such as distance, duration, and the quality of the walking environment, all of which impact the overall travel experience. An increasing number of scholars are now focusing on the comfort of walking behaviour and its interaction with other stages of the travel process, conducting more targeted and dynamic evaluations. A meta-analysis of factors affecting walking comfort has revealed that spatial qualities of the community pedestrian system—such as sociability, compactness, convenience, and aesthetics—as well as perceived safety and well-being, all influence walking comfort (Dadpour et al., 2016). While both subjective perceptions of pedestrians and the measurable physical qualities of the community pedestrian system can reflect walking comfort to some extent, the degree and pathways through which these factors influence walking comfort may differ.

In terms of influence degree, some scholars argue that the perceived quality of urban design may be more important for walking comfort than measurable physical characteristics themselves (Johansson et al., 2016). Perceived walkability is positively correlated with walking behaviour, while the impact of spatially measured walkability on walking behaviour is relatively small (Van der Vlugt et al., 2022). Other scholars suggest that the correlation between spatial quality and travel comfort is stronger than that of perceived spatial quality (Lin and Moudon, 2010). For vulnerable groups, destination connectivity is directly and positively related to the duration of utilitarian walking but negatively related to the duration of recreational walking, with walking behaviour being unrelated to individual perceptions of the environment (Van Dyck et al., 2013).

In terms of influence pathways, spatial quality often affects pedestrian perception, leading to different travel behaviours, which in turn result in variations in walking comfort (Ewing and Handy, 2009). More recent research, combining mobile signaling and POI data, suggests that factors such as the functional

amenities, quantity, and distance of walking destinations can indirectly influence pedestrian perception, thereby affecting travel behaviour (Qiao and Yeh, 2023). At the start and end points of a travel chain, good walkability characteristics of the pedestrian system can reduce the burden of walking and encourage low-income commuters to use public transportation more frequently (Ha et al., 2023). During the transfer stage of the travel chain, some scholars have studied the relationship between the types of roads on Bus Rapid Transit routes and citizens' perceptions of walkability and the distance walked to bus stops (Jiang et al., 2012). Others have collected environmental factors of the walking areas around subway stations at a micro-scale through citizen satisfaction surveys, analysing how the objective design quality of the pedestrian environment (Gupta et al., 2022) or the perceived subjective walkability (Gan et al., 2021) promotes subway usage.

METHOD

Through an exploratory qualitative design, semi-structured interviews were conducted from March to April 2024. We recruited a sample of individuals aged 19 to 45 who lived in the selected Kongjiang sub-district in Shanghai, China. All interviewees had participated in the Kongjiang sub-district 15-minute community life circle initiative in 2023 and had extensive and detailed knowledge of all the roads and communities within the site.

Site selection

The Kongjiang sub-district is located in the central part of Yangpu District, covering an area of 2.15 square kilometres and comprising 25 neighbourhoods (Figure 1). According to data from China's Seventh National Census, the Kongjiang sub-district has a registered population of 85,100 people across 32,500 households, with a resident population of 102,800 people (Figure 2). It represents a complete 15-minute community life circle.

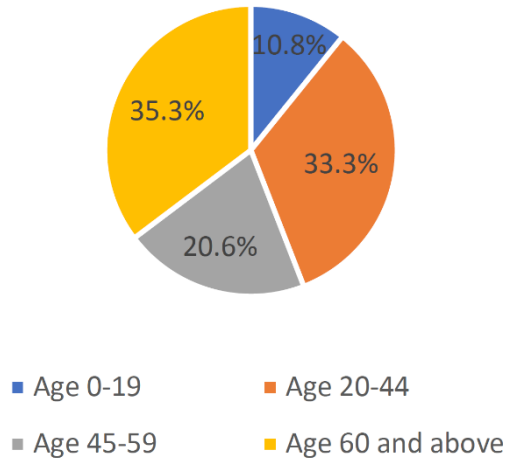

Figure 1. Location and scope of Kangjiang sub-district. Shanghai, photo credit: Author's illustration.

Figure 2. Population composition of Kangjiang sub-district. Shanghai, photo credit: Author's illustration.

The Kongjiang sub-district is intersected by Shanghai's inner ring road and contains 20 roads, with two major arterial roads running both north-south and east-west. In terms of public transportation, the sub-district is served by dozens of bus routes, and two metro lines have stations within the area. The buildings in the region are relatively small in scale, with public service facilities evenly distributed. The

land use is primarily residential, with a significant presence of commercial buildings along the streets (Figure 3). Overall, it represents a typical modern 15-minute community life circle in China.

Figure 3. Status of Kangjiang sub-district. Shanghai, photo credit: Author's illustration.

Sampling and recruitment

The study recruited two types of interviewees: experts and residents. Given that the Kongjiang sub-district includes two communities with dormitories for Tongji University students, the experts interviewed consisted of urban design scholars and urban design students, who, as residents, also brought a professional perspective. The residents interviewed included government officials and ordinary citizens, with government officials increasingly involved in community planning due to the promotion of the 15-minute community life circle.

During the preliminary 15-minute community life circle project, our design team found that residents under 18 and over 60 years of age typically have more singular travel needs, which do not cover a range of scenarios such as commuting, shopping, medical visits, and leisure activities. Therefore, the sample included 5 experts and 5 residents, aged between 25 and 60 years. All interviewees held a university degree or higher. More than half of the interviewees averaged between 5,000 and 10,000 steps or more per day (n=7). Further details of the sample are shown in Table 1.

Table 1. Participant characteristics. Source:

Number	Identity	Sexual	Age	Daily steps

Data collection and analysis

The study's semi-structured interviews were designed with 10 questions regarding pedestrian comfort during the travel process in the Kongjiang sub-district. Each question required the interviewees to answer individually. Interviewers strictly followed the outlined questions during the interviews but could adjust the approach depending on the interviewees ' specific situations.

Data were collected through face-to-face and telephone interviews conducted by the authors, who had prior training and experience in qualitative interviewing. During the interviews, the author informed interviewees of the necessity of recording and obtained their consent. It was assured that respondents' identities would be replaced with letters, and any sensitive information would be deleted during the later stages of data use. Within 24 hours after each interview, the recordings were transcribed, and the author organized the records, thereby completing the initial interview process.

The study utilized Colaizzi's seven-step phenomenological method to analyse the interview data (Colaizzi, 1978). This process involved carefully reading the interview transcripts to identify statements of significant meaning, coding recurring significant statements, and summarizing the coded points. Using detailed and comprehensive descriptions, similar viewpoints were identified, and key thematic concepts were refined. Any ambiguous points were verified by returning to the interviewees for clarification. The interview content from the same respondent was independently analysed by two authors, and the results were compared and synthesized to summarize the themes.

RESULTS AND DISCUSSIONS

Theme one: Public transport-led travel mode choice

Interviewees described their daily travel modes for different purposes such as commuting or school, shopping, medical visits, and leisure, and they identified the stages where walking most frequently occurred within these various travel modes. The interviewees consistently reported that the subway and private cars remained the dominant modes of transportation, with walking often serving as a means to access these other modes of travel. Additionally, for traditional Chinese communities, electric scooters were also highlighted by respondents as an essential tool for daily travel.

"The electric scooter parking is right below my building, and the weather in Shanghai always doesn't motivate me to walk. I only walk when heading to the subway station or a designated pick-up point,

and usually for no more than 3-5 minutes." (No.3, Urban design expert, male, daily step count: 0-5,000)

"I believe health is essential, so I choose to commute by bike, usually taking 10 minutes to get from my dormitory to the studio. The distance and time needed to find a shared bike while walking are quite variable, but I find it healthier this way. I only choose ride-hailing services when in a hurry, such as when going to the doctor." (No.1, Urban design student, female, daily step count: 5,000-10,000)

"Ever since I got an electric vehicle, all my various trips have been by car, and walking only occurs when getting in and out of the car. However, in my work, there are many times when I have to walk to communities." (No.8, Government official, male, daily step count: 5,000-10,000)

"I specifically rent a house close to my company or a subway station, so I can control my arrival time at the office by walking. If it's within one subway stop, I usually opt for a shared bike, and if it's farther, I only take a taxi." (No.6, Resident, male, daily step count: 5,000-10,000)

In the choice of travel modes, there was no significant difference between interviewees; the decision to walk or not was primarily influenced by the availability of vehicles and commuting distance. Walking in the community often occurred while heading to or transferring between public transportation, highlighting the importance of paying attention to pedestrian comfort on these routes.

Theme two: Safe, shaded and convenient places for pedestrian

Interviewees described the types of places where walking typically occurred in their daily routines and identified locations and reasons that contributed to uncomfortable walking experiences. For most daily travel, urban roads outside the community were primarily used, but for interviewees who seldom walk for travel (n=4), sidewalks and public spaces within the community were significant walking areas. The most frequently mentioned causes of discomfort during walking included chaotic and unsafe traffic conditions (n=7), a lack of shade (n=6), and the need to navigate stairs (n=5).

"I don't find it necessary to walk within the community and even tend to dislike it. If I must walk, I prefer public spaces outside the community that offer higher spatial quality." (No.3, Urban design expert, male, daily step count: 0-5,000)

"My walking is always purposeful, so I mainly walk along sidewalks inside and outside the community. I think safety and efficiency are most important, and I particularly dislike having vehicles pass by when I'm walking." (No.7, Resident, female, daily step count: 5,000-10,000)

"Since my daily routine is a straight line between work and home, my walking occurs only within the community. Our community has great landscaping, and I enjoy strolling within it. However, I find it very unpleasant when cars occupy the open space in front of buildings." (No.9, Government official, female, daily step count: 10,000-15,000)

When describing the reasons for discomfort, urban design experts were noticeably quicker and more accurate in identifying specific causes compared to ordinary travellers. However, both groups shared a primary concern for pedestrian safety at crosswalks. Moreover, crosswalks, subway transfer

corridors, overpasses, and similar locations should remain focal points for improving walking comfort, supporting the previous theme that walking primarily occurs near public transportation.

Theme three: The divergence in perspectives of pedestrian comfort's evaluation factors

Interviewees were asked to describe the importance of various evaluation factors related to pedestrian comfort. According to the literature review, these evaluation factors includen emotional perceptions during walking, physiological responses during walking, walking characteristics, physical spatial features of the community, personal characteristics, and travel characteristics.

Walking characteristics (such as distance, duration, and whether walking alone) were considered the most important evaluation factors by the majority of interviewees (n=6). In contrast, personal characteristics (such as attitudes towards walking and physical condition) were deemed the least important by most interviewees (n=6). Additionally, interviewees consistently prioritized physiological responses over emotional perceptions in terms of their impact on comfort. Interestingly, the spatial features of the community (such as convenience, aesthetics, and cleanliness) were rated as moderately important (n=6), with interviewees offering somewhat ambiguous negative evaluations.

"If the walking distance exceeds my psychological expectation, I will choose another mode of transportation... this threshold is about 5-10 minutes." (No.6, Resident, male, 5,000-10,000 steps)

"I don't intentionally focus on the surrounding environment because my mood and body will tell me whether I'm comfortable. The purpose of the walk subconsciously shapes my expectations, leading me to either a good or bad mood." (No.1, Urban design student, female, daily step count: 5,000-10,000)

To better understand the differences in opinions between residents and experts, the study assigned importance scores weighting from 6 (most important) to 1 (least important) based on the rankings. The importance score for each evaluation factor was then calculated (Formula 1). Further details of the sample are shown in Table 2.

$$\text{Influence factor importance score} = (\Sigma \text{ frequency} \times \text{weight}) / 10 \quad \text{(Formula 1)}$$

Table 2. Influence factor importance score.

Influence factor	Comprehensive score	Resident score	Expert score
walking characteristics	5	5	5
physiological responses	4.2	4.6	3.8
travel characteristics	3.5	2.2	4.8
emotional perceptions	3.4	4.2	2.6
spatial features	2.8	2.8	2.8
personal characteristics	2.1	2.2	2.0

Before the interviews began, participants were informed to consider walking as a segment of the overall travel experience. Despite this, differences remained between experts and residents in their understanding of travel characteristics and the role they play. Residents believed that physiological responses and emotional perceptions during walking had a greater impact on comfort, but they generally did not consider travel characteristics to be important. They repeatedly mentioned physical

spatial elements such as greenery, noise, and shade in the walking environment, but their focus was on the personal perceptions these elements elicited rather than the elements themselves.

"As long as there's enough shade and little noise during my walk, I can remain physically and mentally comfortable." (No.10, Government staff, female, daily step count: 5,000-10,000)

"What I hate most is sweating during a walk, so I try to walk as little as possible in an environment that's as pleasant as possible……walking with someone I like greatly influences my comfort." (No.7, Resident, female, daily step count 0-5,000)

Experts, on the other hand, were more focused on travel characteristics and physiological responses but paid less attention to emotional perceptions. They generally agreed that studying the impact of travel characteristics on walking comfort is necessary, as experience suggests that these characteristics subconsciously influence perceptions even before the walk begins.

"Before setting out, I make sure to note which parts of the journey will involve walking, and whether my trip is for something positive or negative affects my view of the walk. In short, my mood is predetermined before I start walking, but my physiological responses may vary." (No.2, Urban design student, female, daily step count: 0-5,000)

"I also have some preconceived notions about walking before I set out, but I'm open to enjoying the walk and observing the positive features of the road and environment, which may lead to new emotions." (No.4, Urban design expert, female, daily step count: 5,000-10,000)

Notably, in addition to the six categories of influencing factors provided to participants, weather conditions (n=6), such as temperature and humidity, were most frequently mentioned by both groups as important factors affecting walking comfort. This underscores that physiological comfort is a fundamental aspect of participants' understanding of walking comfort.

Theme four: The most comfortable commercial street

The study selected 12 iconic roads from the Kongjiang sub-district, including main roads, secondary roads, and internal community roads (Figure 4). Interviewees were shown street-view images of these roads in pairs and were asked to recall their walking experiences on each. In the paired comparison, the more comfortable road was assigned a value of 1, while the other was assigned a value of 0. The comfort ratings for all roads were then compiled based on these comparisons (Table 3).

Table 3. Influence factor importance score.

Roads	Comprehensive score	Variance(s^2)	Experts' average	Variance(s^2)	Residents' average	Variance(s^2)
Huangxing road	2.2	0.40	2.2	0.7	2.2	0.2
Songhuajiang road	0.8	0.40	1	0.5	0.6	0.3
Jiangpu road	1.2	1.07	0.8	0.7	1.6	1.3
Kongjiang road	1.8	1.51	2	2	1.6	1.3
Changling road	1.3	1.79	1.4	2.3	1.2	1.7
Shuangyang road	1.9	1.21	1.2	0.7	2.6	0.8
Yanjixi road	1.3	0.90	1.8	0.7	0.8	0.7
Yuanquan road	1.5	0.94	1.6	1.8	1.4	0.3
The First Kongjiang Cun	1.4	0.71	1.4	0.8	1.4	0.8

Wang Chun Jia Yuan	0.7	0.68	0.6	0.8	0.8	0.8
The new fengcheng	2.7	0.23	2.8	0.2	2.6	0.2
The second fengcheng cun	1.2	0.84	1.2	0.7	1.2	0.7

Figure 4. The selected subjects for the comfort evaluation. Shanghai, photo credit: Author's illustration.

Subtheme: Main road

Both the expert and resident participants consistently identified Huangxing Road as the most comfortable main road (s^2=0.4), particularly among the majority of residents. The difference between the two groups emerged in identifying the least comfortable road: experts pointed to Jiangpu Road (s^2=0.7), while residents considered Songhuajiang Road to be the least comfortable (s^2=0.3). Overall, Songhuajiang Road was regarded as the least comfortable by the respondents (Figure 5).

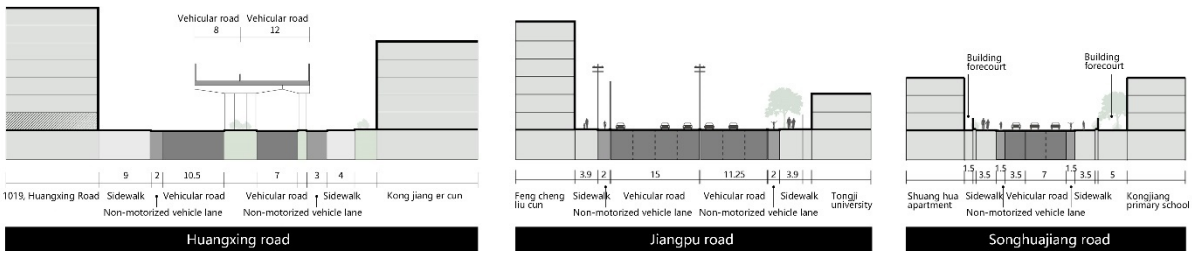

Figure 5. Three representative main roads. Shanghai, photo credit: Author's illustration.

"The sanitation on Songhuajiang Road is quite poor; I often step on something dirty on my way to and from work." (No.9, Government official, female, daily step count: 10,000-15,000)

"Huangxing Road may have an overpass, but the greenery is well-maintained, and I can barely see the overpass in my line of sight … Jiangpu Road feels too open, almost deserted." (No.7, Resident, female, daily step count: 0-5000)

Subtheme: Secondary main road and branch road

When considering experts and residents as a whole, the comfort of the four selected secondary main roads and branch roads were quite similar. However, the majority of residents identified Shuangyang Road as the most comfortable (Figure 6).

"The comfort of Shuangyang Road comes from a sense of familiarity, which is the most important spirit in our Chinese communities... Good neighbourly relationships are very important." (No.5, Urban design expert, female, daily step count: 5,000-10,000)

Figure 6. Shuangyang road. Shanghai, photo credit: Author's illustration.

Shuangyang Road is lined with numerous grocery stores located on the ground floor of residential buildings, providing considerable convenience to residents. At several key intersections, small landscape features have been installed at street corners, offering visual comfort to pedestrians. Additionally, certain sections of the road have been equipped with reversible lanes, which help prevent congestion during peak hours, keeping noise levels relatively low. The Chinese-style neighbourhood relations are largely fostered by the close connection between these grocery stores and residents' daily lives. The shop owners and residents are often neighbours, and this repetitive commercial interaction has shaped a modern Chinese community commercial street.

Subtheme: Intra-community road

The study selected four communities— the First Kongjiang Cun, Xin Feng Cheng, Wangchun Jiayuan, and the Second Fengcheng Cun—each differing in their time of construction and population composition. Both the interviewed experts and residents unanimously found the internal roads of Xin Feng Cheng to be the most comfortable for walking (s^2=0.23), while the internal roads of the Second Feng Cheng Cun were deemed the least comfortable (s^2=0.68) (Figure 7).

"During our work on the 15-minute community life circle project, we found that in communities named with cun, the internal roads are often uneven, and there is a common occurrence of mixed traffic between pedestrians and vehicles. The outdated building facades along the roadsides and poorly managed greenery also fail to provide visual comfort within the pedestrian's line of sight," (No. 4, Urban design expert, female, daily steps 5,000–10,000).

Figure 7. Two differentiated intra-community road. Shanghai, photo credit: Author's illustration.

The New Fengcheng community is one of the few mixed-type communities within the Shanghai inner ring road, featuring townhouses, high-rise buildings, and hotel-style apartments. Completed in 2005, it is considered one of the higher-quality residential developments in Yangpu District. The section of Kongjiang Road where this community is located is quiet, with lush greenery that provides a tranquil environment amidst the bustling city.

The Second Fengcheng Cun community is a typical worker's new community built in Shanghai during the 1950s. Yangpu District, being a hub for industry with a large working-class population, hosted four of the nine worker's new community sites in the city's "20,000 Workers' Housing Units" project, with a total of 10,000 units in Yangpu alone. From the first through the fourth Fengcheng Cun are exemplary of this type of community. When these workers' new communities were built, housing was arranged in clusters of 100-200 units, with 4-5 acres of open space reserved for public green areas and activity spaces; each new community of 1,000-2,000 units was equipped with comprehensive public facilities. However, due to the age of these developments, the living environment in such communities has become relatively outdated compared to current living standards. During the 15-minute community life circle renovation process, there have been numerous complaints from residents regarding the quality of the community environment.

Discussion

The semi-structured interviews revealed several key insights into pedestrian comfort within the Kongjiang neighborhood, highlighting the interplay between travel mode choices, the crucial quality of comfort pedestrian places, and the divergence in pedestrian comfort evaluation factors between experts and residents. Respondents also rated the streets they thought were the most and least comfortable. A significant finding is that pedestrians usually connect between transportation modes like subways, private cars, and electric vehicles. This reliance on motorized and public transport highlights the urgent need for enhancing the comfort of pedestrian infrastructure, particularly in areas around transport hubs and crosswalks. Due to the lack of consideration for safety, convenience, and shade, these interviewees rated these transfer places near the transportation hubs as the most uncomfortable places at present.

The divergence in evaluation factors between the two groups is particularly telling. While residents prioritize immediate, sensory experiences—such as the impact of greenery, noise, and weather—experts lean towards objectivity of cause and effect like travel characteristics and physiological responses. Residents considered the most comfortable commercial streets to be those characterized by a strong sense of community spirit and well-maintained greenery. This gap underscores the importance of integrating both subjective and objective elements in urban planning to create pedestrian environments that are not only functional but also emotionally satisfying.

CONCLUSIONS

This study explored the evaluation factors of pedestrian comfort on traditional commercial streets within a 15-minute neighbourhood in Shanghai, comparing the perspectives of urban design experts and residents. By utilizing semi-structured interviews, the findings highlight that walking characteristics and physiological responses significantly influence perceived comfort among travellers. Experts tend to focus more on the travel characteristics and physiological response in walking, while traveling residents prioritize experiential factors, such as perceived safety and convenience.

The research underscores the importance of considering both expert and travellers' viewpoints to create a more comprehensive evaluation framework for pedestrian comfort. By bridging the gap between these perspectives, urban planners can develop more effective, inclusive, and user-centered strategies for the design and management of traditional commercial streets. This approach not only enhances the pedestrian experience but also supports the broader goals of urban vitality, economic sustainability, and social interaction in these culturally and historically significant spaces.

Future research could extend this study by exploring pedestrian comfort in different types of travel destinations to understand how different contexts influence comfort perceptions. Additionally, quantitative methods, such as large-scale surveys or sensor-based assessments of pedestrian movement and behaviour, could complement the qualitative findings, providing a more comprehensive understanding of pedestrian comfort.

ABSTRACT

Streets, as an important component of urban public space, have received increasing attention for their spatial quality. Pedestrian-friendliness is one of the core connotations of street spatial quality in the street design guidelines issued in major cities around the world, such as London, New York, Shanghai and Shenzhen (Jiang et al.,2012; Chen et al.,2017). Scholars in different fields have developed frameworks of evaluating and analysing the pedestrian-oriented street spatial quality in the overall city scale and proposed reference for design strategies (Long & Tang, 2019; Marvin et al.,2019; Lu & Tan, 2019; Istrate & Chen, 2022). Meanwhile, living street is one typical street carrying the daily activities of local residents. It is of great importance to study the relationship between the physical environment of living street space and people's walking behaviours for contributing a walking-friendly city.

This paper aims to explore the interaction between the psychological perceptions of residents and the built environment of the living streets. Two typical open residential areas in Shenzhen, totalling 18 streets, were selected. It firstly develops a morphological framework of measuring the physical environment of street space, which includes twenty indicators in four categories: street morphology, street function, street traffic and street greening. Meanwhile, semantic differential (SD), structured Interviews and Questionnaires are used to investigate the psychological perceptions of the residents. 17 pairs of adjectives are used in the SD questionnaire. Factor analysis is used to extract the common metrics in the SD evaluation. Correlation analysis is then adopted to explain the relationship between the indicators of living streets morphology and resident's perceptions. Based on this, suggestions could be provided to enhance street built environment that could be more vibrant and pedestrian-friendly. It is hoped that the improved understandings of this underlying relationship would provide reference for proposing pedestrian-friendliness design strategies for living street space in the future.

Keywords: Living street space, Open residential district, Pedestrian friendliness, Street morphology, Semantic differential

INTRODUCTION

Recently, the quality of pedestrian-oriented street spaces has garnered increasing attention. Cities such as London, New York, Shanghai, and Shenzhen have successively issued urban design guidelines, street design manuals, and relevant policies that emphasize the importance of enhancing street quality (Jiang et al., 2012; Chen et al., 2017). Living street refers to an urban road within a residential area where more than 60% of the land on both sides of the street is used for residential purposes, and the shops on both sides of the street are mainly focused on catering and lifestyle services. These living streets, as the most frequently utilized spatial carriers for residents' daily commutes, leisure travel, and various life activities, not only fulfill the function of facilitating traffic but also create socially significant spaces for community interaction. However, many streets face issues such as unreasonable scales, monotonous spatial experiences, and uncomfortable pedestrian environments. Given the current shift in urban environmental construction from "incremental development" to "stock renewal," exploring street space environment issues in residential blocks based on residents' subjective perceptions is of great theoretical and practical significance for creating pedestrian-friendly street spaces and pedestrian-friendly cities.

Pedestrian friendliness is a crucial attribute for measuring street space quality. Experts and scholars from various fields have explored methods for evaluating and optimizing street space pedestrian environments from multiple perspectives. Many studies on street walkability focus on the meso- and macro-levels, examining how walkable environmental factors and built environment elements affect residents' walking behavior (Cervero et al., 1997; Koohsari et al., 2015). Other researchers have delved into the micro-level, investigating how street space forms, scales, streetscape features, and municipal facilities impact pedestrian behavior (Jaskiewicz et al., 2000; Dover et al., 2014; Yin et al., 2016). Given that living streets in residential blocks are crucial public spaces and important carriers of public activities, it is essential to study the relationship between street space form elements and pedestrian behavior from the perspective of urban design, based on residents' subjective perceptions and at the meso- and micro-scales. Unlike residential areas in other Chinese cities that, before the 1980s, experienced closed management due to the planned economy’s danwei (work unit) courtyard model, Shenzhen’s residential neighborhoods during this period did not fully implement property management and gated access control. Consequently, some residential neighborhood streets can be shared with the city, and the well-developed surrounding retail commercial facilities make these open residential areas more vibrant and dynamic. Therefore, this paper focuses on the type of open residential districts in Shenzhen, aiming to study the impact mechanisms of the built environment of living streets on residents' subjective perceptions. The goal is to provide recommendations for creating pedestrian-friendly street spaces and building pedestrian-friendly cities.

METHODOLOGICAL FRAMEWORK

This paper firstly conducts field research and resident interviews on open residential areas in Shenzhen, and conducts preliminary data collection. Next, a framework for measuring the built environment of living streets in open residential districts in Shenzhen was constructed, including street morphology, street function, street traffic and street greening. And then the semantic

differential method is used to analyse residents' psychological subjective perception evaluations. Evaluation factors are firstly selected, and adjustments are made based on the pre-survey results from residents' on-site questionnaires and the subjective evaluation factors for pedestrian-friendliness are determined. Factor analysis is then further applied to cluster the evaluation factors, leading to the identification of the principal components of residents' perception evaluations. Finally the relationship between pedestrian's psychological perceptions and the physical environment of street space was explored. Key environmental factors influencing residents' walking experiences were identified, which could provide reference for design strategies to enhance the walkability of living streets.

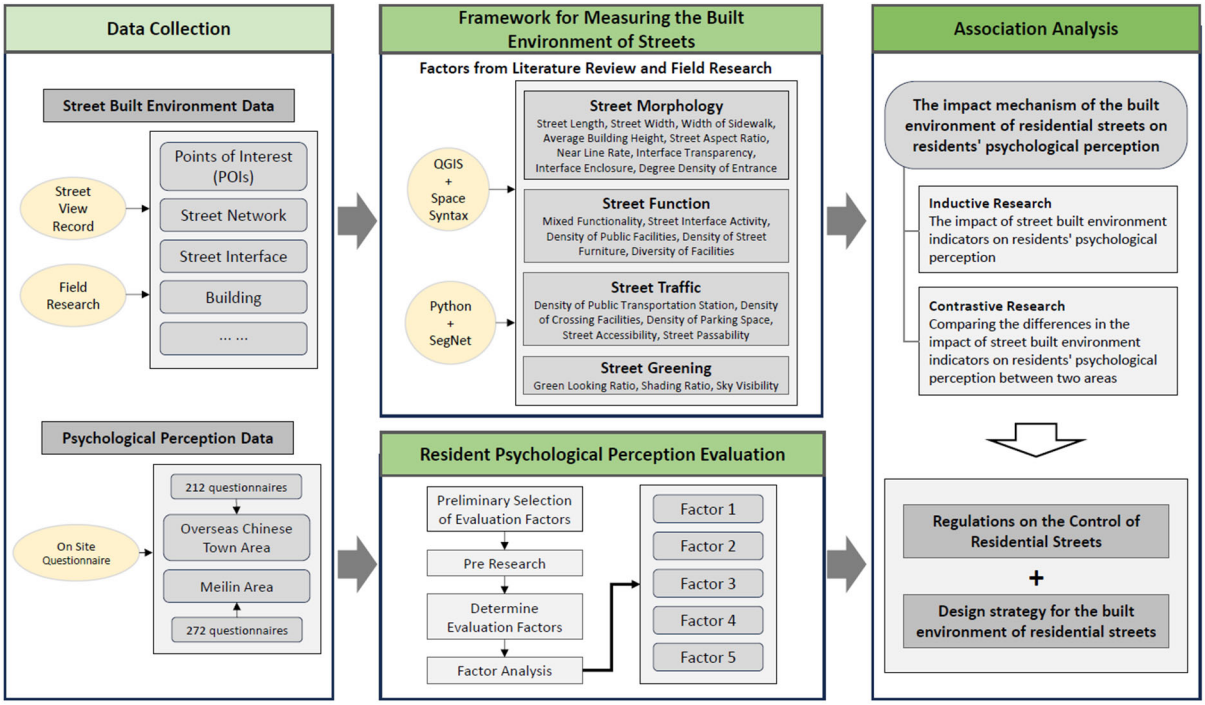

Figure 1. The framework of the study.

Psychological perceptions of pedestrian friendliness

A questionnaire survey was conducted using the semantic differential method (SD) to assess pedestrians' psychological perceptions. Semantic differential Proposed by Charles E. Osgood in the 1950s, it measures attitudes using bipolar adjective scales. It is usually used to measure people's experience with a product or a scenario (Osgood et al., 1957). Factor analysis was employed to determine the psychological evaluation structure of pedestrians regarding the streets and to calculate evaluation scores for each street based on common factors, thereby quantifying residents' subjective assessments of the streets at different levels. Factor analysis is a statistical method used to extract common factors from a group of variables with overlapping information. It is primarily applied when the number of variables is large and there is a certain degree of correlation among them. By studying the relationships between these variables, it groups strongly correlated variables into categories, thereby significantly reducing the number of variables and summarizing new factors that reflect the majority of the original information (Bartholomew, D. J.,1995) .

Based on the characteristics of open residential districts in Shenzhen, this study considers the impact of street spatial environment, atmosphere creation, and attractiveness on pedestrian behavior and

psychology. Drawing on the research of several scholars (Zhang, 2000; Dover et al., 2014; Yin et al., 2016) and through a pre-survey questionnaire, 17 adjective pairs were ultimately selected as subjective evaluation factors. These factors include: Satisfaction level, Walking Comfort, Quietness, Sense of Liveliness, Attractiveness, Space Openness, Convenience, Continuity, Greening Richness, Activity Richness, Interface Neatness, Functional Completeness, Safety, Tree Shading Coverage, Facility Completeness, Willingness to Linger, and Daily Communication Frequency. Each evaluation factor was assigned a 5-point rating scale: very poor, poor, average, good, and very good, corresponding to scores of -2, -1, 0, 1, and 2, respectively.The survey was conducted using an interview-style questionnaire approach. A total of 25 questionnaires were planned for each street, amounting to 450 questionnaires in total. Ultimately, 212 valid questionnaires were collected from the OCT area and 272 from the Meilin area, achieving a response rate of 97%. The demographic structure of the respondents in both areas was similar, with each demographic proportion closely aligning with the overall statistical averages.

Physical environment of street space

The framework for measuring the built environment of streets includes data on four spatial attributes: street morphology, street function, street traffic, and street greening (Li et al.,2019; Shi et al.,2020). The definition and quantification methods of various built environment indicators are shown in Table2. For the built environment survey, data on spatial elements were obtained by using CAD topographic maps as the base material, supplemented by field surveys for data correction. The survey content covers four sub-indicators: street morphology, street traffic, street function, and street greening.

Table 2. Definition and quantification of built environment indicators

Dimension	Indicator	Concept Definition	Measurement Method
Street Morphology	Street Length	Pedestrian average crossing width.	——
	Street Width	Total street segment length of the sample street.	____
	Width of Sidewalk	Sidewalk width of the sample street.	$w_a = S_a \,/\, 2L$ S_a represents the effective sidewalk area. L is the street segment length.
	Average Building Height	Average facade height of street interface.	$H_a = \frac{\sum_{i=1}^{n} s_i}{2L}$ S_i represents the street-facing facade area of building i. L is the street segment length.
	Street Aspect Ratio	Weighted ratio of building height to street width.	$P_i = \sum_{i=1}^{n} h_i \times l_i \,/\, d_i \times L$ h_i represents the height of building i along the street, l_i is the street-facing length of building i, d_i is the distance from the building i to the road centerline, and L is the street segment length.
	Near Line Rate	Represents the proximity of the street interface to the street boundary, or the degree of concavity and convexity of the interface.	$N' = \frac{\sum_{g=1}^{n} s_g}{\sum_{j=1}^{m} s_j + \sum_{g=1}^{n} s_g} \times 100\%$ n is the number of street segments divided by the variation in distance between the street-side interface and the boundary, s_g i is the area between the smallest boundary distance interface and the boundary across segments. m is the number of segments with the smallest distance between the interface

			and boundary, s_i is the area between the side interface and the nearest interface in different segments.
	Interface Transparency	The visual openness or closure of the buildings or enclosed interface on both sides of the street to pedestrian.	$C = \frac{0 \times a_1 + 0.5 \times a_2 + 1 \times a_3}{L}$ a_1, a_2, and a_3 represent the lengths of closed, semi-closed, and open interfaces. L is the street segment length.
	Interface Enclosure Degree	Calculate the proportion of buildings, walls, columns, and fences in the street view image.	$V_e = \frac{B_n + W_n + S_n + F_n}{A_n}$ B_n is the number of pixels for buildings in the image, W_n is the number of pixels for walls, S_n is the number of pixels for columns, F_n is the number of pixels for fences, and A_n represents the total number of pixels in the image.
	Density of Entrance	Ratio of the number of entrances along the street to the street length.	$D_e = S_e / L$ S_e is the number of entrances. L is the street segment length.
Street Function	Mixed Functionality	The balance of types and quantities of functional facilities along the street; quantified using the information entropy of functions.	$J = \frac{H}{H_m} = -\frac{\sum_{i=1}^{n} P_i \ln P_i}{\ln N}$ J represents the mixed functionality index, P_i is the percentage of different functional areas of street-facing buildings relative to the total area, and N is the number of functional categories.
	Street Interface Activity	Percentage of commercial interface length along the street.	$P_C = L_C / 2L$ L_C is the total length of commercial building facades on both sides. L is the street segment length.
	Density of Public Facilities	Number of public activity facilities per unit length of the street.	$D_f = N_f / 2L$ N_f represents the number of public activity facilities along the street, including outdoor spaces such as plazas, parks, courtyards adjacent to the street boundary. L is the street segment length.
	Density of Street Furniture	Density of functional street furniture per unit length of street, including seating, phone booths, vending machines, and sanitation facilities.	$D_sf = N_sf / 2L$ N_{sf} is the number of street furniture within the street area. L is the street segment length.
	Diversity of Facilities	Calculate the variety and number of different types of facilities to obtain a comprehensive evaluation value.	$H' = -\sum_{i=1}^{S} \frac{n_i}{N} \cdot \log_2\left(\frac{n_i}{N}\right)$ s is the total number of facility types, n_i is the quantity of the i-th facility type, and N is the total number of all facility types.
Street Traffic	Density of Public Transportation Station	Number of public transportation stations per unit length of street.	$D_t = N_t / L$ N_t is the number of bus stops and entrances of rail transit stations in the street. L is the street segment length.
	Street Accessibility	Measure of street network accessibility using 800-meter angular integration from space syntax.	$NAIN = \frac{NC\text{^}1.2}{TD + 2}$ NC is T1024 Node Count R800 metric. TD is T1024 Total Depth R800 metric.
	Street Passability	Measure of street network passability using 800-meter angular choice from space syntax.	$NACH = \frac{\log_2(Ch + 1)}{\log_2(TD + 3)}$ Ch is T1024 Choice R800 metric. TD is T1024 Total Depth R800 metric.
	Density of Crossing Facilities	Number of crossing facilities such as pedestrian crosswalks per unit length of street	$D_c = N_c / L$ N_c represents the number of crossing facilities, and L is the street segment length.
	Density of Parking Space	Number of parking spaces per unit length of street.	$D_p = N_p / L$ N_p is the number of parking areas along the street. L is the street segment length.
Street Greening	Green Looking Ratio	Based on street view image data, use image semantic segmentation with Segnet technology to extract the average proportion of greenery elements in pedestrian recognition	$V_g = \sum_{i=1}^{N} P_g / P$ P_g represents the greenery elements in pedestrian view images. P represents all elements in the pedestrian view images.

	images taken at 21-meter intervals on each street.	
Shading Ratio	Shading area ratio of tree canopy vertical projection along the street.	$D_s = S_S / S$ S_S is the shading area of tree canopy vertical projection. S is the street area.
Sky Visibility	Based on street view image data, use image semantic segmentation with Segnet technology to extract the average proportion of sky elements in pedestrian recognition images taken at 21-meter intervals on each street	$V_s = \sum_{i=1}^{N} P_S/P$ P_S is the sky elements in pedestrian view images. P is all elements in the pedestrian view images.

Correlation analysis between psychological perceptions of pedestrian friendliness and built environment

This study first employed principal component analysis (PCA) to simplify the multiple variables related to residents' perceptions of pedestrian friendliness. As a type of factor analysis, PCA reduces the dimensionality of the original variables by extracting uncorrelated principal components, thereby simplifying the data structure while retaining the main information of the original data and effectively avoiding multicollinearity issues. Compared to other factor analysis methods, PCA is more data-driven and does not require assumptions about latent factors. Therefore, by analyzing the SD factor data on residents' pedestrian friendliness, this study extracted several principal components that reflect residents' perceptions of pedestrian friendliness, which served as the dependent variables for the subsequent correlation analysis.

Following this, Pearson correlation analysis was used to explore the relationship between built environment indicators of livable streets and the principal components of residents' perceptions of pedestrian friendliness. Pearson correlation analysis quantifies the strength and direction of the linear relationships between these variables by calculating the correlation coefficient between each street environment indicator and the principal components of pedestrian friendliness. This analysis helped identify key street environment factors that significantly influence perceptions of pedestrian friendliness. These factors provide further insights into how the built environment affects residents' walking experiences, offering guidance for optimizing street design and improving pedestrian environments.

Case: two residential districts

This paper focuses on the type of open residential districts in Shenzhen. The first one, Overseas Chinese Town (OCT) area, is located in Nanshan District, Shenzhen. It was built in the 1980s and underwent large-scale planning, design, and unified construction in the early stages of construction. The residential area is shown in Figure 1, covering approximately 70 hectares. The residential buildings in each plot are mainly 7-9 story multi story buildings with high building density. This article selected 8 residential streets with typical spatial characteristics as research samples (A1-A8, see Figure 1,2 and Table 1).The second one, Meilin District, is located in Futian District, Shenzhen. It was built in the late 1980s to early 1990s and was one of the urban construction projects carried out during the early stages of Shenzhen's reform and opening up. The residential area is shown in Figure 2, covering approximately 130 hectares. Unlike the OCT area, the Meilin area is influenced by multiple developers

who develop and construct land parcels and time periods, and has more diverse contact information with other residential areas. This article selected 10 residential streets with typical spatial characteristics as research samples (B1-B10, see Figure 3,4 and Table 1).

DATA STATISTICS AND PRELIMINARY ANALYSIS

Psychological perceptions assessment of pedestrian friendliness

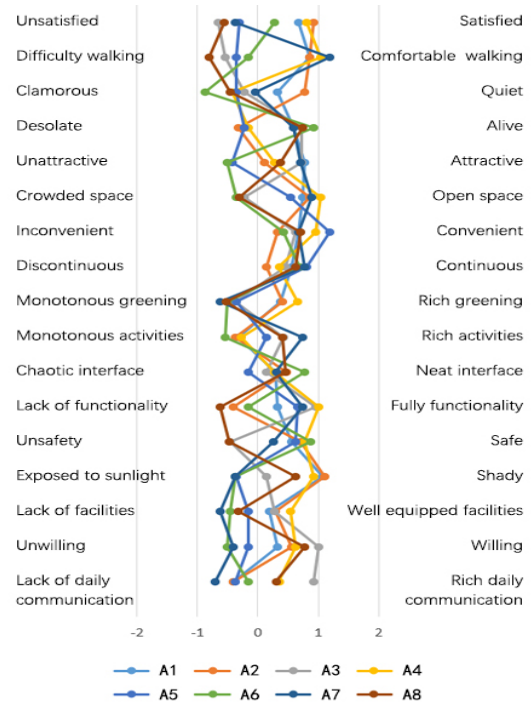

Figure 5. Evaluation curve of street design in sample Streets of the OCT district (SD)

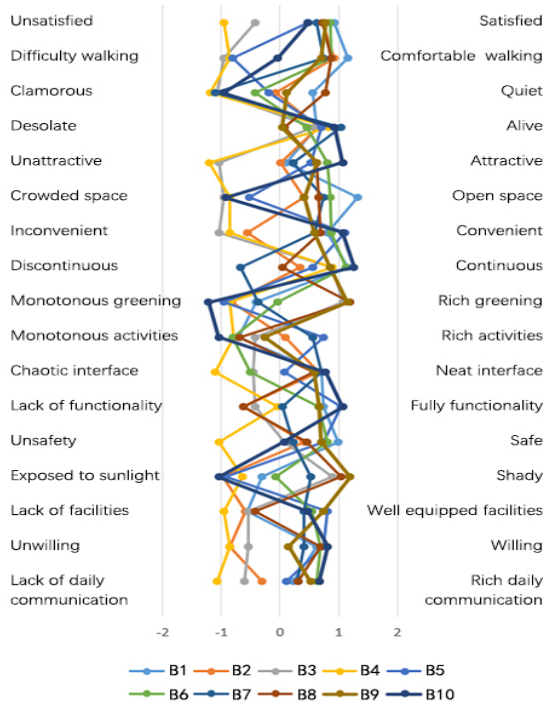

Figure 6. Evaluation curve of street design in sample Streets of the Meilin district (SD)

The statistical analysis of the survey data resulted in the SD measurement tables for pedestrians' spatial perceptions of each street (Figures 6 and 7). The average scores for various attributes mostly range between 0 and 1, indicating that the subjective perception of walkability in the livable streets within the study area is generally at a moderately favorable level. By comparing the scores of streets in the two areas, it is evident that pedestrian satisfaction in the Meilin area is slightly higher than in the OCT area. Specifically, Meilin scores slightly higher in attributes such as attractiveness, space openness, convenience, continuity, landscape richness, safety, and tree shading coverage, reflecting a certain level of recognition for Meilin's efforts in pedestrian space scale and streetscape construction. On the other hand, the OCT area scores slightly higher in factors such as walking comfort, quietness, sense of liveliness, activity richness, interface neatness, functional completeness, facility completeness, willingness to linger, and daily communication frequency. This suggests that the OCT area has some advantages in terms of resident participation in activities and the adequacy of living facilities. Additionally, there is considerable variation in the spatial characteristics and levels of recognition among the streets within Meilin.

Furthermore, a longitudinal comparison of the evaluation attributes reveals a noticeable differentiation among them, with some attributes exhibiting relatively high or low values. For instance, despite being renowned for its greenery, the OCT area has a negative mean score for greening richness. These results indicate that the influence of the built street environment on residents' psychological perceptions requires further investigation.

Built environment measurement

For the data of built environment, after sorting out the built environment data of all streets, it was found that the streets in the two areas were quite different in terms of construction scale and size.

The overall street scale of OCT was larger, the buildings were low, and it was relatively open. The street scale of Meilin area was relatively narrow, but the layout of store functions, public facilities, street furniture, etc. was richer.

In terms of street greening, the overall green looking rate and shading rate of OCT Area are higher than those of Mei-lin Area, while the overall sky visibility is slightly lower than that of Meilin Area. A1 and B8 are the streets with the highest green view rate in the area, while A6 and B6 are the streets with the lowest green view rate in the area. From their street view images, you can clearly feel the difference in the experience of walking in them. The same is true for the analysis of sky view rate.

RESULTS AND DISCUSSIONS

SD factor analysis of pedestrian friendliness

In this study, sixteen variables, excluding satisfaction, were distilled into five principal components with eigenvalues greater than 1 (Table 3). Using SPSS software, the initial eigenvalues, variances, and cumulative variances of the five factors were calculated. The results show that these five principal components explain a cumulative variance of 72.494%, indicating that the five factors extracted from the 16 original variables can reasonably explain the perception of walkability in the living streets.

Factor 1 includes six evaluation variables: daily communication frequency, willingness to linger, facility completeness, functional completeness, attractiveness, and convenience. This factor primarily describes the degree to which various functional attributes and facilities support residents' social interactions and engagement, and is thus named the "Social Interaction" factor. Factor 2 includes five evaluation variables: walking comfort, space openness, quietness, safety, and interface neatness. This factor focuses on the overall pedestrian experience within the street environment, encompassing both psychological safety and physical comfort, and is therefore named the "Pedestrian Environment" factor. Factor 3 includes two evaluation variables: landscape richness and tree shading coverage. This

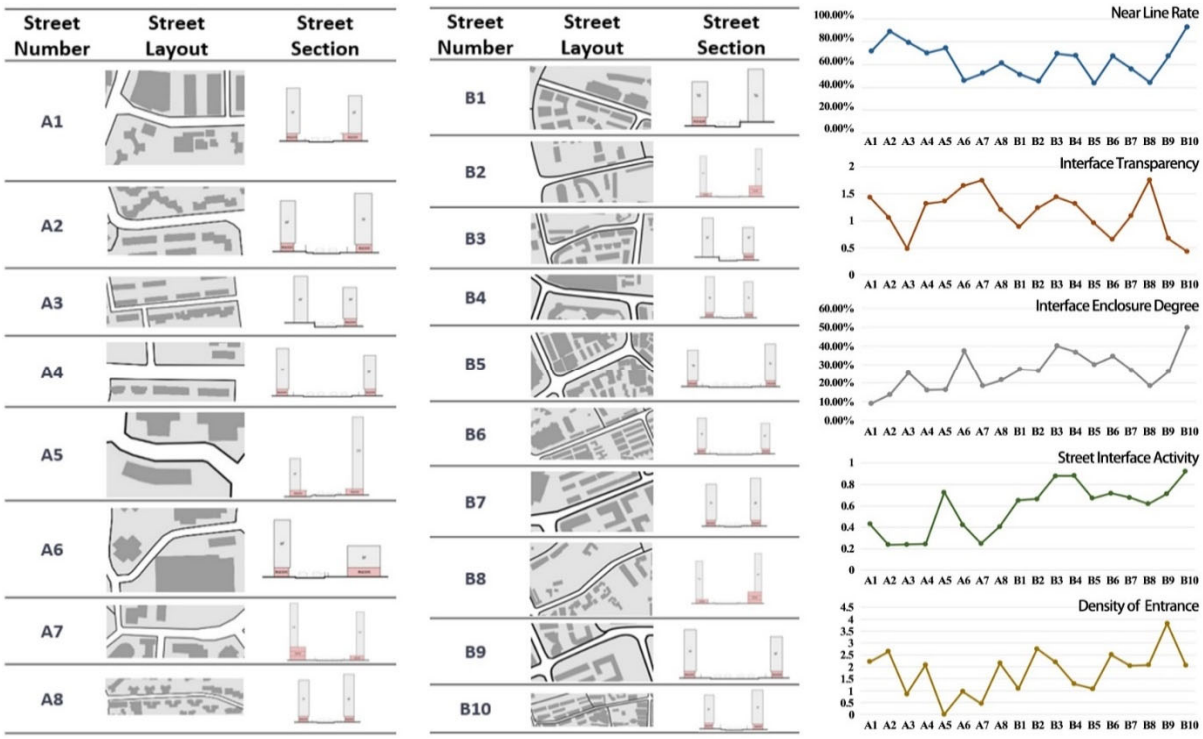

Figure 7. Analysis of the Built Environment of the Street

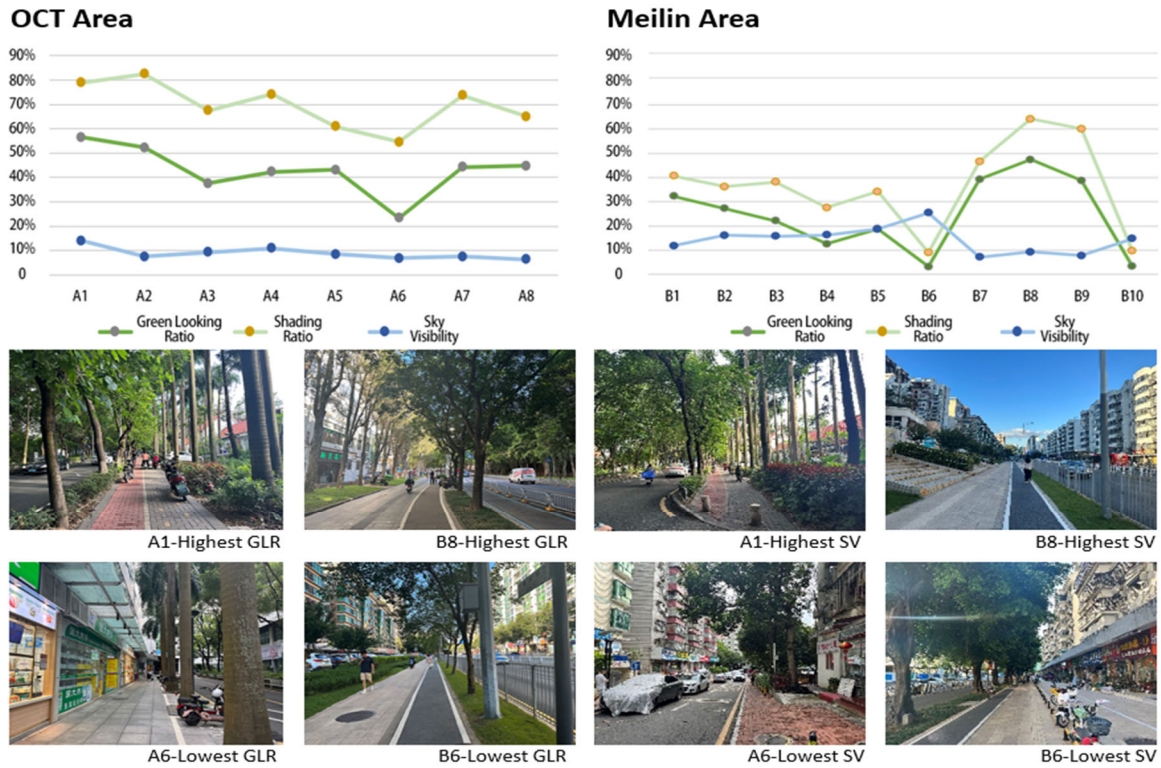

Figure 8. Analysis of the Built Environment of the Street

factor mainly describes the characteristics of the street's greening environment, reflecting the quality of the ecological environment, and is named the "Landscape and Greening" factor. Factor 4 includes two evaluation variables: sense of liveliness and activity richness. This factor primarily describes the

level of street activity and the diversity of events, and is named the "Street Vitality" factor. Factor 5 includes one evaluation variable: continuity. This factor focuses on reflecting the continuity and consistency of buildings on both sides of the street, and is named the "Interface Continuity" factor.

Table 3. Component matrix after factor load rotation

SD Factor	Principal Component Factor				
	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5
Daily communication frequency	.805	.112	.213	.152

Table 4. Factor score coefficient matrix

SD Factor	Principal Component Factor				
	Social Interaction	Pedestrian Environment	Landscape and Greening	Street Vitality	Interface Continuity
Walking Comfort	-.137	.379	-.097	-.014	-.065
Quietness	-.151	.264	.046	.009	.077
Sense of Liveliness	-.170	-.035	-.040	.846	.168
Attractiveness	.185	.067	-.138	.000	-.043
Space Openness	-.147	.363	-.073	.022	-.064
Convenience	.178	.106	-.180	-.160	.103
Continuity	-.037	-.089	.035	.124	.794
Greening Richness	-.105	-.084	.573	-.041	.093
Activity Richness	.126	.005	-.024	.410	-.577
Interface Neatness	-.011	.217	-.091	.130	-.234
Functional Completeness	.231	-.004	-.193	-.112	.253
Safety	-.045	.237	-.015	-.125	.061
Tree Shading Coverage	-.036	-.114	.566	-.029	-.069
Facility Completeness	.270	-.137	.131	-.150	-.007
Willingness to Linger	.293	-.157	.060	-.032	-.032
Daily communication frequency	.340	-.195	.059	-.026	-.134

The common factors were described through linear combination functions of the original variables, and the factor coefficients of each principal component factor were calculated using regression under the least squares criterion (Table 4). When calculating the "Social Interaction" factor, evaluation attributes such as "Daily Communication Frequency" and "Willingness to Linger," which describe residents' social interactions, were assigned higher weights, while most other adjectives received negative weights, consistent with the actual representation of the factor. Similarly, the evaluation attributes with higher weights in the "Pedestrian Environment," "Landscape and Greening," "Street Vitality," and "Interface Continuity" factors also align with their respective actual representations.

Based on the factor score coefficients and the values of each variable, the evaluation scores for each sample street based on the common factors were obtained (Table 5), as well as the evaluation scores for each area (Table 6). The tables indicate that in terms of social interaction, the OCT area slightly outperforms the Meilin area, suggesting that OCT has a slight advantage in the layout of social spaces or the configuration of social facilities. However, the difference between the two areas is not significant. In terms of the pedestrian environment, the OCT area has a noticeably higher score than the Meilin area, indicating that pedestrians in the OCT area experience a more comfortable and safer walking environment. Although the landscape and greening scores for both areas are negative, the OCT area scores relatively higher, suggesting that its greening level is slightly better than that of the Meilin area, though both areas have room for improvement in this regard. Regarding street vitality, the Meilin area scores higher, indicating that its streets likely have more commercial activities, attracting more foot traffic. In terms of interface continuity, the Meilin area scores significantly higher than the OCT area, suggesting that the street design in Meilin is more cohesive, allowing for a smoother pedestrian flow. Overall, the OCT area performs better in social interaction, pedestrian environment, and landscape greening, while the Meilin area excels in street vitality and interface continuity. It is evident that the OCT area places greater emphasis on pedestrian comfort and safety, whereas the Meilin area focuses more on street vitality and spatial continuity. The strengths of each area provide valuable insights for further street design and urban planning.

Correlation analysis between pedestrian friendliness and built environment

The correlation analysis between the street evaluation factor scores of the two residential areas and the various indicators of the built environment across four dimensions is presented in Table 7.

Street Morphology: Street Length, Width of Sidewalk, Average Building Height, and Near Line Rate did not show any correlation with the five evaluation factors. Street Width exhibited a moderate positive correlation with the "Pedestrian Environment" factor (.563*). Interface Enclosure Degree showed a positive correlation with the "Interface Continuity" factor (.590**). Density of Entrance was positively correlated with the "Social Interaction" factor (.643*) and also with the "Landscape and Greening" factor (.527*). This correlation was not anticipated; a potential reason could be that higher Density of Entrance increases the visual diversity of the street and makes green landscapes more visible and easier to experience. Street Aspect Ratio showed a negative correlation with the "Interface Continuity" factor (-.566*), which contrasts with previous understanding. The reason for this might be that higher Street Aspect Ratios are usually associated with taller and more spaced-out buildings, leading to a reduced perception of interface continuity. Additionally, Interface Transparency was negatively correlated with the "Social Interaction" factor (-.683**). High transparency in street interfaces implies less shielding or privacy protection, making residents feel exposed in public spaces and reducing their willingness to engage in social interaction. Moreover, the lack of correlation between Width of Sidewalk and the evaluation factors suggests that the sidewalk width in these two areas may sufficiently meet pedestrian needs, resulting in unclear correlation analysis outcomes.

Street Functionality: Street Interface Activity did not show any correlation with the five evaluation factors. Mixed Functionality was positively correlated with the "Street Vitality" factor (.520*). Density of Public Facilities and Density of Street Furniture were positively correlated with the "Social Interaction" factor (.603*, .565*). Diversity of Facilities showed a positive correlation with the "Pedestrian Environment" factor (.799*). However, Street Interface Activity, Density of Public Facilities, Density of Street Furniture, and Diversity of Facilities did not show a correlation with the "Street Vitality" factor, which was contrary to the hypothesis. These built environment characteristics, while enhancing the quality of public spaces, did not significantly influence resident social behavior patterns

Table 7. Correlation analysis results between street built environment indicators and evaluation factor scores（OCT Area and Meilin Area）

**. At the 0.01 level (double tailed), the correlation is significant.
*. At the 0.05 level (double tailed), the correlation is significant.
r: Correlation coefficient; P - : Significance

or interaction frequency. Street vitality is often driven by a combination of social, cultural, and economic factors, such as community social networks and the prosperity of commercial activities.

Street Traffic: Density of Parking Space was negatively correlated with the "Pedestrian Environment" factor (-.564*), while the other street traffic-related indicators did not show any correlation with the five evaluation factors.

Street Traffic: Density of Parking Space showed a negative correlation with the "Pedestrian Environment" factor (-.564*), Street Accessibility exhibited a highly positive correlation with the "Social Interaction" factor (.660**), and Street Passability was positively correlated with the "Pedestrian Environment" factor (.540*). The remaining street traffic-related indicators did not show any correlation with the five evaluation factors. The data results show that a higher density of parking spaces occupies pedestrian areas and restricts walking paths, negatively impacting residents' walking experience. Higher street accessibility implies stronger connections between neighborhoods, making it easier for pedestrians to access various public facilities, which promotes social interaction. Additionally, higher street passability enhances pedestrians' ability to move quickly and conveniently.

Street Greening: Sky Visibility did not show any correlation with the five evaluation factors. Green Looking Ratio was positively correlated with the "Landscape and Greening" factor (.635*). Shading Ratio showed a positive correlation with the "Pedestrian Environment" factor (.558*), and with the "Landscape and Greening" factor (.521*), but a negative correlation with the "Interface Continuity" factor (-.525*). This suggests that the more orderly and continuous the interface morphology, the less conducive it is to the formation of a shaded environment.

CONCLUSIONS

The study conducted a factor analysis on the pedestrian psychological evaluation data for the sample streets, summarizing the psychological evaluation structure into five principal components: Social Interaction, Pedestrian Environment, Landscape and Greening, Street Vitality, and Interface Continuity.

From an urban design perspective, based on built environment data and correlation analysis results, we propose the following strategies to enhance the walkability of livable streets in open residential districts:

(1) Optimize Public Facilities and Street Functionality to Enhance Mixed Functionality: By increasing the diversity of functions along the street and enriching the configuration of public facilities, the perception of social interaction and street vitality among residents can be effectively enhanced. Improved Mixed Functionality promotes interaction between different activities, thereby increasing the overall friendliness of the street.

(2) Improve Interface Design and Spatial Enclosure to Enhance Street Comfort: Thoughtful design of the street interface and spatial enclosure, especially when Interface Transparency is within the range of 1.00 to 1.30, can significantly enhance residents' positive perception of street vitality. This suggests that residents have specific preferences for street space, and a moderate degree of spatial enclosure can provide a more comfortable walking experience, as overly open spaces are not necessarily better.

(3) Strengthen the Design of Residential Entrances and Street Node Public Spaces to Provide Diverse Activity Spaces: By optimizing the design of residential entrance spaces and public spaces at street nodes, and enhancing the behavioral guidance function of these areas, more activity opportunities can be provided for residents. Moderately increasing the Density of Entrance can help boost street vitality, but excessively high density may lead to negative experiences. Therefore, in the design process, it is essential to appropriately configure public spaces such as node plazas to further enhance street activity and friendliness.

ABSTRACT

Many major Chinese cities have entered a phase of urban renewal to address the shifting spatial needs driven by changes in population structure. Effective updates to urban spaces require finer-scale population data. However, publicly available data is often limited to the "Jiedao (an administrative unit under the district)" level, which includes multiple communities, making it challenging to access more granular population data—an obstacle for urban renewal planning. This study focuses on an overlapping area of Nanjing Old Town and Qinhuai District, to explore a downscaling population estimation method based on residential morphology and location characteristics. The method refined population data from the Jiedao level to residential plots and buildings. Firstly, a synthetic population with residential information for the study area was generated using a Bayesian network (BN) and iterative proportional fitting (IPF). This synthetic population then guided the initial classification of residential buildings, resulting in nine types. Each type was further subdivided into 30 clusters using a Gaussian mixture model (GMM). Gaussian distributions were constructed based on the household unit area within each cluster. The distribution probability of the synthetic population across different household unit ranges within these clusters was calculated to derive the population. Finally, this population was redistributed to individual buildings based on each building's total area and the POI (Point of interest) density. The study revealed that the building with the highest population was a 7-story slab-type building. High population density (≥10 people per 100㎡) was found only in buildings with 2-7 floors, while 72.9% of high-rise buildings had low population densities (0-2 people per 100㎡). The findings suggested that high floor area ratios did not necessarily correlate with high residential density and might even result in low population densities. Therefore, re-establishing the relationship between population and residential morphology is crucial.

INTRODUCTION

Urban renewal strategies are widely adopted by cities both domestically and internationally during periods of slowed urbanization, primarily to mitigate the negative impacts of significant demographic shifts at the socio-economic level (Rose et al., 2012). On the physical level, these strategies focus on

revitalizing small, fragmented spaces that emerged during rapid urban expansion (Zhou and Ding, 2022). Consequently, this stage has highlighted the correlation between urban spatial forms and population characteristics (Patino and Duque, 2013; Wang and Ren, 2019; Li and Li, 2024). For example, there is a strong connection between aging residential communities and an aging population, as well as between urban spaces and the distribution of the floating population. However, most of these studies have either been qualitative or conducted at a large scale. From the perspective of urban renewal, there remains a lack of analytical tools that directly link small-scale urban morphology with population data.

Census data serves as the primary source of population information across the country (Zhang and Ming, 2022). However, current census data cannot reliably provide direct population at small geographic unit levels (Calka et al., 2017; Hecht et al., 2018). Therefore, many studies have constructed estimation models using auxiliary data that reflect regional population density variations to allocate census data to smaller estimation units. This approach is commonly known as "population spatialization"(Wang et al., 2016; Han et al., 2019) or " population downscaling"(Rubinyi et al., 2021; Wan et al., 2023).

The core of existing research has been centered on achieving more accurate population data, with the quality and precision of auxiliary data being critical factors (Beck et al., 2018; Qiu et al., 2020). For instance, many studies that use remote sensing imagery as auxiliary data initially relied on land cover and land use data to identify habitable areas (Mennis and Hultgren, 2006) and estimate population based on land type zoning. However, the limited variety and low resolution of land use data, along with the heterogeneity of population distribution within the same land type, have made it difficult to achieve refined population distribution (Bai et al., 2015; Wang et al., 2016). In response, subsequent studies have utilized higher-resolution remote sensing imagery to differentiate between residential and non-residential land directly associated with census populations (Balakrishnan, 2019). Today, LIDAR data can capture building heights, prompting many researchers to develop 3D building models (Chen et al., 2021). Thus, the ongoing emphasis on residential spatial morphology through remote sensing imagery has revealed that the form of residential buildings directly influences the accuracy of population estimation.

Although the importance of residential building information for population estimation has been well recognized, the expansion of regional scale leads to morphological differences in residential buildings, which in turn cause variations in population density (Alahmadi et al., 2016; Rubinyi et al., 2021; Mei et al., 2022). Currently, remote sensing imagery alone is insufficient for detailed identification. Future research should include more precise and comprehensive building type information, combined with architectural morphology knowledge, to enhance the accuracy of population estimation (Wan et al., 2023). Therefore, by classifying residential building types and studying population density from an urban morphology perspective, we can explore the relationship between population and residential morphology, and provide more comprehensive data on residential patterns to support urban renewal efforts.

In reality, residential areas often experience housing vacancies, which can increase errors in population estimation. Many studies have utilized nighttime light data to represent actual population

density and reduce estimation errors (Han et al., 2019). However, the low resolution of nighttime light data and the inability to identify light sources lead to significant errors in small-scale population estimates (Yang et al., 2019). As vector point data, POI data provide precise location and type information. Although POI types are not directly related to population distribution, the actual population capacity of residential buildings can be inferred from the quantity and diversity of surrounding POIs (Sadeghi et al., 2023).

Using census data as the control total for population estimation may have led to the overestimation or underestimation of certain categories when subdivided by different land or residential types. Synthetic populations, however, can replace census data as the control total, offering an advantage by including additional statistical indicators like the construction year and number of floors of residential buildings. This may make them better suited for matching with residential building types compared to census data. Synthetic populations have often been employed in large-scale analyses and simulations, such as transportation modeling and forecasting (Zhou and Ding, 2022). With the growing research on synthetic populations in recent years, their application has expanded to smaller spatial scales, providing more accurate and valuable data for various urban decision-making processes. Thus, in small-scale population estimation, beyond focusing on the quality of auxiliary data, using synthetic populations as the primary data source to control population estimation may be a more effective method for improving accuracy.

This study focuses on urban renewal needs by classifying residential forms to estimate population characteristics, assessing the actual utilization of residential space resources, and reconstructing the relationship between population and residential forms. This study aims to address several key issues: First, what method should be used to classify residential forms? Second, what approach should be adopted for creating synthetic populations? Third, how can a matching mechanism between synthetic populations and residential buildings be effectively established?

STUDY AREA AND DATA

Nanjing has a history of over 2000 years of city construction and currently has a permanent population of more than 9 million. In recent years, as the focus of construction has shifted from the old city to the new districts, the urban form and landscape of the old city have remained relatively stable. Furthermore, census data is relatively comprehensive and accessible. Therefore, the research area has been selected as Qinhuai District within the old city, which includes 7 Jiedao(an administrative unit under the district). Since this study involved population downscaling estimates based on census data, the research subjects should match the census scope and pertain to residential plots. Consequently, all residential plots within the research area have been compiled (Figure 1). The data used in this study are categorized into three types: morphological data, population data, and POI data (table 1). population data includes 1% national sampling data from 2015 and census statistics from Qinhuai District in 2020. POI data includes 18 types, with 12 POI types selected for the study based on Pearson correlation analysis.

METHOD

Figure 2 shows the research process, which was divided into three main parts: synthetic population generation, residential building classification, and population-building matching. The first part involved generating a synthetic population for the study area using Bayesian networks (BN) and the Iterative Proportional Fitting (IPF) algorithm. The second part included two stages of residential building classification: the first was based on construction year and the number of floors, and the second involved further subdivision using selected morphological indicators and clustering algorithms. The third part assigned the synthetic population to different building types and estimated the population count for individual buildings accordingly.

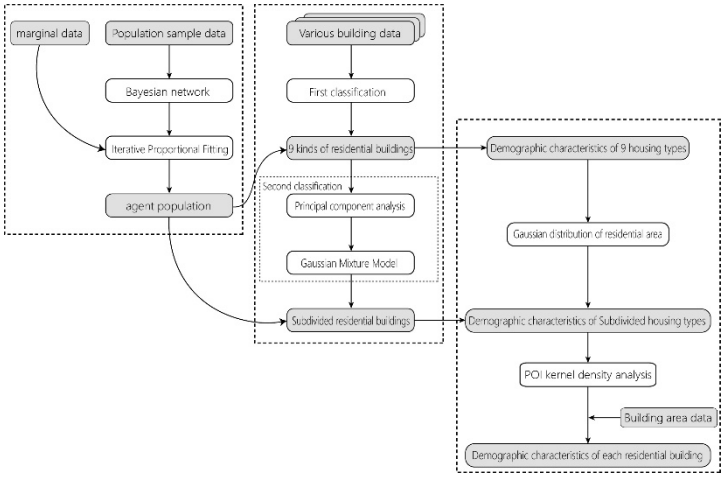

Figure 2. Flowchart for disaggregating Jiedao population into residential buildings population studies.

The model construction for synthetic population generation

There are three main methods for creating a synthetic population: Synthetic Reconstruction (SR), Combinatorial Optimization (CO), and Statistical Learning (SL) (Sun et al., 2018). The choice of method primarily depends on the type, scale, and quality of the available data. In this study, the sample data represented only 0.1% of the population, along with accessible marginal data. Therefore, based on the decision tree tool(Fabrice Yaméogo et al., 2020), a combination of SL and SR was deemed the most appropriate. Consequently, the synthetic population was constructed using BN for SL and IPF algorithm for SR. First, the study used the Tabu search algorithm and the Akaike Information Criterion (AIC) to construct and select the optimal BN. Six indicators from the sample data were used as network nodes: household size, number of residential rooms, number of floors, residential building construction year, age, and per capita housing area (Table 2). Then, the IPF algorithm was applied to adjust the synthetic population, ensuring a better fit to the census data.

Table 2. Nodes and their values in the Bayesian network.

Variable	Definition	Values
HS	Household size	1、2、3、4、5、6、7、8
NRR	Number of residential rooms	1、2、3、4
NF	Number of floors	Bungalow、2—6、7 floors and above
RBCY	Residential building construction year	1979 and before、1980—1989、1990—1999、2000—2009、2010 and after
AGE	Age	0—14、15—64、65 and above
PCHA	Per capita housing area	8 and below, 9—12, 13—16, 17—19, 20—29, 30—39, 40—49, 50—59, 60—69, 70 and above

Classification of residential buildings

The population sample data identified three key attributes: construction year, number of floors, and household unit area (calculated as the product of per capita housing area and household size). These three variables formed the basis for classifying residential buildings. First, an initial classification was conducted using the construction year and number of floors. Then, the Gaussian Mixture Model (GMM) was employed to subdivide the typologies further. This process involved dimensionality reduction of the morphological indicator dataset (Table 3), followed by clustering with the GMM algorithm. Finally, manual adjustments were made to some clusters with significant morphological differences, ensuring that buildings within the same type had similar morphological characteristics.

Table 3. Residential building morphology indicators.

Attribute	Description
Building footprint area	Building floor area
Total building area	The total area of each floor
Shape index	The relationship between the building's perimeter and footprint area
Aspect ratio	The aspect ratio of the building's minimum bounding rectangle
Area ratio	The ratio of the building's footprint area to the area of its minimum bounding rectangle
Number of floors	Number of building floors
The side surface area ratio of the building	The ratio of the building's side surface area to its total surface area.

Population estimation for residential buildings

The matching of population and buildings was discussed at different levels of building classification：first, the matching of population with residential building types classified by construction year and number of floors; second, the matching of population with more finely subdivided residential building types, aiming to estimate the population of individual buildings. In the first level, the corresponding synthetic population was directly assigned to each building type. In the second level, the population assigned in the first step was further subdivided to align with the clustered residential building types. This subdivision was achieved by using the household unit area variable to link the population with the buildings. First, a sufficient number of building samples was drawn from the building clusters to calculate the area of individual housing units, yielding the mean and standard deviation for each type. A Gaussian distribution was then constructed based on these values. Next, the probability density values for different household unit area intervals within the synthetic population were calculated across the various Gaussian distributions. These probability densities were then normalized so that the sum of probabilities for each residential area interval across different building types equaled one. Finally, the synthetic population for each building type was calculated based on the relative probabilities. The calculation formulas used were as follows:

$$f_t(\mathrm{A}) = \frac{1}{\sigma_t\sqrt{2\pi}}\exp\left(-\frac{(A-\mu_t)^2}{2{\sigma_t}^2}\right) \quad (1)$$

$$P_t(\mathrm{A}_k) = \int_{A_{k1}}^{A_{k2}} f_t(\mathrm{A})dA \quad (2)$$

$$\tilde{P}_t(A_k) = \frac{P_t(A_k)}{\sum_{t=1}^{T} P_t(A_k)} \quad (3)$$

$$O_t = \sum_{k=1}^{\mathrm{n}} o_k \times \tilde{P}_t(A_k) \quad (4)$$

In the formula, $f_t(\mathrm{A})$ represents the Gaussian distribution for the subdivided building type t, A_k represents the residential area interval for the synthetic population, $P_t(\mathrm{A}_k)$ denotes the probability density of the residential area interval [Ak1,Ak2] within the Gaussian distribution of building type t, $\tilde{P}_t(A_k)$ represents the relative probability of the residential area interval [Ak1,Ak2] within the Gaussian distribution of building type t, T denotes the total number of building types, O_t is the population count for building type t, and o_k is the synthetic population for residential area interval Ak.

After assigning the corresponding synthetic population to the subdivided building types, the population was further distributed to the individual building level, with the allocation weighted by each building's area and POI (Point of Interest) density. The formula used was as follows:

$$O_i = O_t \times \frac{s_i d_i}{\sum_{i=1}^{j} s_i d_i} \tag{5}$$

In the formula, O_i represents the estimated population for building i, s_i represents the total area of building i, and d_i represents the POI density for building i. The POI density was determined through a series of steps: first, Pearson correlation analysis was used to identify the optimal bandwidth for each type of POI (Table 4). Next, kernel density analysis was applied to generate POI density grids for each type. Finally, principal component analysis was used to integrate these grids into a composite POI density layer, which was then used to calculate the POI density for each building.

Table 4. The Pearson correlation coefficients and optimal bandwidths for each POI type.

Types of POIs	Pearson correlation coefficient	Optimal bandwidth（m）
science and education culture	0.951	700
transportation facilities	0.861	300

RESULTS AND DISCUSSIONS

Clustering Results of Residential Buildings and Gaussian Distribution of Housing Area for Each Type

Residential buildings were classified into nine typologies based on the construction year and number of floors. Figure 3 highlights the distribution characteristics and quantities of each typology. Typology 1 encompasses the largest number of buildings, representing traditional courtyard-style residences primarily located in the southern part of Nanjing's old city. Typology 3 is the most common among multi-story residential buildings (2-6 floors). For buildings with seven or more stories, Typology 6 is the most numerous, reflecting a shift during the 1990-1999 period towards mid-rise (7-11 stories) and high-rise (12 or more stories) residential construction. After 2000, the volume of residential

construction significantly declined, and the development of multi-story residential buildings gradually ceased.

Based on the Gaussian Mixture Model (GMM), the eight building typologies (excluding Typology 1) were further subdivided into a total of 30 residential building clusters (Figure 4). Each cluster showcased the five most representative building floor plans to illustrate morphological characteristics, with slab-style residential buildings being predominant across all typologies. For multi-story slab-style residences, Typology 2 features buildings approximately 40 meters in length with a depth of 8-10 meters. Typology 3 includes buildings with greater lengths and depths than those in Typology 2, particularly in cluster 3-4, where lengths reach around 60 meters and depths range between 10-15 meters. While these clusters are less common, the main clusters are 3-2 and 3-3, with lengths of 40-50 meters and depths of 9-13 meters, showing a noticeable increase in size compared to Typology 2. Typology 5 is dominated by cluster 5-2, featuring buildings approximately 40 meters in length and 10 meters in depth, which are slightly smaller in scale compared to Typology 3, with more uniform dimensions. Typology 7 shows an overall increase in size compared to cluster 5, with the main cluster being 7-1, featuring lengths of 40-50 meters and depths of 10-13 meters. In summary, multi-story slab-style residential buildings typically had lengths ranging from 40-50 meters and depths of around 10 meters.

Slab-style residential buildings with seven or more stories are primarily distributed across Typology 4, 6, 8, and 9. These buildings are characterized by more flexible length variations, with depths ranging from 11 to 15 meters, consistent with Liu Quan's research on the specific depth values of slab-style residences(Liu and Ding, 2014). Another notable feature is the relatively smaller length of these buildings. Slab-style residences composed of 1 or 2 units typically have larger average depths compared to those composed of multiple units, a distinction particularly evident in cluster 8-2.

For ease of analysis and discussion, this study categorizes all residential buildings arranged around a single core as tower-style residences. Multi-story tower-style buildings first appeared in cluster 3-1, where each floor typically contained 3-4 household units, with floor areas ranging from 200 to 230㎡. Subsequent tower-style buildings primarily featured 7 or more stories. The tower-style residences in cluster 4-1 share similar characteristics with those in cluster 3-1. Typical high-rise tower-style residences were found in clusters 6-1 and 8-3. Both clusters have similar average story counts, however, cluster 6-1 tends to have more square-shaped floor plans, while cluster 8-3 features a greater length-to-width ratio.

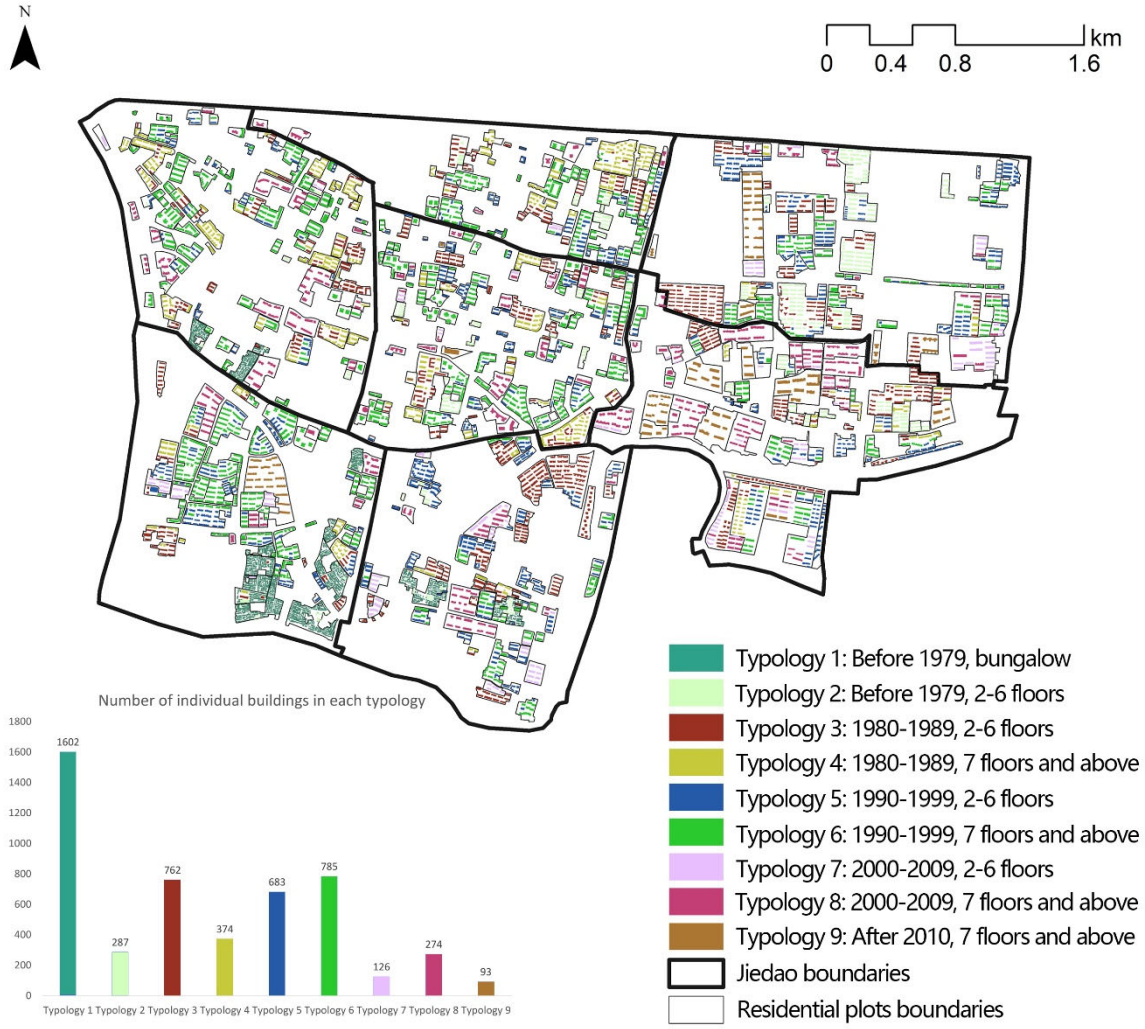

Figure 3. Distribution characteristics and quantities of the nine residential types.

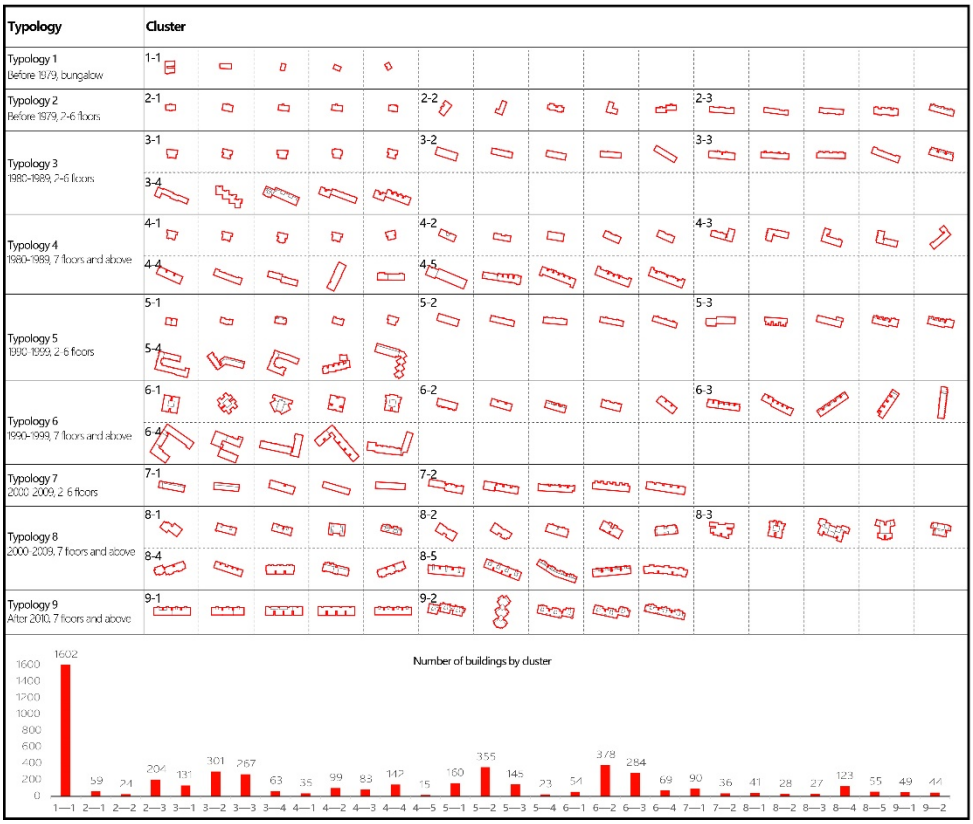

Figure 4. Typical floor plan analysis and quantity characteristics of 30 residential clusters.

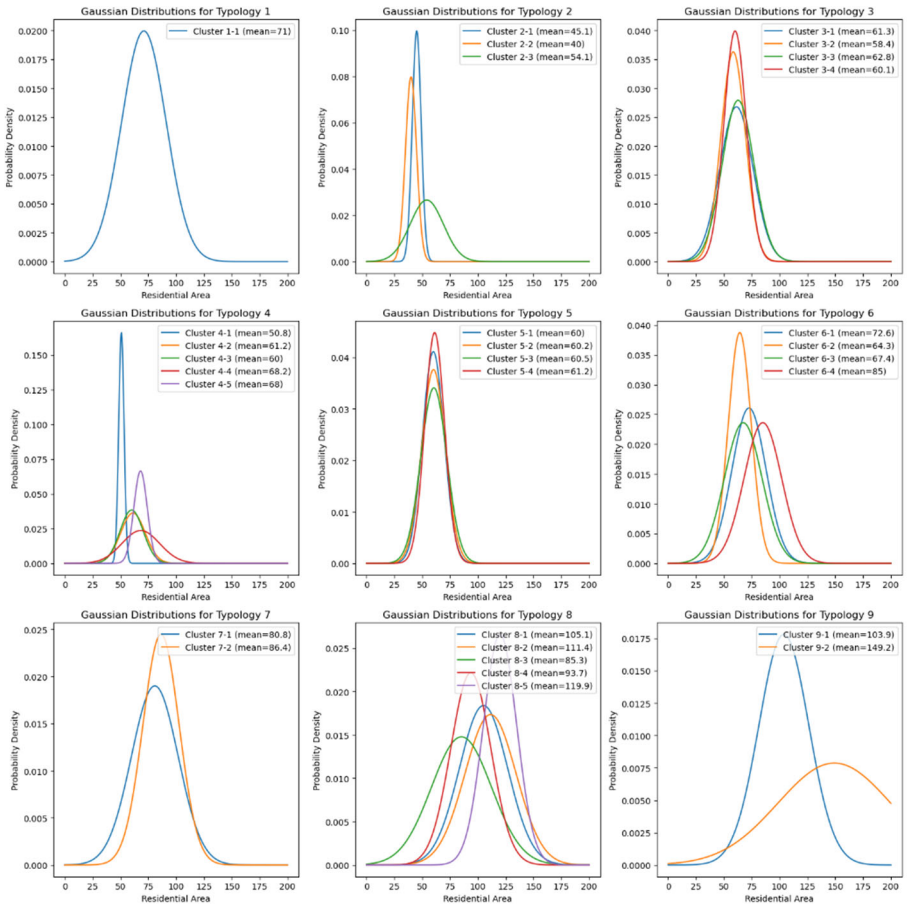

Figure 5. Household unit area distribution characteristics of 30 residential clusters.

The 30 residential building clusters display various trends in household unit area distributions (Figure 5). Overall, the average household unit area increases progressively from Typology 2 to Typology 9. Typology 1, representing historical courtyard-style residences, defaults to single-unit homes, resulting in a larger average residential area compared to Typology 2 from the same period. Among multi-story residences in Typologies 2, 3, 5, and 7, the largest average household unit areas were found in 2-3 (54.1㎡), 5-4 (61.2㎡), 3-3 (62.8㎡), and 7-2 (86.4㎡), respectively. For seven-story and higher buildings in Typologies 4, 6, 8, and 9, the maximum average household unit areas were found in 4-4 (68.2㎡), 6-4 (85㎡), 8-5 (119.9㎡), and 9-2 (149.2㎡), respectively. All of these are slab-style residences. Tower-style residences were primarily found in clusters 3-1, 4-1, 6-1, and 8-3, with average household unit areas of 61.3㎡, 50.8㎡, 72.6㎡, and 85.3㎡. In general, the household unit area of tower-style housing is smaller than that of slab-style residences with similar number of floors.

Synthetic population and building matching

The preliminary matching is based on nine building typologies. The typologies were assigned to residential plots for analysing (Figure 6). Figure 6 shows that Typology 5 has the largest population, with 77,188 people, followed by Typologies 4 and 6, each with populations exceeding 70,000. Typology 1 has the smallest population, with only 3,317 people, followed by Typology 9 with 9,930 people. Using the age structure from the Nanjing Municipal Bureau of Statistics' report from the seventh national population census as a benchmark—with 12.75% for ages 0-14, 73.55% for ages 15-64, and 13.70% for ages 65 and older—only the residential plots in Typologies 7, 8, and 9 meet these criteria. The combined population in these three typologies totals 66,817, which was only 18.10% of

the synthetic population. In all other typologies, the proportion of the working-age population was below the benchmark, while the proportion of the elderly population exceeded the standard.

The population of individual buildings was redistributed according to the population of 30 residential types using formula (5). Figure 7 shows the population of each building and the 30 residential types. At the cluster level, cluster 5-3 had the largest population, with 32,635 people, followed by cluster 6-4, with 28,516 people—both from the 1990-1999 period. At the individual building level, 50 buildings housed populations of 536 or more, primarily located in the Hongwu Jiedao and Chaotiangong Jiedao, with only two being high-rises. Of these, 16 buildings had populations exceeding 879, belonging to clusters 4-5, 5-4, and 6-4. These were slab-style buildings with 6 to 9 stories. Therefore, the relationship between population size and total building area is not simply linear, and a high floor area ratio does not necessarily indicate high residential density.

In this study, population density was categorized as high (10 or more people/100㎡), medium (3-9 people/100㎡), and low (0-2 people/100㎡). Figure 8 reveals that, with Typology 8 as a dividing line, Typologies 1 through 7 show a clear positive correlation between average population density and average total building area. The exception is the high-rise tower in cluster 6-1, which showed a negative correlation, indicating that the actual population might be far below its theoretical capacity. Beyond Typology 8, the correlation shifts to negative, suggesting a change in the housing supply-demand relationship around the year 2000. From a cluster perspective, clusters 2-1, 2-2, 4-1, 4-5, and 5-4 were identified as high-density residential areas, making up 5.89% of the total, with buildings ranging from 2 to 7 stories, only cluster 4-1 was a tower-style residence. Low-density housing was found across single-story, multi-story, and 7-story-and-above buildings, with a concentration primarily in 7-story-and-above buildings within Typologies 6, 8, and 9.

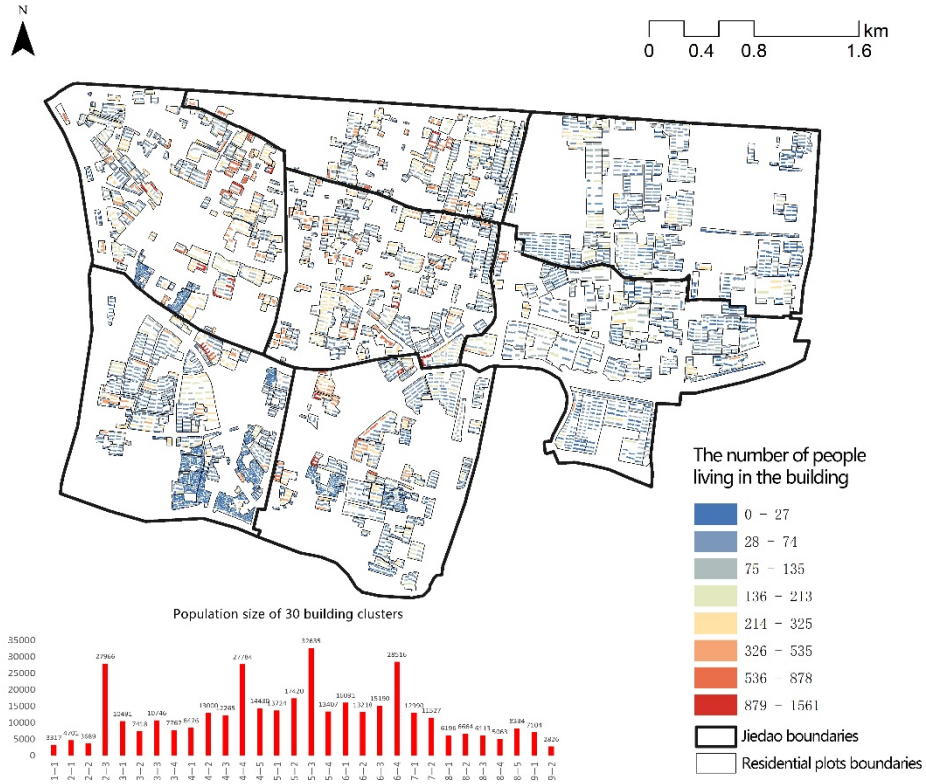

Figure 7. Distribution of individual buildings and population size, and the population size for 30 residential clusters.

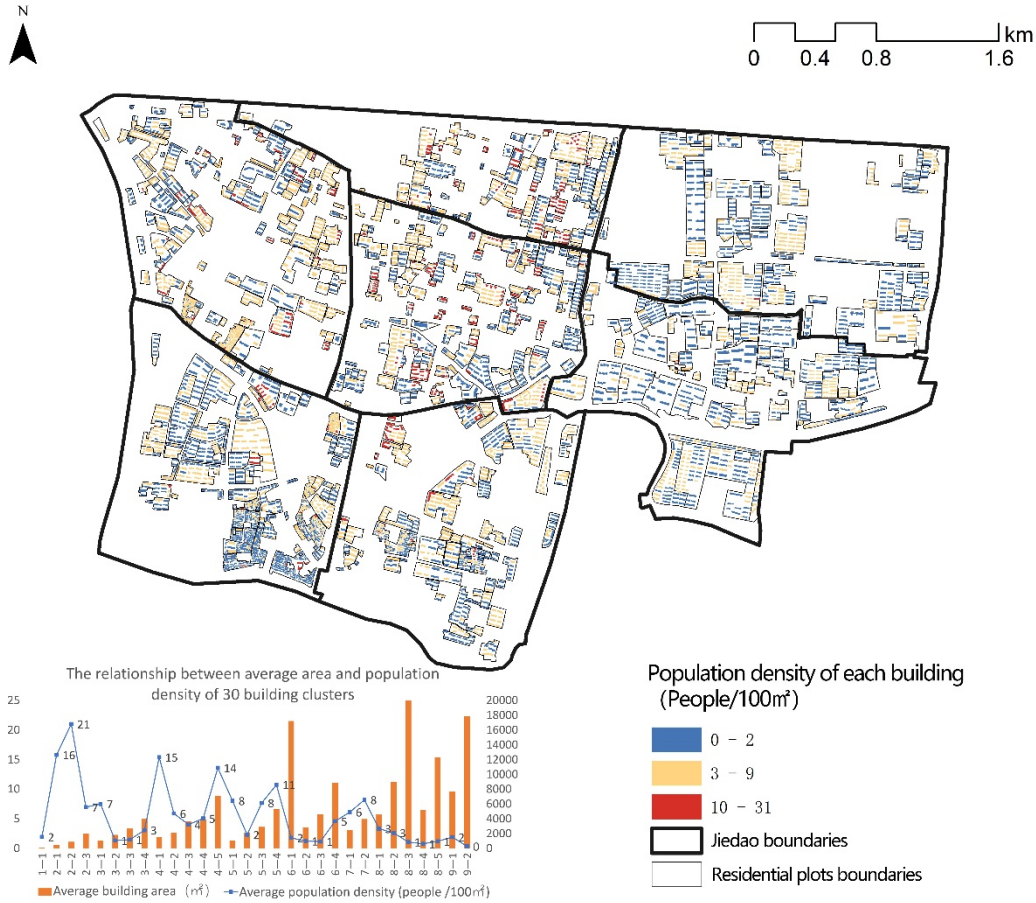

Figure 8. Population density of individual buildings and the average total building area and population density for 30 residential clusters.

Discussion

This study innovatively combined machine learning algorithms with morphological typology knowledge to explore the interdisciplinary challenge of estimating residential building populations. However, several potential limitations exist. First, the synthetic population may overlook rare samples. The sample data used in this study was derived from the national population, but only the subset from Qinhuai District, representing just 0.1% of its population, was extracted. The limited sample size may reduce the accuracy of the synthetic population in reflecting the actual population. Future research should aim to use more granular data to enhance the model's estimation performance. Second, there may be errors in the Gaussian distributions of household unit areas for the 30 clusters. In this study, the estimation method for each cluster primarily relied on street view map observations, supplemented by field surveys. Given the large number of estimates required, only about 40% of the residences in each cluster were sampled to construct the Gaussian distributions which could affect the accuracy of population estimates. To minimize these errors, future research should focus on updating and refining the survey data. Third, the study lacks model validation. At present, this research remains theoretical, and the data presented has not been field-verified. Further investigation is necessary to confirm the accuracy of the findings.

CONCLUSIONS

This study began by generating a synthetic population dataset for the research area using Bayesian networks (BN) and the Iterative Proportional Fitting (IPF) algorithm. Residential buildings were classified into 30 types after two classifications. Gaussian distributions were constructed based on household unit area, and these distributions were employed to calculate the relative probabilities of synthetic populations for each cluster. This process provided estimates of the synthetic population for each cluster. Ultimately, the synthetic population was further detailed and matched to individual buildings. Analysis of the population characteristics revealed that residential building population density varied widely, ranging from as low as 0 people per 100㎡ to as high as 31 people per 100㎡. Notably, the 16 buildings with the highest population counts were all 6-9 story slab buildings, while 72.9% of high-rise buildings had a population density of only 0-2 people per 100㎡. This suggested that a high floor area ratio has not necessarily correlated with high residential density and may have led to excessively low population densities. Therefore, estimating population characteristics based on the classification of residential morphology is beneficial for reestablishing the relationship between building forms and population distribution.

This study demonstrated several advantages by using a synthetic population with residential information, rather than relying solely on basic population statistics, to guide residential building classification and model estimation. First, it enhanced the correlation between population and morphological data, facilitating the classification of residential forms and directly linking them to population numbers. Second, having accurate synthetic populations for classified residential types improved the accuracy of the estimates. Third, it allowed for the analysis of additional population characteristics, such as age structure, beyond mere numbers. However, this approach remained in its preliminary stages. To ensure accuracy, future research should compare various construction methods to determine the most effective model.

From an architectural perspective, this research aimed to uncover the relationship between residential buildings and population by estimating the number of inhabitants. The analysis of residential morphology was primarily focused on overall exterior and planar forms due to the large sample size. As a result, comparisons of residential forms with different population characteristics were largely based on exterior morphology. Future research could delve deeper into specific residential forms and analyze population differences more thoroughly, leading to more detailed and actionable insights.

ABSTRACT

Brazilian medium-sized cities, like Campos dos Goytacazes, have within them peculiarities that enlighten their own process of urban expansion. In this paper, we aim to discuss the articulation between two conditions that broadly guide it. Socio-spatial segregation, a process characterized by the concentration of certain social segments in different regions or neighbourhoods (VILLAÇA, 1998), and accessibility, a crucial dimension of sustainable urban mobility that enables urban activities to be reached by certain individuals or group of individuals from different locations in the city (PEREIRA et al., 2017). Through the analysis of location, shape and frequency of large horizontal housing isolated polygons in the urban fabric of Campos dos Goytacazes, in the state of Rio de Janeiro, Brazil, and the expansion of the road network since 1980, we aim to develop spatial correlations to contribute to a critical review on the conflicting ability to move around the city depending on the social group of origin. Thus, we hope to highlight the radical spatial detachment of segregated social groups from parts of urban space.

Keywords: Accessibility, segregation, medium-sized city, Campos dos Goytacazes.

INTRODUCTION

Brazil's medium-sized cities have gained prominence in terms of production of urban space and urbanization. A comparison between the 2010 and 2022 Censuses shows that of the 12 million increase in the Brazilian population, 8.3 million people are concentrated in medium-sized cities. In addition, 278 Brazilian municipalities have a population between 100 and 500 thousand inhabitants and are classified as medium-sized cities, an increase of 12% compared to the 2010 Census, when there were 245 Brazilian municipalities with a population between 100 and 500 thousand inhabitants (IBGE, 2023).

Although it is still too early to define the data from the 2022 Census as a trend towards the re-spatialization of the population across Brazilian territory, it is undeniable that medium-sized cities play a specific role in the country's urban arrangement. Driven by the migration caused by the global Covid-19 pandemic in 2020, the more widespread possibility of remote working, the constant increase in the

cost of living and the perception of violence in the metropolis, medium-sized cities have been consolidating themselves as a representative space in the process of urban expansion in Brazil. The medium-sized city of Campos dos Goytacazes (Figure 1), in the north of the state of Rio de Janeiro, has a prominent regional political and economic position, given that its territory is home to the second largest oil and natural gas producing basin in the country, the Campos Basin. It is the largest municipality in the state of Rio de Janeiro, with a territorial unit of 4,032.487 km², 13 districts plus the central district and a population, according to the 2022 Census, of 483,540 inhabitants, approximately 90% of whom are urban.

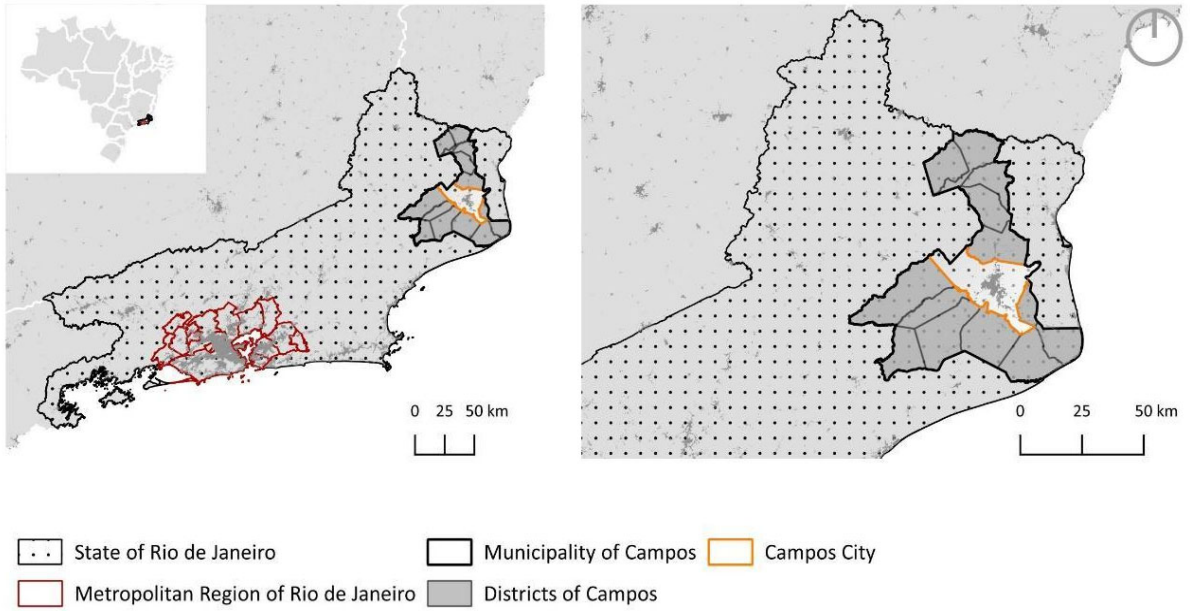

Figure 1 - Location of the Municipality of Campos dos Goytacazes in the State of Rio de Janeiro.Source: Author, 2024.

In the 1980s, the process of shaping the urban space of Brazilian cities was crossed by the proliferation of what we call horizontal housing isolated polygons (Hhip's), a phenomenon in which Campos dos Goytacazes was no exception. This new housing typology is essentially characterised by grouping residential units on a vast portion of land with its perimeter surrounded by ostentatious boundaries separating inside and outside, highlighting the dynamics of the city's spatial control, which segregates and limits the equal use of urban spaces by all city dwellers.

Hhip's reinforce a discontinuous mode of urban growth, disconnected from the city's main historical and consolidated centrality. The demand for large tracts of low-value land as a criterion for this real estate product drives the displacement of the Hhip's to the edge of urbanisation, promoting fragmented urban expansion. What's more, to transfer the housing of high-income social segments from the central area to the edges of the urban perimeter, it was necessary to double down on the expansion of urban mobility based on the private automobile matrix.

This article seeks to analyse the distribution of Hhip's in the territory and their relationship of dependence on road infrastructure and the predominance of individual motorised transport, which reproduce the historical process of segregation in Campos dos Goytacazes, Rio de Janeiro. The first part of the article discusses the emergence and consolidation of closed horizontal residential spaces

in Brazilian cities, urban mobility policy in Brazil and the preponderance of road mobility infrastructure production aimed at individual transportation.

In the second part, we present the methodology that was developed using a multi-scalar and multivariate qualitative and quantitative approach to analyse the phenomenon articulated between the real estate production dimensions of the Hhip's and the structuring road axes of urban mobility. For data and information on the Hhip's in Campos de Goytacazes, primary data was collected in the archives of the Municipal Department of Urban Planning, Mobility and Environment of Campos dos Goytacazes City Hall. Socio-economic data was taken from the IBGE (2010) and vehicle fleet data from DETRAN-RJ (2024).

In the conclusions, we argue about the essential characteristics of this much desired and widespread real estate product, the Hhip's, which demand vast tracts of land on the edges of the consolidated urban fabric. By relying on road accessibility, they promote fragmented urban growth and accentuate the historic process of socio-spatial segregation which characterises the urbanisation of Brazilian cities.

Production of horizontal housing isolated polygons (Hhip's)

The study of horizontal housing isolated polygons as a housing typology (GOMES, 2024) has been recurrent in various scientific fields such as sociology, anthropology, geography and urbanism since its emergence in the mid-twentieth century in the USA. The concern that leads scholars to turn their attention to the phenomenon of the proliferation of Hhip's in the most varied cities around the world is due to one main cause: the suspicion that Hhip's symbolise a much more profound transformation in society than merely a new possibility for urban dwelling (BLAKELY and SNYDER, 1997).

The repeatedly disseminated ideal of living in privatised, homogenised, walled and mainly controlled spaces indicates that there is an articulated global movement that assumes and promotes this type of housing as the contemporary ideal of living. This urbanisation movement is based on the neoliberal logic that the qualities and benefits of the city, such as safety, accessibility, mobility, housing, education, health cannot be delivered and managed by the public authorities and must therefore be produced, offered and managed by the private sector.

Thus, like Sposito (2013), "...we have adopted the generic expression 'closed residential spaces'..." (SPOSITO and GOES, 2013) because we reiterate that more important than their legal status is the reality of their existence in the urban territory. We would like to point out that in the course of this work we will also frequently use the nomenclature 'polygons' followed by the adjectives 'isolated', 'housing' and 'horizontal'. As this work highlights the morphological analysis of the process of urban configuration promoted by the expansion of spaces for private housing use on the edges of the city of Campos dos Goytacazes, we emphasise the power of form in structuring the urban fabric, and for this reason, at certain point we have replaced the name 'space' by 'polygons'.

In Brazil, the most relevant path that studies the phenomenon of closed horizontal residential spaces, connects it with the significant increase in insecurity and the growth of violence in large cities. Caldeira (2011) and Sposito (2013) will focus their research by determining that the main cause of the advance of closed residential spaces as a mode of urban dwelling is urban insecurity.

According to Caldeira (2011), recent transformations in social dynamics, driven by technological revolutions, restructuring of the world of work, exhaustion of a model based on nationalism, and neoliberal postulates such as privatisation, individualism and inefficiency of public power, have reconfigured the way in which the dominant social segments permeate urban space and segregate themselves in closed residential spaces. This allows us to suspect that the self-segregation of the elites in the urban territory operated under the capitalist mode of production is still confirmed as a rule in the process of producing urban space and, therefore, merits analysis that identifies how this contemporary socio-spatial segregation is reflected in the daily lives of different social groups and their accessibility.

Urban mobility

Urban mobility has become a central principle of the urbanisation process, rather than one of its consequences (ASCHER, 2004; URRY, 2007; BERTOLINI, 2017). The sharp growth in the mobility of people and goods has been accompanied by a transformation in the size and shape of cities. Under the influence of new technologies, the dynamics are intensifying, and the processes of urban expansion and fragmentation are shaping urban centres, which are interspersed with both functionally specialised areas and natural areas, connected by transport infrastructure and the continuous flow of people, goods and information (ALVIM; IZAGA et al., 2024).

In Brazil, mobility conditions in cities with more than sixty thousand inhabitants (VASCONCELLOS, 2013) present a picture where journeys by public transport are longer and take longer on average than those made by individual transport, which are 62% shorter and spend 58% less time. Despite the advances represented by the National Urban Mobility Policy (Law No. 12,587/12) and its monitoring (BRASIL, 2018), a policy based on benefits and exemptions given to cars and motorcycles and inadequate public transport policies still prevail, which have increased its cost and decreased its reliability, generating many inequities.

Campos dos Goytacazes Sustainable Mobility Plan (2022), although it aims to "... incorporate the principles of sustainable mobility, with a focus on public transport and non-motorized transport, through the adoption of guidelines and measures oriented towards a safe, efficient and accessible urban transport system" (CAMPOS DOS GOYTACAZES, 2022, p. 4), privileges in its text the treatment of the infrastructure of the road system to the detriment of public transport planning.

In Campos dos Goytacazes, cars and motorcycles have increased by almost 174% in the last 20 years, while the population has grown by 18% (IBGE, 2022; DETRAN RJ, 2024). In other words, we've gone from a ratio of one vehicle for every 6 people in 2000 to almost half that in 2022, one vehicle for every 2.5 people. There was a vertiginous growth rate of 68% between 2000 and 2010 and it remained stable at 63% from 2010 to 2022, above the state average, which varied between 56.5% in 2010 and 51.6% in 2022.

As far as public transport is concerned, the bus system is considered to have a lack of lines to certain regions, non-compliance with timetables and the scrapping of the fleet, providing a poor-quality service (ARAUJO, 2012; CRUZ, 2021; SILVA, 2022). The lack of open data on the structure of journeys highlights the operational and planning difficulties faced by the body responsible, the Municipal Institute of Traffic and Transport (IMTT). The City Council's policy of subsidising fares, with the implementation of the "Citizen Card", has had an impact on the increase in journeys since 2009

(ARAÚJO, 2012; p.52). The city has two terminals, the Roberto Silveira Bus Terminal, the departure point for all inter-district lines, and the Luiz Carlos Prestes Urban Terminal, which serves urban lines. The organisation of the lines is radial, from the centre to the outlying neighbourhoods, promoting little adherence to the territory, resulting in poor accessibility. With a predominantly flat configuration, organised by a central, historically established main district, with other nuclei configured in a dispersed manner, Campos has 55 km of cycling routes in place, with improvements and expansion of the network expected over the next few years. This situation means that the bicycle (MARINO, QUINTANILHA *et al*., 2021) is the only remaining option for the population with lower incomes, who live in the outlying areas.

Figure 02 – Aerial photo of Campos dos Goytacazes. Source: Author, 2022.

METHOD

The approach is based on studies of the urban morphology of the contemporary city (PANERAI, 2006; SOLÀ-MORALES, 1997; COSTA, 2015), where we seek to explore tools that allow us to think of the agglomeration as a whole, to identify its parts and describe its forms.

In line with Lefebvre's interpretation of the city as a projection on the ground of social relations, Panerai (2006) highlights elements that organise the territory. The road, the regular projected grid of extensions, to which are superimposed, with the development of means of transportation and communication, dynamics that produce fragmented and diffuse fabrics in the contemporary city. Based on this, he defines the constituent elements of the urban fabric as threefold: the road network, land parcels and buildings.

Likewise, for Solà-Morales (1997), the layout is the most permanent dimension of urban form, understood as a real and collective synthesis of existing and future built form. Solà-Morales develops an understanding of the temporal process of its constituent elements - subdivision, urbanisation and building - from which he lists six forms of urban growth in cities: i- grid extension, ii- suburban growth based on the logic of the road and in contiguity with the main urban nucleus, iii- peripheral urbanisation, in discontinuity with the main urban nucleus, iv- the garden city, v- informal urbanisation or favela and vi- monofunctional polygons.

We will adopt a multi-scalar and multivariate qualitative-quantitative approach to analyse the phenomenon articulated between the real estate production dimensions of the Hhip's and the structuring road axes of urban mobility in the municipality of Campos de Goytacazes. The analysis is based on the research carried out at the Municipal Department of Urban Planning, Mobility and Environment of Campos dos Goytacazes City Hall, where 42 Hhip's were found with approval licenses (Figure 03) (GOMES, 2023).

To map the urbanization growth, in the time frame between 1984 and 2024, the Google Earth mapping database was used. Socio-economic data was taken from IBGE (2010) and urban mobility data from DETRAN-RJ (2024).

RESULTS AND DISCUSSIONS

The occupation of the territory of Campos dos Goytacazes began on the right bank of the Paraíba do Sul River, with the urban core being established on the highest part, around the current Praça São Salvador. The direction of occupation is from the coast towards the interior, from Farol de São Tomé towards the Paraíba do Sul River, where sugar cane mills were installed in the 18th century. From 1837 to 1875, the urban area grew very little, but this changed with the arrival of the railroad in 1873. The vectors of the city's expansion until the mid-20th century were influenced by the 1902 Urban Plan, developed by Saturnino de Brito, and the 1944 Urbanization Plan for Campos, developed by Coimbra Bueno e Companhia Ltda.

At that time, three vectors of growth were identified: one in a westerly direction, another in a southerly/easterly direction, towards the coast and the appearance of the urban area of Guarus on the other bank of the river, to the north. In the middle of the 20th century, a quadrilateral is identified with dense occupation, defined by the river and the railroad beds, with some prominent nuclei to the south (Costa, 2005). At the end of the 20th century, there was a vector of growth towards the coast, as well as urban growth along the BR-101 towards Vitória.

Since the appearance of the first closed horizontal residential space, the Residencial do Horto condominium of single-family houses, in 1981, this form of housing has been proliferating assiduously in the urban fabric of Campos dos Goytacazes. The emergence of Hhip’s largely depends on the availability of vast tracts of idle land that can be divided up into smaller plots for the development. Thus, the very nature of the real estate business in terms of launching a larger number of condominiums requires the search for urban land of lower value, in order to maximise business profits. Historically, the urban land least valued by the real estate market has been located on the edges of the urban perimeter, i.e. on the limits of what is urban and what is rural. Generally, the further away from the centrality(ies), where access to urban facilities and infrastructures is greater, the lower the value of the land.

For this reason, the phenomenon of the proliferation of Hhip’s takes place in a very specific part of the city's territory: on the edge of urbanisation, on the margins of the consolidated city, where the land is of low value, but where there is the possibility of access to the main urban centrality quickly and efficiently.

From an analysis of the city's urban growth, highlighted every 10 years since the first Hhip’s appeared, the developments are set up exactly where the consolidated urban fabric meets the non-urbanized one (Figure 4).

CONCLUSIONS

Freed from dependence on the city, the Hhip's model gains autonomy in relation to urban space, detaches itself from complex urban issues and becomes independent to praise its original qualities. While the narrative of violence and urban insecurity is being inflated by the hegemonic media, the condominium offers control and harmony. While the public space is dirty, gray and chaotic, the condominium is immaculate, green and peaceful. While everyone circulates in the city, only a few circulate in the condominium. While in the city there is encounter, enjoyment and celebration, in the condominium there is isolation, apathy and boredom. In the city there is freedom, in the condominium there is domination.

Despite this, there is only one condition external to the Hhip's that still binds it to the urban space. Even if the horizontal condominium denies the qualities of concentrating the benefits of the city, its inhabitants still depend on the city for their daily living. In fact, it is undeniably included and participates in the urban organisation.

Although the trend towards the evolution of the programmatic content of the design of closed horizontal residential spaces aims for almost absolute independence from the city, including all these functions within its internal perimeter, there is still a dependence on a collective urban element that is essential for the implementation and survival of the condominium: the circulation routes that allow its residents access to the consolidated city. The transfer of housing from the city to the condominium is based on the ability of its future residents to afford the costs and time spent commuting between the city and the condominium.

Villaça's (1998) question as to what comes first - investment in urban infrastructure equipment or the need for infrastructure to meet an urban expansion already underway - is answered in this case. Hhip's operate like plugs, which basically need an efficient road network - a network that doesn't even depend on municipal investment, because they are usually state and federal highways - to connect and suck in the useful effects of agglomeration that have already developed and matured in that city.

This way of fitting Hhip's typomorphology into urban dynamics, developed by urban space developers, alerts us to a mode of urban growth that is opportunistic and disconnected from the commitment to the city's community character.

The constant and frequent coupling of these fragments to the road network that connects them to the open city is structured in a powerful business model that, by maximizing the value of urban land and aligned with public interests, transforms the urban fabric, alters the usual events of urban expansion traditionally driven by more organic processes and disqualifies the open city as a public space and, therefore, to be watched over and cared for by a community.

The construction of Hhip's in areas close to the regional road system establishes itself as a belt around the central urban core. At the same time, detached from this, poorer centers are developing on the more distant outskirts (Figure 5). In other words, if on one hand we have the extensive use of cars by the inhabitants of the Hhip's, which are on average 6km from the central area, on the other hand we observe the fragility of the public transport that serves the more distant districts, which are organised in a discontinuous way in relation to the central urban core. This dynamic exacerbates the historical process of differentiated appropriation of space, with the discontinuous expansion of the urban sprawl resulting from the selective expansion of the city, in which differences in accessibility produce inequality and express the historical process of segregation of its organisation.

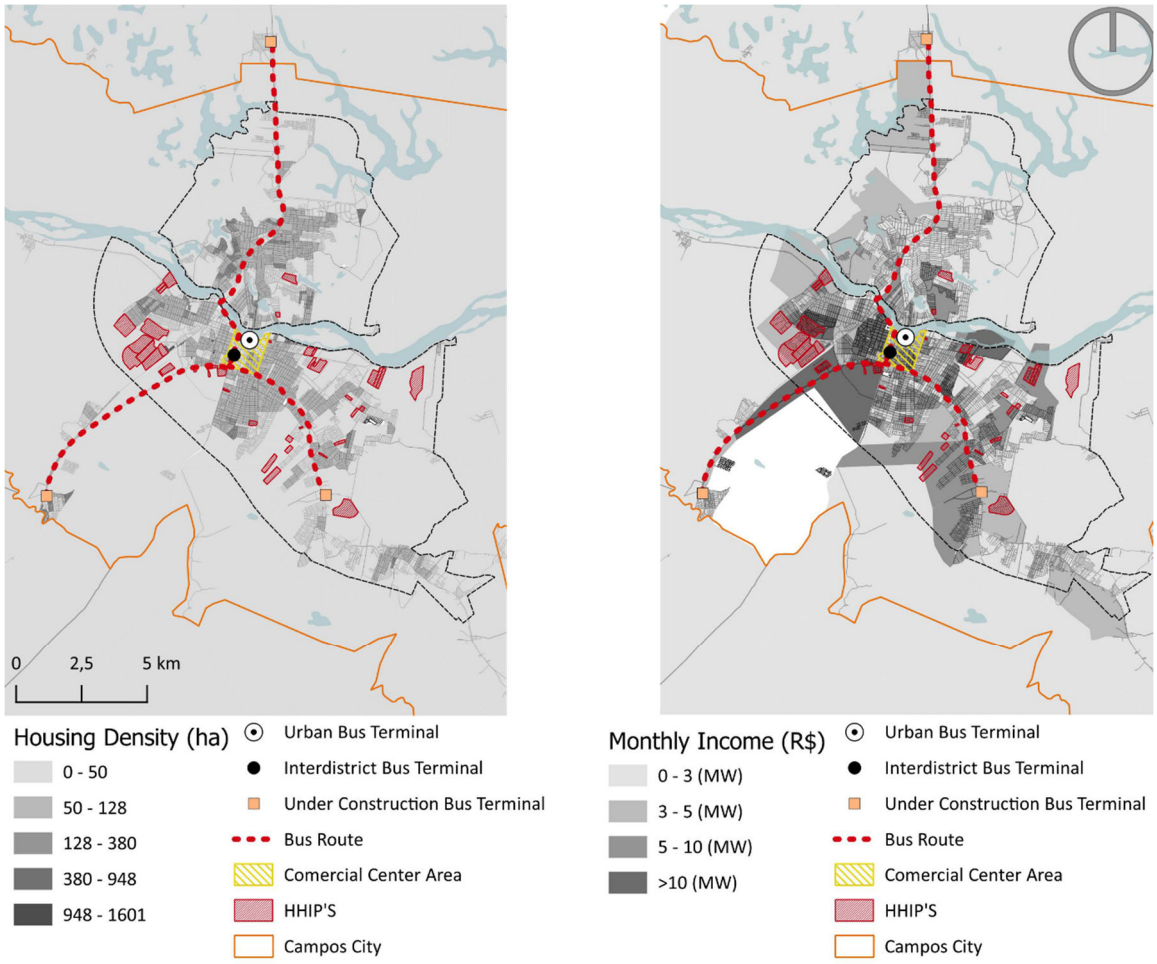

Figure 5 - Housing density and monthly income in the city of Campos dos Goytacazes. Source: Author, 2024.

Thus, the research highlighted three important urban growth trends driven by the close connection between the proliferation of Hhip's on the edges of urbanization and the reinforcement of urban mobility based on the private road matrix.

Hhip's encourage a fragmented urban growth that reinforces the emergence of peripherical areas of concentrated poor population and the emergence of areas contiguous to the traditional center of the city concentrated by higher incomes.

Roads are considered the main element of urbanization, defining a hierarchy between the three fundamental elements of the urban shaping process: streets, urban blocks and buildings.

Upper classes auto-segregation in Hhip's goes hand-by-hand with the urban and mobility planning models, privileging the richest and relegating to the poorest the outlying areas where the transport service is inefficient.

ABSTRACT

With the rapid urbanization in China, the homogenization and gentrification issues in the regeneration of old cities have become prominent, posing negative impacts on the authenticity of residential historical areas. Based on urban sociological and phenomenological theories, combined with field observation records and design practice, this paper takes the "Preservation and Regeneration of Xiaoxihu Block in Old South City Area, Nanjing" as an empirical case to systematically analyze the phenomenon, motivations, practical goals, and design strategies of "authenticity remodeling". By examining the two driving forces behind authenticity remodeling, the paper reveals the demands of residents' rights protection and cultural consumption development underlying authenticity remodeling. Furthermore, from the perspectives of "home" and "consumption", the paper analyzes how the Xiaoxihu regeneration practice maintains the authentic life of the community and effectively stimulates new authenticity experiences. The Xiaoxihu practice provides an autonomous, gradual and open ideal state of "authenticity remodeling", offering an empirical reference for responsible and socially sustainable urban regeneration in residential historical areas.

Keywords: Authenticity, Urban Regeneration, Residential Historical Area, Home, Consumption

INTRODUCTION

Connotation and Significance of Authenticity

"Authenticity", a concept with extensive and profound connotations, occupies an important position in multiple disciplines such as cultural heritage protection and natural ecosystem maintenance. It has also been introduced into the research scope of urban geography and sociology, becoming a theoretical tool for analyzing urban phenomena. In her book "Naked City" (2010), Sharon Zukin employed the perspective of "authenticity" to examine the remodeling of place characteristics and the game among diverse groups during the urban regeneration process in New York, opening up a new theoretical horizon for urban regeneration research (Zukin, 2010). "Authenticity" research focuses on the genuineness and uniqueness of places (including spaces and people's activities), and has significant theoretical and practical value in resisting homogenization and gentrification issues caused by urban regeneration.

"Authenticity" is not merely a static description of physical spaces or cultural symbols but a comprehensive concept that closely connects the temporal and spatial dimensions. Pursuing "authenticity" is essentially an emotional attachment and continuous maintenance of a certain kind of life and the urban spaces that support it, allowing the historical accumulation of living habits and cultural images to be embodied and serving as a yardstick for judging whether the urban living experience is authentic or not. Meanwhile, "authenticity" is dynamic and ever-evolving. Each generation or newcomer constructs a unique sense of belonging to neighborhoods, communities, buildings, public spaces, and resident groups based on their unique historical backgrounds and individual experiences. This process deeply reflects the influence of the era on individual and collective memory, and how these memories shape and remodeling the "authenticity" of the city.

Therefore, deep reflection on "authenticity" highlights the crucial role of the temporal factor, prompting us to confront the challenge of finding an ideal state of "coexistence" between maintaining existing "authentic life" and creating new "authenticity" to address the challenges and opportunities brought by urban regeneration and explore the path of socially sustainable urban development.

Research Object: Overview of Xiaoxihu regeneration Practice

Xiaoxihu Block, located in the Southern Historic District of Nanjing, China, is one of rare historic communities that have maintained the traditional spatial form and social structure. By 2016, 810 households and 25 enterprises were located within the 4.69-hectare block, with the population beyond 3,000 and the per capita living area of only 10m² without complete public services and infrastructure. The Block exhibited a decayed and chaotic living environment. During the summer of 2015, the Nanjing Planning Bureau and the Qinhuai District Government jointly initiated a volunteer action involving graduate students from three universities to explore preservation and regeneration strategies. After expert evaluation, it was determined that the team from Southeast University would undertake the planning and design, while the Nanjing Historic Urban Area Protection and Construction Group would be responsible for project implementation. Through a series of explorations, the Xiaoxihu regeneration practice has formed a small-scale, gradual preservation and regeneration path with the participation of multiple entities (Han, 2022). Based on understanding and respecting the evolution of the historical environment, the Xiaoxihu regeneration design aims to improve residents' living quality, preserve the ambiance of daily life, and integrate cultural creativity, cultural tourism and other new forms of business, has achieved good social, cultural and economic benefits. It is an important practice case of urban regeneration in residential historical areas.

The regeneration practice provides architects and theorists with an important academic perspective, interpreting design issues from a sociological perspective to explore a truly "human-centered" urban regeneration. Li Hua defines "good enough city" as an urban concept opposite to "massive demolition and construction": the city is a process of continuous evolution rather than revolution, with the goal of shaping a "decent" life rather than building a "perfect" city (Li, 2022). Based on observations of the Xiaoxihu practice, Wang Hui raises the question of who benefits from "urban regeneration," inquiring from the perspective of "spatial justice" about whom the regeneration is for (Wang, 2022). Zhang Jingxiang et al. interpret the Xiaoxihu regeneration mechanism from the perspectives of autonomous regeneration collective action and actor-network theory (Gao and Zhang, 2023; Wang and Zhang, 2022).

Research content and Structure of this paper

Based on urban sociological and phenomenological theories, combined with field observation records and design practice, this paper takes the "Preservation and Regeneration of Xiaoxihu Block in Old South City Area, Nanjing" as an empirical case to systematically analyze the phenomenon, motivations, practical goals, and design strategies of "authenticity remodeling".

Starting with an analysis of the phenomenon of "authenticity remodeling" , this research interprets the crises and motivations of "authenticity remodeling" from the two forces of "Origins vs. New Beginnings" (Zukin, 2010), placing urban regeneration in the context of resident rights protection and cultural consumption development to clarify the controversies and challenges in "authenticity remodeling" and find a responsible and sustainable design stance for practice. Furthermore, from the two dimensions of "home" and "consumption", this paper analyzes how the Xiaoxihu Block maintains the authentic life of the community in preservation and regeneration design practice and effectively stimulates new authenticity experiences. The former interprets the human-centered stance and delicate design that maintain authentic life experiences through the practice of "deducing the whole story from small traces"; the latter summarizes the authenticity remodeling strategies of the neighborhood as a cultural consumption destination in plain language. On this basis, this paper analyzes the ideal state of autonomous, gradual, and open "authenticity remodeling" constructed by the Xiaoxihu regeneration project, summarizes its experience, and provides an important perspective and reference for the research and practice of urban regeneration in residential historical areas.

Origins vs. New Beginnings": The Two Driving Forces in "authenticity remodeling"

In the process of urban regeneration in residential historic areas, the dynamic process of "authenticity remodeling" profoundly reflects the interweaving and interaction between the two forces of "origins" and "new beginnings": on the one hand, each generation believes that the place where they reside throughout their lives has original characteristics; on the other hand, new generations create their own unique features (Zukin, 2010). In view of the commercialization trend of historical residential areas in China, the current contestation of demands between "indigenous residents" and "consumption" participants (capital, merchants, consumers, etc.) plays a more central role in remodeling the authenticity of residential historic areas.

"Origins": The "Right" of Residents to Live Here

Lefebvre's concept of "the right to the city" focuses on citizens' geographical right to occupy urban centers: the right to stay live in place, to afford one's residence (Lefebvre, 1996). The notion of "origins" encompasses residents' residential rights to a specific area, rooted in their long-term life experiences and emotional attachments. "'Origins' suggests instead a moral right to the city that enables people to put down roots. This is the right to inhabit a space, not just to consume it as an experience. Authenticity in this sense is a continuous process of living and working, a gradual buildup of everyday experience, the expectation that neighbors and buildings that are here today will be here tomorrow." (Zukin, 2010: 5-8)

"Authenticity" is not merely the continuation of streetscapes and architectural styles but also a guarantee of the right to maintain residents' living continuity and collective memory, serving as the cornerstone for the sustained existence and development of residential communities in specific areas. Understanding the "origins" of residential historic areas should avoid a simplistic retrospection to the architectural forms of a particular historical period, which is both impractical and unreasonable given the intricate historical context of cities. Instead, focus should be placed on the continuation of current residents' living experiences and cultural memories, viewed as a dynamic manifestation of historical inheritance.

The Xiaoxihu project in Nanjing, as an exemplary practice in urban regeneration, effectively safeguards residents' continuity of living in the community through prioritizing "retention" and "renovation" over "demolition" and implementing strategies of "self-regeneration, organic regeneration, and continuous regeneration." This process, through close communication between community planners, architects, and residents, ensures the effective communication of residents' opinions and the full satisfaction of their needs, thereby strengthening the narrative power of "origins" authenticity. Amidst the rapid urbanization tide, it upholds respect for life and the continuation of memory, marking an essential shift in the value orientation of urban regeneration.

"New Beginnings": The Irresistible Force of the Consumer Era

Zukin highlights the complexity of authenticity in urban spaces, where it can be both a quality of historical continuity and a product of contemporary cultural innovation and redevelopment (Zukin, 2010). Authenticity remodeling is not just about preserving the past but also about creating new, meaningful experiences and cultural identities in the present.

As modern cities are increasingly characterized by glass and concrete "boxes," the brick buildings, winding lanes, and vibrant scenes of old city life in the Xiaoxihu historic district have emerged as a unique cultural landscape, attracting citizens and tourists with their cultural temperament and aesthetic value. "Origins" evoke people's deep-seated nostalgia, prompting reflections on the complex connections between history, present, and future, generating diverse imaginations and explorations, and driving people's consumption desire for cultural values and fresh experiences.

Here, people experience the thrill of rejecting the standardized urban landscape of modernism and escaping the fast-paced urban life. The pursuit of individual freedom and relaxed living inspires the design and production of consumer goods and spaces, which not only carry new lifestyles but also serve as visual symbols, reinforcing the unique cultural identity of the place—a "new beginnings" authenticity.

This has given birth to new spaces in Xiaoxihu—places with both local cultural products and global marketing features. The Textile Dyeing Museum and Lantern Workshop rejuvenate ancient crafts through modern design and cultural consumption packaging. The emergence of new businesses such as cafes, music bars, craft beer bars, and plant shops integrates into the daily lives of young people, enriching the cultural ecology of the district. The convergence of local, Sichuan, Japanese, and Southeast Asian cuisines not only showcases the diversity of consumer culture in the context of globalization but also highlights the unique charm of Xiaoxihu as a "new beginnings" authenticity location. Urban regeneration creates new consumption spaces and relies on these spaces to respond to contemporary lifestyles, thereby enhancing urban attractiveness and commercial value.

Practical Objective: Coexistence of "Home" and "Consumption"

The "authenticity remodeling" of residential historic areas is a dynamic and interactive process that encompasses the adjustment of spatial forms, the preservation and reproduction of historical memories, the continuation and reconstruction of residents' rights, and the introduction and expansion of consumer culture.

"Is Xiaoxihu a commercial district or a residential area? Is it an attractive tourist spot in the city or a place for daily life? These ambiguities and intermediate states precisely reflect certain normalities and true realities of the city." (Li , 2022: 41-46) The regeneration practice must effectively respond to the dual propositions of "home-consumption" and find the ideal state of "authenticity remodeling."

The Xiaoxihu project reflects that the significance of the existence of this generation of Chinese architects is not only to do architectural design, but also to do social design (Wang, 2022). The design team of Xiaoxihu, serving as the project designers orchestrated by the government, design consultants for public-private partnerships, and quality controllers for residents' self-directed regenerations, becomes a coordinator among multiple stakeholders throughout the entire process from design planning to implementation and even operation and maintenance (Bao and Sun, 2022). They focus on how to maintain residents' "authentic life" experiences while simultaneously crafting new "authenticity" experiences favored by consumers, thereby achieving the coexistence of "home" and "consumption."

Preserving "Authentic Living" from the Perspective of "Home"

In the book "Home," Alison Blunt and Robin Dowling argue that home is not merely a "place" where we reside and live; it transcends this physicality, embodying a concept and imagination that encompasses a sense of belonging, desire, and intimacy (Blunt and Dowling, 2022). Home is both material structure and profound manifestation of human perception, emotion, attitude, and identity.

"Origins" implies the continuity of life, the accumulation of experiences, and the aspiration for the permanence of home. The "origins" authenticity manifests in the "everyday life" developed through residents' long-term habitation, usage, and habits. Designers should pay attention to the existing social structure and real needs of the community, and design around the core content of "daily life" as a "home" perspective, so that residents can continue to live in the familiar environment and participate in open urban activities. The design team of Xiaoxihu, through their sincere and locally-rooted approach, successfully constructed a framework that intertwines human connections and geographical context. As a result, a profound connection between people and land, as well as history, present, and future, is realized and embodied within the residential space (Bao and Sun, 2022).

In "The Geography of the Lifeworld," David Seamon describes "Rootedness, Appropriation, Recovery, At-easeness, and Warmth" as qualities that constitute "at-homeness." From a phenomenological perspective, he notes that both the "body-subject" and the "feeling-subject" require time to familiarize themselves with and attach to new environments, both desiring minimal changes in their lived world (Seamon, 2022). This continuity is intimately linked to "at-homeness." The design practices of Xiaoxihu's residential and public spaces respect and embody Continuity of Living Space, Stable Sense of Boundaries,The Blankness in Design, A Sense of Coziness in Space, and The Collectivity of the Community, fully interpreting these five qualities of "at-homeness" to preserve the authenticity of "home."

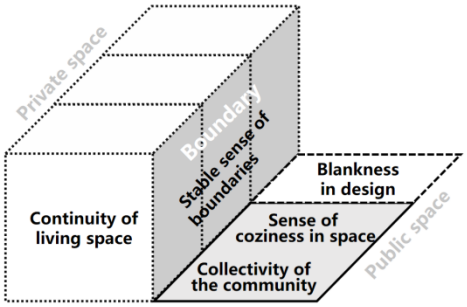

Figure 2. Authenticity Design from the Perspective of "Home", photo credit: Wang.

"Rootedness" · Continuity of Living Space

"Rootedness" is the power of home that organizes the habitual and physical dimensions of personal living spaces (Seamon, 2022). It embodies residents' inner desire to maintain space minimal changes, involving not just cognitive analysis of spatial structures but also facilitating a seamless integration between space and individual behavior patterns, marking a more intrinsic, direct, and vital connection between space and individual existence.

"Rootedness" is a crucial component of authenticity experiences, representing the authentic and genuine aspects of residents' lives. Design should preserve this continuity and habituation in the relationship between people and space. Mr Long's home is a demonstrative courtyard in the Xiaoxihu project. The Mr and Mrs Long have always been accustomed to washing in the courtyard. The architect adjusted the kitchen design according to this living habit of theirs, arranging the operating platform along the south window and locating the sink in the courtyard outside the window (Figure 3), and designing a canopy for this purpose, which preserves the habit of using water and facilitates the interaction between indoors and outdoors. Through a deep understanding of the residents‘ habitual wishes, this kind of "Rootedness" specific and micro-design, which exists widely in the various spatial and temporal corners of the micro-renewal practice in Xiaoxihu, fully respects the residents’ living habits (Bao and Sun, 2022), and also maintains the residents' "authenticity" experience.

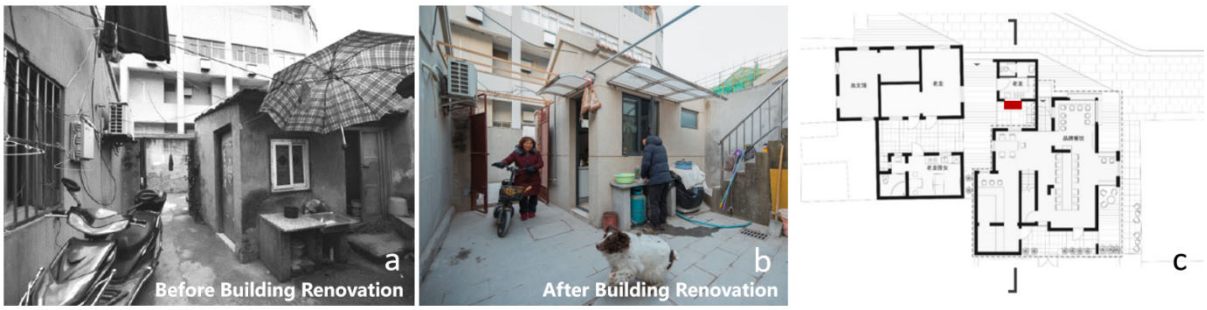

Figure 3. Renovation of Mr Long's home, photo credit: Libao Group(a), Hou Bowen(b), Bao(c).

"Appropriation" · Stable Sense of Boundaries

The concept of home essentially involves the appropriation and domination of space, a sense of control over space as a resource. When space is inappropriately interfered with or violated by external forces, the occupant's right to possession is challenged, leading to a sense of loss of control, which triggers deep emotional and subjective responses from the occupant, which may be manifested as direct feedback at the "feeling-subject" level, such as anger, anxiety, or discomfort (Seamon, 2022).

"Appropriation" provides residents with a spatial order that belongs to and relies on them. A moderate sense of appropriation is a manifestation of place attachment, expressing an authentic human-land relationship that deserves respect and preservation. The regeneration design should fully respect the demands of neighboring residents, maintaining the stability of boundary perceptions through considerate design. In the renovation of No. 5 Madao Street, the street-facing section was transformed into commercial space, while the courtyard within housed the autonomous regeneration of three residential units. The initial design aimed to increase commercial space utilization by designing the commercial section from one level to two levels, raising the roof above its original height. This change evoked a sense of discomfort among courtyard residents who felt their space was being violated. During the design optimization process (Figure 4), the architects lowered the roof ridge height of the new second-story building as much as possible and retreated the "one-span space" adjacent to the courtyard to create an outdoor platform, thus successfully eliminating the sense of "appropriation" brought about by the elevated roof. By giving way to the public interest and forming a stable boundary between public and private spaces, the authenticity experience of "at-homeness" of the residents is maintained.

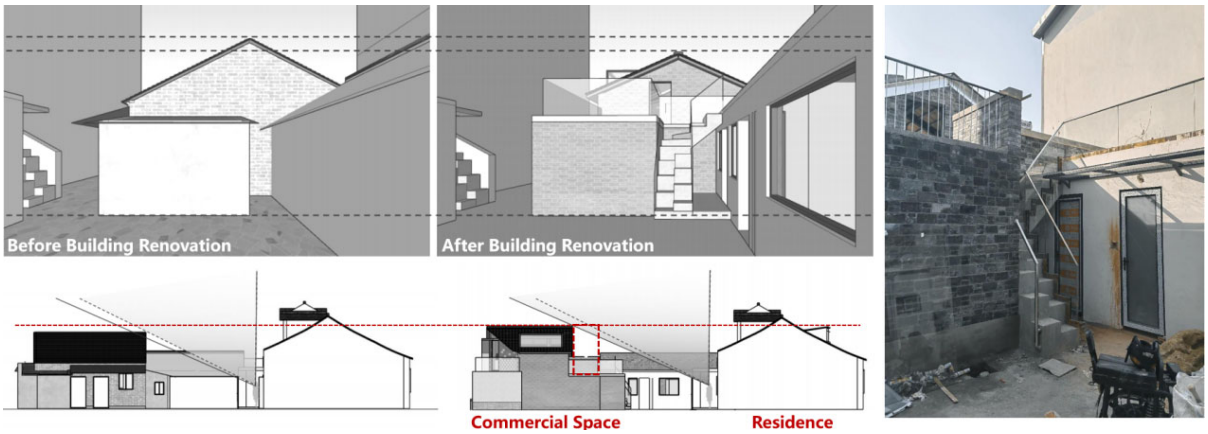

Figure 4. Renovation of No. 5 Madao Street, photo credit: Bao and Wang.

"Recovery" · The Blankness in Design

In exploring the mechanisms of rest and recovery, the individual seeking rest needs to achieve a state of stasis and relaxation. The process of "recovery", in this context, refers to the nourishing and accumulating effect of space on the energy and vitality of the individual (Seamon, 2022).

Returning to an authentic lifestyle, where rest and relaxation are taken for granted, constitutes a vital aspect of the quality of "at-homeness". In the Xiaoxihu Block, there exists a vibrant vegetable garden (Figure 5, bottom) where an elderly resident cultivates various vegetables in foam boxes and plastic buckets, chatting on wooden chairs beside their plots during breaks. This garden narrates the passage of time: in autumn, corn kernels are spread on the ground to dry for storage; in winter, the second-floor balconies are adorned with Nanjing's beloved air-dried bacon. This open space was preserved by the development company, LiBao Group, and the community planner during the regeneration process, and this "authenticity" left behind has brought a sense of rest to the elderly and other community residents, and has become a spiritual garden for the community's recovery and regeneration. The triangular open space behind No. 31 Xiaoxihu was also left "blank" (Figure 5, top), with the design team retaining two gracefully positioned Tanghuai trees along the path, where residents continue to utilize the space beneath them (Bao and Sun, 2022). The "blankness" in design is a crucial strategy to maintain the authenticity of the place, and the "do-nothing" of the design is to better allow the residents to "do-something", so that the residents can define their interaction with space and time.

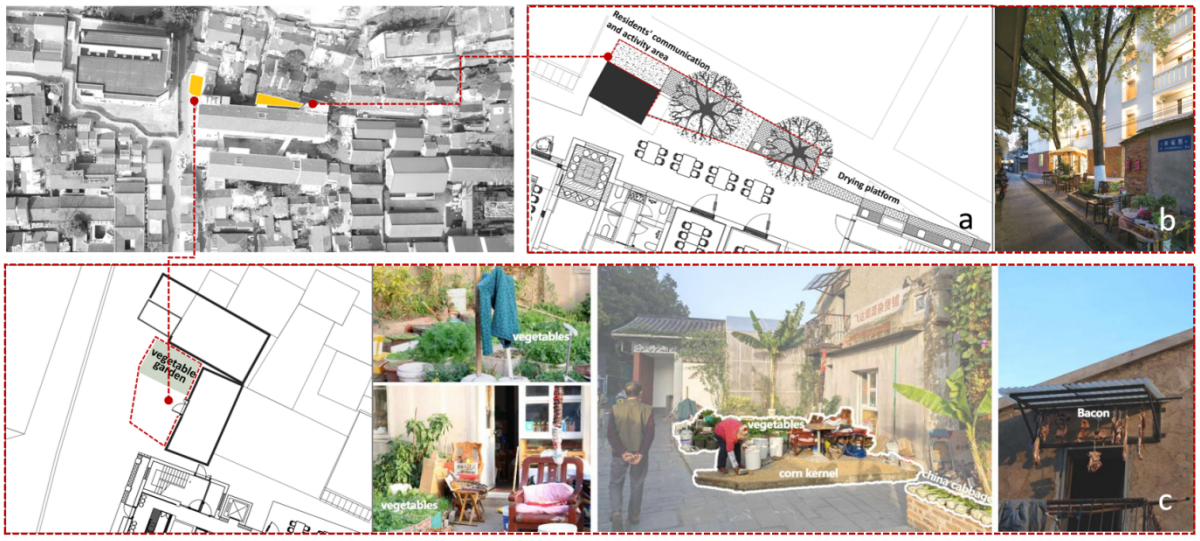

Figure 5. The triangular open space (top) and vegetable garden (bottom) in Xiaoxihu Block, photo credit: Bao(a), Hou Bowen(b), Wang(c).

"At-easeness" · A Sense of Coziness in Space

"At-easeness" signifies a state where individuals can present their most authentic selves in a space, transcending the constraints of social roles (Seamon, 2022). This state embodies one's true, unadorned nature, aligning closely with the philosophical concept of "authenticity." A "cozy" space encourages individuals to experience a pleasant life within their environment.

Seating is a vital prop for creating "at-easeness" places, connecting space and the human body and fostering more lingering and social situations. The diverse seating designs in Xiaoxihu Block inspire a

variety of cozy behaviors (Figure 6): parents waiting for their children to finish school sit or lean on wooden chairs and stone benches along the alleys, construction workers rest on stone benches, and elderly community members chat about life's details on artistic groups of stainless steel stools. These scenes collectively construct a vivid and harmonious "place ballet" (Seamon, 2022), demonstrating the positive role of "cozy" spaces in promoting community belonging and individual happiness.

Figure 6. Seating usage scenarios in Xiaoxihu Block, photo credit: Wang.

"Warmth" · The Collectivity of the Community

"Warmth" embodies an abstract yet profound emotional connection, a vital component of the "authenticity" experience from the "home" perspective, nourished by both space and collective activities. It sustains a joyful and companionable atmosphere (Seamon, 2022), encompassing individuals' sense of belonging and identity to their families and communities.

Shaping spaces and planning activities based on the local context and community needs is crucial for fostering a sense of community collectivity. The houses to the north of Xiangluan Temple burned down, leaving an open space, the design team meticulously restored the Republican-era villas to the north, transforming the enclosed space with Xiangluan Temple into a community square with a traditional stage at the eastern end. This square has become a venue for spontaneous cultural and sports activities and performances organized by surrounding residents (Figure 7), hosting events such as the Qinhuai Lantern Festival lighting ceremony and the Xiaoxihu Theatre Festival (Dong and Han, 2022). The design of public spaces contributes to stimulating community collectivity by shaping memory places where residents can rest daily and perceive history, forming an essential foundation for collective authenticity perception.

Figure 7. Xiangluan Square and residents activities, photo credit: Prof Han Dongqing's team(a), Fang Fei(b), Xue Liang(c), Wang(d).

Design Inspiration for "New Authenticity Experience" from the Perspective of "Consumption"

Consumption culture, as a powerful driving force, is gradually shaping residential historic areas into urban "cultural destinations". This process is a transformation of social space and material entities under the intertwined forces of government policy direction, developer investment, media publicity, and consumer experience preference (Zukin, 2010).

The regeneration practice of Xiaoxihu, with its preserved old alleys and buildings as the foundation, has transformed the space into an artistic and fashionable arena, fostering a series of social and leisure venues for citizens and tourists. It creates a delightful atmosphere that sparks consumers' imagination and offers an enjoyable experience. It embodies Jane Jacobs' essence of building vibrant urban districts, featuring harmonious coexistence of old and new buildings, rich street experiences, continuous attraction of people, and diversity of spatial uses (Jacobs, 1961). The multidimensional aesthetic presentation of alleys, buildings, art, merchandise, and dining experiences aligns with cultural consumers' pursuit of individuality, jointly creating a spatial experience that embodies both cultural heritage and modern life, enriching the "New Beginnings." authenticity of Xiaoxihu.

"Dressed up the Space": The Permanence of Architecture and the Everlasting Freshness of Decoration

On the block scale, Xiaoxihu emphasizes the protection and restoration of the overall structure and morphological characteristics of the historic community. On the architectural scale, it respects the architectural types and styles of different historical periods, selecting materials and craftsmanship that harmonize with the historical environment for renovation or reconstruction, demonstrating "permanence" in architectural form and style. If "architecture" is likened to "people," then "decoration" is akin to attire. Xiaoxihu's commercial atmosphere is akin to a continuous "dressing up," with stylized decorations updated roughly annually to accommodate different business types and brands (Figure 8), continuously creating new visual stimuli and enduring appeal for consumers. The "new beginnings" authenticity experience intensifies within the context of "consumption." The tension in Xiaoxihu Block from the juxtaposition of novelty and difference from "Consumption" perspective and continuity and stability from "Home" perspective.

Figure 8. Everlasting Freshness of Decoration, photo credit: Wang(a), XiaoHongShu(b).

The everlasting freshness of decoration is also evident in Xiaoxihu's diverse urban exhibitions, which enrich visitors' experiences through indoor and outdoor displays related to seasonal changes, city events, and traditional culture. Integrating urban exhibitions with micro-regeneration has become a trend in shaping new urban spaces and promoting traffic growth (Zhang, 2021). Residents, citizens, and tourists can experience and interact firsthand, deeply perceiving the close connection between regeneration activities and personal lives, and appreciating the authenticity rooted in Nanjing's "Old South City Area" history, culture, and residents' lives.

"Accompaniment and Atmosphere": The Accompaniment of Elements and the Atmosphere of Place

Environmental atmosphere needs to be captured and perceived with the help of creating a spatial "continuum" through the establishment of complete paths and flow sequences, and forming a perceivable rhythmic beauty (Li, 2023). The Xiaoxihu district, based on its original winding and freely extending street network, with pocket plazas, creative seats, art installations and colourful shop signboards dotted on both sides, as well as walls made of different materials and climbing greenery, which together construct a spatial environment that always accompanies and attracts the public and tourists (Figure 9), and strengthen the accompaniment of the tour paths - strolling along the lanes, the scenery changes with each step - enriching the authenticity experience intertwined with "origins" and "new beginnings".

Figure 9. strolling along the lanes, the scenery changes with each step, photo credit: Wang.

The regenerated district has been widely disseminated through self-media platforms, using images as a medium to showcase snippets of personal life while also shaping Xiaoxihu's social recognition as a "new beginnings" authenticity experience destination. In this process, the power of "web hotspot" and dissemination has been deeply recognized by planners and designers, with "ambience" becoming an essential consideration in place-making. Taking No. 31 Xiaoxihu as an example, the building, originally a four-story apartment from the 1970s, has been transformed into a boutique hotel integrated with commercial spaces on the ground floor. During the renovation, designers appreciated the intricate and rhythmic design of the original balconies, choosing to preserve them while optimizing the facade rhythm and architectural details. This fusion of the "origins" authenticity of old residential buildings with the low-saturation ins aesthetics preferred by younger generations created a unique atmosphere (Figure 10), attracting citizens and tourists to visit the block, thereby becoming the focal point of "new beginnings" authenticity experiences in Xiaoxihu.

Figure 10. "Internet-celebrity Balcony" at No. 31 Xiaoxihu, photo credit: Bao(a), Wang(b), Hou Bowen(c).

Embrace and Enter": The Publicness of Space and the Inviting Sensation of Interfaces

The Xiaoxihu Integrated Control Center plot gradually evolved into a public space during its regeneration (Figure 11),. The site used to be a parking space for the power supply company, but in the process of renewal, based on the consideration of municipal needs and the value of the site, it was transformed into the main street of the Xiaoxihu block and the commercial spaces on both sides of the street. The transformed plot, now fully public, integrates public facilities and commercial functions, serving as a symbolic southern entrance to the Xiaoxihu block (Dong and Han, 2022). The regeneration enables Xiaoxihu to "embrace" citizens and tourists, inviting them into the block.

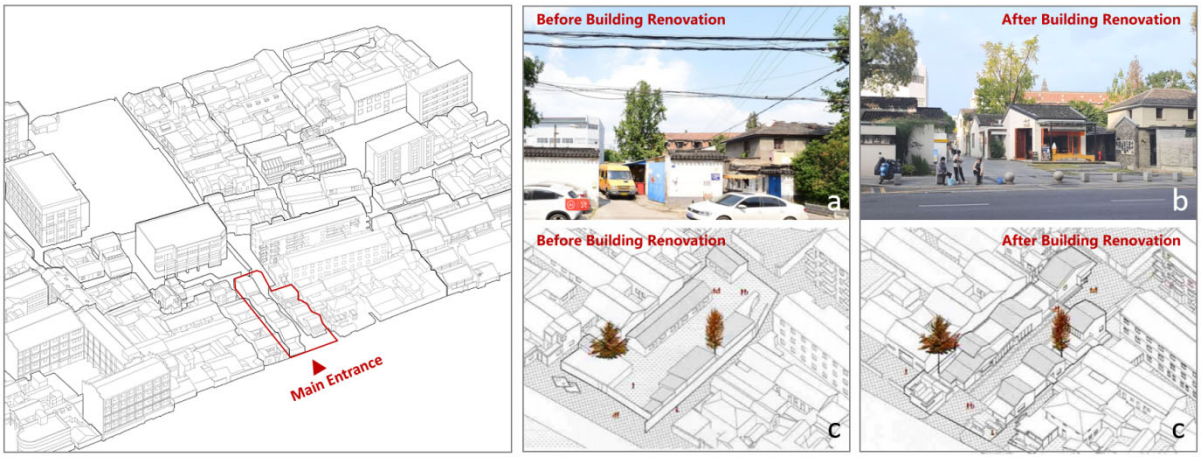

Figure 11. Regeneration of Xiaoxihu Integrated Control Center Plot, photo credit: Baidu Street View(a), Wang(b), Prof Han Dongqing's team(c).

Collaboratively designed by architects, interior designers and merchants, Xiaoxihu's commercial interfaces exude an "inviting sensation." Standing by the roadside, one can glimpse through low walls, stylish courtyards, and transparent glass, and see the textures of interior walls and the ambient lighting cast upon them, almost as if already stepping into the restaurant or café. The large glass with permeability of sight appears flexibly on all facades and walls of the building, inviting people passing by from different angles (Figure 12). Under these "embraces" and "invitations" from the space and interface, people complete the visual experience and consumption of space, well-designed spatial hierarchy, visual elements, colour rendering are fully perceived by consumers, the fashionable and relaxing sense of these commercial spaces bring people "new beginnings" authenticity experiences.

Figure 12. Xiaoxihu Commercial Spaces: The Inviting Sensation of Interfaces, photo credit: Wang.

Conclusion: The Ideal State of Autonomous, Gradual, and Open "authenticity remodeling"

Based on preceding observations, practices, and reflections, we can conclude that the regeneration of Xiaoxihu embodies an ideal state of autonomous, gradual, and open "authenticity remodeling".

"Autonomy" refers to respecting residents and their choices. The regeneration practice of Xiaoxihu safeguards the rights of original residents to "continue living here", which serves as the fundamental premise for preserving the "authenticity lifestyle." The subjectivity and participation of individual residents in urban regeneration are fully prioritized. The practice of community planners in Xiaoxihu "returns to the concern for people," implementing a tailored approach for each household. They listen attentively to residents' aspirations, ranging from ideas for renovating their courtyards, considerations regarding neighborhood relations, to imaginations of community collective memories. In their fragmented daily lives, community residents are able to participate deeply in the process of community planning and design through decision-making (Bao and Sun, 2022). After the regeneration of Xiaoxihu, a large number of original residents still live there, retaining the courtyard form, lifestyle, living tradition, and the "origins" authenticity experience with local characteristics.

"Graduality" is a prudent strategy against drastic remodeling of authenticity and safeguards "origins" authenticity. Xiaoxihu's two-tier control system, comprising 15 "planning management units" and 127"micro-regeneration implementation units" (Dong and Han, 2022), supports the "small-scale, gradual, courtyard-by-courtyard" regeneration model, averting authenticity crises such as fractured community identity and homogenized neighborhoods caused by large-scale, mass-produced regeneration. Ample design cycles and fine services for each household ensure that the design team, grounded in a profound understanding of residents' authentic lives, implements regeneration designs. This strategy avoiding the disintegration of the differentiated authentic experiences of different families and individuals by the "fast-food," standardized designs. "Gradual" regeneration also shapes an intertwined texture and harmonious fusion of new and old, commercial and residential spaces, creating a more vivid "authentic" place.

"Openness" signifies respecting the objective law that authenticity is constantly dynamic, integrating the memories and new vitality of the present era into the existing environment, continually creating and evolving novel authenticity experiences. Xiaoxihu's regeneration design adheres to the principle of "practical utilization", preserving the unique image of historic areas while ingeniously integrating modern elements suitable for new consumption formats. This open and inclusive regeneration design satisfies the diverse needs of the new era. The blend of visitors' experiences and residents' daily lives fosters interactions between fashion and tradition, sophistication and earthly charm. A "truly living" Xiaoxihu exudes a unique charisma that seamlessly blends "new beginnings" and "origins" authenticity experiences, making it a place where "residents feel at ease, neighbors are delighted, and travelers are drawn".

The regeneration of Xiaoxihu, "authenticity remodeling," has achieved an "coexistent and win-win situation" in enhancing living quality, bolstering community vitality, fostering cultural consumption, and promoting cultural tourism development. It provides invaluable insights for responsible and sustainable urban regeneration in residential historical areas today.

ABSTRACT

This study undertakes a comparison of the subtropical cities of Florianópolis and Brisbane that share a common geographical latitude of 27.5° South, with location on the eastern coastline of Brazil and Australia respectively. The juxtaposition aims to explore the distinctive characteristics and socio-cultural dynamics that define these two cities. Through a morphological approach, we assess the natural environment, historical, and cultural facets of Brisbane and Florianópolis, shedding light on the intricate interplay between nature and human societies in the form of these distinct latitudes. A historical analysis unfolds from the urban evolution of each city from the establishment of urban grids in their development as colonised places. Critically, socio-cultural dimensions have been underplayed in the appraisal of the dynamics of urban evolution. By considering the perspectives of indigenous communities, settlers, and migrants, the study seeks to unravel the unique palimpsest of identities that contributes to the socio-cultural fabric of each sub-tropical city. The paper concludes with analysis and synthesis of the intersection of natural environments, settlement histories, and socio-cultural dynamics, providing insights into the commonalities and distinctions between Florianópolis and Brisbane. The conclusions drawn offer a deeper understanding of the complex relationships between nature and human societies, contributing to discussions on sustainable urban development that considers cultural perspectives, and the coexistence of diverse communities in sub-tropical latitudes.

Keywords: Morphology, Subtropical, Florianópolis, Brisbane

INTRODUCTION

Both subtropical cities of Brisbane and Florianópolis share a similar latitude in the southern hemisphere approximately 27.5°S (Figure 1). Brisbane is the capital city of Queensland in Australia and is situated on latitude 27° 28’ South, approximately 750 km due north of Sydney. Florianópolis is also a capital, but of southern Brazil’s Santa Catarina state and is situated 27° 48’ South.

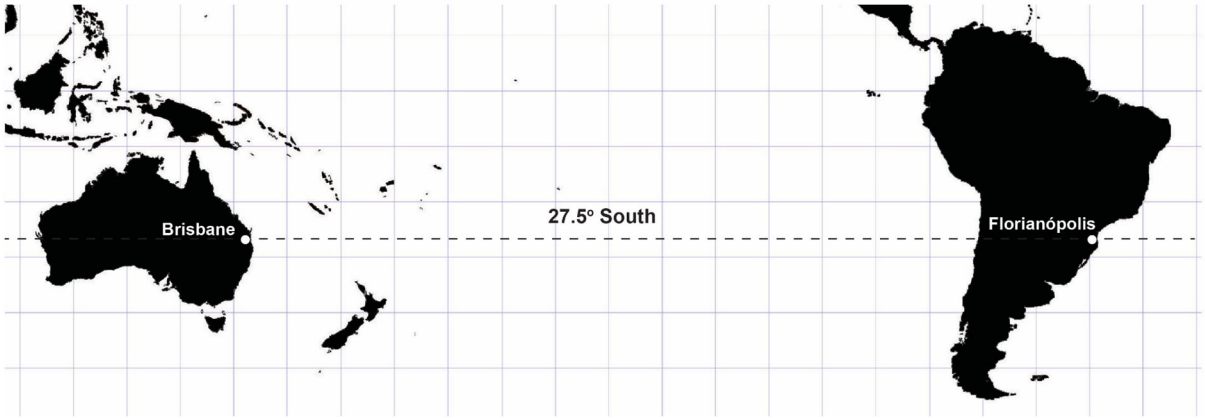

Figure 1. Map showing the 27.5° latitude line passing through Florianópolis and Brisbane. Source: Authors

The cities share an almost identical sub-tropical climate with Florianópolis, which is slightly wetter and more humid than Brisbane. Looking at the comparative regional maps of Brisbane and Florianópolis (figure 2), we see a similar coastal topography in the presence of large island formations. The most striking comparative feature being the urban footprint of Brisbane is almost entirely located on the mainland, whereas Florianópolis is dispersed with the city centre orientated on the Island. A small town called Dunwich, located on the west coast of the neighbouring Stradbroke Island (Minjerribah) has a very similar appearance to that seen from the island of Florianópolis, however it did not develop significantly in urban scale, partly due to the resistance to build a physical transport link to the island. Both urban centres share a strong relationship and conflict with their waterways. Brisbane's central business district (CBD) is almost entirely surrounded by the Brisbane River with Spring Hill forming its northern boundary. Floripa likewise has a CBD that is almost surrounded by its north and south bays with its large hill to the east hemming in the CBD. Both cities are located on the east coast of their respective continents sharing similar access to islands, lake systems, sand dunes and amazing beaches. Both cities have the backdrop of large mountain ranges to the west.

The locations of both cities were inhabited originally by first nations people who enjoyed the bounty of resources from the land and sea. Brisbane (Meaanjin) was inhabited by the Turrabul and Yaggera peoples and Florianópolis by the Carijo Indians, ancestors of the Guaranis. Both groups of indigenous peoples were either driven away, murdered or in Brazil's case enslaved or relocated in missions as is the colonial way of doing business. Traces of first nations people's activities are found in the form of bora rings (ceremonial spaces) and middens along the neighbouring coasts of Brisbane and in cave art on the Isle of Santa Catarina. Brisbane and its surrounds still have communities of first nations people with a deep connection to their land.

In front of the Florianópolis Parish Church, there is a square, Praça XV de Novembro, with its paving reproducing a design with folklore motifs. According to data from the library of the Brazilian Institute of Geography and Statistics, it was from there that the city began to expand and this area is home to a large number of historic buildings, which display the original architectural features preserved by law. During the 19th century, the square was planted with trees of great size, such as the Centennial Fig Tree (Figure 3). Interestingly, this type of tree planting is also found in the Brisbane CBD (Figure 4).

According to Conceição (2011), artisanal mullet fishing is a resource that is as highly valued today as it was by the Azoreans when they first arrived on the island. The importance of this tradition is

economic, cultural and social, and the fishing method is carried out by artisanal fishermen using traditional techniques, such as the use of trawl nets on the beach. This practice is often carried out in a community manner, involving entire families and preserving cultural practices passed down from parents to children over successive generations. From there, we see another cultural similarity between the two cities addressed here, since according to Barker and Ross (2003), Brisbane also has a fishing activity aimed at sea mullet, which is important for commercial, recreational and indigenous fishermen.

Due to the different colonising histories of the Portuguese (in Brazil) and British (in Australia) the original settlement timings vary significantly, with Florianópolis being settled some 350 years ago, and Brisbane settled approximately 200 years ago. Both started as ports in their early years with the first historical buildings of each settlement located on the southside and adjoining their respective waterways. Their cities' colonial grids were defined by this relationship to the water. In Florianópolis' case, the main historical town stretches roughly east - west parallel to the coast with the main church and square dominating the harbour side, along with the main market and commerce areas.

Therefore, we have chosen in this article to begin by addressing the cities separately, starting with Florianópolis in Brazil. Both cities will be given a historical contextualization, followed by a section on physical and spatial issues, and then on to the socioeconomic aspects, always focusing on the influence of all this on urban morphology. Only after this individual approach to each city, the article presents the comparisons in the discussion and conclusion.

FLORIANÓPOLIS

Historical Context Of The Urban Network's Structure - Florianópolis

For a general overview regarding Brazil, Garcia (2015) points out that archaeological research estimates that the Brazilian territory was already occupied more than 12,000 years ago by different ethnic groups. The presence of at least 1,400 different peoples who would have inhabited Brazil before the arrival of Europeans was recognized, and those adopted different reactions when in contact with the colonisers, including large displacements with the intention of escaping slavery or conflicts. At the time of the maritime "discoveries" Pedro Alvares Cabral, Portuguese navigator and explorer, arrived in Brazil on April 22, 1500, a date considered to be the beginning of Portuguese colonisation. Kern (2000) speaks of the intention of conquest of gold, silver, or the souls of the Indians through missions to evangelise them.

This settlement of Brazil by the Portuguese began on the coast, with the intention of establishing sugar cane plantations, mills, and ports. Parallel to this, the colonists organised expeditions in search of labour, metals and precious stones. The brazilian city we are approaching in this article, Florianópolis, is an island of the coast of the southern region of Brazil, and upon the arrival of the colonisers, the Europeans saw these territories occupied by indigenous groups called Kaingang, Xokleng, Xetá and Guarani, and the domination of these territories involved a series of violent and systematic actions that ended up decimating and impacting the local population in a permanent and lasting way (Garcia, 2015, 92).

At this time, of the beginning of the 16th century, ships travelling to the River Plate Basin stopped on the island to pick up supplies such as water and food, which later led to the the recognition of the

settlement with the name of “Nossa Senhora do Desterro” (currently Florianópolis) around 1675, with the arrival of a coloniser from the São Paulo region, Francisco Dias Velho, with his family. According to Vaz (1991) the part of the island chosen to establish this settlement remains until today as the city's central business district (CBD).

During his time there, Dias Velho arrested a crew of a pirate ship carrying silver, confiscating its assets to the Royal Treasury. A year later, the pirates who had escaped returned, caused destruction, and killed him. After that the place was abandoned until twenty-three years later when French navigator Amadèe Frèzier arrived on the island and found around 150 people, led to the place by Lisbon native Manoel Manso de Avelar. Thus began a new phase in the occupation of the site (IPHAN - The National Historic and Artistic Heritage Institute in Brazil). The settlement of Desterro was elevated to the category of village in 1726. Around ten years later, due to its strategic position for the Portuguese crown in Brazil, it began to be occupied militarily. At that time, fortresses began to be built. Portugal recognized the convenience of fortifying the island and taking care of its settlement and commissioned Brigadier José da Silva Paes, appointed governor of the local prison, to carry out this mission.

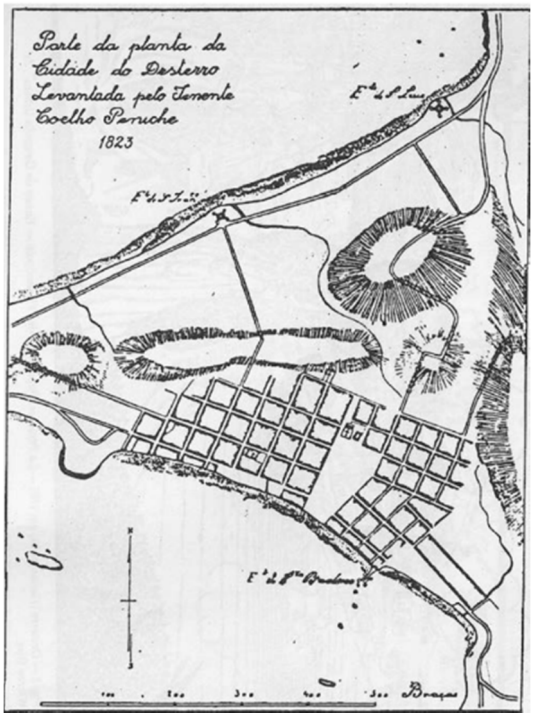

Figure 5. Floor plan of Florianópolis from 1823. Source: Peluso Júnior, 1991

Silva Paes began the construction of the Government House, the four fortresses and the project of the main Church. Saboya, Reis, and Bueno (2016) point out that until the 18th century, the occupation of the Island was practically restricted to the immediate vicinity of the initially founded village and other specific occupations scattered throughout the interior of the Island and adjacent continental coasts. Measures were taken to help occupy the Island, highlighting the Azorean settlement, which began in 1748. Between that year and 1756, around six thousand immigrants disembarked, populating the Island and the nearby continent. The same authors also note that as a consequence of this immigration there was an occupation focused on agriculture, forming a territorial structure that persists, in part, being drastically modified only with the development of urban occupation focused on tourism present today.

The city plan was subordinate to the sea, promoting a densification of housing in the western part of the city. The house groups that at the time marked the directions of the streets that were being formed. After a certain point the guiding element was no longer the beach, but the base of the hill on which the houses were built. In 1819, the city's densification progressed to the east of the square, on the plain that facilitates the street layout (figure 5)parallel to the beach (Peluso Júnior, 1991).

After Brazil adopted a republican form of government in 1889, according to Castelhano et al. (2023), until 1950 there was a strengthening of the State's capital status, a period with administrative and industrial activities, and improvements in commerce and services activities. The construction of the Hercílio Luz bridge, in 1926, marked a moment of political, economic and social transformations, being the first road connection between the Island and the mainland. The arrival of the bridge on the island was in a not so noble region, alongside the cemetery, the waste incineration, factories and the city's workers' village. Little by little and with subsequent plans for the city (Ferraro and Yunes, 2016). From the 1940s onwards, this portion and the entire central area of the city began to change its configuration.

Physical And Spatial Aspects - Florianópolis.

Florianópolis has most of its territory on the island of Santa Catarina and a small portion on the mainland. The island part of the municipality was strategically positioned as a refuelling point for ships heading to the Prata River Basin and military intending a defensive occupation (Conceição, 2014). Although its relief was very rugged, with hills ranging from 400 to 532 m, and with its east coast facing the open sea, which difficult for ships to dock, on its west coast, its proximity to the continent formed an area protected from the bad weather and a natural harbour that, according to Conceição (2014), was the driver of the city's development for almost 2 centuries. The proximity to the continent in the narrowing of the channel offered ships two bays, the north bay and the south bay, with calm waters where access to land was facilitated by the existence of plains with a greater aptitude for occupation, as can be seen on the map produced in 1710 by French navigators (Figure 6). It was in this region where the channel narrowed that the first settlement on the island was formed, today the central region of Florianópolis. The island's mountainous topography is depicted at the bottom of the 1716 French map (Figure 7).

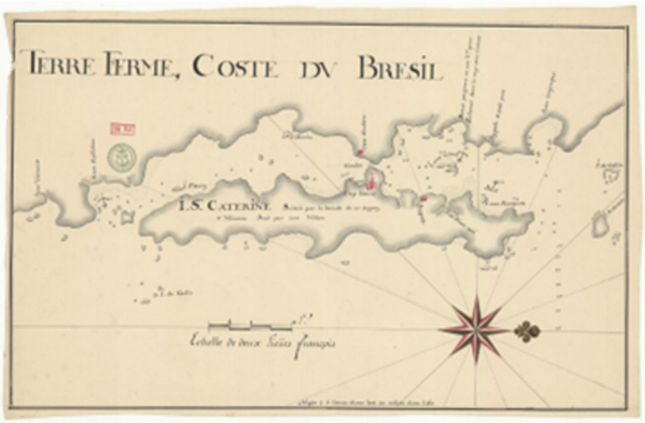

Figure 6. French map of Santa Catarina Island (1710). Source: National Library of France (gallica.bnf.fr)

Figure 7. Island of Santa Catarina map. Located on the coast of Brazil (Carte Particuliere de l'Isle de Ste. Catherine. Située à la Côte du Bresil). Source: National Library of France (gallica.bnf.fr)

With a mountainous massif that cuts the island from south to north, in the portion facing to mainland there are plains that favour the formation of mangroves, while on the island Atlantic side the slope is steeper with dune formations and extensive beaches (Figure 8). This island geomorphological conformation favoured an initial occupation in the plains on the west coast and in small areas along the entire coast. Another important aspect that guided the occupation of the island was the water network, formed by small river basins with their rivers, lakes and lagoons, the main water formations being Lagoa da Conceição and Lagoa do Peri. This initial occupation sought proximity to water sources, both at the sea and at the mouths of rivers (Figures 9 and 10). Thus, parishes were born that were, in large part, the basis of the current consolidated neighbourhoods, configuring a polynuclear occupation on the island, the basis of the urban structure that currently exists in Florianópolis.

Figure 10. Spanish map by Tomas Lopez from 1777 with the first occupations on the island of Santa Catarina, highlighting the location of the fortresses. Source: Florianópolis City Hall

In 1673, Francisco Dias Velho officially occupied the island territory, following the principle common to the Portuguese island layout at the time: a chapel facing the coast, with a square between it and the sea, flanked by the colonists' houses. Added to this form of occupation, the port dynamics established there led to the first urban structure in Florianópolis maintained to this day. In Figure 11, the map from the first decade of the 19th century shows this configuration.

Figure 11. Urban structure around the port in the first decade from the 19th century. Source: Florianópolis municipal archive collection.

Figure 13. Florianópolis Center - Public Market by the sea - early 1990s. Source: http://fotosantigasFlorianópolis.blogspot.com

The construction of the Hercílio Luz Bridge will reinforce this process of centrality of the port area with a slow occupation process and which will maintain the initial foundations of the land structure until the beginning of the 19th century (Figures 12 and 13), still with a strong relationship with the sea. The characteristics of the Island's relief created difficulties in displacements and the old trails, normally at the bottom of the valleys, are becoming the main paths and routes that today structure the island's mobility system.

Focused on increasing mobility, given this road structure that is difficult to expand, there has been, since 1970, a large investment in expanding connecting roads and implementing extensive embankments, aiming to make areas available for the road system (Sugai, 2015). Florianópolis' urban expansion and development initiatives have included, among other measures, the execution of landfills along the city's coast. Lisboa (2004) notes that until 1990, four landfills were built in the city, three on its island portion and one on its continental portion (Figure 14).

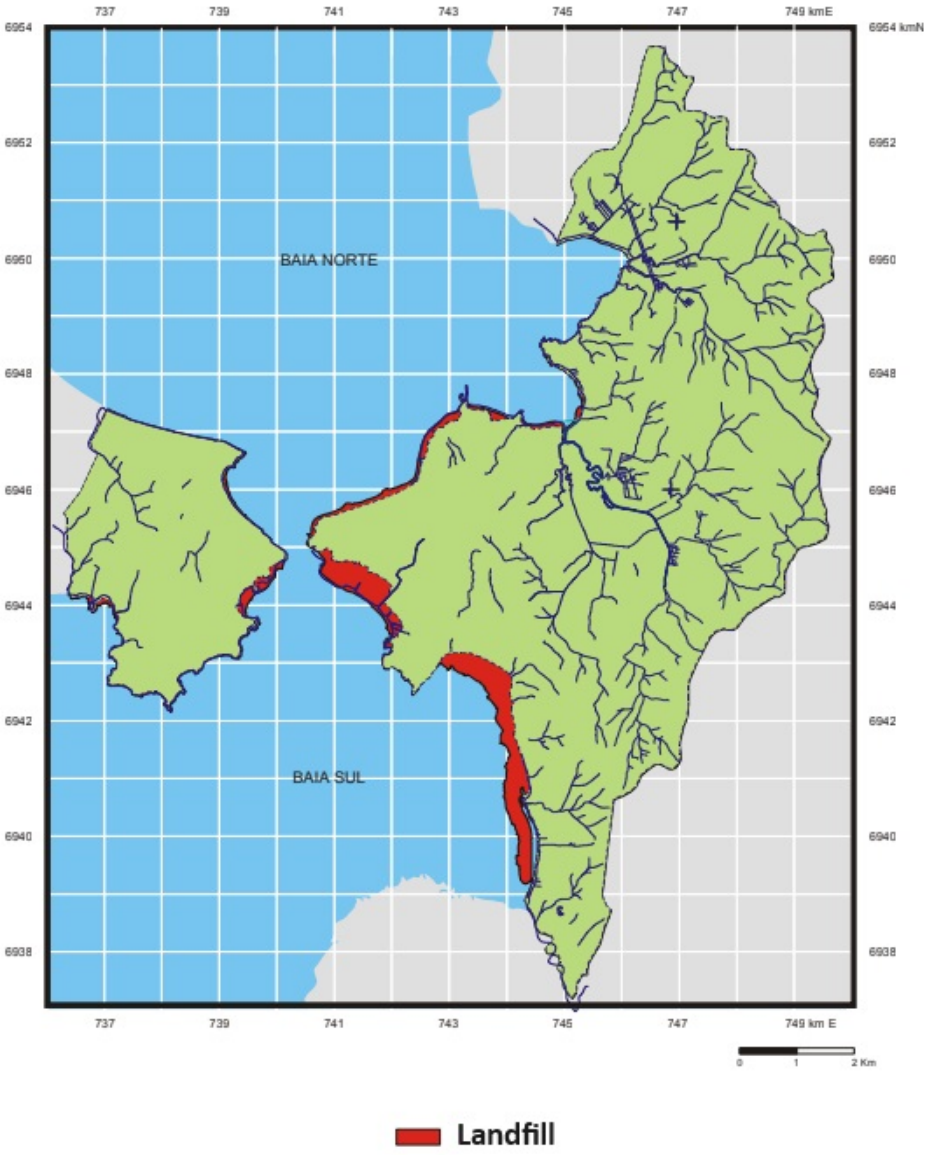

Figure 14. Morphological change of the coastline between 1966 and 2002. Source: LISBÔA, 2004. pg.62.

Of the 433 km² of Florianópolis' territory, 9 km² were created by landfilling (Prochnow, Dal Santo and Amey, 2009). In addition to the need for larger spaces, there are also difficulties in island urban development in Florianópolis due to its geographical barriers. The rugged terrain not only slows down the city's growth, but also hinders the flow of goods and people. The landfills would come from the need to increase road connections, between the island and the mainland and several more central locations on the Island of Santa Catarina itself, being the main reason for their construction and installation.

The first landfill, called Baía Sul, was built in the early 1970s, starting from the Hercílio Luz bridge to the southern coastal region of the island. The intervention aimed to induce growth in the southern region of the city, which is less valued compared to the north. The development of the south of the island was stimulated by a local road expansion and restructuring plan, essentially prioritising travel by private cars (LISBOA, 2004). The second landfill, called Baía Norte, expanded, also in the 1970s, in the opposite direction to the first, from the Hercílio Luz bridge to the northern coastal region of the

island, directing the city's growth towards the local hydrographic network and of the recently installed campus of the Federal University of Santa Catarina (LISBOA, 2004).

Two other landfills in Florianópolis were carried out in the following decades, according to the same logic as the first two, but differing in their processes due to the environmental protection laws consolidated by the Federal Constitution of 1988, which restrict the uses and changes that the intervention could be carried out, based on environmental impact studies (LISBOA, 2004). The third landfill, called Saco da Lama, was the first one to be located on the mainland of the city, on the other side of the Hercílio Luz bridge. The landfills moved the sea away from its central area and radically changed the character of the city.

According to Andriani, 2017, the most recent landfill to date was built with the aim of creating an avenue on the Sea side of the Continental part of Florianópolis, to ease traffic in that area (Figure 15). The work on this landfill began in 2004, amidst great controversy regarding environmental issues, and was completed in 2012, transforming this part of the coast into a three-lane avenue with one-way traffic heading north, which is the same direction as the two streets, mainly to alleviate traffic congestion (Andriani, 2017).

Figure 15. Location of the last landfill made on the mainland. Source: Google Earth, adapted by Anna Pimenta according to Andriani, 2017.

The expansion of occupation of the old peripheral centres occurred slowly until the mid-1970s, but these investments in landfills, road infrastructure and the beginning of tourism on the island began to attract interest from the real estate sector. In 1976, a new Master Plan was approved that focused on improving road access to beach neighbourhoods with a view to their development. During this period, the expansion of urban growth began towards the north of the Island. Although there was an incentive

in the legislation for occupation towards the east, this only intensified at the end of the 90s. Figure 16 with orthophotos of Florianópolis in the years 1938, 1957, 1977, 1994, 2002, 2007, 2016 and satellite image from 2024, allows us to visualise the evolution of the city's occupation.

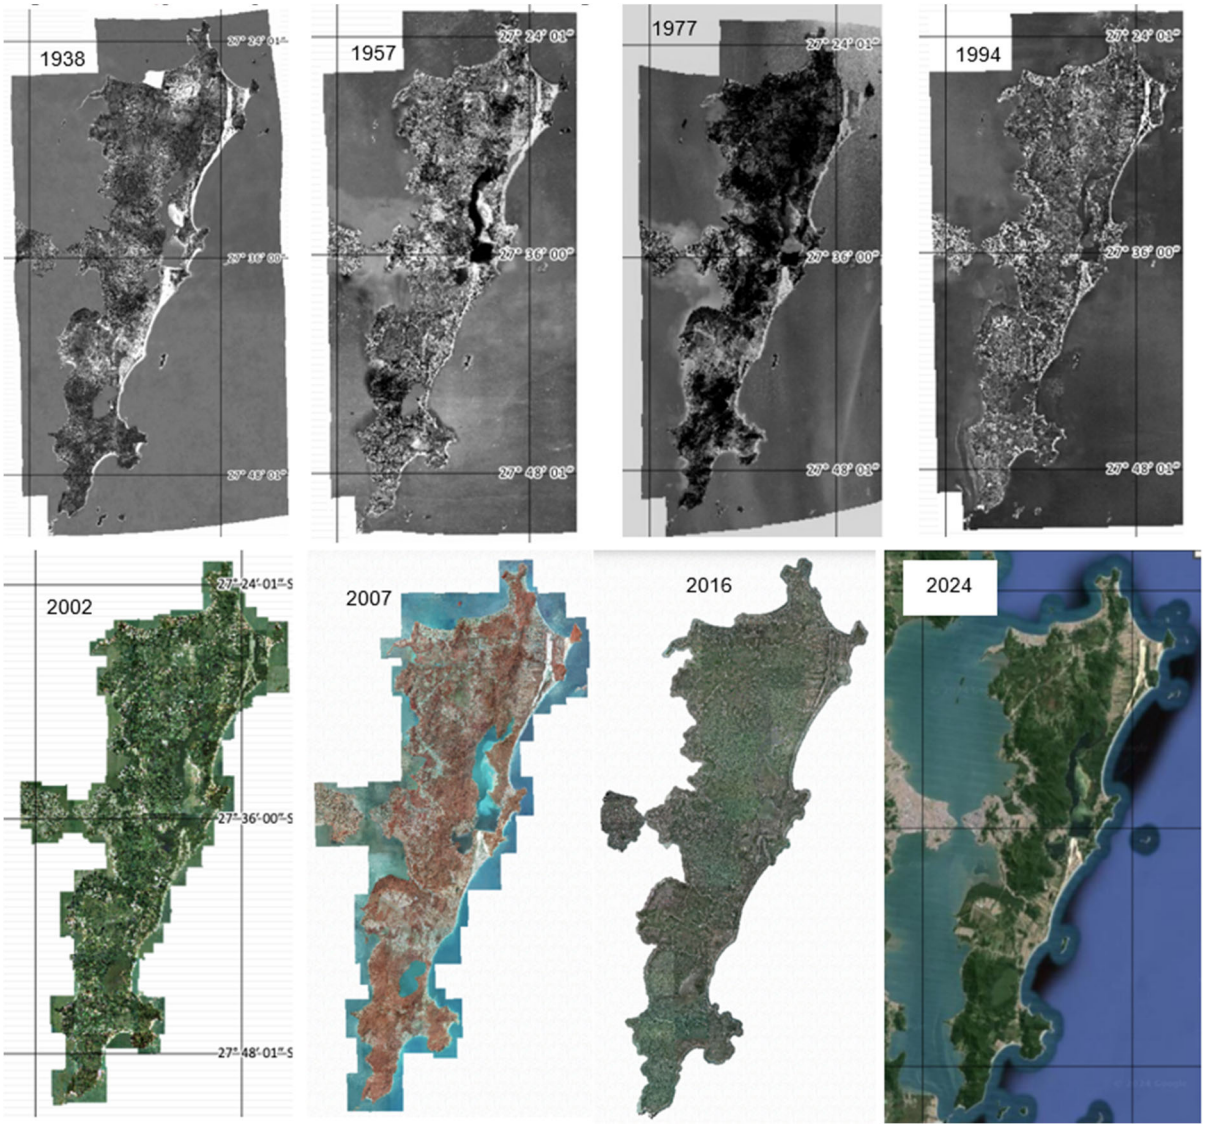

Figure 16. Florianópolis Orthophotos from 1938 to 2016 and satellite image from 2024. Source: Elaboration from Florianópolis City Hall (geofloripa.pmf.sc.gov.br)

Figure 17 shows the evolution of the urban area during periods of greatest growth (between 1977 and 2012). It is observed that the central-western zone of the island and the continent were almost completely consolidated until 1977, with few changes in subsequent periods. There was an increase in occupation between 1977 and 1994, most significantly in the North region, in the Canasvieiras and Jurerê neighbourhoods, and to the south in the Campeche plain. In the second period of great growth, there is again an intensification of occupation in the North region, but at this time in the Ingleses and Rio Vermelho neighbourhoods, which today is one of the main growth vectors on the Island along with the consolidation and expansion of the Planície do Campeche. The 2019 map of the urban area and the current satellite image do not show a major expansion in occupation, however there was a significant increase in population in the period, highlighting an ongoing verticalization process. In all periods, alignment with the structuring road axes is identified.

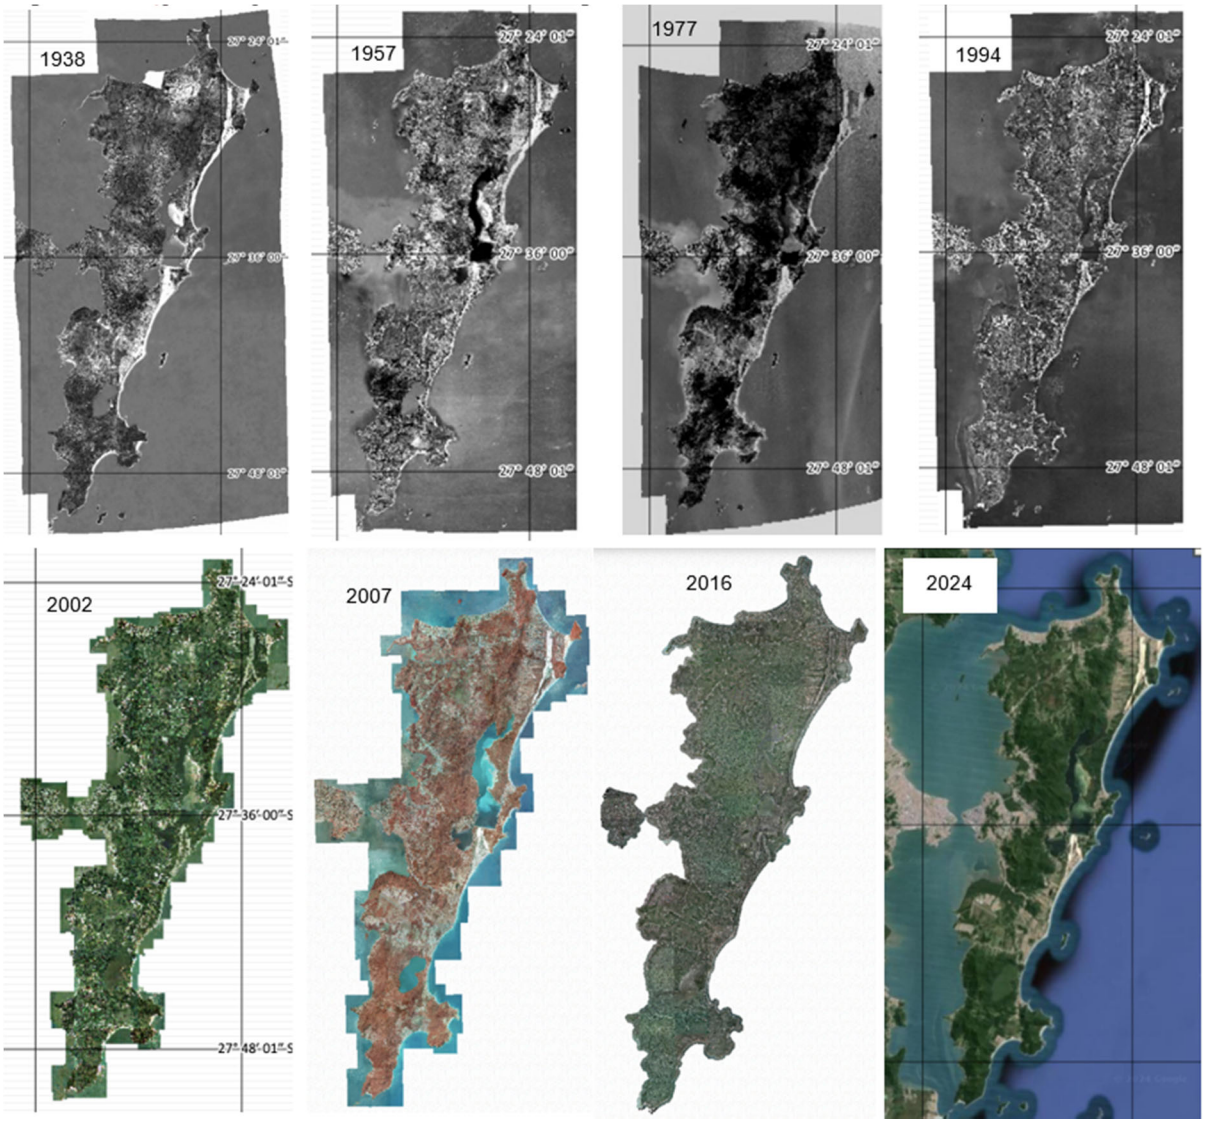

Figure 17. Urban area of Florianópolis evolution. Source: Elaboration from Florianópolis City Hall (geofloripa.pmf.sc.gov.br)

These were considered the main physical and spatial aspects that influenced the changes in the urban morphology of the city of Florianópolis over the years. However, we cannot fail to consider the influence of socioeconomic aspects on urban morphology by shaping income distribution, housing quality and infrastructure. Income affects the location and quality of residences and services, while urban planning policies and regulations reflect economic interests and determine land use. Therefore, these aspects will be addressed in the next section of this article.

Socio-Economic Aspects (Consolidation And Configuration Of Housing Neighbourhoods) - Florianópolis

Florianópolis' residential neighbourhoods may be roughly classified into two main types, according to their origin and resulting street layout: the first comprises planned portions which, for the most part, have more regular grids and are located in lower and flatter terrains. The second includes neighbourhoods that developed largely spontaneously and have a street system based on one or very few main roads organising fragmented and disconnected streets.

Another important distinction is between the central areas and those located at the beaches around the main Island. While the first has a more uniform and regular street layout, the others are much more heterogeneous and have both types of layouts. In these latter areas, two traditions coexist: on the one side, traditional settlements that transformed from rural areas into incipient urban areas, and later received a lot of interest from the real estate market because of their position near the beaches. On the other, tourism-led developments carried out by large profit-seeking firms and land owners.

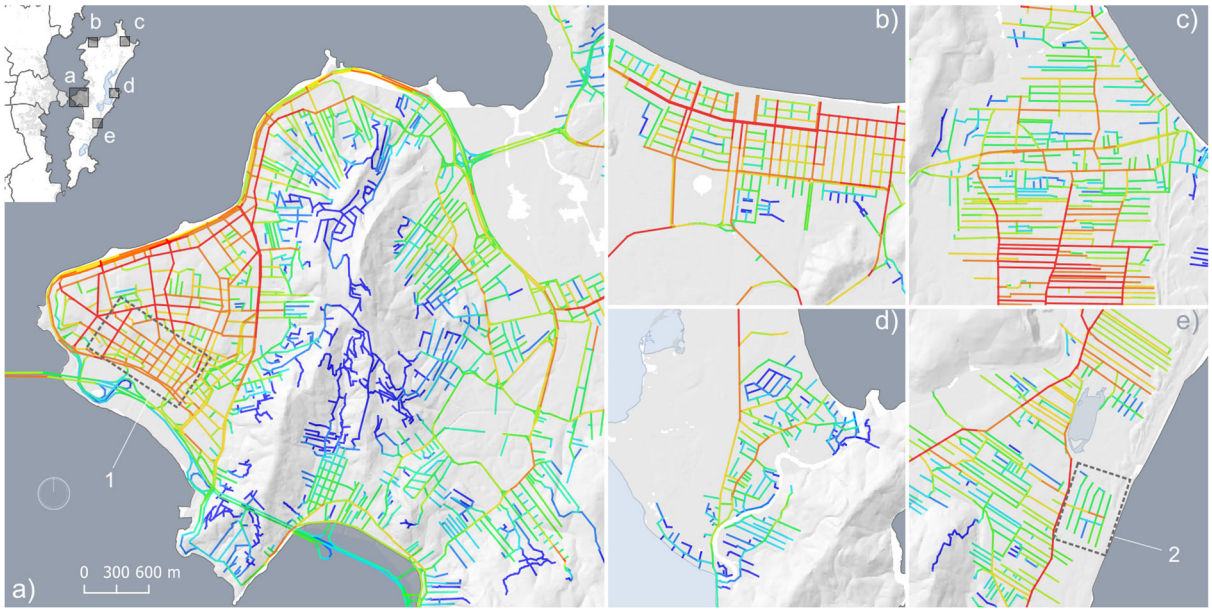

Figure 18. Street layouts of Florianópolis' historic centre and of four of its beachside neighbourhoods. Source: edited by the authors with original data by IBGE (2010) and Municipality of Florianópolis.

Figure 18 shows the street layouts of Florianópolis' historic centre and of four of its beachside neighbourhoods. They are represented by their level of Local Integration at the 1200m radius, meaning that street segments in more vivid colours (red and orange) are, on average, closer to other streets within the radius. Blue hues represent the opposite: street segments that are, on average, distant from the immediate (1200m) vicinity. Figure 18a shows that the historic centre has a regular grid on the South that corresponds to the foundational nuclei (marked "1"), and that the layout of the surrounding streets are more fragmented. The central hill is an extreme case of such fragmentation, being linked to socioeconomic processes of spontaneous occupation by low-income populations in search of well located places near jobs and other amenities. Figure 18b shows a modern and planned seaside neighbourhood (Jurerê) with its regular grid, while Figures 18c and 18d show more traditional neighbourhoods that developed around unplanned street layouts. These areas are heavily dependent on just a few streets. Finally, Figure 18e shows an hybrid neighbourhood with mostly irregular and fragmented street grid, developed spontaneously, and a small and more recent planned neighbourhood (marked as "2"). Both of the planned and regular seaside neighbourhoods cater to high income groups and tourists, while the spontaneous areas are more socially mixed.

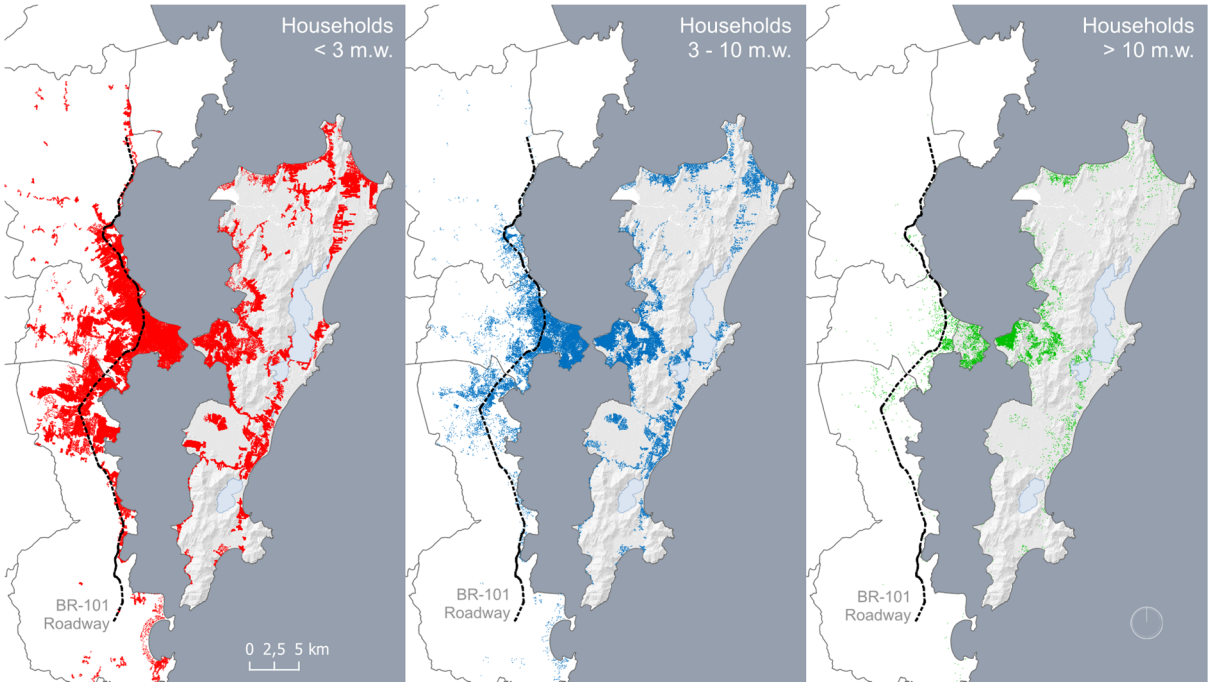

Figure 19. Distribution of residences by income classes (per capita). Note: m.w. = minimum wage. Source: edited by the authors with original data by IBGE (2010).

Another important characteristic of Florianópolis' residential neighbourhood is the distribution of income groups between the Island and the mainland. Figure 19 shows that there were still numerous households of the low-income group in the Island in 2010 (last available data) but, as Sugai (2015) has shown, the pattern of change in the last decades has been their displacement and relocation on the fringes of adjacent cities. Little by little, traditional neighbourhoods are being occupied by upper class residents coming from other Brazilian cities - and even from abroad - in search of natural coastal landscapes, services and other amenities, raising land and values and housing costs in the process.

BRISBANE

Historical Context Of The Urban Network's Structure - Brisbane

Aboriginal civilisation is considered one of the longest surviving cultures in human history, with evidence tracing their ancestry back over 50,000 years to arrivals from the Indonesian archipelago. Originally forming semi-nomadic hunter-gatherer tribes, they lived within well-defined geographical boundaries (Schub and Smith 2024). The first inhabitants and traditional owners of the Brisbane River area are the Aboriginal groups of the Turrbal, and Jagara people (Greenop and Memmott, 2007, 216). Their place values and place-making activities, being points of orientation for spiritual, social and cultural reference and including sites of large gatherings (Greenop and Memmott, 2007, 214), were numerous and widespread throughout the region. Kerkhove (2018) confirms the pre-colonial existence of a number of meeting and camping grounds to the south of the river which featured swamps, woodlands, and rainforests. Traditionally called Kurilpa ('place of bush rats'), this area, now known as West End and South Brisbane, was rich in resources and a popular hunting location for game (Figure 20).

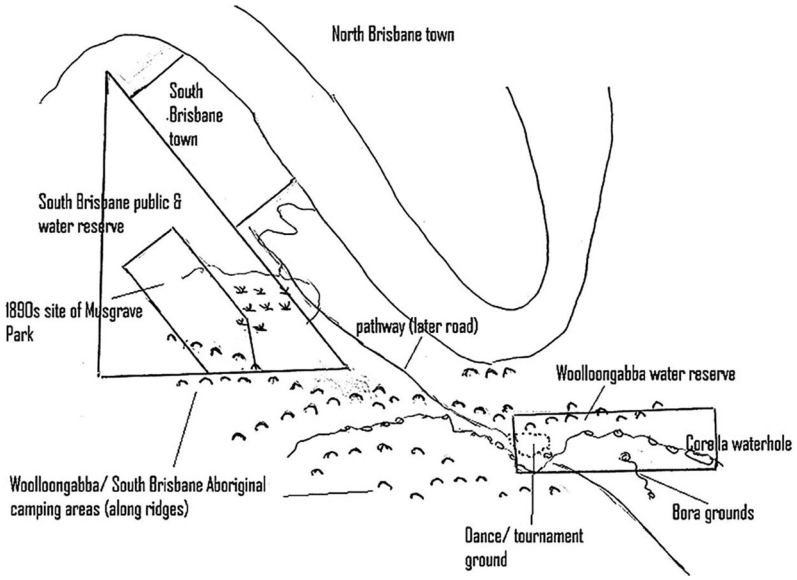

Figure 20. Location of Water/Recreation Reserves and Aboriginal camps (Kerkhove 2018).

Moreton Bay is a wedge-shaped embayment situated between the mainland and the offshore barrier islands. Coastal headlands are most notable on the dune islands, which are formed from tertiary basalts. Moreton and North Stradbroke Islands (Minjerribah) are characterised by high rocky headlands in their north-east corners, specifically Cape Moreton and Point Lookout, respectively (McPhee, 2017).

British occupation followed John Oxley's discovery and survey in 1823 of a large tidal river suitable for settlement (Johnson, 1988, 12; Johnson and Gregory, 1989b, p.238). A convict colony, initially known as Moreton Bay Settlement (Johnson and Gregory, 1989b, 242) was soon established on the banks of the river some 16 km upstream from the sheltered Moreton Bay and housed only the hardiest of criminals from the penal colony in Sydney. The settlement was short-lived and was closed in 1839, and the transportation of convicts officially ceased in 1841, with the official proclamation that ended the penal colony declared shortly after in 1842 (Gough and Ogilvie, 1985, 8; Johnson, 1988).

Even during the period when the convict settlement was being dis-established, preparations for free-settlement were already well underway. Starting in 1839, three surveyors had been sent to Moreton Bay to conduct trigonometrical surveys (Figure 21) in order to determine topography as well as to report on the condition of soils, water and timber supply, with a view to recommending sites for towns, villages and other purposes (Johnson, 1988).

Figure 21. Dixon, R (1839) Plan of Brisbane River and Moreton Bay. Source: State Library of Queensland.

Figure 22.. Dixon's map of Brisbane Town 1840. Source: State National Library of Australia.

The following year, Dixon drew up a plan (Figure 22) proposing the layout for the new town, incorporating a system of large square grids, each ten chains long, and streets one chain wide or 66 feet/ 19.8 metres (Johnson and Gregory, 1989a, 260), with the original prisoners' barracks building providing the reference for the main alignment (Johnson, 1988, 34). Dixon's plan was subsequently modified by Henry Wade with the principal revision being the modification of the square blocks into rectangular grids (Figure 23).

There was considerable debate regarding the suitable width of streets, partly due to Governor George Gipps' view that Brisbane would not develop into a very significant town; the only concession to the original plan of relatively narrow streets, was the provision for a main central street (Queen Street) to be wider than the others with a width dimension of 1.21 chains or 80 feet/ 24.4metres (Johnson and Gregory, 1989a; Johnson, 1988; Mellor, 1960). Siksna identified that the settlement pattern of Brisbane was based on 200x90m 'medium rectangular blocks' with a street spacing mesh of 221x111m; internally divided with 20 equal back-to-back lots (Siksna, 1997, 30).

Australia shares many characteristics with America in terms of city block settlement patterns (Siksna 1997) and the frequent, significant changes in urban form driven by successive economic cycles. Both countries have relatively young towns and cities, with the earliest settlements being spatially minimal compared to their later expansions. Rapid change is a constant, making the study of urban morphology less organised and structured than in Europe (Conzen, M.P., 2001).

In Europe, historic centres allow for the assessment of morphological patterns through the interpretation of existing forms. In contrast, Australia's urban fabric has fewer historic buildings, necessitating a greater reliance on archives and records for morphological analysis. However, the relative youth of Australian cities, combined with a tradition of meticulous British surveying, recording, and archiving practices, provides a wealth of secondary data suitable for morphological research.

Figure 23. Ham, T. and Co. (1863). Ham's Map of the City of Brisbane, Queensland, 1863. [Cartographical material].

Physical And Spatial Aspects – Brisbane

The Greater Brisbane area has most of its urban territory on the mainland, with only the small-town settlements of Dunwich, point Amity, and Point lookout on North Stradbroke Island (See Figure 24), this being the converse situation with the case of Florianópolis. The city area mainly consists of undulating to low hilly lands, generally below 80 metres in elevation, but rising to around 120 metres, with a few isolated higher hills to the West of the city centre, which reaches 255 metres. This region also includes very low-level plateaus to the South, which are small remnants of an ancient surface that sloped gently toward the coast. The low hilly areas typically have gentle to moderate slopes, while the middle to upper slopes of higher ridges, particularly in the western suburbs and on isolated prominent hills, are moderately to steeply sloped. This region features a variety of rock types, including carbonaceous shales and lithic sandstones. Additionally, a narrow, north-south band of rhyolitic tuff (ignimbrite) is found east of the city (Beckmann et al. 1987).

The climate is subtropical and maritime, featuring hot, humid, and rainy summers, and short, mild, relatively dry winters, with minor rain peaks around June-July. About two-thirds of the annual rain falls between November and April. Brisbane's climate data shows an average annual rainfall of 1146 mm, maximum and minimum temperatures of 25°C and 19°C, and an annual evaporation of 1630 mm. Frosts may occur from June to August, mainly in low-lying inland areas (Beckmann et al. 1987).

Most of the native vegetation has been destroyed due to urban and rural development, with the remaining areas significantly altered. The least disturbed remnants are found on steep lands (mainly west of the city), poorer soils, and wet or saline lands on the lower plains and coast. Several major vegetation formations are closely linked to soil differences influenced by parent rocks, nutrient content, water regimes, and salinity. The main vegetation types include: (a) Eucalyptus open forests and woodlands; (b) Paper Bark tea-tree open forests and woodlands in poorly drained coastal plains and valley bottoms; (c) Closed forests with emergent hoop pine, found along streams, in sheltered valleys, and on southern slopes (Beckmann et al. 1987).

Figure 24. Depicts the extent of urban sprawl of South East Queensland 2024 – adapted from Queensland Globe online resource. The approximate extent of the city in 1895 (from McKellars Map) is highlighted in yellow. Dunwich, the small-town settlement on North Stradbroke Island is indicated with a purple dot. The extent of land subdivision to create the container terminal for the Port of Brisbane is indicated with a red outline. Source: Earthstar Geographics. During the twentieth century, Brisbane's expansion was fuelled by the electrification of tramways and the development of a suburban rail network. By 1901, Brisbane had a population of 120,000, representing just a quarter of the population of Sydney or Melbourne. Despite this, the city continued to extend its reach, with railway lines constructed to Moreton Bay for recreational purposes, as well

as to Southport, Coolangatta, and Tweed Heads. In 1915, the first subdivision in Surfers Paradise was established (Spearritt, 2009). The power of Brisbane as a main urban centre stemmed from the amalgamation of numerous small towns and shires into an expanded Brisbane City Council that controlled an area of nearly one thousand square kilometres, and governance over metropolitan services and finances (Minnery and Chow, 2010). At the end of World War II, the car became a symbol of independence, prosperity, and luxury worldwide, with the USA leading the charge during its post-war boom. This period saw the rise of suburban living, with privately owned suburban shopping centres replacing traditional high streets. Drive-in cinemas, fast food joints, bottle shops, and dry cleaners became hallmarks of this new suburban culture, epitomising convenience and modern living. International delegations, including the Lord Mayor of Brisbane visited the USA to witness the promise of this new world firsthand.

In Brisbane, American traffic engineers were enlisted to solve traffic congestion problems in the narrow CBD streets. By the late 1960s, the tram system was dismantled, and the CBD street network was converted into a one-way system. This transformation included constructing the Riverside Expressway, Captain Cook Bridge, and the Southeast Freeway connecting the city to the coast. The new elevated Riverside Expressway severed Brisbane's connection to the river, leaving the riverbanks in shaded, dark under crofts. A similar disconnection was anticipated with a proposed road along the northeast side of the CBD and the river shore, which would further disconnect the city from its river.

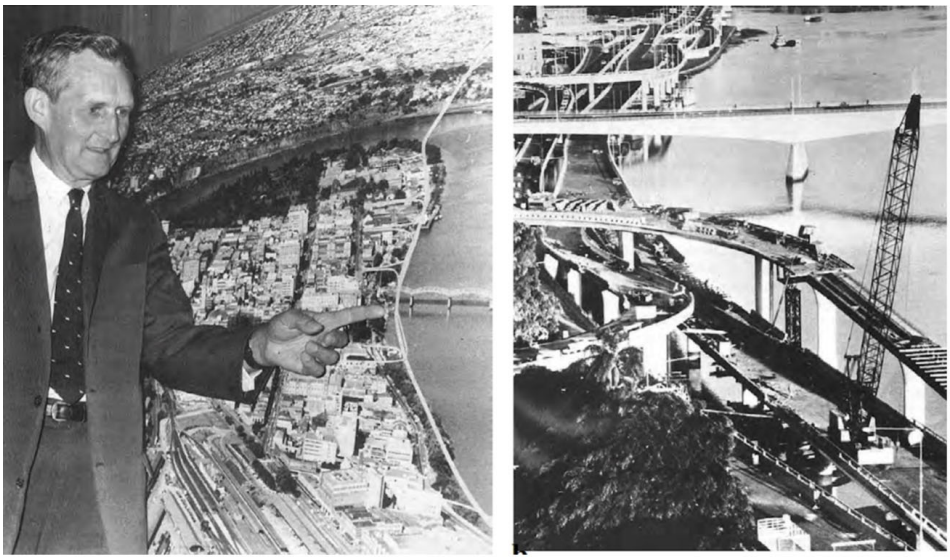

Figure 25. Riverside Expressway traversing the edge of the Brisbane River. a: Wilbur Smith, in 1968 demonstrating the line of the proposed Riverside Expressway, a main feature of the Brisbane Transportation Study. b: Construction of the Riverside Expressway nearing completion in 1974. Source: (Cole, 1984).

Since the 1970s, three rapidly expanding urban areas in Southeast Queensland have united to form a continuous 200 km coastal city. Brisbane, which lacks surf beaches, saw its residents travelling two hours to smaller, developing towns with stunning beaches for over a century. Starting in the late 1950s, the ‘Gold Coast’ to the south and the ‘Sunshine Coast’ to the north were marketed as prime holiday destinations. As small coastal towns merged with each other and with Brisbane, they created one of the longest urban coastal strips in the world, with a population nearing three million. Brisbane, a state capital with a modest industrial base, has been connected to these two holiday coasts through freeway-driven suburban expansion. Consequently, these coastal areas have experienced such rapid

population growth that their economies now depend not only on vacationers and retirees but have integrated into the broader metropolitan economy that now dominates the coastline (Spearritt, 2009).

As part of its corporate visioning process in 2002, the Brisbane City Council created an aspirational city's identity through the concept of a "city designed for subtropical living" (Kennedy, 2018). Despite these goals the Central Business District (CBD) of Brisbane has undergone significant intensification in development resulting in numerous skyscrapers. Greater Brisbane, typical of other Australian large cities like Sydney and Melbourne, is a sprawling car-reliant city, that has nonetheless concentrated construction investment at their CBDs, that has manifested an urban form compression and exaggerated vertical city skyline.

Figure 26. Nighttime view of Brisbane CBD. In the foreground is 'One William Street', 'Brisbane Skytower' dominating the right skyline, and in the left distance is 'The One' Building. Source: Paul Trotter

The tallest towers are predominantly residential, with the 90 storey (270 metres) 'Brisbane Skytower', followed closely by the 82 storey (264 metre) 'The One' building. Government also contributes to the proliferation of high-rise towers, with the Brisbane City Council occupying the 38 storey (151 metre) tall 'Brisbane Square', while also on the river edge the Queensland Government Executive is located in the 46 storey (260 metre) 'One William Street' building. The goal of subtropical living is significantly challenged in developer driven super high residential towers due to the height related climatic variables of skyscrapers (Jory, 2018), internalised air-conditioned living is the consequence.

Socio-Economic Aspects (Consolidation and Configuration of Housing Neighbourhoods) - Brisbane

The period of economic development in the new free settlement was initiated in 1841 by free traders and tradesmen who had established shops through leasing space in the former convict premises; this was soon followed by the first sale of land in 1842, by auction in Sydney for £100 per acre (Gough and Ogilvie, 1985; Johnson and Gregory, 1989a, 261; Johnson, 1988). The new town experienced a steady

growth during its formative decades, with commercial and trading businesses emerging concurrently as the migrant population increased. The first census in 1846 showed that there were 960 people living in Brisbane, and 2258 people spread across the region; by the 1851 census Brisbane's population had increased to 8375 (Gough and Ogilvie, 1985,.8; Johnson and Gregory, 1989a, 106).

It was not until 1867 that the settlement underwent its first economic boom following the discovery of gold by James Nash at Gympie, some 170 km north of Brisbane. The huge influx of people that followed triggered an unprecedented growth in primary industries, and a period of prosperity and building activity that would last 15 years and would not be equalled for a century. It was eventually ended by the cutting out of the gold and the world financial crisis of the early 1890s (Holthouse, 1982, p.41). Brisbane had become a significant shipping port with minerals, rural products and sugar as its primary exports. It was the capital of the annexed state of Queensland and was to be proclaimed a city in 1902. The population of greater Brisbane at the time of the 1901 census was 119,428 people. The period of economic growth continued up to the advent of World War I (Australian Bureau of Statistics, 2009). From 1918, Queensland's economic base continued to be mainly foreign trade to the UK (73% of total exports); primary goods being wool (41%), butter (19.5%) and meat products (24.5%).

In 1925, the City of Brisbane Act (1924) came into effect, rationalising civic government by amalgamating 18 former local government areas under a single administration, the Brisbane City Council (Holthouse, 1982, p.55). Despite strengthening Brisbane as an economically powerful civic entity, the impact of the Wall Street Crash of 1929 brought about the Great Depression in Australia during the early 1930s. Nevertheless by 1935 Queensland emerged with employment levels restored, stimulated from public works expenditure and the recovery of wool, wheat and metal prices to pre-depression levels (Australian Bureau of Statistics, 2009). Optimism was short-lived however, due to the onset of World War II which once again stifled economic growth and development in the city. The post-war decades from 1944 found Brisbane dilapidated and neglected, and it was to recover much more slowly than either Sydney or Melbourne. However, in the 1960s, with new mineral discoveries in Queensland, the city finally entered an enduring phase of prosperity from which Brisbane emerged as a modern city through a program of large-scale urban and civil construction, which has been sustained until the present day.

In summary, there have been two significant economic periods in Brisbane's history that have generated two distinct morphological periods of urban development in shaping the form of the city. These are approximately its initial growth from 1840s up to 1914; and then, following fifty years of relative fallow activity, a rapid growth from the 1960s to the present day, a period where the metropolitan population has increased from approximately 600,000 to 2.5 million.

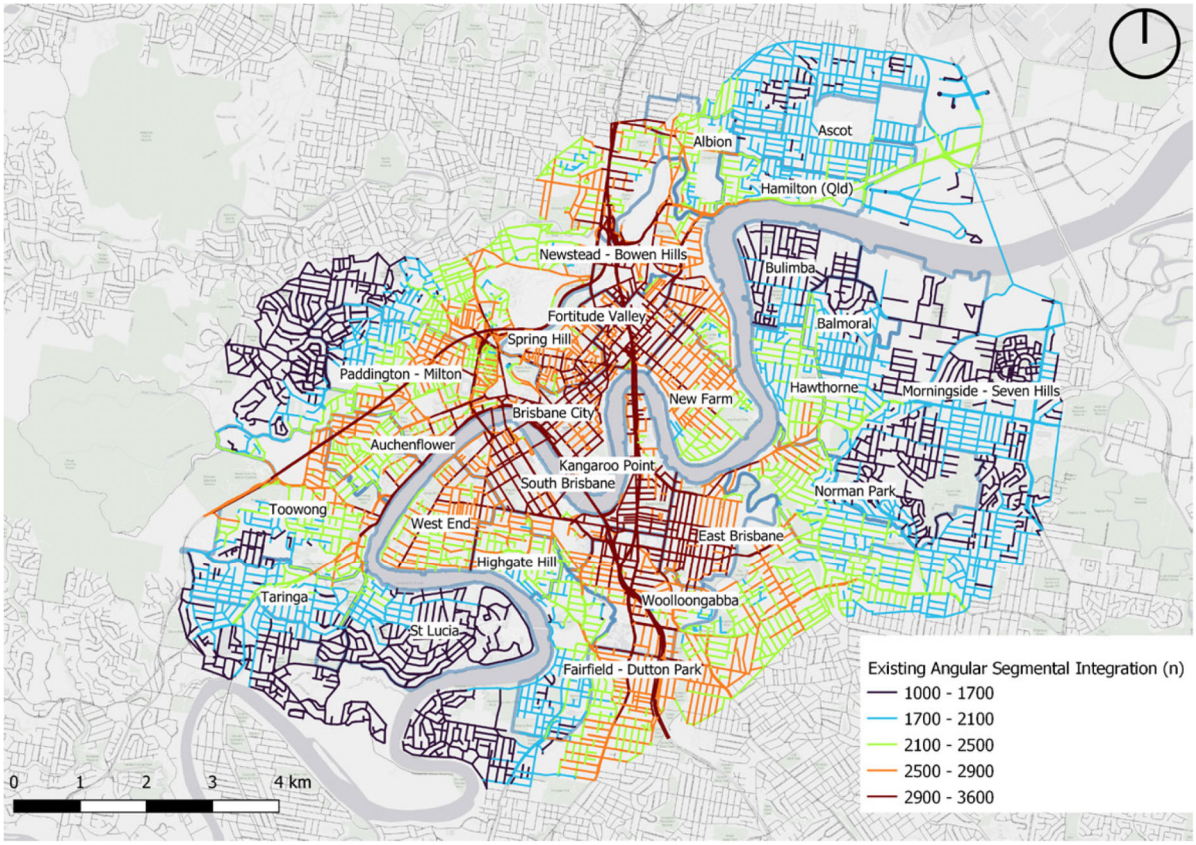

Figure 27. Space Syntax modelling of Inner Brisbane road network (Firat and Ozgun, 2023).

Connectivity refers to how well a street is linked with neighbouring streets. A hierarchy of connectivity can be established from streets with numerous connections (deemed highly connected), whereas those with fewer connections are considered to have low connectivity (Firat and Ozgun, 2023). Figure 27 maps the main arterial routes (Red) in the central area. The Riverside Expressway (Figure 20) is the principal spine, being the Pacific Highway from the Gold Coast is the south, extending across the Brisbane River to the West edge of the CBD and continuing towards Toowong as Coronation Drive. The other significant trunk road runs north from the Woolloongabba across the Story Bridge towards Newstead and beyond.

Adjacent streets to these main roads present as the next highest category of street connectivity, reducing in intensity particularly into the remote neighbourhood areas created by the winding river bends. These more secluded residential ‘pockets’ tend to have higher land values, and therefore higher household incomes, as can be deduced from Figure 28.

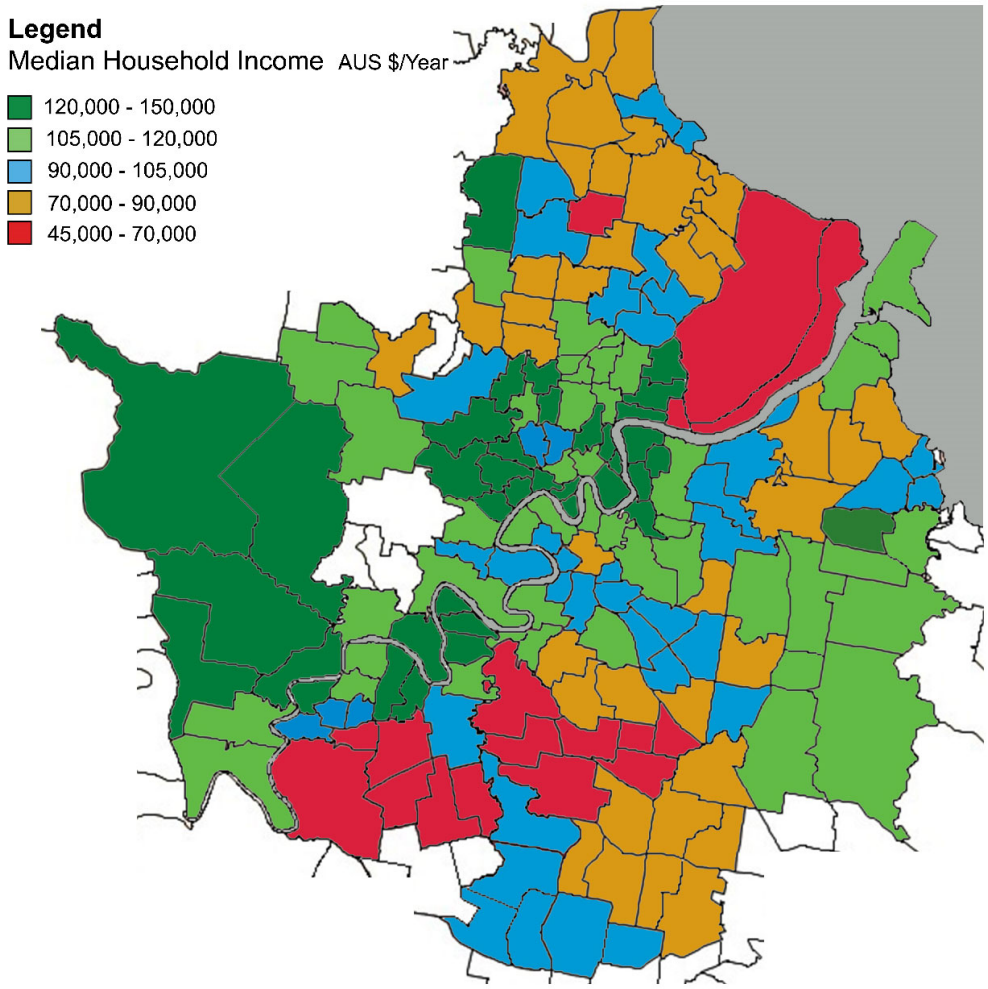

Figure 28. Distribution of residences by household income. Adapted from Willing and Pojani (2017).

The distribution of income groups across suburbs in Brisbane is mapped in Figure 28 ranging from the lowest socio- economic status (Dark Green) to the wealthiest neighbourhoods. In both Brisbane's inner city (85%) and its surrounding metropolitan area (79%), the majority of housing consists of single-family homes. High-rise apartment buildings are primarily located in the city centre, where employment and office buildings are also concentrated. Residential areas tend to be low-density and spread out extensively. Compared to global standards, Brisbane is a safe, clean, and well-kept city, abundant in parks and greenery. Schools are funded at a central level, leading to relatively uniform quality across different suburbs. The city centre benefits from an extensive public transport system, including trains, buses, river ferries, and bike-sharing options. However, while this network reaches most suburbs, service frequency drops notably outside the inner city. Car ownership is prevalent, with more than 80% of households in Brisbane owning a vehicle (Willing and Pojani 2017). Inner-city housing affordability continues to be an issue.

DISCUSSION

Throughout the histories of both cities, there have been notable shifts in cultural perceptions that have significantly influenced their urban development patterns and transportation networks. Initially established as colonial towns, their primary roles were centred around functioning as ports and fortifications, safeguarding the exploitative economic practices of the era. The surrounding waterways

and oceans were perceived not only as crucial conduits for merchant trade and vital sources for fisheries but also as potential security threats from foreign powers.

The 1960s and 1970s marked a period of rapid urban expansion in both cities, characterised by a vision aligned with the "American Dream" of connectivity and individual mobility through widespread car ownership. This phase of development was notably marked by unchanged perceptions of their waterways as obsolete or abandoned ports. Rivers and bays were seen as obstacles to the necessary connectivity required by automobiles, leading to the construction of large freeways, accompanied by land reclamation, bridges, and tunnels to mitigate the physical disruptions caused by these natural features.

In Brisbane, the pursuit of this automobile-centric vision led to the abandonment of its electric tram network and the neglect of train corridors. Simultaneously, the construction of the Riverside Expressway, a massive infrastructure project overshadowing the city's riverbanks, dramatically altered Brisbane's relationship with its river, disconnecting the city from this vital natural element. Similarly, Florianópolis undertook large-scale infrastructure projects, including the construction of freeway bridges and land reclamation efforts that distanced the city from its northern and southern bays. Additionally, Florianópolis introduced active transport corridors along the reclaimed edges of its bay and proposed speculative plans for marina developments along its shoreline.

During this period, both cities also developed a strong attachment to their coastal beaches, which became a focal point of real estate speculation and rising property values, spurring rapid development in these coastal areas. While Brisbane's distance from its beaches was not mitigated by the construction of a bridge to nearby islands, as was the case in Florianópolis, the city instead addressed beach access by continuously expanding its freeway networks. This resulted in the duplication and triplication of routes to both the northern and southern coastal areas, namely the Sunshine Coast and the Gold Coast. In Florianópolis, a similar strategy was employed, with the development of freeways to facilitate beach access by circumnavigating the western side of Santa Catarina Island.

Despite the enduring emphasis on car-centric development in both cities, significant changes in the perception of waterways have emerged since the late 1980s. In Brisbane, the community's relationship with the river was notably reshaped by two key projects. The first was the extensive land acquisition in South Brisbane for the development of the World Expo 88, which prominently featured the river along the event's southern bank opposite the central business district. This area was later transformed into a cultural and tourist precinct known as South Bank, featuring an artificial beach. The second major project was the development of the Riverside Centre on Eagle Street, which, rather than turning away from the river, embraced its waterfront location by creating publicly accessible spaces and ensuring that two-thirds of the tower's tenancies faced the river. These initiatives have continued to drive river-focused urban development in Brisbane, symbolising a broader shift in urban planning that reconnects the city with its waterways.

A principal point of difference is the scale of the cities, while Brisbane is currently at a population of approximately 2.5 million people over an area of 6000km2 and density of 3.46 persons/hectare (World Population Review, 2024). Florianópolis is just over 0.5 million across 674.8 km2 with an urban density of 7.96 persons/hectare (IBGE Cities, 2023). The corresponding and contrasting urban footprints are clearly differentiated in Figure 2. While Brisbane is a relatively low density city, its CBD has a highly

concentrated urban development with a few tower buildings exceeding 80 storeys in height, whereas Florianópolis has a more even density distribution with buildings of lower height. Brisbane developed almost entirely on the mainland centred on the river, while leaving the islands to the sand mining industry, low density tourism, and local indigenous inhabitants. In Florianopolis, the historical urban centre was on its principal island with expansion onto the mainland facilitated by the bridge connections.

CONCLUSION

In both Brisbane and Florianópolis, shifts in cultural perceptions have profoundly shaped their urban development and transport networks. Initially viewed as essential for trade and defence, waterways were later seen as obstacles to car-centric growth during the mid-20th century, resulting in large-scale infrastructure projects that distanced both cities from their rivers and bays. However, since the late 1980s, there has been a renewed appreciation for these natural elements, particularly in Brisbane, where river-focused development projects have reestablished connections between the city and its waterways. This evolving relationship highlights the dynamic interplay between urban planning and cultural values.

This paper has been a broad assessment of parallels between two cities of the sub-tropics on opposite sides of the globe, separated by 201 degrees of longitude. Not only do the cities reside on almost the same degree of latitude at 27.5 degrees south each metropolis finds itself expanding around similar climatic, topographic, oceanic opportunities and constraints. It is hoped that further detailed analytical research will build upon the inertia of this initial study.

ABSTRACT

Geotechnologies have played a significant role in landscape analysis and the enhancement of public administration, providing an innovative and efficient approach to understanding and planning urban development. The application of geospatial tools enables a more precise analysis of the elements comprising the landscape, from topographical aspects to the distribution of public services. In Sobral, detailed mapping aids in identifying flood-prone areas, contributing to the development of strategies for the prevention and mitigation of natural disasters. Furthermore, geotechnology has been crucial in optimizing urban infrastructure, including the planning of new developments, roads, and green spaces. This results in more effective management of municipal resources, fostering a more sustainable and resilient urban environment. This study aims to demonstrate how the use of these technologies has impacted the municipal administration of Sobral, Ceará, through data collection, interviews, and other methods. It is important to recognize that the potential of these tools extends beyond disaster analysis and prevention, infrastructure optimization, and transparency promotion. Municipal management could further benefit by strategically using these resources to guide public investments. With accurate technical readings and georeferenced data, resource allocation could be more efficient, addressing the specific demands of each region and ensuring a more equitable development.

Keywords: geotechnologies, landscape analysis, public administration

INTRODUCTION

Geoprocessing is a field of geographic science that has gained prominence in recent decades in urban planning and management, as it has emerged as a tool capable of modernizing the process of collecting, processing, manipulating, and analyzing spatial data. Data collection and organization procedures were for a long time carried out in the public sphere through handwritten records organized in physical files. With the advancement of Information and Communication Technologies (ICTs), these procedures began to be conducted through operating systems that allowed for the manipulation, generation, and plotting of data via spreadsheets, graphs, tables, and text documents.

However, despite these advances, limitations still existed regarding the location and spatial analysis of data.

Geoprocessing emerged in the mid-1960s in Canada as part of a government program to create a natural resource inventory. In Brazil, the use of Geoprocessing tools began in the 1980s in Higher Education Institutions (Bolfe, Matias, and Ferreira, 2008). Over the years, Geoprocessing tools gained greater prominence with the popularization of geoinformation through spatial query software and GPS-based location applications, such as Google Earth and Google Maps, SIGWebs, and free GIS software for creating thematic maps and manipulating vector and raster data, such as Quantum GIS.

Despite increased access to Geoprocessing tools and developers' efforts to create more intuitive interfaces to facilitate user handling, there remains a gap in the use of spatial data by public administration. Issues include: low familiarity with Geoprocessing and its contributions to planning and management; lack of resources for investing in technological infrastructure and trained personnel; and more archaic issues such as resistance from some public managers (Lopes and Silva, 2013; Câmara et al., 2005).

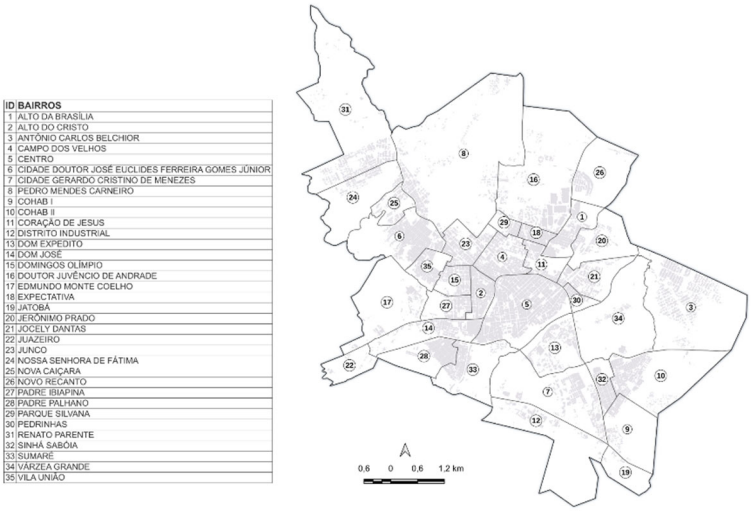
Thus, this paper aims to present the contributions of Geoprocessing to urban space planning and management, using the city of Sobral - CE, as an example. This topic is chosen because, despite the contributions of Geoprocessing tools for a more in-depth understanding of the territory and better spatial analysis of the aspects and dynamics that constitute urban space, it is still neglected or even unknown in municipal public administrations. The underutilization or deprivation of Geoprocessing tools in city halls represents a loss for urban space planning and management, as the preparation of diagnostics, decision-making processes, and the development of interventions and public policies require precise and geolocated data about the various aspects constituting territorial dynamics (Campos, 2022; Bitti et al., 2021; Silva and Lopes, 2013).

THE CITY OF SOBRAL

The municipality of Sobral - CE has an estimated population of around 212,437 inhabitants (IBGE, 2010) and is located in the northwestern portion of the State of Ceará. It is composed of 17 districts, including the main district. Sobral stands out due to its role as a regional hub for commerce and services, as well as its significant prominence in industrial production compared to neighboring municipalities, a fact that contributed to the creation of the Sobral Metropolitan Region in 2016 (Rodrigues; Teles; Holanda, 2020). The map below illustrates the location of the municipality of Sobral within the State of Ceará, as well as its territorial boundaries and district divisions.

Map 02 - Location, Territorial Boundaries, and District Division of the Municipality of Sobral – CE. Source: IPECE (2019); Created by the author using data from the Municipality of Sobral (2023).

Among the districts that make up the territory of Sobral, we highlight the main district, where the economic activities that give the municipality prominence in the northern region are concentrated and where most of the movement flows converge. The main district currently consists of 35 neighborhoods, as shown in the map below:



ID	BAIRROS
1	ALTO DA BRASÍLIA
2	ALTO DO CRISTO
3	ANTÔNIO CARLOS BELCHIOR
4	CAMPO DOS VELHOS
5	CENTRO
6	CIDADE DOUTOR JOSÉ EUCLIDES FERREIRA GOMES JÚNIOR
7	CIDADE GERARDO CRISTINO DE MENEZES
8	PEDRO MENDES CARNEIRO
9	COHAB I
10	COHAB II

Map 03 - Official Neighborhood Division of the Main District of Sobral. Source: Created by the author using data from the Municipality of Sobral (2023).

The urban space of Sobral presents complex issues that impact the city's growth and development, requiring constant monitoring by the public authorities. Among these issues are real estate speculation, particularly in the opening of subdivisions; processes of irregular occupation in high-risk areas; disputes involving environmental issues; crime monitoring and social vulnerability; mobility and accessibility problems, among others.

Given this complexity, the importance of mapping and monitoring socio-spatial aspects is emphasized, as their spatial location allows for a more precise and integrated analysis of urban phenomena, which is essential for the decision-making process in the public sphere (MOURA, 2005). Currently, the mapping and monitoring of these aspects contribute to Sobral's urban planning by generating important information through georeferenced data regarding land use and occupation as well as urban territorial dynamics.

The use of Geoprocessing applied to the planning and management of Sobral's urban space began in 2006 with the National Program for Administrative and Fiscal Management Support for Brazilian Municipalities - PNAFM, which aimed to modernize the administrative and fiscal management of municipalities, including the creation of a Multipurpose Technical Register and the development of a Generic Value Plan.

Within the PNAFM, the Situar Project was created, aiming to promote the development and implementation of a Territorial Information System for the Municipality of Sobral. The project's activities were carried out by the Planning Secretariat - SPLAN. At the time, in addition to the implementation of the Territorial Information System, an aerial photogrammetric survey was also conducted, enabling a deeper understanding of the city's socio-spatial aspects

Later, in 2013, the Secretariat of Urbanism, Historical Heritage, and Environment of Sobral (SEURB) was established. In this context, Geoprocessing became consolidated in Sobral's urban planning, becoming part of SEURB's organizational structure with the creation of the Mapping and Geoprocessing Cell, which was managed by Geographers and Civil Construction Technologists. Currently, the Mapping and Geoprocessing Cell is part of the organizational structure of the Secretariat of Urbanism, Housing, and Environment - SEUMA, where it has been renamed the Geoprocessing and Monitoring Cell. The inclusion of "monitoring" is justified by the fact that, in addition to developing activities using Geoprocessing techniques and technologies (including mapping), it is also considered important to monitor the progress, setbacks, and interactions of different aspects of the city.

Regarding the organizational structure, it is important to highlight that the Geoprocessing and Monitoring Cell is directly connected to the Urban Planning Coordination - COURB. In this department, Geoprocessing operates on two fronts: through the Geoprocessing and Monitoring Cell and through the Urban Cadastre Cell.

Concerning the techniques and technologies used, both the Geoprocessing and Monitoring Cell and the Urban Cadastre Cell use a Geographic Information System (GIS) for their procedures, which allows for the processing and manipulation of spatial data as well as the creation of maps. The system used is part of the open-source software Quantum GIS (QGIS), which has gained popularity in recent years due to its free access and user-friendly interface. Among the various functionalities of QGIS used by these cells, the use of the PostgreSQL Spatial Database Management System and its geographic extension PostGIS stands out, enabling data to be worked on in a shared and real-time GIS environment, optimizing the data update process and preventing the risk of data loss since the information is stored in the cloud.

In addition to QGIS, other sources of geographic data are also used, such as Web Mapping Google Earth and shapefile (.shp) files from official government websites, for example, data provided by the

Brazilian Institute of Geography and Statistics (IBGE) and the Institute of Research and Economic Strategy of Ceará (IPECE).

Regarding specific spatial data for the municipality of Sobral, it is important to mention that in 2017, the municipality was included in the Urban Development Program for Regional Hubs of Ceará - Vales do Jaguaribe and Acaraú, which aimed to strengthen fiscal and tax management in regional hub cities located in the Jaguaribe Valley and Acaraú Valley regions. The program aimed to promote tax re-registration, strengthen the multipurpose technical property register, develop/update the generic value plan, among other objectives. To achieve this, it was necessary to construct a robust set of updated and accurate spatial data from which the proposed actions could be carried out.

In March 2017, a service contract was signed between the Secretariat of Cities and the company Topocart Topografia Engenharia e Aerolevantamento S/S LTDA, through which the city of Sobral was provided with Tax Re-registration (through Aerial Photogrammetry for Digital Planialtimetric Mapping, Multipurpose Technical Real Estate Registration, Furniture and Streets); Updating of Municipal Tax Codes; and Development/Updating of the Generic Value Plan.

The products resulting from the contracted service were crucial in supporting Sobral's urban planning. Among the main ones, we can mention: georeferenced aerial photogrammetry images of the main district and the districts of Aracatiaçu, Taperuaba, and Jaibaras; Digital Terrain Model - DTM; 1-meter contour lines; road polygons (street boundaries), road axis, buildings, lots, blocks, among others.

Finally, through this contract, the Municipality of Sobral also gained access to the WebGIS Topovision, which serves as an online platform where some spatialized data is available for consultation, used by the departments and coordinations that constitute the public administration, especially those dealing with urban land issues, such as land subdivision; land regularization; licensing; urban cadastre; urban planning, among others.

All the cartographic material resulting from the aforementioned contract is currently used as a basis for socio-spatial analyses of the municipality. It is important to note that the Geoprocessing and Monitoring Cell is responsible for updating this data and conducting surveys of socio-spatial data not covered by the aforementioned contract. Currently, efforts are being made to compile spatial data related to the main district centers and rural areas to enhance planning focused on these areas.

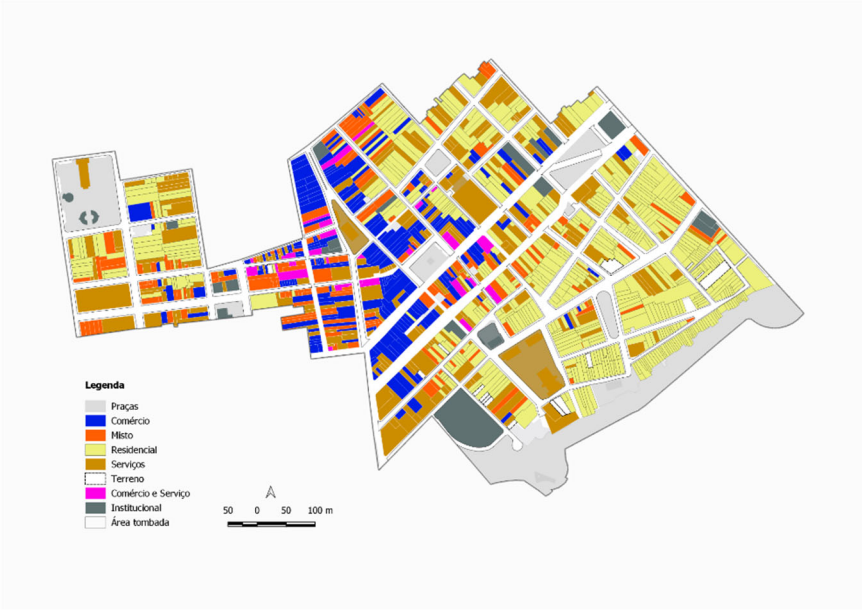
To demonstrate the contributions of Geoprocessing to public planning and management, we will present below some analyses of the urban dynamics and socio-spatial aspects of the city of Sobral, based on cartographic mapping.

GEOPROCESSING AND URBAN SOCIO-SPATIAL DYNAMICS IN SOBRAL

The understanding of the structure and materialities that constitute urban space presupposes an understanding of socio-spatial dynamics, socio-spatial aspects, and the political, economic, and socio-cultural transformations that occur in space over time. The analysis of urban space must consider the historical context, transformative agents, and socio-spatial aspects in the process of urban evolution (Corrêa, 1989); (Souza, 2013); (Santos, 1985). However, it is important to emphasize that an effective socio-spatial analysis requires knowledge of the location and interaction of urban socio-spatial phenomena in space and time (Xavier, 2017).

Among the most important aspects for understanding urban socio-spatial dynamics are land use and occupation. Understanding the city through the spatialization of land use and occupation allows us to identify space-time transformations influenced by the capitalist system that have impacted and continue to impact the redefinition of types of use and the establishment of urban functions (Santos, 1985). Thus, the spatialization of land use and occupation enables the identification of important issues related to socio-spatial dynamics, such as identifying expansion vectors; locating areas with urban voids; densely populated areas; points of conflict and increased movement flows; areas served and underserved by public services, among others.

The process of land use and occupation in Sobral is strongly linked to its historical context, in an urban structuring influenced by economic cycles such as livestock farming, which began in the 18th century, and cotton cultivation, which became established in the 19th century. Besides the economic aspect, land use and occupation were also influenced by social actors connected to the Church and the State in the 19th and 20th centuries, with the implementation of infrastructure and urban interventions that remain to this day as references in the urban space and have transformed the socio-spatial dynamics of Sobral (Rocha, 2017; Aragão, 2014).The following map illustrates the updated classification of land use and occupation typologies in the area listed by the National Institute of Historical and Artistic Heritage - IPHAN, located in the city center:



Map 04 - Land Use and Occupation Typology in the Listed Area of the Centro Neighborhood. Source: Created by the author using data from the Municipality of Sobral (2023).

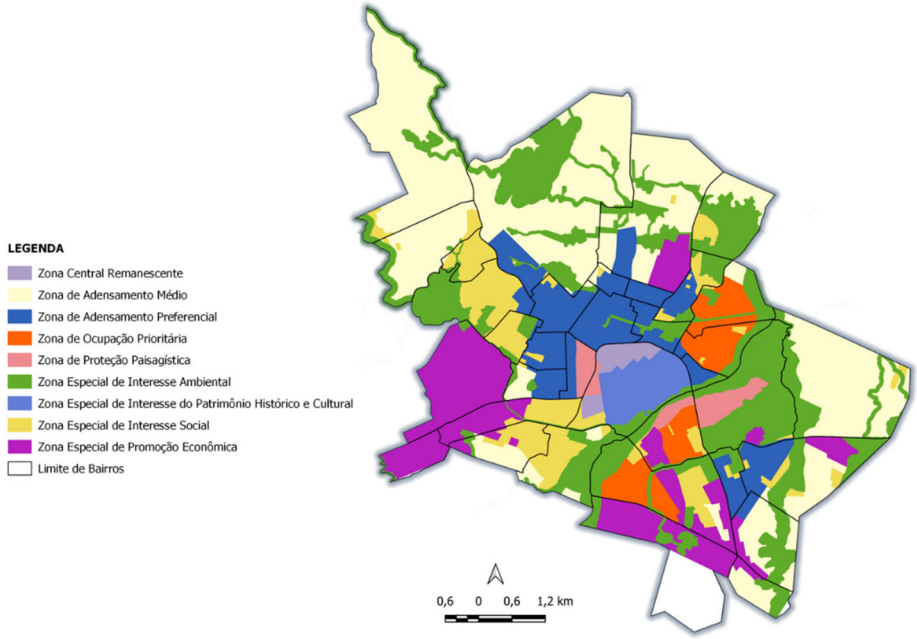
The reading of the above map allows us to visualize some manifestations of urban dynamics over time. In summary, the blue-colored lots represent part of the consolidated commercial area. The commercial concentration results in a higher flow of movement in this area, leading to mobility and accessibility issues, as well as strong real estate speculation due to the higher cost per square meter in the generic value plan. A significant point to note on the map is the concentration of residential lots to the east, northeast, and northwest, reflecting the establishment of residential buildings and urban facilities in the 19th century (Aragão, 2014).

Another important issue shown on the map is the more balanced distribution of service lots, which is present not only in the listed area but throughout the Centro neighborhood. This more harmonious distribution reveals a trend towards the consolidation of new centralities. Identifying urban voids in land use and occupation spatialization is also of great value to public administration, as it serves as a warning for inspection needs in these areas to ensure compliance with urban legislation and the social function of property.

Further addressing the contributions of Geoprocessing to urban planning and management and considering the importance of mapping and monitoring land use and occupation, we also highlight the significance of urban zoning spatialization as a means of ensuring territorial organization and guiding land use and occupation. Zoning is an urban planning and management tool through which the city is divided into areas subject to different guidelines for land use and occupation (Souza, 2002).

In a GIS environment, it is possible to delineate the areas that make up the urban zoning by assigning information to them. The spatialization of zones allows for the identification of: areas to receive large-scale developments; neighborhoods that may or may not experience vertical expansion; neighborhoods where density needs to be more restricted; locations where occupation should be prioritized; sections where the priority is to protect the landscape and environmental resources; and areas where the priority is to meet social housing demands

In addition to defining zoning areas and overlaying them with other layers, it is also possible to categorize zones according to their specific characteristics and assign colors or styles to make them visually more identifiable. In the map below, you can see the urban zoning of the main district of Sobral, categorized by colors:



Map 05 - Urban Zoning of Sobral – CE. Source: Created by the author using data from the Municipality of Sobral (2023).

In urban planning responsibilities, it is important to emphasize that beyond issues related to land use and occupation, attention must also be given to the importance of the circulation of people and goods

for the production and reproduction of urban space (Gottdiener, 1993); (Villaça, 1998); (Santos, 2004). Mobility and accessibility are socio-spatial aspects that require special attention from public authorities since the entire socio-spatial dynamic depends on a fluid urban network as well as on infrastructure for mobility and accessibility that can meet the demands of the population and different sectors of the economy.

Mapping and monitoring socio-spatial aspects related to mobility and accessibility allow for the identification and tracking of obstacles that may compromise socio-spatial fluidity, such as: identifying areas underserved by transportation services; points of convergence or intense flow; conflict points; slow traffic; demands for accessibility, among others. Additionally, it is also important to highlight that the pursuit of sustainability through encouraging the use of public transportation or walking also depends on a more detailed understanding of the territory, which allows for the assessment of the feasibility of proposed interventions in infrastructure for mobility and accessibility.

The following map illustrates part of the infrastructure for mobility and accessibility in the city of Sobral through the spatialization of bus routes; bus stops; bike lanes; green corridor lanes; and the civic axis, which aims to encourage walking over the use of motorized transportation in this part of the city center.

Map 06 - Infrastructure for Mobility and Accessibility in the Centro Neighborhood. Source: Created by the author using data from the Municipality of Sobral (2023).

Regarding the implementation of green corridors along stretches of the road network, it is important to highlight that in recent years, the public administration of Sobral has sought to strengthen local sustainability through sectoral plans such as the Arborization Plan and the Urban Mobility Plan, as well as by ensuring the protection and preservation of natural resources through the establishment of the Special Environmental Interest Zone (ZEIA) and the designation of Permanent Preservation Areas (APPs).

Ensuring the protection and conservation of natural resources in urban areas is currently a true challenge for municipal public managers, given the various interests of social actors who have the

power to make decisions that can directly or indirectly affect environmental quality in cities (Quintas, 2006).

It is in the face of the complex web involving the production of space and different land uses (SANTOS, 2004), as well as the social relations established within it, that environmental issues become a focal point, necessitating measures to ensure preservation or conservation. The delimitation and mapping of green areas and preservation areas contribute to this task.

The urban planning sector in the city of Sobral has in its geographic database the mapping of these areas, which is frequently used for consultations in land subdivision processes and licensing, as well as for the inspection of construction works. In urban zoning, green areas and environmental preservation areas constitute the so-called Special Environmental Interest Zone (ZEIA), which can be seen in the following map:

Map 07 - Delimitation of the Special Environmental Interest Zone and Location of Squares, Parks, and Green Areas. Source: Created by the author using data from the Municipality of Sobral (2023).

Regarding areas within the urban perimeter, it is important to emphasize that the city of Sobral has grown amidst water resources that connect throughout the territory, extending from the more densely populated areas to areas with less intense occupation but currently facing strong real estate speculation, mainly through the opening of new subdivisions.

In this way, mapping the ZEIA allows for the visualization of sections where the likelihood of environmental impacts or damage would be greater, providing a basis for the actions of the urban inspection sector, and also indicating areas where the environment is more susceptible to human interference.

CONCLUSIONS

In recent years, geoprocessing tools have transcended the academic realm, gaining prominence among society and public authorities due to technological advancements that popularized the use of

spatial data (Bolfe; Matias; Ferreira, 2008). However, despite the progress in information technologies; the development of intuitive geoprocessing software and SIGWEBs; access to internet networks and georeferenced data from reliable sources; and the variety of contributions geoprocessing offers, it is still a fact that many public administrations plan and manage cities without the support of mapping and monitoring territorial data. Thus, this article aimed to analyze and demonstrate the contributions of geoprocessing to urban planning and management using the city of Sobral - CE as a case study.

The research methodology involved an initial bibliographic survey on the contributions of geoprocessing to public planning and management to demonstrate its benefits and the challenges faced by municipalities regarding its adoption. Additionally, analyses of the city of Sobral were conducted based on thematic maps to understand how the use of Geographic Information Systems (GIS) and Remote Sensing can enhance the knowledge of elements that make up the urban space and the understanding of socio-spatial dynamics. Finally, the role of geoprocessing in the Municipality of Sobral was discussed as support to the Urban Planning Coordination, through the Geoprocessing and Monitoring Cell and the Urban Cadastre Cell.

Data collection instruments for the research included: testimonies from professionals responsible for the Geoprocessing and Monitoring Cell and the Urban Cadastre Cell; information gathered from the Municipality of Sobral; and consultations of municipal data available in the PostGIS database and SIGWeb Topovision. For the preparation of city maps, the Quantum GIS (QGIS) software version 3.22.10 Biatowiesa and shapefile (.shp) files provided by the Municipality of Sobral were used.

Regarding the structure of this article, we began with an introduction to the research, followed by Section 02, which provided a brief analysis of urban planning and management in its historical process and its relevance to the consolidation of cities. Then, in Section 03, we addressed geoprocessing and its evolution with technological modernization. In item 3.1, we analyzed in-depth the applications and contributions of geoprocessing in public management, followed by item 3.2, where we examined the role of geoprocessing tools in the planning and management of the city of Sobral - CE.

Thus, throughout this study, we sought to present the contributions of geoprocessing to urban planning and management, using the city of Sobral - CE as a positive example. The choice of this topic is justified by the fact that, despite significantly contributing to a deeper understanding of the territory and a better spatial analysis of the aspects and dynamics that constitute urban space, geoprocessing is still underutilized or even unknown in municipal public administrations (Campos, 2022; Bitti et al., 2021). This fact raised concerns as we recognized the relevance of geoprocessing as a supportive tool for planning and managing the city of Sobral, particularly in supporting the development of Public Policies, Sectoral Plans, Master Plans, and decision-making processes.

It is hoped that the reflections presented here will lead to a better understanding by municipal public administrations, the academic community, and civil society of the contributions of geoprocessing to urban planning and management.

ABSTRACT

Favelas are established informal settlements in South American metropolises, and although they are an integral part of the city, they are extensively studied due to their formation processes and urban morphological aspects. The forms, uses, and functions of these informal areas are a consequence of land use and various modes of utilization, making them complex, fluid, and dynamic, defined by the residents' practices. These spaces exhibit different gradients of privacy, ranging from open areas (such as pathways, stairs, ramps, or crossings), semi-open areas (such as galleries, balconies, private stairs, and terraces), to enclosed areas, which infiltrate private and semi-private contexts, disrupting the traditional hierarchy. To understand these spaces, the research juxtaposes the studies of the Italian School of Urban Morphology by Muratori, Caniggia and Canella. The goal is to reconstruct and narrate the aspects and complexity of human relationships with the urban form in the slums of Santa Marta (Rio de Janeiro) and Paraisópolis (São Paulo), and to demonstrate that the informal city is perfectly coherent with the sociocultural dynamics of the favelas. The research involves a comparative analysis of the two public spaces within each favela, examining dimensions, morphology, color, modes of space appropriation, and particularly, the process of local rooting. The various narratives have contributed significantly to the understanding of informal public spaces.

Keywords: Morphology, Territory, Urban, Informal, Space.

INTRODUCTION

The topic of precarious settlements as spatial, economic, and socio-cultural systems has become a focal point of critical attention in contemporary studies of cities and metropolises over recent decades. Informal settlements have long been regarded and treated as fragile phenomena destined to evolve, more or less forcibly, into formal configurations. After the era of "tabula rasa" practices, which persisted until the 1970s and aimed at destroying settlements under the economic pressures of planned cities, contemporary reality shows—contrary to this vision a shift in the dynamics of urban development, marked by the emergence of informal entrenchment processes. These unstable and precarious settlements, even after partial and forced removals or reductions, calcify in space, solidifying and embedding themselves into the collective imagination, leading to an unprecedented physical and cultural transformation of cities. This paradigm shift gives rise to widespread phenomena

of non-replacement: the population of informal settlements—constantly and steadily growing—becomes consolidated. The process of entrenchment manifests through a growing sense of social belonging among the inhabitants and, above all, through the physical embodiment of this city, which transforms, adopting logics of stabilization and reorganization.

This theme has been the subject of a broad field of research, encompassing various disciplines, including the social sciences, which have sought to examine the development and transformation of informal settlements, the community practices that emerge within them, and the dynamics of identity and cultural rooting. However, few studies focus on the urban and spatial forms produced in these spaces, considering morphological analysis as a strategic tool to interrogate, understand, and interpret the phenomenon. Informality cannot be reduced to a mere illegal urban practice, a planning issue, or an economic model; it is primarily a mindset, a strategy. If a planned city is, by definition, ordered by a specific set of norms designed to regulate social life and anticipate its development, informality is a leveling system that introduces chaos into order, an adaptive attitude that embraces the lack of a comprehensive strategy and accepts surprise and chance as inevitable elements of life. To fully understand their structural logic, a general comparative observation is insufficient; it is essential to comprehend the local specificities of each territory.

In order to obtain a precise and accurate reading of informal morphological structures, the research focuses on a specific typology of informal settlement with its own distinct characteristics: the favela. The favela is an urban phenomenon that integrates into the territory as part of the city's morphology, shaping its design without adhering to urban planning principles: street layouts are not pre-determined, and infrastructure systems are implemented after spatial occupation, defined by the availability of space. Furthermore, it is a territory that does not follow the guidelines and norms dictated by land use and zoning laws: land appropriation, typically public, occurs without the owner's consent.

The research systematically and rigorously analyzes the morphological structure of the urban fabric of Santa Marta favela in Rio de Janeiro and Paraisópolis in São Paulo. Through close and detailed observation, it explores the mechanisms by which these inherently ephemeral urban bodies develop self-regulation codes that allow them to become stable phenomena over time and space.

The case studies were carefully chosen to maximize spatial diversification and cover the widest possible spectrum of the phenomenon. There are several reasons for this operational strategy: first, the case studies allow for an "inside" analysis of the favela, establishing a direct relationship with residents. This context-dependent approach enables the intersection of practical and theoretical knowledge, subjective and objective viewpoints on the same level. Second, the methodology allows for the development of specific expertise on the subject, a strategic condition for understanding the urban and social dynamics of informal settlements. Third, the case studies can be employed in all stages of the research for different purposes, whether exploratory, descriptive, or explanatory. Face-to-face interviews were a crucial and incisive investigative tool, bringing the voices of informal actors to the forefront of the analyzed themes.

The analyzed case studies consist of a system that emerges from spatial limitations and, over time, triggers processes of intense functional interaction with public space to compensate for the limitations of internal spaces. In this sense, the research aims to understand the various processes and dynamics,

meticulously investigating them and using complementary methodologies to analyze the formation processes of two significant favelas in Brazil: Santa Marta in Rio de Janeiro and Paraisópolis in São Paulo.

Through the construction of a “morphological atlas,” the work documents the phenomenon of actions, forms, and urban spaces analyzed from within the urban body. In this regard, it draws on strategies for reading the urban fabric derived from morphological analysis of the city, with particular reference to authors from the "Italian School," such as Saverio Muratori (1959, 1960, 1963), Guido Canella (1960), and Gianfranco Caniggia (1971, 1977), used by Alessandro Tessari (2020, 2024) in Informal Rooting: An Open Atlas and Paraisopolis: Um Atlas Morfologico.

The research is conducted in two phases: at the territorial scale, where the growth and transformation processes of the two favelas in relation to the metropolis are observed, and at the local scale, where the micro-spatial transformations and the syntax of the urban fabric’s evolution are identified and understood, with particular focus on public spaces.

ANALYSIS OF INFORMAL PUBLIC SPACE

To understand informal urban spaces, their capacity for regeneration, and their consolidation in the face of various challenges, this research investigates the morphological process of forming public spaces. The transformation of informal space occurs through various modes, forms, and processes. Although a comprehensive observation of the territory may not represent a complete picture of reality, it is useful for defining some recurring patterns and behaviors. The capacity of a space to aggregate in constant dynamism reflects a network of social relations created by individuals, which Lefebvre considers essential for maintaining, stimulating, and experiencing the space. In this sense, Harvey argues that enjoyment has a dialectical relationship with the capacity for space production, as open, public spaces are generated by the individual's ability to use them. They are the form and response of the process, rather than its product, incorporating social, economic, ideological, and technological aspects into the physical construction process. That is, the physicality is intertwined with the relationships that the previous authors include in the process. Since, as previously mentioned, the process is dynamic, there is a constant reconstruction, reinvention, and interpretation of daily needs.

The authors, therefore, share and reaffirm the changing nature of favela space, recognizing the complexity of the informal phenomenon through its capacity for aggregation, enjoyment, constructive process, space-time, and form. These aspects are unlikely to be perceived unless observed with a rigorous method, which, though not necessarily complex, must be capable of interpreting and redesigning these relationships. Public space within the informal city is a direct consequence of the daily movements and relationships constructed by its residents. It results from a gradual construction that is difficult to perceive from beginning to end, not composed of a single idea, and cannot be strictly defined as a classified element. Its dynamism and variation often blur the boundaries between the public and private sectors, particularly at the scale of the home, where the family living space extends to the enjoyment of other residents due to its position within the hierarchies built into the favela’s fabric. For example, a narrow street may serve as a passageway but also as a space for enjoyment among nearby residents; a veranda may become a public element and a collective meeting place; intimate space may become a social area. The same can be said of rooftops, which on weekends may

accommodate as many people as a planned public square. Therefore, its dynamism should be studied with equal rigor. Mehrotra asserts that the kinetic city is incomprehensible if viewed as a two-dimensional entity; it must be perceived as a city in motion, in a constant state of reinvention and self-transformation (Tessari, 2020).

A deeper investigation reveals that this is not the logic of informal spaces primarily because they present constant shifts in organization, and secondly, because they exhibit overlapping relationships with varying degrees of intimacy, never entirely public or private. Faced with this complexity, the study of public spaces combines elements of territorial morphological analysis, including those related to historical development processes, topography, vegetation, land subdivision, building density, facade relationships, development direction, and interventions, with the urban analysis framework introduced by Lynch, which considers paths, access, nodes, and boundaries, to understand the composition of public spaces. By combining these elements at the block scale with selected public spaces, various relationships and outcomes were revealed, providing substantial insight into the nature of public spaces.

The informal settlements studied demonstrate several recurring dynamics from their inception, allowing for a necessary final summary to generalize the specific conclusions drawn. In almost all cases, their origin traces back to rapid and unexpected occupation; the chosen location for invasion is always residual territory, whether a natural area with rugged topography, land subject to hydrogeological risks, or an abandoned and unused part of the formal city situated among formal infrastructure networks.

Figure 2. Volumetric axonometry Community of Paraisopolis. São Paulo.

ANALYSIS OF INFORMAL PUBLIC SPACE

METHOD

METHOD 1 – SANTA MARTA (RIO DE JANEIRO)

The choice of Santa Marta as a study area is based on several theoretical and practical reasons. Firstly, it represents a typical informal community in Rio de Janeiro. As one of the oldest favelas in the city's center, it has been the site of struggles to defend the right to exist. Clinging to the steepest and most rugged of the many 'morros' that shape the Rio landscape, Santa Marta holds iconic status in the collective imagination. Its geographical location and stark contrast with nearby formal neighborhoods are recurring elements in many of Rio's favelas. Santa Marta gained fame far beyond national borders due to media events that brought it into the global spotlight, making it a symbol of Rio's popular culture and, more broadly, Brazilian culture. Studying this favela, therefore, means investigating the 'universal' characteristics of this type of settlement.

The accessibility and safety of Santa Marta were decisive factors in ensuring continuity and consistency in the analysis. Located in the southern zone of the metropolis—the richest and most developed area—it is well-connected to public transportation, making it easily accessible at all hours of the day and throughout the year.

The analysis of Santa Marta takes place on two levels: an urban-territorial scale reading and an examination of the urban space generated within it.

The first analysis studies the recurring dynamics that help understand the origin and formation of the favela, starting from the most complex aspects of the context, such as the organization and structure

of the internal circulation system, the expansion and occupation of the territory, the creation of new geographies, and the favela's ability to absorb changes in its surroundings and flexibly respond to environmental traumas. This organizational syntax does not refer to repeated material models in space, following a predetermined scheme, but rather to "spatial action models"—processes that generate spaces, rather than fixed forms. These models involve the documentation of residents' daily practices, such as the construction, use, and transformation of the urban fabric, which then leads to the creation of material forms.

Closer observation allows for the analysis of a specific public space within the favela, where the majority of community actions and interactions are concentrated.

The public space analyzed is located in the southern part of Santa Marta, along a staircase that accommodates the steep slope of the area and facilitates the passage of many residents in and out of the favela. The strategic location of this space, connected to the Rua Francisco de Moura road, near the starting station of the inclined plane and the city's main public transportation routes, makes it the official gateway to the community—a place not only for transit but also for socialization and gathering. The key element that transforms this mobility infrastructure into a collective and economic hub is its role as a transitional space: the boundary between the formal and informal city. The proximity of the two urban fabrics triggers processes of mutual influence, which impact the quality of construction and public space, creating an openness unusually extended toward the formal neighborhood of Botafogo.

Figure 3. Photography of the public space. Santa Marta, Rio de Janeiro

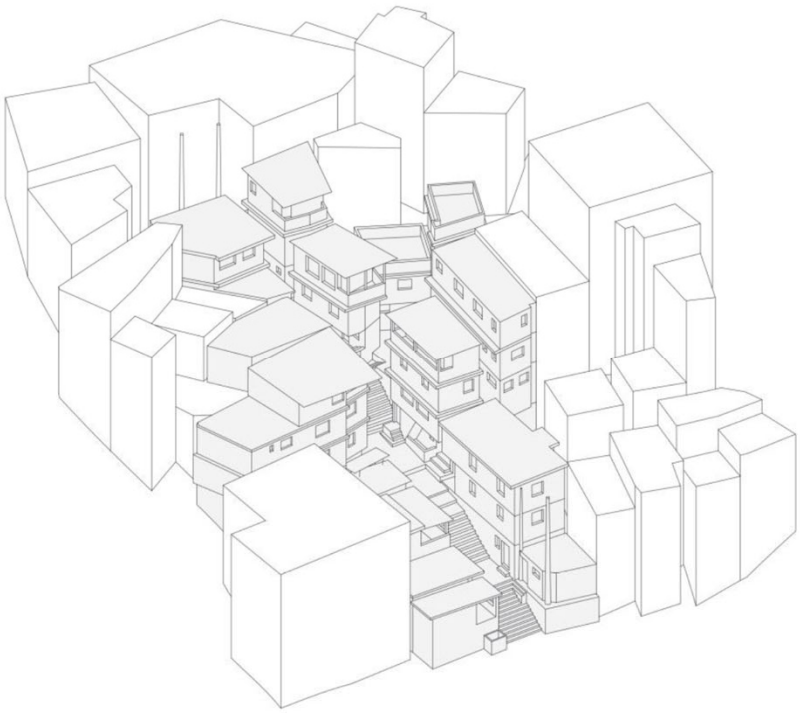

Figure 4. Volumetric of the public space. Santa Marta, Rio de Janeiro.

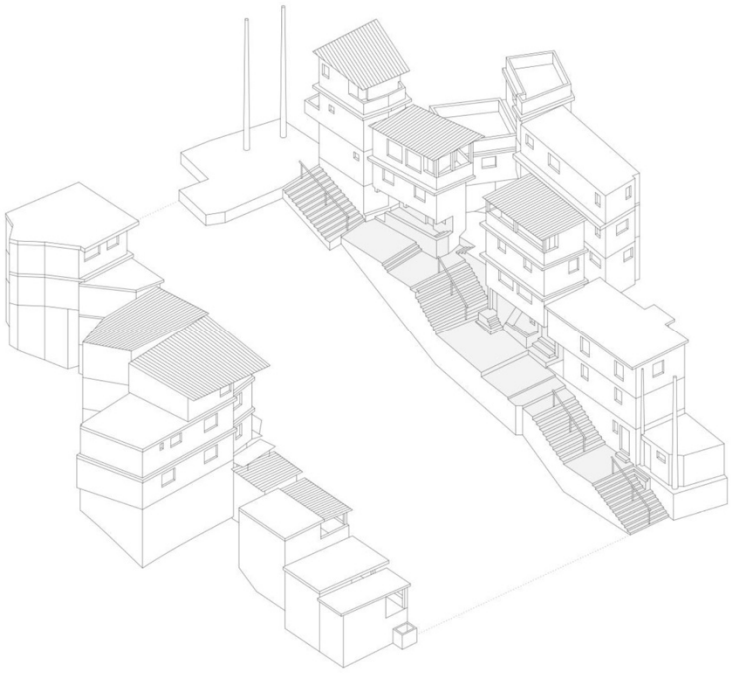

Figure 5. Volumetric section of the public space. Santa Marta, Rio de Janeiro.

Spatial Morphology. The infrastructure on which Public Space 1 is situated is a large staircase, constructed as part of the Favela Bairro project to replace and consolidate the pre-existing inclined dirt path that once served as access to the community. The staircase comprises four flights of steps,

interspersed with wide platforms, covering a total elevation of approximately eighteen meters. This structure provides access to the central-southern sector, the most populous and densely built area of Santa Marta. The construction of this staircase initiated two significant urban transformation processes: the densification of the surrounding residential buildings, which saw property values quickly rise to levels approaching those of formal neighborhoods, and the internal transformation of housing systems, particularly the ground floors, which were converted into public spaces or artisanal workshops. These small commercial activities, numbering around ten along the entire staircase, contributed to the creation of a flourishing local micro-economy, establishing Public Space 1 as a social catalyst within the community.

Urban Elements and Colors. The primary urban materials that shape the public space include the concrete staircase, featuring a central metal handrail, and a series of semi-private platforms in front of commercial establishments, distributed along the double frontage of the buildings. The staircase serves as the dominant urban element, guiding, through its sequence of ramps and landings, the points of higher and lower activity within the system. While dependent on the staircase, the platforms play an equally strategic role by helping to transform a mobility infrastructure into a distinctive urban space with its own identity. These micro-spatial areas are often equipped with canopies for protection from the sun and rain and furnished with fixed seating made of concrete or wood. The vibrant colors of the space aim to create a domestic and familiar atmosphere for customers. Together, the staircase and platforms—anchored into the steep topography—form a cohesive spatial entity with significant urban presence, further reinforced and amplified by the colorful buildings that surround them.

Social Appropriation. The flow of passersby using the staircase to enter and exit the community generates a dynamic and chaotic scene, animating the public space, particularly on weekdays when the favela is more reliant on the formal city. This social energy has led to another mode of appropriation by residents, who use the staircase as a popular place for resting, meeting, and socializing. The transformation of infrastructure into public space is a common phenomenon in favelas, where the drive for private occupation of free areas often halts in the face of the essential need for internal movement. The intense flow of people up and down the staircase blends with those who use it as an open-air amphitheater, a natural extension of the private environment. Public Space 1, extending towards the Botafogo neighborhood, presents an atypical dimension of theatricality for the favela, where community spaces are generally fragmented and shielded from the outside.

Rooting. The staircase infrastructure, established as a strategic axis of mobility, plays a pivotal role in stabilizing the urban fabric of the southern sector, shaping its spatial hierarchies and social dynamics. This rooting process results in the appropriation of the infrastructure by residents, transforming it into a collective platform. Several factors contributed to this transformation. First, the preservation of the staircase's open space, which has resisted occupation despite building pressures from the southern sector of Santa Marta. Second, the transformation of housing systems, which have adapted to the new public platform by developing micro-spatial solutions that enhance its collective usability and expand its public dimension. Finally, the staircase has been redefined as a multi-level plaza, functioning not just as a transit space but as a place where the complex web of social relationships—crucial to the construction of identity and a sense of belonging in the informal city—are woven together.

METHOD 2 – PARAISÓPOLIS (SÃO PAULO)

The research initially aimed to analyze various blocks within Paraisópolis and, from this analysis, develop a comparative framework of the different urban fabrics found in each block. The method involved field research, conversations with residents, photographs, graphic surveys, on-site drawings, and other necessary studies. Paraisópolis comprises a total of 33 blocks, each with configurations that vary based on several morphological factors, shaped by their position within the territory and the relationships built between different influencing elements. The most notable diversifications occur where there are significant elevation changes, requiring the adaptation of the built environment to the natural terrain, with linear lots gradually adjusted to accommodate orographic conditions. This has led to a substantial population increase, reflected today in the dense construction of buildings without setbacks or clear urban limits. To conduct a more detailed analysis of public spaces, the research focused on six main blocks.

For each of these blocks, a thorough field analysis was conducted, supported by existing cartography, historical photographic archives, maps, and bibliographies that introduced and detailed certain historical and structural aspects of the area. The most critical part of the research was done on-site, with visits and the simultaneous development of a critical perspective necessary for understanding the morphological transformations at the block level. This process resulted in analytical diagrams of the selected spaces, followed by data elaboration for presentation. The analysis was carried out across three levels of observation:

This first level involved a broad examination, starting with the historical development of the area to understand polarizations, development trends, and the phases of growth, densification, and verticalization across the different built sectors within the pre-selected blocks. Additional observations focused on topography, hydrography, vegetation, original land subdivisions, and boundaries.

The second level of analysis focused on interpreting the built environment, shaped by how the factors observed in the first level have been adapted. This included assessing each building's height, its orientation and development, facades, and the relationships between the buildings and their immediate context. Also observed were the conditions of each building in terms of upkeep and deterioration, their functions, and any public interventions either within or surrounding the block.

The third level zoomed in on the details, examining the dimensions of built and unbuilt spaces within or along the edges of the blocks, access points, pathways, nodes, and the ground layout, which is defined by the distribution of pedestrian and vehicle routes within the blocks. Lastly, the analysis considered the public spaces within the blocks, their location and distribution, and how residents interacted with these areas.

As mentioned, these analyses are presented in greater detail in this study. However, it is important to note that the goal of this methodology is to create an intersection of overlapping factors that shape the blocks. It is not solely a thematic observation of structure and functionality, but rather an understanding of the transformations generated by the interaction of the three levels of analysis in each context. This approach aims to produce data about the various territories of the favela, which is often limited in other studies to socio-economic data and generally lacks spatial analysis. It's worth

noting that not all observations were made on-site; in some cases, pre-existing maps were used in combination with collected data and the author's own knowledge.

The public space analyzed is located in Block 66, at the edge of the Grotão sector, and is connected to one of the residential complexes built by the state of São Paulo 15 years ago for the social relocation of residents from high-risk areas. The "Campo de Futebol Palmeirinha" (Palmeirinha Football Field), situated within this urban fabric, is the largest and only sports complex in the entire favela. More than just an open space in the urban agglomeration, it serves as a significant social hub. It is a key symbol of the favela’s struggle and resilience, having remained intact and preserved from the beginning of the occupation of the entire complex. The field has never been overtaken by activities other than football and the most important community events in the favela’s history.

Figure 6. Photography of the public space. Paraisopolis, São Paulo.

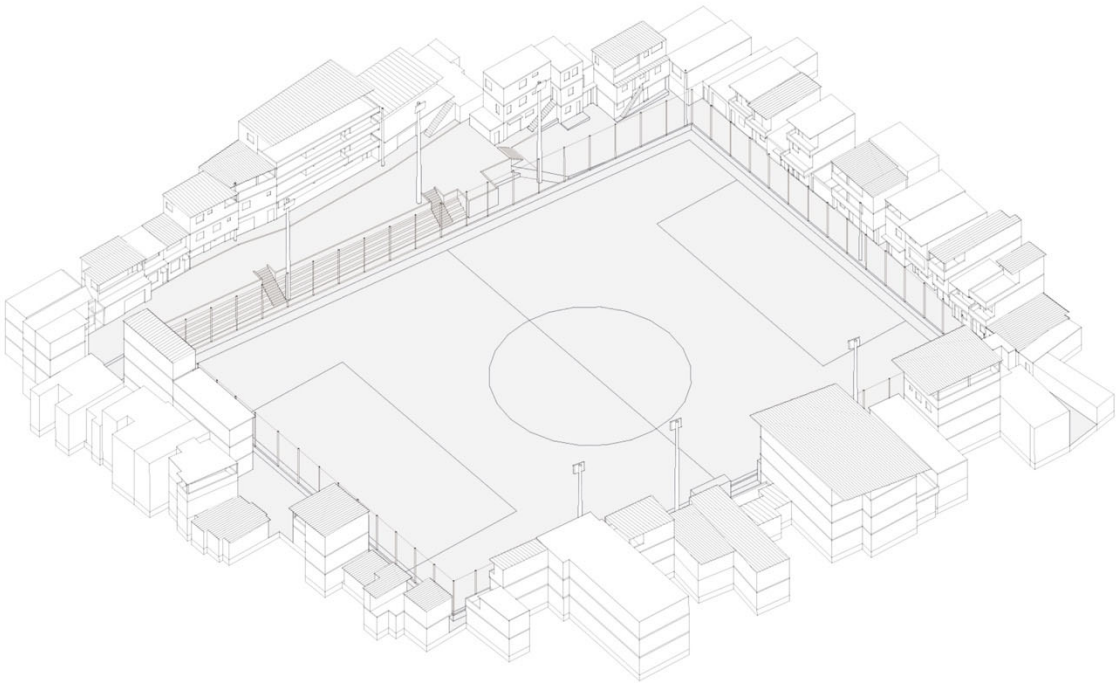

Figure 7. Volumetric axonometry of the public space. Paraisopolis, São Paulo.

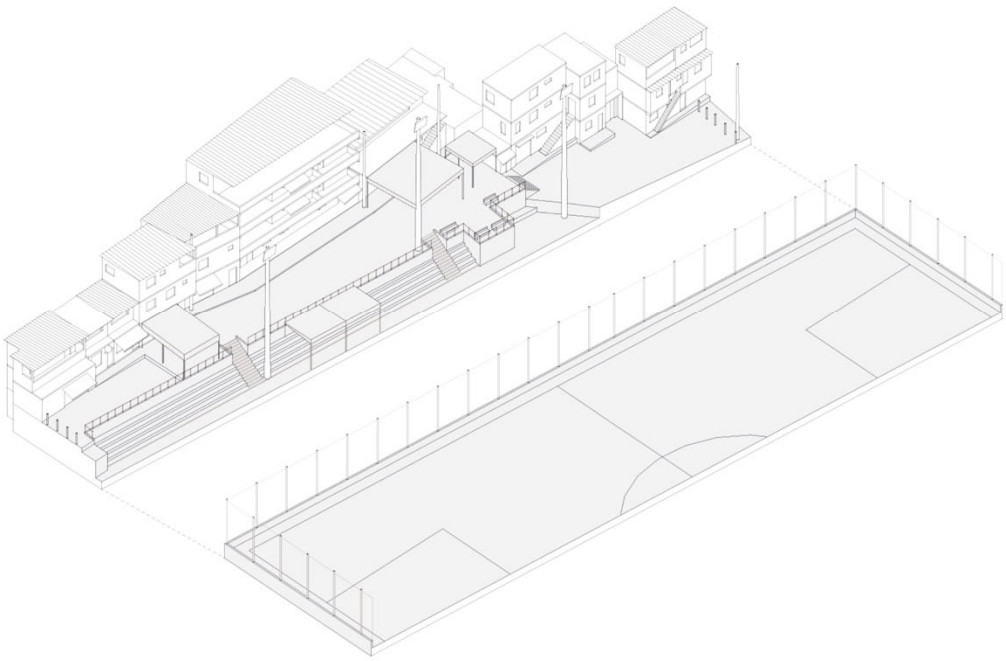

Figure 8. Volumetric section axonometry of the public space. Paraisopolis, São Paulo.

Spatial Morphology

The spatial configuration of Space 66_01 presents a variety of solutions that arise from the relationship between the football field and the surrounding built environment. To the east, access to the center of the block is provided by a pedestrian and motorcycle alley, nearly linear, about 2 meters wide, and paved with concrete. This path is often obstructed by parked motorcycles and trash. The southern sector, in contrast, has a completely different character. At a higher elevation, accessed via platforms and ramps, this area features broad unoccupied spaces, which have been adapted for various uses such as restaurants, bars, and a community center connected to sports activities. Additionally, the stands offer spectators a complete view of the field.

Urban Elements and Colors. The football field is the central urban element defining this space. It is grass-covered, surrounded by fences, and equipped with lighting for nighttime use, as well as spectator stands. Like many informal settings, the field serves multiple purposes beyond its primary function. The platforms, originally built to navigate elevation differences, are repurposed during events, functioning as stages, play areas, and, with the help of tents and tarps, educational and theatrical spaces. The platforms take on the role of an inclined square, becoming a significant space for social and community interaction. Another key element in shaping the social space is the presence of trees and plants that provide shade, which are also used to support tents and stalls during events. A final important urban feature is the micro-transformation of ground-floor facades in the southern sector and along the western route. Temporary additions such as benches and nylon coverings create informal seating and shaded areas, allowing for external tables and providing spaces for spectators during events. Colors play a crucial role in characterizing the space. Buildings surrounding the football field, particularly the taller ones, often adopt vibrant colors that make them highly visible, especially through the open fencing. The colors frequently reflect the teams participating in tournaments, and

the buildings also serve as platforms for communication and advertising banners, further enhancing the identity of the space.

Social Appropriation. Two main forms of social appropriation occur in this space. The first happens in the western sector, where commercial activity thrives along a busy corridor, with vendors, restaurants, and bar tables creating a dynamic environment. The second form of appropriation takes place in the southern sector, where the higher elevation limits pedestrian access, offering a more secluded area for social gatherings. This space hosts community events, parties, meetings among favela groups, and cheering moments during football matches, making it one of the most vital daytime gathering spots in the favela. This vibrancy has been captured in numerous reports, photographs, and videos shared online.

Rooting. Rooting provides a fascinating lens through which to observe the impact of this public space. The football field, a public infrastructure project, has been carefully maintained by the local community and represents a pivotal moment for the favela. Its construction was initially seen as a disruption, but the community has responded with several strategies, most notably the verticalization and formalization of the facades of buildings facing the field. Another strategy is visible at ground level, where every available space between the block and surrounding buildings has been transformed for public use. These areas include the lower sections of platforms near the fences, pathways, and informal meeting points, all of which revolve around the football field as a central gathering space.

CONCLUSIONS

Contrary to the widespread belief that favelas lack public spaces, the conducted analysis demonstrates not only their existence but also their essential structural role in defining the hierarchies and urban morphology of Santa Marta and Paraisópolis. In both favelas, public spaces play a fundamental role in psychological, social, and physical dynamics. These spaces are where a complex network of values and images is constructed, forming the community's identity. They represent an element of balance, providing a territory of resistance between the pressures of informal construction and the need for interaction and sharing. Within the hierarchy of "continuous informal space," public areas serve as support structures that unite the various levels of usage within the favela, adapting to transformations.

The study of public spaces proves to be complex, given their independence from formal structures. In formal public spaces, there exists a clear correspondence between urban form and social use; conversely, in informal contexts, this connection becomes tenuous, complicating interpretation. Fragmented and unfinished areas can transform into socially significant places, while formalized spaces, endowed with attractiveness, may be invaded by new constructions or turned into open dumps. This contradiction between spatial availability and the generation of public spaces is intricate, and the analyzed cases attempt to navigate it, offering interpretations linked to their geographical and urban contexts.

Morphological analysis has revealed the processes through which these spaces have developed and their rapid evolution over time. Observing social practices of meeting and celebration has supported

the interpretation of spatial appropriation phenomena. Finally, the analysis has focused on the signals of the public spaces' rooting within the community.

The public spaces examined do not easily fit into typical categories; they manifest as dynamic systems in which actions and uses are more significant than morphological structure. This variety renders each space both ordinary and unique, utilized daily without restrictions imposed by built forms, where new meanings emerge through individual or group appropriation. In this freedom of use, these spaces become special and irreplaceable.

The analysis of public spaces in Santa Marta and Paraisópolis reveals elements of interest for understanding the phenomenon of informal urbanism. While the construction of housing spaces is often the result of individual initiatives, public spaces originate from collective needs. These spaces may appear as areas left undeveloped, yet every construction implies the necessity for an external public space with a defined hierarchy. Each new construction considers the existing context; the order of this process is determined by public space, which plays a crucial role in the physical organization of the informal fabric.

Public spaces are characterized by their accessibility to residents, intimacy, and strong symbolic and identity connotations, where norms and values of a social group are recognized. These meeting places facilitate a complex framework of actions driven by affections and interpersonal bonds. Their structure is continuously adapted and modified through a lengthy and unstoppable urban composition process. This ongoing transformation is largely managed by the residents themselves, individually or through participatory groups.

New streets are created, existing pathways are closed or diverted, and areas of collective use are encroached upon by new constructions. In this dynamic scenario, public spaces assume a fundamental role in organizing pathways and social dynamics within the community, becoming true "condensers of social life," where cultural and identity values are formed and exchanged.

Public spaces frequently serve as extensions of the domestic realm. Doors and windows, as connection points between these two dimensions, remain open, facilitating fluid interaction between public and private spaces. The internal environment is infused with the external space, both functionally and aesthetically, highlighting the residents' personalization through transformations of use and aesthetic controls.

The connection between public spaces and daily social dynamics is evident, with each space successfully constructing a consolidated image within the community through urban and architectural strategies implemented by local residents. The alterations made to ground floors originally designated for residential use, now creatively converted into commercial spaces, along with aesthetic transformations of facades and the use of greenery, illustrate the cooperation between residents and the physical materialization of public spaces.

Public space in the favelas is characterized by a close connection to social dynamics and everyday life; all spaces manage to construct a consolidated image within the community through temporal urban and architectural strategies enacted by local residents. These actions include radical transformations of ground floors of buildings originally intended for residential use, creatively converted into commercial areas, aesthetic alterations of facades toward the street, featuring unusual color

modulations or high-quality finishes, and generous use of greenery, such as domestic plants or small to medium-sized trees. These dynamics clearly frame the indispensable and synergistic cooperation between residents and the physical manifestation of public spaces.

Public spaces in Santa Marta and Paraisópolis are shaped by often unpredictable social appropriation dynamics connected to levels of social use; their reversible nature frequently allows for fluctuations between public, semi-public, and private domains. Primarily developed and managed by residents, these spaces reflect their needs and aspirations. Their development process is not coordinated by a fixed plan but consists of a day-to-day program shaped by the changing perceptions and visions of the inhabitants.

In both favelas, informal public spaces adapt to various geometric, dimensional, and formal conditions, taking on a wide variety of morphological configurations. As spaces generated from pre-existing conditions, they are not characterized by rigid, preconceived elements but rather exhibit an adaptive quality that allows them to embed into different scenarios and transform them progressively. Space is shaped, articulated, and invented according to specific functional needs, levels of usage, and the unpredictable circumstances of local social life.

Public spaces in Santa Marta and particularly in Paraisópolis frequently arise at intersections of streets and pedestrian movement, depending on higher foot traffic and, consequently, greater social safety. One triggering factor in this dynamic is the establishment of commercial, recreational, or cultural activities that ignite the transformation of areas not originally configured as public spaces. Even architectural elements or urban furniture of private premises, such as awnings, sidewalks, or tables, often remain available for collective use, even outside operational hours, contradicting the widespread notion of favelas as sites of hyper-privatization.

The public spaces of both favelas are available for transformation, mutation, and evolution into other conditions. They are not codified by elements that rigidify them within space; rather, they are open systems that can progressively expand into adjacent areas through expansion, infiltration, or budding, creating additional public uses without altering their functionality and reversibility.

In light of the reflections presented, three significant aspects emerge. First, public spaces in both favelas are produced, managed, and controlled by the local population. Second, informal public spaces follow models of collective production and development; their growth is guided by a “shared vision” that evolves over time and is influenced by economic, political, cultural, and social factors. The development process aligns with the fluctuating and mutable expectations of residents. This notion of gradual development and constant evolution allows for the understanding of public space as an urban material that is "unfinished." The production and utilization of informal public space are integral parts of the same process; they are continually created, used, and transformed. The third and perhaps most significant aspect concerns the attribution of meanings and collective values to public spaces, representing the clearest signal of the ongoing social and cultural rooting within the favela.

ABSTRACT

This article presents a critical analysis of the impacts of Urban Megaprojects (UMPs) on cultural memory and heritage, using the Cais do Valongo in Rio de Janeiro as a case study. Grounded in theories of urbanism, heritage, and memory, we investigate how UMPs trigger cultural and infrastructural transformations, often marginalizing social practices and expropriating collective memories. The Cais do Valongo, recognized as a space of Afro-Brazilian memory, is analyzed as a territory of resistance and resilience amidst processes of erasure and invisibilization caused by political and urban decisions. The patrimonialization of the Cais signals the re-signification of urban spaces politically contested. Methodologically, the research selected three UMPs that significantly transformed the urban form and spatial dynamics of Rio de Janeiro's port zone in the 20th and 21st centuries, using official documents, interviews, and scientific texts. The results focus on identifying cultural and infrastructural transformations and their impacts on heritage preservation and Afro-Brazilian cultural memory. The article concludes with reflections on the relationship between UMPs and cultural memory, emphasizing the importance of sensitive and inclusive urban planning for the preservation of local histories and identities.

Keywords: Urban revitalization; Gentrification; Afro-Brazilian memory; Porto Maravilha; Cultural heritage preservation.

[47] "Cais" is the Brazilian Portuguese term for "wharf." We do not translate the name "Cais do Valongo"; however, in some contexts, references to the location may use the word "wharf."

URBAN MEGA PROJECTS AND THEIR IMPACTS ON AFRO-BRAZILIAN CULTURAL MEMORY: A CRITICAL STUDY

To understand the impacts of Urban Megaprojects (UMPs) on cultural memory, we propose a brief review of the narratives that define UMPs within urbanism, drawing on the studies of Lungo (2007), Lungo and Smolka (2007), Moura (2011), and Vainer, Oliveira, and Lima (2012). These authors perceive UMPs as instruments for restructuring urban space in favor of capital, often funded by public resources and promoted by multilateral agencies, which replace traditional urban planning and result in socio-spatial segregation and territorial fragmentation (Moura, 2011).

We assume that the socio-spatial segregation caused by UMPs uproots local populations and fragments territories. In the case of Rio de Janeiro's Port Zone, gentrification has impacted Afro-Brazilian memory, threatening its rich cultural heritage. We reflect on how urban design and land-use management affect territorial practices, breaking the ties that sustain cultural memory. For Lungo and Smolka (2007), UMPs transform land value and use, affecting land structures and introducing new urban functions.

These dynamics also involve private economic agents, with the public sector as a partner, promoting land speculation. Moura (2011) notes that UMPs intricately link the public and private sectors, justifying themselves by the need for connection with the global scale and triggering economic development and urban restructuring. These projects generate impacts on land structures, real estate appreciation, and changes in the social division of space, with little significant socio-environmental consideration (Moura, 2011).

The academic literature is divided on UMPs: some view them as appropriate practices for the contemporary world, while others highlight their harmful exclusionary effects, rooted in neoliberal principles that connect local spaces to global wealth flows, often through public-private partnerships and marketing strategies (Moura, 2011). Under the discourse of requalification, UMPs restructure spaces for capital flows, resulting in architectural and urban icons, but also in socio-spatial segregation (Moura, 2011).

Considering the impact of UMPs, we must question whether they create conditions for the establishment of modernity clusters amidst socio-economic exclusion zones, thereby intensifying urban segregation (Lungo, 2007). In Rio de Janeiro's Port Zone, especially at Cais do Valongo, UMPs threaten the Afro-Brazilian cultural memory embedded in the area. Moura (2011) argues that these projects often cause ruptures in socio-economic and cultural structures, accelerating gentrification processes and environmental impacts by altering the urban form.

Vainer, Oliveira, and Lima (2012) emphasize that the ruptures caused by UMPs can be institutional, urbanistic, legal, real estate, political, symbolic, and scalar. These changes significantly impact the daily dynamics of the local population, crossing cultures and their tangible and intangible heritage, triggering the expropriation of knowledge and practices, and contributing to the erasure and invisibilization of black memory in Brazil, particularly in Rio de Janeiro's Port Zone (Bandeira, 1990).

The relationship between large urban projects, erasure, and the invisibility of afro-brazilian memory

Urban Megaprojects (UMPs) are large-scale urban interventions often promoted with the goal of restructuring and modernizing urban space. Funded by both public and private resources, they seek to meet the demands of capital, triggering a series of territorial disruptions that profoundly affect the socioeconomic, cultural, and environmental dynamics of the areas where they are implemented. Harvey (2008) argues that these projects operate within the logic of capitalist accumulation, transforming cities into commodities at the service of global capital. In this process, collective memories, especially of historically marginalized groups such as the Afro-Brazilian population, are often erased or rendered invisible.

The impact of UMPs on the Port Zone of Rio de Janeiro, particularly at the Cais do Valongo, is a paradigmatic example of how these interventions affect Afro-Brazilian memory. Bandeira (1990) alerts us to the attempts to erase Black identities in Brazil, emphasizing the importance of preserving the territories where the knowledge and practices of these cultures were carried out. The Cais do Valongo, as a disembarkation site for enslaved Africans, is a central space in the history of the African diaspora in Brazil. As Lima (2018) explains, Cais do Valongo symbolizes the legacy of slavery and Afro-Brazilian resistance, being a place of memory of a traumatic past where, "The exceptional universal value attributed to it was centrally justified by its character as a site of memory of the Atlantic slave trade and cultural and political resistance of the Black population to a long history of violence and exclusion" (Lima, 2018, p. 99).

The discovery of the Cais do Valongo in 2011, during the Porto Maravilha construction works, and its recognition as a World Heritage Site by UNESCO in 2017, highlighted the importance of preserving this place. Suiama (2023) points out that Cais do Valongo was the largest slave port in the Americas, where approximately 800,000 Africans were disembarked. However, the wharf was progressively erased from urban history with the construction of the Empress Wharf in 1843, and later buried as part of the new port works in Rio de Janeiro in 1906 under the Pereira Passos Urban Improvement Plan.

This process of erasure, according to Bandeira (1990), is part of a historical strategy of making Black cultures invisible in Brazil. The ethnic diversity among enslaved people was used as a mechanism to fragment their identities, weakening social cohesion among them. Bandeira describes how the imposition of the Portuguese language was one of the main forms of “cultural domestication” used by colonizers to silence African voices, rendering the “[...] ethnic diversity manipulated as a fragmenting mechanism of social origin identity, making African languages inoperative as an instrument of interaction and cohesion” (Bandeira, 1990, p. 9-10).

This cultural erasure is part of a broader exclusion process that Nascimento (1978) describes as forced “assimilation,” masked under the discourse of national unity. Nascimento denounces how this assimilation serves to suppress Afro-Brazilian memory, perpetuating a structure of domination that marginalizes Black contributions to the formation of Brazilian society.

In the context of UMPs, Missiatto (2021) discusses the “polysomic nature of whiteness,” which permeates various spheres of society, including architecture and urbanism. She argues that the production of urban space is shaped by a white perspective that marginalizes other forms of territorial

appropriation, contributing to the invisibility of non-white cultural identities, as "the polysomic nature of whiteness operates through a multiplicity of meanings, values, and norms associated with whiteness that permeate various spheres of society" (Missiatto, 2021, p. 256).

Thus, the UMPs that have traversed the Port Zone from the Pereira Passos Improvement Plan to the Porto Maravilha project contribute to the deterritorialization of Afro-Brazilian communities, driving processes of gentrification that result in the physical and symbolic extinction of their spaces of memory and resistance. The modernizing logic that guides these projects, with its hygienist bias, ignores or minimizes the histories and experiences of these communities, erasing their territories and their contributions to the city's formation.

It is important to highlight that the control of urban territories, as identity-laden cultural spaces, is also constantly under dispute. Haesbaert (1997) reminds us that the concept of territory can be understood as "an appropriated space, in which appropriation takes place on various scales, involving political, economic, and above all, identity control" (pp. 36-37). In other words, we are dealing with human practices on territory that constitute territorialities, described as "[...] a set of relationships developed by a collective with the space they inhabit, mediated by instruments of control and appropriation, both concrete and symbolic" (pp. 36-37). Applying these concepts to the context of urban transformations materialized by Urban Megaprojects (UMPs) that impacted the port area of Rio de Janeiro, we observe that such urban interventions on this historical territory of Afro-Brazilian practices result in the continuous deterritorialization of the identity ties of the Black population. As Haesbaert (1997) points out, deterritorialization48 is the process of "disassociation of a community or individual from their original territory," often associated with globalization processes and capitalist transformations that "uproot" the identities and cultural practices once embedded in that space (pp. 258-259).

Therefore, when discussing Urban Megaprojects (UMPs) in the context of Rio de Janeiro's Port Zone, it is essential to consider not only the physical impacts of these interventions but also the profound effects they have on the preservation of Afro-Brazilian memory and identity. Missiatto (2021) points out that Black deterritorialization is a process rooted in the African diaspora and perpetuated by urban marginalization policies that reinforce the coloniality of thought and power in Brazilian cities. In this way, UMPs not only restructure the physical space but also contribute to the erasure and invisibility of Afro-descendant memories and identities within urban contexts.

Memory and gentrification: the Cais do Valongo and conflicts in the Port Zone

The concept of memory is closely linked to territory, as it is revealed in the cultural and identity practices anchored in urban spaces, the territorialities exercised through that territory. In the context of Urban Megaprojects (UMPs), such as the Porto Maravilha project, these memories are often erased or marginalized, especially when the focus is on reconfiguration and gentrification of space, as discussed by Lungo and Smolka (2007). The Port Zone of Rio de Janeiro, particularly the Cais do

[48] Associated with the concept of deterritorialization, the discussion also extends to that of reterritorialization. Haesbaert (1997) clarifies that reterritorialization is described as the subsequent movement to deterritorialization, in which a new territory is constructed or appropriated, usually involving "[...] new arrangements of control and appropriation, which can be both physical and symbolic" (p. 154-155).

Valongo, emerges as an emblematic example of this process of erasure and cultural resistance (Vassallo & Cicalo, 2015).

We cannot discuss UMPs in the port zone of Rio de Janeiro without addressing how gentrification processes act to erase and render Afro-Brazilian memories invisible. As Ribeiro (2018) clarifies, the concept of gentrification revolves around two key elements: (i) physical interventions in the territory and (ii) population replacement, that is, the removal of poorer residents by wealthier groups. This process, as noted, is not limited to the physical transformation of space but also involves a profound social and cultural reconfiguration of the affected areas. Anchored in Zukin (1995), Ribeiro (2018) highlights that one of the "new forms of gentrification" is related to the transformation of public space, which, after being restructured architecturally and urbanistically, becomes regulated by new norms of use that end up excluding its usual visitors and replacing them with groups of greater economic power (Ribeiro, 2018, p. 1342).

The author also reminds us of that other dynamics of exclusion manifest themselves in different ways, such as commercial gentrification, which, according to Van Criekingen and Fleury (2006), occurs when pioneering merchants in certain areas remodel their establishments to attract a new, wealthier clientele, transforming the region's socioeconomic profile (Ribeiro, 2018, p. 1342). There is also the gentrification of new constructions, described by Davidson and Lees (2005), which involves the construction of high-end housing in central or industrial areas, drastically altering the local social fabric without necessarily displacing previously established low-income residents but creating a hostile environment for their permanence (Ribeiro, 2018, p. 1342). These contemporary forms of gentrification reinforce the exclusionary logic of UMPs, which not only transform the urban landscape but also erase cultural identities, particularly in areas with a strong Afro-Brazilian presence, such as Rio de Janeiro's port zone.

Grounded in this perspective, we understand that UMPs, driven by the discourse of modernization and progress, tend to transform the territory to serve the interests of capital, often resulting in population displacement and the erasure of memories associated with these places (Moura, 2011). In the case of the Port Zone, the revitalization led by the Porto Maravilha project, covering five million square meters and aimed at requalifying the region for mega-events like the 2014 World Cup and the 2016 Olympics, and currently, in 2024, undergoing intense real estate speculation, neglected the preservation of Afro-Brazilian cultural practices and memory long rooted in the area (Lima, 2018).

The Cais do Valongo, rediscovered in 2011 during Porto Maravilha's works, symbolizes the African diaspora and the legacy of slavery in Brazil. Its *patrimonialization* by UNESCO in 2017 was a significant milestone in recognizing the traumatic past of the Atlantic slave trade. However, as Pollak (1989) points out, memory and identity are constantly contested, and in the case of Valongo, the transformation of the area into a tourist product sparked tensions between urban development policies and Afro-Brazilian communities' demands for preservation and respect for this sacred space (Pollak, 1992).

The urban transformations driven by UMPs carry an exclusionary dimension. As Vassallo and Cicalo (2015) argue, the Porto Maravilha project was developed to attract real estate and tourism investments, without considering the needs and identities of local communities. This process resulted

in the gentrification of the region and the expulsion of low-income populations that had traditionally occupied the area, reproducing dynamics of racial and socioeconomic exclusion (Vassallo & Cicalo, 2015). This reality echoes Moura's (2011) analyses, which highlight that UMPs tend to transform the social division of urban space, creating enclaves of modernity and wealth at the expense of destroying culturally significant territories.

In the specific case of the Cais do Valongo, the attempt to silence Afro-Brazilian history becomes clear in how the space was rediscovered and incorporated into the tourist circuit. Cultural erasure, as described by Missiatto (2021), manifests not only in the physical destruction of territories but also in the symbolic and identity-based *invisibilization* of Black communities, whose memories are instrumentalized for market purposes. The Cais do Valongo, a place of Black memory and cultural resistance, was transformed, under the discourse of revitalization, into a tourist attraction, disregarding the deep meaning the site holds for Afro-descendant communities (Lungo & Smolka, 2007).

“The extermination of a people's memories can itself be the erasure of that people, as the removal of certain minority groups from the annals of history imposes on their ancestry and descendants the weakening of their identities and social consciousness, furthering the symbolic, psychological, and cosmological disappearance of their otherness.” (Missiatto, 2021, p. 258).

The *patrimonialization* of the Cais do Valongo further reflects the complexity of memory disputes in the urban context. For Black movement leaders, Valongo is a symbol of resistance and ancestry, and its preservation must be guided by reflections on the enslaved past and the fight against racial discrimination. However, for municipal managers and investors, the archaeological site is primarily seen as a tourism development opportunity, aimed at attracting a higher-income audience (Vassallo & Cicalo, 2015). This tension between memory and modernization highlights the exclusionary nature of UMPs, which often prioritize profit and real estate speculation over the preservation of local history and identities.

As Pollak (1992) asserts, political memory is a field of dispute, and in the case of the Cais do Valongo, this dispute translates into a divergence between demands for memory tourism and economic development aimed at reconfiguring the area. For these memory spaces to truly contribute to reconstructing Afro-Brazilian history, it is essential that local communities' voices are heard, and their narratives respected. Institutionalizing places like the Cais do Valongo is an important step, but without an inclusive management and preservation process, there is a risk of turning these resistance spaces into tourist products devoid of deep cultural significance.

METHODOLOGY

This study adopts a qualitative approach, focusing on document analysis and the review of scientific literature to understand the impacts of Urban Megaprojects (UMPs) on the Cais do Valongo and Afro-Brazilian cultural memory. The research is based on a rigorous review of academic and historiographical sources that discuss processes of urbanization, the preservation of cultural heritage, and the social effects of large-scale urban interventions. The theoretical review included texts addressing the concepts of collective memory, urbanism, and gentrification, such as the works of

Lungo and Smolka (2007), which explore socio-spatial dynamics and the exclusionary effects of UMPs in Latin America.

In addition to consulting academic articles, books, and documents that detail the Pereira Passos Urban Reform Plan and its relationship to Afro-Brazilian memory, the research draws on primary and secondary sources to establish a historical connection between the port area's enslaved past and the present context, evidenced in the Porto Maravilha project. The investigation also considers reports from cultural organizations, such as UNESCO, and journalistic materials, providing a current perspective on the debates surrounding the *patrimonialization* of the Cais do Valongo and the broader implications of urban revitalization in the area.

The selected UMPs, which have transformed the urban form and spatial dynamics of the Rio de Janeiro port area during the 20th and 21st centuries, are analyzed through the lens of two complementary perspectives proposed by Lungo and Smolka (2007). The first focuses on the transformative action on the form of urban space, particularly on how urban planning prioritizes physical, aesthetic, and symbolic dimensions. The second examines the economic valuation of land resulting from these large projects and their impact on socio-spatial distribution.

PRESENTATION OF RESULTS

Based on the discussions developed thus far, this section presents an analysis of the results obtained, organized into three main topics: *The Pereira Passos Plan: modernization, sanitation, and the erasure of Afro-Brazilian memories in Rio de Janeiro*; *Impacts of Urban Modernization: the construction and demolition of the Perimetral Overpass*; and *Porto Maravilha: impacts of UMPs (Urban Megaprojects) and the preservation of Afro-Brazilian memory*. These topics highlight the relationship between large-scale urban reforms and the erasure of Afro-Brazilian cultural memory, showing how urban transformations throughout history, culminating in recent UMPs, have led to social, symbolic, and spatial ruptures in Rio de Janeiro's port area. Throughout the analysis, the impact of these interventions on the preservation of Afro-Brazilian memory, particularly in historically significant locations like Cais do Valongo, is examined, raising critical questions about the role of urban policies in perpetuating the invisibility of Afro-descendant communities.

The Pereira Passos Plan: modernization, sanitation, and the erasure of afro-brazilian memories in Rio de Janeiro

The Pereira Passos Urban Reform Plan, implemented between 1903 and 1906, marked a significant milestone in the history of Brazilian urbanism, aiming to modernize Rio de Janeiro and align it with European standards. Mayor Pereira Passos drew inspiration from two major urban movements: the Paris Urban Renewal Program (1853-1870), led by Haussmann, and the City Beautiful Movement, which began in the United States in the 1890s. This study, as outlined in the methodology, follows the analysis proposed by Lungo and Smolka (2007), where the first perspective addresses the physical and symbolic transformation of space, and the second, land value appreciation and socio-spatial changes.

The hygienist urbanism promoted by Haussmann, mirrored in Passos' actions, reorganized the urban landscape through the demolition of areas deemed unhealthy and the creation of new avenues and squares. However, as the analysis of sources suggests, these physical interventions also contributed

to cultural erasure, especially of the Black population that occupied the Valongo area, as noted by Azevedo (2016). The territory, which once housed a dense network of meanings related to Afro-Brazilian memory, underwent a process of cultural deterritorialization, being transformed in favor of a Europeanized vision of the city. The layers of territorial reconfiguration demonstrate the transformative power of Urban Megaprojects (UMPs).

The Cais do Valongo, a memory site linked to the transatlantic slave trade, was overlaid by the Cais da Imperatriz (Figures 1, 2, and 3) in a clear attempt to silence and make invisible Afro-Brazilian memories (Azevedo, 2016). This erasure process directly relates to the second perspective of Lungo and Smolka (2007), which discusses how land value can be elevated and how new uses of space are created, often at the expense of the original populations.

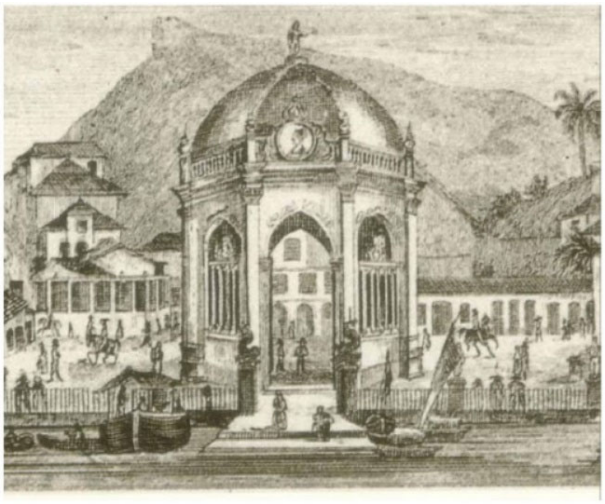

Figure 1: Cais do Valongo beautified for the disembarkation of the Empress, lithograph by Friedrich Pustkow, circa 1844. State Library of Rio de Janeiro. Source: Lima, Sene, & Souza (2016).

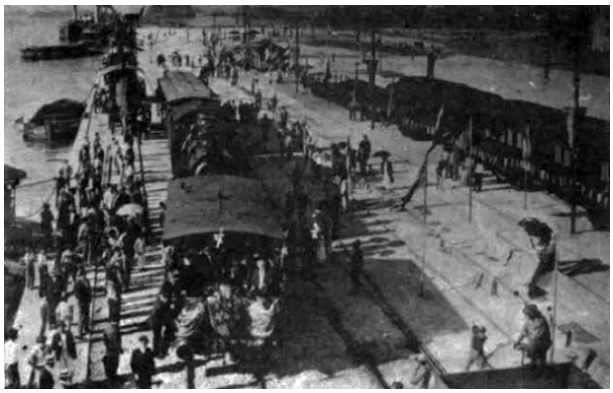

Figure 2: Inauguration of the first 500 meters of the wharf in 1906. Most of the landfill in the port area was created by leveling the Morro do Senado, demolished to create the circulation axis between Lapa and Estácio (Credit: Augusto Malta/General Archive of the City of Rio de Janeiro). Source: MultiRio. (n.d.).

The historical context, therefore, reveals a series of interventions that not only modified the urban form but also reshaped how Afro-Brazilian cultural memory was experienced in the city. The exclusion of Black populations, promoted through forced displacements and the criminalization of their cultural practices, exemplifies how large-scale urban decisions, typical of UMPs (Urban Megaprojects), reconfigured local sociability. As pointed out by Arantes (2005), the socio-spatial segregation caused

by the Pereira Passos reforms cannot be separated from the attempt to control the identity expressions of marginalized populations, reinforcing racial control and cultural erasure.

In conclusion, the Pereira Passos Plan exemplifies how UMPs, by transforming the territory, directly affect the preservation of memory and cultural practices. Although the reforms brought infrastructural advancements, the displacement of vulnerable populations and the erasure of Afro-Brazilian memory represent symbolic and urban ruptures that persist to this day.

Impacts of urban modernization: the construction and demolition of the Perimetral Elevated Highway

The construction of the Perimetral Elevated Highway, between 1957 and 1978, was part of Rio de Janeiro's modernization efforts aimed at improving traffic flow in the port area and connecting strategic parts of the city. Although the project fulfilled its function of facilitating mobility, the cultural and historical impacts were significant, including the destruction of landmarks such as the Central Market and the Pharoux Hotel (Figures 4 and 5). In addition to disrupting the visual and physical integration between the port area and the historical downtown, the elevated highway symbolized the disconnection between new infrastructure and local urban life, neglecting the cultural memories and identities of communities in favor of economic restructuring.

As Fridman (2013) argues, the urban planning initiatives of the Vargas Era, which influenced projects like the Perimetral, proposed the creation of proletarian housing and the eradication of slums and tenements, transferring families to healthier housing units. However, these hygienist interventions

led to the formation of impoverished peripheries, displacing working-class populations to distant neighborhoods, often lacking adequate transportation and services infrastructure (Fridman, 2013, p. 215). This model of urban intervention created a disconnect between infrastructure policies and the needs of local communities, exemplifying how economic modernization can overshadow the preservation of urban memories.

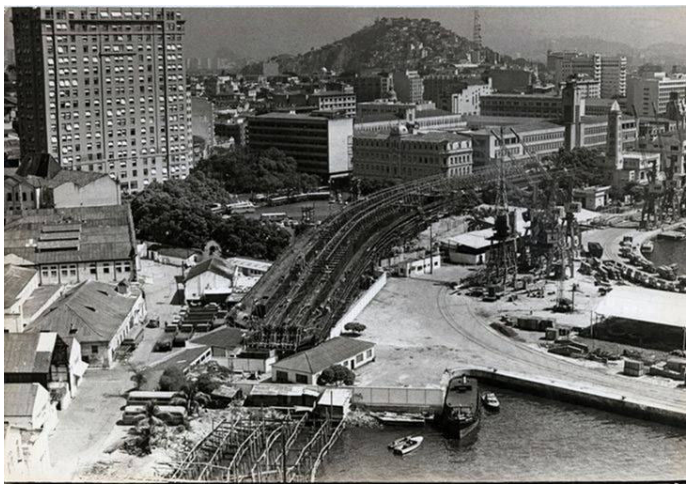

Figure 4: Construction of the Perimetral Viaduct over Praça Mauá, where the Museu de Arte do Rio (MAR) is now located. On the right, the pier where the Museu do Amanhã stands today, and on the left, the A Noite Building. Source: Diário do Rio. (n.d.).

Figure 5: Misericórdia Region, 1900. To the southwest, one of the towers and part of the Municipal Market. In the center, aligned with several buildings, the farthest to the left is the Hotel Pharoux. Behind it are the Escola da Magistratura do Estado do Rio de Janeiro, the Naval Museum, and the Ministry of Transportation (H-shaped building). Behind it, the Casa de Câmara e Cadeia, and to its right, part of the Imperial Palace. Source: Histórias e Monumentos. (n.d.).

The demolition of the Perimetral Elevated Highway, between 2013 and 2014, marked the beginning of the Porto Maravilha project, one of the Urban Megaprojects (UMPs) in the port zone (Figure 6). Although the stated intention was to revitalize the region and recover its historical heritage, it can be conjectured that this type of intervention primarily serves the interests of global capital, functioning as a form of real estate speculation. The relationship between modernization and urban memory,

particularly Afro-Brazilian memory, is characterized by a persistent tension, where cultural preservation does not always align with economic development.

Figure 6: Implosion of the Perimetral Viaduct on November 24, 2013, to replace the Avenida Rodrigues Alves / Perimetral with the Binário do Porto and Express / Túnel Marcello Alencar roads. In the background to the right, the Cidade do Samba. Source: Engenhareia. (2017, May 11).

We must not lose sight, as Lungo and Smolka (2007) remind us, that UMPs (Urban Megaprojects) often operate under the logic of economic restructuring, frequently resulting in socio-spatial segregation and cultural exclusion. In the case of the Perimetral Viaduct, the project helped shape Rio de Janeiro to align with global capital flows, but at the cost of key historical layers that shaped the local identity.

The demolition of the viaduct and the revitalization of the area around Cais do Valongo illustrate the complexities of reclaiming Afro-Brazilian memory in the city. Declared a World Heritage Site by UNESCO on July 9, 2017, Cais do Valongo stands as a symbol of resistance and memory of the African diaspora. The study of the construction and demolition of the Perimetral Viaduct demonstrates how UMPs deeply impact a city's cultural memory. While the demolition was justified as part of a revitalization process, it highlights the challenge of balancing modernization with historical preservation, especially in areas like the port zone that hold profound cultural significance. The Porto Maravilha project emerges as one of the primary UMPs, aiming to revitalize the port region, redefining the territory and its heritage. However, as with the Perimetral, the project also raises questions about the impacts of modernization on local cultural memory and identity, sparking debates about real estate speculation and social exclusion.

Porto Maravilha sought not only to restructure the physical infrastructure but also to integrate economic development with cultural heritage. The Cais do Valongo, valued as a World Heritage Site, represents this tension between cultural revival and erasure. Nevertheless, the critique remains: is the project perpetuating a model of modernization geared toward global capital interests, as the Perimetral once did? The challenge is to strike a balance between promoting new urban uses and respecting historical memory, ensuring that the region's cultural legacy is not lost in the process of urban transformation.

Porto Maravilha: impacts of UMPs and the preservation of afro-brazilian memory

The Porto Maravilha Project, initiated in 2009, is one of the largest urban revitalization efforts in Rio de Janeiro, aiming to requalify the port area to meet the demands of major international events, such

as the 2014 World Cup and the 2016 Olympic Games. Managed by the Urban Development Company of the Port Region (CDURP), the project follows a model commonly used in Urban Megaprojects (UMPs), aiming to transform urban space to serve the needs of capital, as previously noted by Lungo and Smolka (2007). Like other UMPs across Latin America, Porto Maravilha is funded by public resources and involves international consultants and agencies (Moura, 2011), promoting a "modernizing discourse" that often conceals processes of exclusion and gentrification, which result in socio-spatial segregation (Vainer, Oliveira & Lima, 2012).

Following the elitist urbanization pattern observed in similar projects, Porto Maravilha prioritized the creation of tourist and cultural spaces, such as the Museum of Tomorrow and AquaRio, over preserving the Afro-Brazilian history and traditions rooted in the area (Pinheiro & Carneiro, 2016). This phenomenon aligns with Lungo's (2007) critique of UMPs, which often generate “ruptures in socio-spatial dynamics,” driven by increased real estate speculation and the devaluation of local cultural practices. Paula and Herédia (2018) emphasize that the project encompassed five million square meters, focusing on infrastructure and tourism, while placing Afro-Brazilian cultural memory in the background.

The discovery of the Cais do Valongo (Figure 7) during the Porto Maravilha construction in 2011 underscored the importance of preserving Afro-Brazilian heritage. Recognized as a UNESCO World Heritage site in 2017, the wharf represents the memory of the African slave trade, serving as a space of resistance and anti-racist struggle. However, as Vainer, Oliveira, and Lima (2012) observe, the touristification of the port area has commodified this memory, distancing it from the local identities and narratives. This reflects the effects of UMPs, which, according to Moura (2011), are driven by public-private partnerships under a neoliberal framework, prioritizing economic development at the expense of social exclusion and the destruction of historical and cultural ties.

Figure 7: Reurbanized Valongo Wharf. Source: Lima, Sene, & Souza (2016).

This dynamic is reflected in what Ribeiro (2018) describes as “new forms of gentrification,” where the transformation of public space, alongside real estate speculation, results in the exclusion of former users and residents, who are replaced by wealthier groups. This phenomenon is evident in Porto Maravilha, where real estate speculation significantly increased land prices, leading to housing displacements as many poorer residents could no longer afford to stay in the area (Nascimento, 2019).

This process reinforces the cycle of commercial and residential gentrification, where culturally significant areas are restructured to serve tourism and real estate interests, while Afro-Brazilian traditions and memories are marginalized.

Lungo and Smolka (2007) suggest two perspectives for understanding UMPs. The first relates to the physical transformation of space and the increase in real estate value, aspects clearly visible in Porto Maravilha, where urban reforms raised land prices but also fragmented the relationship between residents and their territory. The second perspective refers to the creation of new functions for specific areas, such as the port zone, which was redefined to attract investments and tourists, often at the expense of traditional populations.

Porto Maravilha thus demonstrates how UMPs can act as mechanisms of urban reconfiguration, not only altering the form and function of space but also deeply affecting local cultural and identity narratives. While interventions in the port zone brought economic and tourism benefits, they also generated tensions between urban development and the preservation of Afro-Brazilian memory. As Bandeira (1990) discusses, cultural erasure is a consequence of colonial practices and capitalist logic that subjugate and marginalize historically oppressed cultures, such as the Afro-Brazilian population.

Therefore, in analyzing the impact of Porto Maravilha, it is essential to consider the social and cultural implications of urban interventions to avoid the erasure of histories and identities fundamental to the cohesion of local communities. The pressures created by real estate speculation and gentrification, as described by Nascimento (2019), reveal that, although the project was presented as revitalization, it also perpetuates inequalities and contributes to the erasure of Afro-Brazilian traditions that form the cultural foundation of the port zone.

CONCLUSIONS

This article analyzes the impacts of Urban Megaprojects (UMPs) on Afro-Brazilian cultural memory, using the Porto Maravilha and the Port Zone of Rio de Janeiro as case studies. Urban modernization, initiated with the Pereira Passos Reform Plan, has historically reconfigured urban space, leading to cultural erasure and social exclusion, particularly of Afro-Brazilian populations. Examples of this process include the overlaying of the Cais da Imperatriz on the Cais do Valongo and the construction of the Perimetral Overpass, both projects that neglected the preservation of local memories and identities in favor of elitist economic and aesthetic interests. Porto Maravilha exemplifies how urban redevelopment can perpetuate gentrification and real estate speculation, marginalizing traditional communities. This article argues that future urban projects should prioritize the preservation of Afro-Brazilian memory and identity, which is essential for urban planning that promotes inclusion and cultural resilience.

ABSTRACT

Singapore's Civic District, once the heart of colonial city, has experienced significant transformation due to rapid urban development. This area reflects the broader issues of Singapore's heritage conservation policies, the dilemma between economic development and the historical integrity of urban landscapes. Despite its rich colonial heritage significance, the district's historical character has been greatly damaged by the modern development. By conducting a diachronic study by the historico-morphological approach, this paper traces the Civic District's morphological transformation through four morphological periods: the early colonial period (1819-1867), the later colonial period (1867-1950), the transitional period (1950-1990), and the cosmopolitan period (1990-present). The morphological analysis underscores how the district's original street patterns, building layouts, and land use have evolved under the social, economic and cultural influences. This study aims to provide evidence for urban planners on how to integrate isolated heritage sites into a cohesive conservation framework. It can serve as a more analytical approach to cope with the current challenges in Singapore's heritage conservation which always prioritise economic value over historic integrity of urban landscape.

Keywords: Urban morphology, urban transformation, historico-geographical approach (Conzenian approach), Singapore, Civic district

INTRODUCTION

Since the independence in 1965 from colonization of United Kingdom, Singapore has undergone extensive urban redevelopment which demolished historic districts to accommodate new constructions. Most old settlements of high population density and poor housing were replaced by modern infrastructure, particularly in the city center, which evolved from a densely populated colonial area into a commercial hub. As a former important colonial port city, Singapore has many colonial historic districts with significant heritage value, which have been impacted by urban renewal.

While the government started conserving some national monuments in the 1970s, comprehensive heritage area-based conservation policies only emerged in 1986 (Teo & Huang, 1995), when the Urban Redevelopment Authority (URA) announced a plan to conserve six historical areas. By that time, much of the building heritages had already been altered or demolished. After institutionalizing heritage

conservation, Singapore still faces challenges. One key issue is that conservation efforts often prioritize the commercial value of areas over historical integrity, leading to a fragmentation of original historic urban landscape. Due to the lack comprehensive approach to take the integrity of urban heritages in consideration, there is a disconnect between conservation objects of different scales and levels. The heritage conservation needs measures that are more sensitive to historical contexts.

This paper focuses on the Civic District of Singapore, a prime example of these challenges. Civic district was nominated as the born place of modern Singapore which was the typical British colonial urban core evolved under colonial planning and new post-independence policies. Historically, this area was the starting point for the establishment of colony and was the administrative centre of the city, and today, this area is close to the central business district of Singapore. Hence, the conflict between economic development and heritage conservation and the fragmentation of conservation sites are also reflected here.

This paper aims to trace the history of the Civic District, analysing its morphological transformations by the historico-geographical approach. Since its introduction by Conzen (Conzen, 1960), this approach has been widely used not only in Western historic towns (Conzen, 1962; 2004), but also in Eastern urban studies with well-established examples (Karimi, 2000; Gu, 2001). It has also been applied by scholars in other historic areas of Singapore (Li & Zhang, 2021). The historico-geographical approach can identify a hierarchy of plan units that reflected the historical development of the urban area. It delineates the morphological regions and examines the consistency and change of these morphological regions through different periods to understand the interplay between morphological change, urban planning, and socio-economic contexts. It is proved that morphological study can provide guidance for townscape management, particularly contributing to urban heritage conservation (Larkham, 2002). The goal of this paper is to offer a framework for assessing how historical planning and socio-economic factors, particularly in scale of historic grain, has influenced the built environment. Additionally, the analysis can establish a theoretical foundation as a historic layering to enhance the current top-down planning strategies.

METHOD

Conzenian approach, known as historic-geographical urban morphology method (Kropf, 2009), was named after urban geographer Conzen (1960). Morphological period refers to distinct phases in the development of a town's physical structure over time, shaped by the socio-economic and cultural circumstances of each era (Conzen, 1960).

Morphological region refers to the area that exhibits a distinct physical or structural form, which reflects its historical development and functional characteristics. These regions are defined based on different form complexes, such as s ground plan, building fabric and land use (Table 1) (Conzen, 1960; Whitehand, 2010). The first-order morphological regions defined by different primary functional areas with distinguishable morphological characteristics shaped by social-economic factors of each special periods. The second-order morphological regions correspond to variations in the plan unit. The three elements including land plots, building block, and street systems—are considered to have high

persistence, as they are less vulnerable to change over time and can therefore carry more historical information. The third-order morphological regions focus on differences in building types and land use, which are more prone to change. Based on this, in each period, the morphological regions of different levels within the Civic District are identified.

Cadastral maps, archives literatures are the data source. Data are collected and overlaid in QGIS, such as cartographic maps of Singapore in 1846, 1893, satellite map in 1950, buildings and roads map in 1988, current open street map data, and planning documents from National Archives of Singapore and National Library of Singapore.

Table 1. . The contribution of different morphological attributes to morphological regions delimitation. Source: Conzen, 2004; Whitehand, 2009

Attribute	Persistence	Contribution to hierarchy
Ground plan (including street, building block, land plot)	High	Mainly high and intermediate rank
Building fabric	Variable but often considerable	Mainly intermediate and low rank
Land use	Low	Mainly low and intermediate rank

ANALYSIS

Origin of the civil district as the British colonial urban centre

During the 1670s, Lord Shaftesbury proposed the Grand Modell (Home, 2013), a colonial urban planning guideline for Britain's global colonies, featuring open squares and square grid plot divisions. As British colonialism evolved, this model was refined, particularly in Asia, where it developed into a hierarchical plan with racial-segregated zoning (Kosambi & Brush, 1988). This stable spatial framework, characterized by governmental areas, open squares (Widodo, 2004), defensive forts, and government buildings, became common in British Southeast Asian colonies. Singapore's first urban plan Jackson Town Plan reflected this model. Implemented by Sir Raffles, it included open spaces, military installations, and government buildings. In the Jackson Town Plan, the area on the north bank of the Singapore River was planned as the Government Area, the center of the colony, and this area was the basis for our study area, the Civic District.

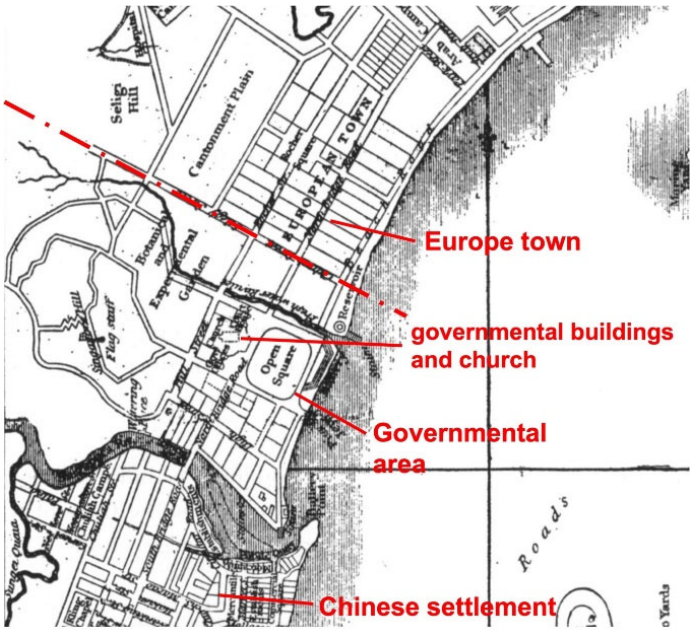

Figure 1. Government area in Jackson Plan. Source: National Archive of Singapore

Morphological Periodization

Based on the periodization in the study of Singapore's history and planning history, four morphological periods were recognised: first period: the early colonial period (1819-1867), second period: the later colonial period (1867-1950), third period: transitional period (1950-1990), and fourth period: cosmopolitan period (1990- now).

The First Period spans from the establishment of the colony in 1819 to 1867. This era represents the early phase of colonial development. In 1867, the authority over the Straits Settlements was transferred from the Calcutta administration of British India to the Colonial Office in London, thus Singapore became Crown Colony. The opening of the Suez Canal in 1869 increased the importance of Malacca Straits, making Singapore an increasingly significant port (Turnbull, 2009; Yeoh, 2003; Abshire, 2011). This led to a population boost and new urban development in the late 19th century. It marked the second period, the later colonial period (1967-1950).

The transitional period spans from 1950 to 1990. Urban renewal became the focus of urban development activities in Singapore after the establishment of colonial autonomous government and subsequent independence since the 1950s. In this period, Singapore turned to an independent state city from a colony, establishing a new stable urban planning framework by around 1990. Subsequently, the fourth morphological period is cosmopolitan period, from 1990s to the present day. Singapore became the fourth-largest foreign exchange market in the world by the 1990s, after only New York, London, and Tokyo (Lee, 2012). Outstanding economic status made Singapore a cosmopolitan city.

Morphological Region Delimitation

First Period: Early colonial period (1819-1867):

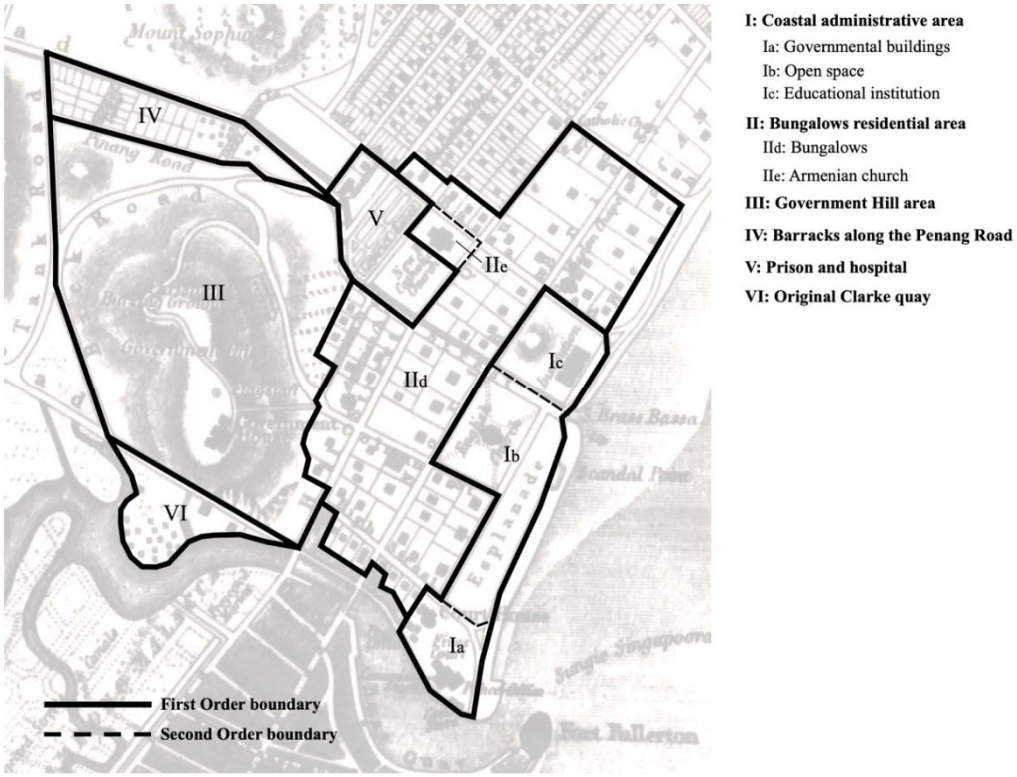

Figure. 2 Morphological Region of the Early Colonial Period (based on 1846 cadastral map)

Singapore's first urban plan, the Jackson Town Plan gazetted in 1822, designated the area north of the Singapore River as the Government Area, which was the predecessor of Civic District. As a public area owned by the colonial government, this region laid the foundation for its role: governmental and public services. Following the British colonial planning framework, the Jackson Town Plan introduced a rectangular grid for the main street networks and land division around the public square in this area, which largely established the road structure. The key elements of a typical colonial city centre—government buildings, churches, and open squares—were constructed during this period. The city's population had not yet experienced significant growth, and high-density residential areas to accommodate a large population had not been built yet (Yeoh, 2003).

Region I is designated as the coastal administrative area (Figure. 2). In the Jackson Town Plan, the main buildings in the Government Area included the English Church, Government Office, Court House, and an open square on the coastline. In the plan, the Court House and government office were symmetrically placed on either side of a church, with all three buildings planned on the western side of the open square (Figure 1). In the planned layout, this group of buildings was aligned along an axis from Government Hill to the coast. However, in the actual built environment, their locations differ from the plan, with this area distributed along the coastline. The public office and courthouse (Ia) were constructed on plots south of the Esplanade (Figure. 2). St. Andrew's Cathedral, the earliest Anglican church in Singapore, which corresponds to the church in the Jackson Plan, was completed in 1836 on the western side of the esplanade. The ground of church formed an open space together with the esplanade (Ib in Figure 4). Raffles Institution, the first school of Singapore colony, provided education for the children of local leaders. Although not included in the Jackson Plan, the school was built the year after the plan's release on a plot north of the Esplanade (Pearson, 1969).

Bungalow residential area (II) is divided into rectangular plots following an orthogonal grid, consistent with aforementioned British colonial planning tradition. Before the Jackson Plan was gazetted, some bungalows[1] had already been built in the Government Area. According to Raffles' orders and correspondence from the 1820s and Jackson's manuscripts, while the Government Area was reserved for governmental buildings in the Jackson Plan, some houses were not removed to make way for public buildings in this period (Pearson, 1953; Cangi, 1993; Eng & Savage, 1985). the Government Area at that time included private residences situated between the esplanade and Government Hill. For instance, the residence of the prominent Chinese merchant Tan Tock Seng (NHB, 2020), the home of Singapore's famous colonial architect Coleman (Cornelius, 2016), and the Caldwell House designed by Coleman, were all built in the bungalow residential area (II) during this period.

Government Hill area (III) is on Bukit Larangan (means Forbidden Hill in Malay), now known as Fort Canning Hill. Raffles established the Government House on Forbidden Hill, and since then, the hill had also been called Government Hill. To the north of Government Hill lies barracks along the Penang road (IV), which was used as barracks to canton sepoys, Indian soldiers in British army (NHB, 2023). Region V was where Singapore's first hospital and first prison were located (Thulaja, 2016).

South of Government Hill is the Clarke Quay area (VI), where the street network had not yet formed. Before the Jackson Plan was introduced, this area was an original kampong. Afterward, it developed into a quay with merchants building business houses, workshops, and residences there. It is recording that notable Chinese merchants of the time, such as Tan Kim Seng and Tan Tock Seng (Cornelius, 2019), built shops in this area.

Second Period: Later colonial period (1867-1950):

During this period, the main change in the study area was a rapid increase in building density, further subdivision of land, and the construction of more public buildings. The Government Area (I) transformed from the colonial administrative core into a multifunctional, high-density urban centre. During this period, more public buildings of various functions were built including community buildings, commercial buildings, museum, and library. It further clarified the role of the Civic District during this period as a civic center, rather than just an area of governmental buildings, as it was in the First Period. Due to the growth of the population, both the number and density of residential buildings significantly increased in the Civic District. The basic structure of the road network in the urban layout remained unchanged, new branch roads were developed. The morphological region delimitation is showed in Figure.3.

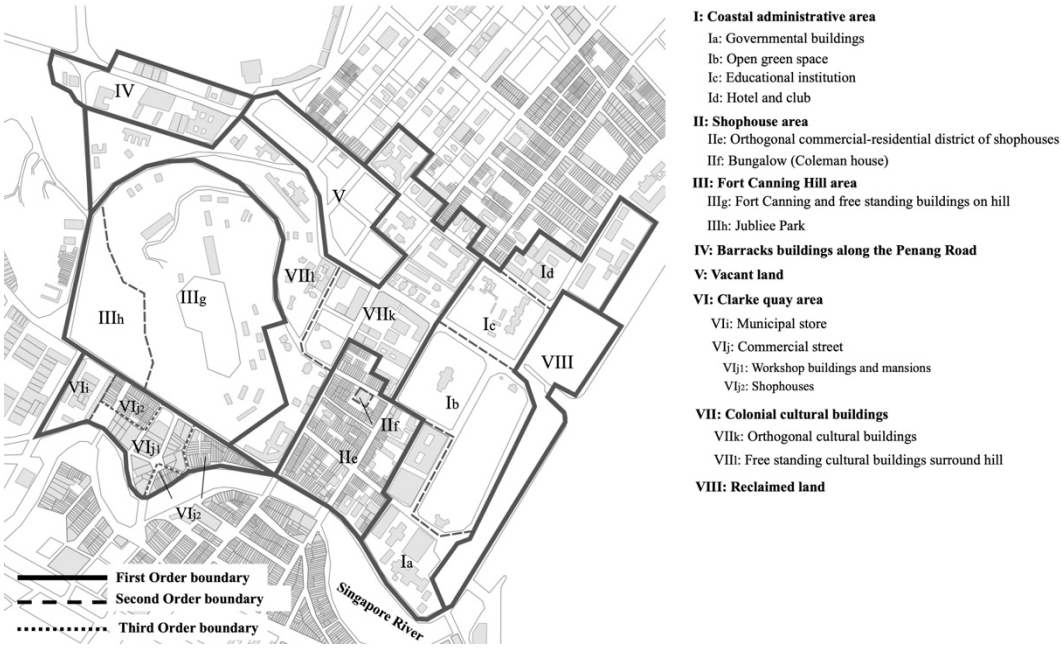

Figure. 3 Morphological Region of the Later Colonial Period (based on 1950 aerial photo)

Costal administrative area (I) expanded northward along the coastline. The Raffles Hotel and several clubs (Id) were established along the coast on the north of Raffles Institution (Figure.3). The open square Esplanade expanded to its current size during this period. It was called "the Padang," in Malay, meaning "field," which later became its official name. With the City Hall and the Supreme Court built in 1929 and 1939, the colonial government building groups surrounding The Padang took the shape as we see today. In the tentative UNESCO World Cultural Heritage description, The Padang and the surrounding colonial civic buildings are referred to as “The Padang Civic Ensemble” to present the heritage value of typical British colonial civic square. It includes the Parliament House buildings to the south of The Padang, St. Andrew's Cathedral to the west which were already built in the first period, and the City Hall and Supreme Court (Ia and Ib).

During the second period, the bungalow residential areas evolved into two distinct zones, shown as Shophouse area (II) and Colonial cultural buildings area (VII). Shophouse area became a district composed of shophouses streets. This newly emerging type of building and plan during the period was a commercial-residential district characterized by an orthogonal street pattern, with shophouses aligned along the streets, forming dense, continuous rows. Shophouse is a king of mixed-use building commonly found in Southeast Asia and southern China. It typically features a narrow and long shape, with the ground floor used as shop and the upper floors as residential areas (Han & Beisi, 2015). As the population grew, the racially segregated planning zones of the colonial era could no longer accommodate the original population. During this time, the Chinese population overflowed from their original settlement on the southern bank of the Singapore River into the northern bank areas, which were previously designated as the government area and European Town in colonial plan. Due to population growth, the low-density bungalow residential areas, with larger plots, were partially replaced by shophouses which had smaller, more tightly subdivided plots, creating high-density commercial-residential districts.

In colonial cultural buildings area (VII), colonial-style cultural buildings replaced the original bungalows. Part of cultural buildings orthogonally laid out within the orthogonal street grid that was

established in the earlier periods (VIIk). This area includes Singapore's most exclusive theater at the time, the Capitol Theatre (Tan, 2015), the first telephone company, Oriental Telephone Company (Chua, 2011), and the department store Whiteaway Laidlaw (Jia, 2020). Another part (VIIl) consists of free-standing public service buildings arranged along the contours of the hill. This area includes public cultural buildings like the Raffles Library and Museum, as well as community buildings such as the Young Men's Christian Association (Y.M.C.A) and the Young Women's Christian Association (Y.W.C.A).

The Fort Canning Hill area (III) is where Government Hill was located during the first period. In 1859, the government house on the hill was relocated, and construction of military fort Fort Canning began at the original site, which was completed in 1861. From then on, the hill became known as Fort Canning Hill. In the previous period, Clarke Quay area (VI) already served as a commercial hub with trading activities and shop buildings, but no road system had yet been established. During this period, roads was developed in Clarke Quay, connecting it with other areas and forming a distinct street grid. It consisted of the Municipal Store area (VIi) and the commercial street area (VIj). The commercial street area was characterized by a central cross street (VIIj1) flanked by shophouses on either side (VIIj2). The central cross street included wealthy merchants' mansions, such as River House (Yeo, 2018), and various workshops, including a rice mill.

Third Period: Transitional Period (1950-1990):

The main morphological changes of transitional period were due to slum clearance and population decentralization carried out in the 1960s-1970s. As the city centre, the Civic District saw its previously crowded neighbourhoods demolished and the population relocated to suburbs. The land emptied by the slum clearance was restructured and redivided, with high-value commercial properties introduced (Wong, 2001). In 1962, in urban planning consultation from United Nations, UN advisor Eric Lorange recommended redevelopment precincts that included parts of the Civic District (Red highlight of Eric Lorange Plan in Figure.5). These areas encompassed the banks of the Singapore River and the southern section of the central blocks within the Civic District, which were exactly the high-density shophouse streets. In subsequent urban plans, the central blocks of the Civic District were consistently designated as part of a planned commercial corridor (Red highlight of 1963, 1985, and 1988 Plan in Figure.5). This led to the continuous expansion of the commercial buildings area. Large-scale new modern public buildings were constructed, such as major multistorey shopping complexes and luxury hotels. New national landmark buildings were also erected in this area, including the National Library and the National Theatre.

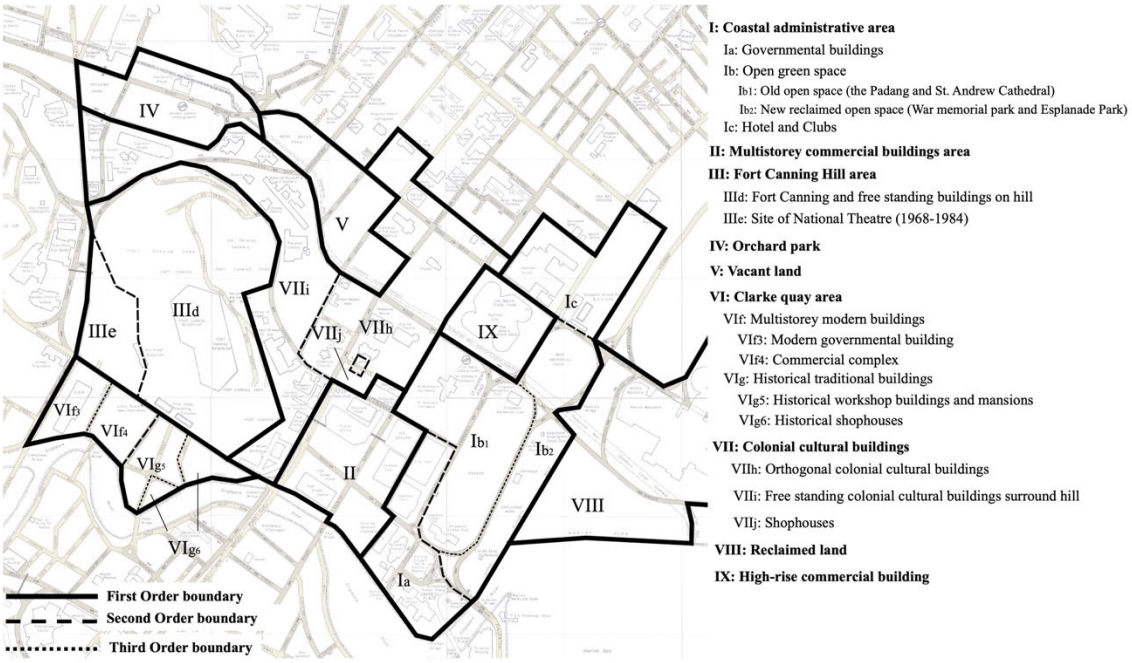

Figure.4: Morphological Regions of the Transitional Period (based on 1988 Aerial Photograph)

Persistent land reclamation altered the coastline of Civic District. For example, costal administrative buildings area (I) expanded during this period. War Memorial Park and Esplanade Park (Ib2) were established as extensions of open space on the newly reclaimed land from last period (Figure.4). Additionally, reclamation of Marina Bay was completed during this time (VIII), which was planned as new commercial and tourism hub. The former costal administrative buildings and The Padang no longer bordered the sea.

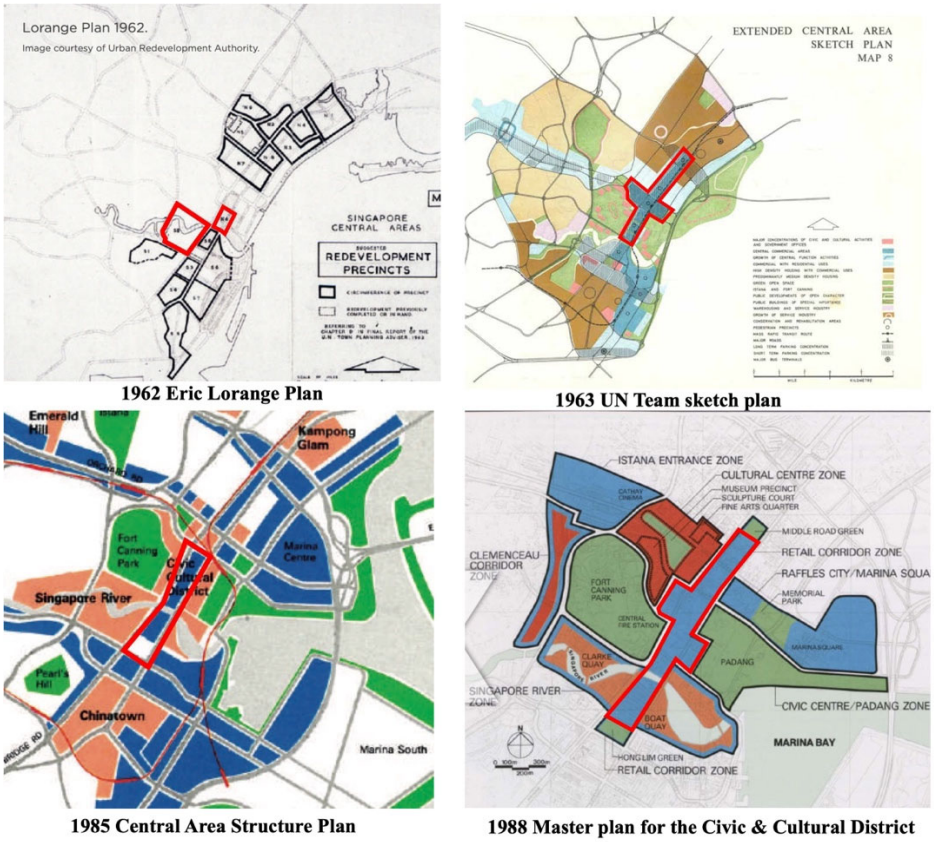

Figure.5 Master plan of the Civic District since 1962 to 1988 (Guo, 2016; URA, 2019)

Shophouses as a high-density residential model from the colonial era were largely demolished in city center during this period due to population decentralization. Previous shophouse area (II) and Clark Quay area (VI) were the most affected by this change. Multistorey commercial buildings area (II), which was shophouse area in last period, saw most of original shophouse districts removed during urban renewal. New buildings were modern multistorey commercial complexes, such as Funan Digital Mall and High Street Centre. Similarly, in Clarke Quay area, some of shophouses (VIf4) were demolished to make way for high-rise hotel, apartment, and commercial complexes (NHB, 2023c).

Site of high-rise commercial building (IX) was original site of Raffle Institution before it was relocated. In this period, the old building of institution was demolished to make way for Raffle City. Raffles City is a 150-meter-tall high-rise complex with four towers, designed by famous modernism architect I.M. Pei. The complex consists of the one-time world's tallest hotel and currently the world's fourteenth tallest hotel. This modernist skyscraper is a new building type in the Civic District, occupying the entire block. Its huge volume and modernist style contrast to the surrounding colonial buildings.

Fourth period): Cosmopolitan period (1990s- now):

In the 1990s, some of the national landmark buildings from the early independent period outdated and no longer met the needs. Some remained and were conserved at their original locations, such as the Supreme Court and Parliament House, while others were demolished and relocated to different areas, such as the National Library. Master plan for the Civic & Culture District was issued in 1988, which is the first special plan for Civic District. Subsequently, first conservation plan of Singapore was

issued in 1989, and a new master plan was issued in 1991. Urban heritage conservation began to gain attention, with the Civic District's role shifting to a cultural tourism destination and a colonial heritage area. As a global city, Singapore required new national landmarks. Marina Bay (VIII), the most significant urban project at the turn of the century, was reclaimed in the early 1990s and completed during this period, becoming a new national landmark (Figure.6). Marina Bay extended the physical area of the Civic District, as indicated in the 1988 master plan of Civic & Culture District. The newly built theatre named The Esplanade, functionally replaced the demolished National Theatre, becoming part of the Civic District.

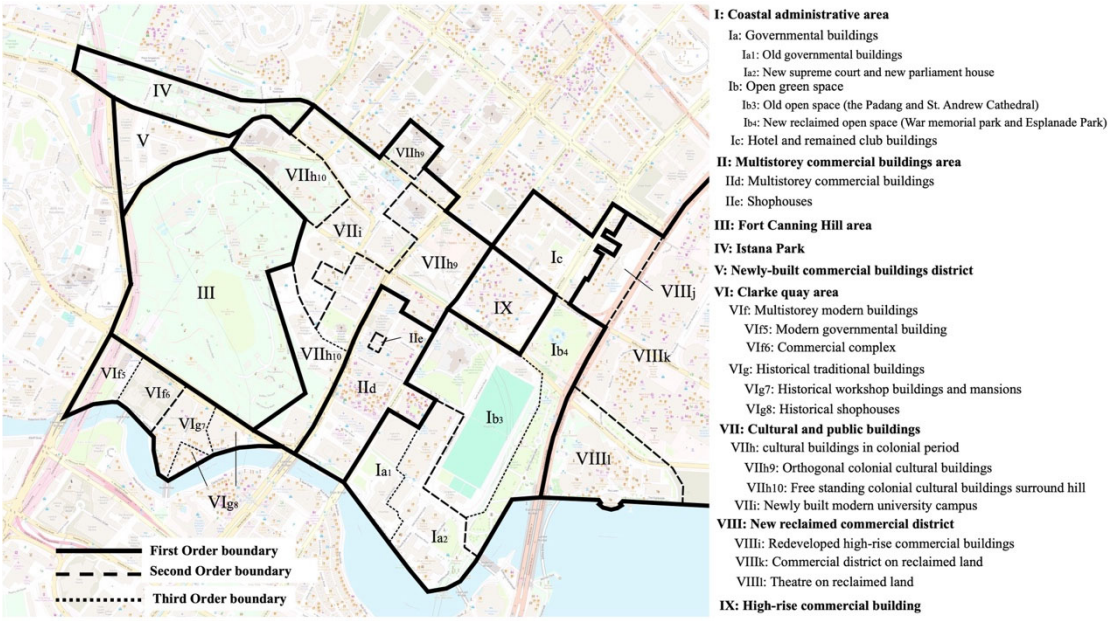

Figure.6 Morphological Regions of the Cosmopolitan Period (based on current Open Street Map)

During this period, indicating the development of a modern commercial building area (II), the boundary between it and Cultural and public buildings area (VII) shifted further north. A new building type emerged in former colonial cultural buildings area (VII): the modern university building. During this period, Singapore Management University established its campus in the Civic District (VIIi), and the former colonial culture area was fragmented by the modern campus buildings.

RESULTS AND DISCUSSIONS

Through diachronic analysis of the four periods the transformation of the different hierarchies of morphological regions of the Civic District are examined. From the first-order morphological regions over four periods, it shows that the origin of the civic district as a colonial center has gradually transformed from a governmental district to a cultural and tourism hub. Costal administrative area (I) and Fort Canning Hill area (II), serving as the eastern and western boundary of the area, has remained stable throughout its development. These two were also the earliest functional area of a colonial administrative center as military and governmental area. The coastal administrative buildings area expanded northward along the coastline during the colonial period. After independence, due to land reclamation, this area no longer relied on the coastline as a boundary, but its morphology has largely remained stable. Similarly, Fort Canning Hill served as the governor's residence in the early colonial period, became a military fortress and was later transformed into a public park after independence. While despite the functional changes, the morphology of this area has remained largely stable with

no significant change. These two areas define the boundaries of the Civic District. Meanwhile, these two areas are where the public functions and heritage of the Civic District are best conserved. Within the constraints of these two zones, development in the Civic District has tended to be more connected to the north and south, rather than west or east oriented.

Compared to the relatively stable morphology of Fort Canning Hill and the coastal administrative buildings, Multistorey commercial buildings area (II) and Cultural and public buildings area (VII) between the hill and the coastal buildings have undergone more frequent changes in form, influenced by the socio-economic context and planning of different periods. These two areas which used to have same pattern in the early colonial period, became differentiated in the later colonial period. The southern area (II) near Chinese immigrant settlements, turned to a high-density commercial-residential area due to population overflow in Chinese settlement (Figure.7). The area developed smaller blocks and more brunch roads based on the rectangular street networks from the previous period. Within the blocks, the land plots are subdivided in a terraced layout along street. The shophouses built on this were narrow and terraced, corresponding to the shape of land parcel. In contrast, the northern blocks (VII), close to the European Town designated in the colonial plan for European residents, evolved into a lower-density area primarily characterized by colonial cultural buildings in the later colonial period with lower land plot density. Correspondingly, the buildings are mainly colonial-style cultural buildings with larger scale than shophouse (Figure.7, Figure. 8)

The differentiation was continued in the transitional period. Due to the extensive urban renewal, the southern area contained shophouses area undergone the plot amalgamation in the transitional period. Land plots and blocks were amalgamated. Shophouses were replaced by modern multistorey commercial buildings. Streets lined with shophouses turned to commercial district dominated by shopping malls. The northern area, however, was less affected by urban renewal. The form of land plots remained stable during this period, with most buildings being preserved due to their value as public and cultural buildings from the colonial era. In the subsequent cosmopolitan period, the boundary between the two areas continued to shift northward due to the ongoing commercial development in the south.

In the morphological regions delimitation, second-order and third-order regions were delimitated based on building types and land use. Their transformation reflects the increasing variety of building types within the macro morphological framework of the Civic District. For example, during the colonial period, the types of secondary morphological regions were still limited, and the building types and land use within each first-order region were relatively uniform. However, after independence, urban renewal disrupted the original layout, especially after the 1990s, when more modern buildings replaced older ones on the original plot. For instance, in the Cultural and public buildings area (VII), the secondary regions were relatively uniform during the colonial period. In the cosmopolitan period, the emergence of modern campus buildings led to significant changes in the secondary regions of this area. Similarly, during this period, the secondary regions of the coastal administrative buildings area underwent substantial changes due to the construction of new government buildings.

CONCLUSIONS

The historic-geographical analysis of the Civic District provides insight into the evolution of Singapore's historical area, tracing its transformation from a colonial administrative center to a cosmopolitan city center. This analysis reveals that the history of the Civic District extends beyond the governmental area planned in the Jackson Plan, highlighting its development into a multifunctional urban area over the colonial period. The existing built heritage in the district encompasses legacies from multiple periods, reflecting the influence of various socio-economic backgrounds on the built environment. The results of the morphological analysis can serve as a reference for conservation planning. Diachronic morphological analysis reveals the development process of the existing isolated heritage site within boarder historic landscape. Meanwhile, the delimitation of morphological regions provides a broader boundary reference for the currently fragmented conservation sites. It complements the traditional top-down planning process and presents an analytical methodology to the current challenges in Singapore's heritage conservation efforts.

Figure.9 Current conserved heritage of Civic District (Based on current Conservation Guideline, Urban Redevelopment Authority, Singapore. Data source: data.gov.sg

There are two kinds of conserved heritage sites in Singapore: Conservation Areas designated by the Urban Redevelopment Authority and National Monument and National Monuments designated by the National Heritage Board (Figure.9). Unfortunately, some urban heritage sites have already been demolished by urban redevelopment, resulting in fragmentation of surviving historical areas. This has resulted in the current designation of conserved sites being further fragmented the historical connections among them. Additionally, the boundaries of some conserved areas only consider isolated historical buildings, without considering the broader urban landscape they were located in.

Morphological analysis showed that individual site belongs to the same morphological region, suggesting a lager urban landscape of historic value. Identifying these regions can help expand the conservation scope and reconnect fragmented heritage sites through historical analysis. Taking the open square (The Padang) as an example, the Padang and the surrounding government buildings were submitted in 2022 as the Padang Civic Ensemble, a typical civic square of British colonial rule, for tentative UNESCO World Cultural Heritage status. In the domestic heritage conservation policy, The Padang was designated as a National Monument in the same year. Thus, The Padang and its

surrounding colonial-era government buildings are now recognized as a conserved heritage site. However, in the conservation policies, these were not included within a conservation area as part of a historic urban landscape with integrated heritage value. Based on the above delimitation of the morphological region, it can be observed that the heritage of The Padang and the surrounding government buildings belongs to the Coastal administrative area (I) in morphological regionalization. This region stems from the tradition of British colonial urban design, characterized by an urban core composed of open squares and the administrative buildings arranged around them. This pattern was established early in the colonial period and expanded along the coastline, stabilizing in function and form during the later colonial period (Figure.10).

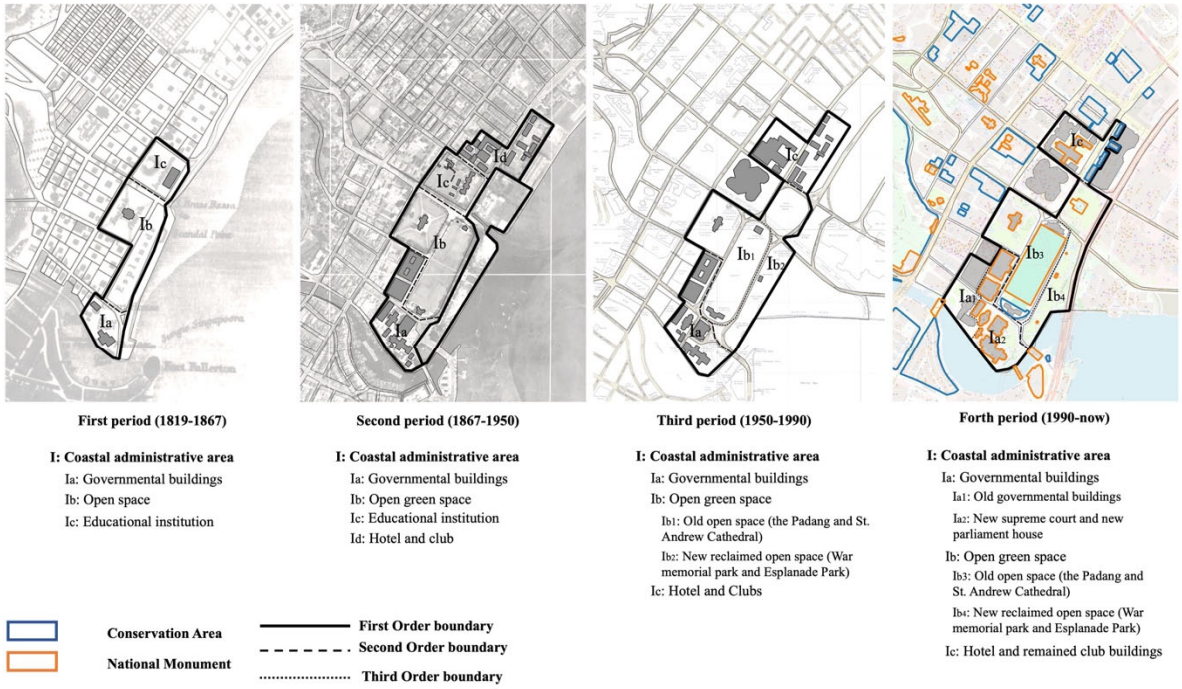

Figure.10 Transformation of Costal administrative area (based on cadastral map of 1846, aerial photo of1950, buildings map of 1988 and current Open Street Map)

The boundary of the first-order morphological region identified in this study can serve as a reference for a broader conservation boundary. The open space and government building complex that once stood along the coastline were no longer located by the coast within the city after independence due to land reclamation. As a result, the connections between these isolated heritage buildings have been overlooked. Managing this series of heritage buildings within a broader area would reflect the historic functional zone these heritage sites once served in the city and highlight their historical connections. Meanwhile, having a larger buffer reduces the potential hazard of new constructions that might greatly differ from their surroundings, disrupting the overall integrity of the historic district. Moreover, the second-order and third-order of morphological regions reflect the building types within the area, which can serve more detailed historical area management. Modern government building areas and historical government buildings belong to different third-level regions. This zoning provides an area-based reference on control coding for ensuring style unity in potential adaptive renovations within historical areas.

This study provides a feasible example of examining the pre-colonial city center of a Southeast Asian city and its evolution from a morphological perspective, but there are still some shortcomings and

areas for improvement. For instance, future research could expand the scope to include all historic districts from the colonial period and their evolution, not just Civic District, to explore the overall development process of historical urban areas. Additionally, a comparative research method based on the same morphological perspective could be applied, focusing on other Southeast Asian cities with historical backgrounds like Singapore, such as Penang and Malacca in the Malay Peninsula, to explore the broader application of morphological methods in the study of Southeast Asian colonial heritage.

Endnote

1. The bungalow originated from the early vernacular houses of South Asia and the Malay Peninsula (King, 1974). During the British colonial period, the British adapted these indigenous houses to create single- or double-story villas with sloped roofs. The wooden structures in vernacular houses were often be replaced with brick walls or brick columns when the British built it.

ABSTRACT

In 2002 De Jong & Rosenmann postulated scalar variations within the scientific framework aimed at research and analysis of the urban, architectural, and technical disciplines. Under the heading of ‘unravelling scales’ twenty-two scale variations are associated to the analytical spectrum of the build landscape. Commencing at the submaterial scale (units with nominal radius smaller than a millimetre) and ending with the global scale (units with nominal radius of 10 000 kilometres), the scale variations cross the scale orders of ‘building segment’, ‘buildings’, ‘building complexes’, ‘ensemble’ and ‘neighbourhoods’ amongst others, claiming morphological positions nine to thirteen within their twenty-two-scale protocol. When compared to the morphological sciences, the aforementioned scale entanglements have produced dependencies within the expression of measurable and quantifiable morphological units valid for medium dense cities, but ineffective as a scientific instrument in the contemporary atmosphere of giga scale undertakings.

The purpose of this paper is to critically reflect on De Jong and Rosenmann's suggested scale order, criticising its validity and contemporary morphological valance. Furthermore, the article will advocate for the revision and probable implementation of new morphological scale orders that incorporate other scale variations that reflect current urbanisation developments. Using case studies from across the world, with a focus on megablocks and compact-city-territories scales, the study will align and introduce the new orders inside De Jong and Rosenmann's scale protocols particularly relevant to the morphological sciences. Conclusions are formed on the transition from traditional scale orders to what could be referred to as 'mega-morphological scales' and new urbanisation units based on compact-city-territory phenomena, emphasising the need for scalar revisions as part of the evolutionary development of urban morphology as a science.

Keywords: Megamorphologies, Scale orders, Compact-city-territory, Morphological units

INTRODUCTION

The concepts of scale have a significant influence on urban form and its broader discourse. (Oliveria, 2016; Kropf, 2018). When examining the city from a variety of perspectives, whether it is comprehending the city as a walkable context (Van Nes, 2021), the morphology of a post pandemic city (Batty, 2021), recognising the urban landscape as intricate systems (Nel, 2022; Salat and Boudric, 2012), or perceiving the individual elements of the city (Fleischmann, et al., 2020), the concept of scale continues to be an essential component in all urban discourses.

Expanding the scope, the relevance of scale continues to be very relevant to all elements of the morphological sciences, as evidenced by the 1.6 million results on Google Scholar that belong to subjects of scale and urban morphology. The scalar evolution within urban morphology has developed significantly over the last decades. Commencing with the three schools of thought (Italian, French and British), the noteworthy differences in analytic perspectives that we observe today, have provided unique analytic nuances in the use and application of scale. The application of scale in the assessment of urban transformations, the typological variations of unitary urban elements to the comparison of villages and cities, has now developed analytical expertise across new scales on either side of the low scale orders, as for example, interiors (Monteiro, 2022), toys (Zhang, 2013) and on the opposite scale, high scale order for example region, urbanised complexes (Krenz, et al., 2017) scale spectrums.

However, the validity and applicability of this framework have been called into question, particularly in the context of contemporary megascale urban developments. Moreover, the rapid pace of urbanization, coupled with the ambitions of larger projects, has led to the emergence of giga-scale projects, which encompass vast areas and complex infrastructures. Projects as Neom (Saudi Arabia), Amaravati (Egypt), and Chengdu Future City (China), as either conceptual or realised projects have begun to challenge the traditional morphological scales, necessitating the development of new frameworks that can accommodate the scale and complexity of contemporary urbanization.

Regional concepts as the Greater Bay Area GBA, drawing together 11 cities, or the concepts of urban and mega regional compaction (Endemann, 2024), have destabilised the interconnections between scale and morphology. Such scalar shifts have highlighted a new focus on the meaning and importance of scale, not as a mere analytical variable, but as an equally critical conceptual tool challenging hierarchical levels of large-scale urban trends.

In this framework, and given the notable trends in developmental scales, we view this as an opportune time to reconsider and reinterpret scale as a crucial determinant, questioning scale’s significance for the field of morphological sciences. This paper seeks to analyse and evaluate the scale orders proposed by De Jong and Rosenmann (2002), assessing what they propose, and its applicability in the present context of new giga projects through case study.

The paper is organised in the following manner. Section one constructs the foundation and premise within and De Jong and Rosenmann's scale proposals. Section two outlines the methodology and case selection, Section three presets four mega block cases in the Greater Bay Area. Section four and five, the discussion and conclusion clarify the transition from traditional scale orders to what could be referred to as 'mega-morphological scales' and new urbanisation units based on compact-city-territory phenomena, emphasising the need for scalar revisions as part of the evolutionary development of urban morphology as a science.

MORPHOLOGICAL SCIENCES AND SCALE ENTANGLEMENTS

In 2002, as part of a publication on Ways to Study and Research Urban, Architectural and Technical Design, De Jong & Rosenmann presented a chapter entitled "Naming Components and Concepts". In this chapter they discussed the dual nature of a problem that connects physical objects to specific names or terms through a scale hierarchy. Their chapter, which is part of a compendium on research methods, highlights the significance of naming that establishes the methodological consequences of measures and comparison. The text not only revolutionised the comprehension of scale in design, but also establishes a simultaneous connection between material nomenclatures and methods of measurement across urban, architectural and technical fields.

In addition to their discussion about research nomenclatures, their chapter devotes a section to the issue of scale. Under heading of "Unravelling Scales", a subsection in the chapter, De Jong and Rosenmann presented twenty-two different scale variations that range from the sub-material level (units smaller than a millimetre in size) to the global scale (units with a size order of 10,000 kilometres) (Table 1). The twenty-two scales traverse various orders, including 'building segment,' 'buildings,' 'building complexes,' 'ensemble,' and 'neighbourhoods,' occupying morphological positions nine to thirteen within their scale protocol, each with measurable metrics, expressed as millimetre (mm), meter (m) or kilometre (km).

De Jong & Rosenmann's definition shifts the focus from understanding scale to the crucial issue of the interdependence between metrics and objects. Object-metrics assess the extent to which disciplinary boundaries and analytical methods restrict or facilitate the exchange of analytical capabilities. 'Light' scale orders are interconnected properties that exist within and across spatial conditions of objects related to architecture, whether it be virtual, real, or perceptual.

At greater depth, De Jong & Rosenmann's low-range scales dependencies are specific to the submaterial scales (scales 2 – 7; submaterial, material, supermaterial, subelement, element, superelement, building component), relevant to materials sciences, and less useful to morphological analysis of the built landscape. Mid-range scale links with urban morphology, making the crossover between the architectural artefact and the neighbourhood (scales 8 – 12: Building part, building segment, building, building complex, ensemble). Upper and midrange orders are specific larger portions of cities, covering neighbourhoods and villages (scales 13 – 15; Neighbourhood/Hamlet, Area/Village, Local District, Borough). Scale emphasis shifts radically at scale orders 16 – 19, covering the orders of sub-regional, regional, sub-national and national hierarchies (Table 1).

Such scale entanglements proposed by De Jong and Rosenmann have established interdependencies in the representation of measurable and quantifiable morphological components. Although these scales are suitable for cities with a moderate level of density, they are not adequate as scientific instruments when it comes to large-scale projects commonly witnessed today.

De Jong and Rosenmann's entire scale spectrum, has to date received limited assessment from within the possibilities they hold for new directions in Morphological sciences and in particular, the scales of giga development. Our hypothesis posits the inclusion of a new scale level called 'subnational' within the existing variations of giga or mega scale morphological frameworks. This would involve

reconfiguring the metrics and indices associated with giga scale and morphological measurements, moving away from the scale ranges of 'building segment,' 'buildings,' and 'building complexes.'

METHOD

This research aims to demonstrate the capabilities of De Jong and Rosenmann's scalar ladder by conducting a comparative analysis between their scalar orders and those used in previous large-scale studies. The emphasis of this analysis is on megablocks as constitutive part to giga-city-territories. Moreover, the presence of giga size projects exposes the material evidence validating the need for further comparison of scale possibilities.

Presented here is a comparative methodology, mirroring De Jong and Rosenmann's scale order with new as well as existing morphological scales to test the fit between current urbanisation patterns with scales hierarchies. The integration of De Jong & Rosenmann's Protocols with 'mega-morphological scales,' has the potential to provide a more precise framework for analysing the intricacies of contemporary giga formations, and moreover, possibly highlight the scale challenges associate with giga projects. Specifically, De Jong & Rosenmann's scale protocols, and its relevance to morphology pertains to scale orders 10 (Building) through 15 (Sub-regional). Outlier examples relate to the examination of typological analysis, specifically focussing on scale order 9 (building segment) and 10 (buildings), evident from ongoing morphological research.

As context for enquiry, the Greater Bay Are (GBA), previously referred to as the Pearl River Delta, is situated in the southern tip of China. The GBA metropolitan entity comprises of 11 cities: Guangzhou, Foshan, Zhaoqing, Huizhou, Dongguan, Zhongshan, Shenzhen, Jiangmen, Zhuhai, Macao and Hong Kong (Bayarea.gove.hk, 2024), with an official population exceeding 86 million (Ibid). The GBA consists of two Special Administrative Regions (S.A.R.) - Hong Kong and Macau, renowned as global hubs for finance and gambling, respectively. Additionally, there are two Special Economic Zones (S.E.Z.) - Shenzhen and Zhuhai, with Shenzhen being renowned as one of the most populous migrant cities. In addition, GBA is equipped with three prominent logistics centres, three international airports, and various ex-urban or previously rural regions such as Longgang, Shunde, and Nansha. The region displays a wide range of spatial conditions and varying degrees of uneven spatial development, all encompassed within an area of 56,000 km^2.

The incorporation of GBA as unitary urbanised entity involves intricate geographical and structural intricacies. For instance, the integration of infrastructure, logistics, and replication at a geographic scale, such as the duplication of cargo handling facilities, or competition between GBA cities, could restrict future growth in terms of available space. The analytical metrics of five cases presented here make use of a five-factor analytical technique to accurately quantify a collection of morphological characteristics expressed through analysis of (a) Block sizes, (b) Block shapes, (c) Road Density, (d) Connectivity and, (e) Proximity.

Each of the five cases consists of case information, an aerial photo, analytical maps for five parameters, calculation results, and analysis. The case information includes the case number, case name, the urbanism type it originated from, and location specifics within China. The aerial snapshot acquired from Google Satellite offers a contextual viewpoints. The morphological study itself, focusses

on five key factors: factor 1 Area (the area of blocks), factor 2 Shape Index (the complexity of block forms), Factor 3 Density (the density of cases and roads), Factor 4 Connectivity (the betweenness of road networks in cases), and Factor 5 Proximity (the closeness of road networks in cases). The determination of factors 1-2 is based on block morphology, whereas factors 3-5 are obtained from the analysis of the road network. The computation results exhibit the values of the subsequent variables for each case, namely: (1) Mean block area in square meters, (2) mean form index value, (3) road density per square km, (4) The outcome of the connection test, (5) Proximity, which is assessed at a local level and cannot be compared between other situations.

The five-factor assessment framework utilises block-level metrics such as size and shape, along with case-level road network analysis including density, connectivity, and proximity. This framework is used to analyse and describe the fundamental elements of the morphological DNA found within the case compendium. The standardised analysis layout allows for quick and easy comparison of cases in the compendium. The aerial views provide a comprehensive understanding of the urban layout, while the mapped factors uncover more specific information. Subsequent analysis will clarify how cases cluster and distribute within the factor space, revealing discernible patterns. However, one's admiration also grows for the distinctiveness that each artefact acquires from its cultural environment, geographical circumstances, and architectural principles. The maps reveal an intricate interaction of forces. Architectural texture provides a privileged understanding of the exposition.

More importantly, factor 1 and 2 - block size (area test by block), examines the scale and dimensions of urban blocks within each case. It is quantified by calculating the mean block area in square meters for each case study. Larger mean block sizes indicate larger urban blocks and scales. Block size metrics can be analysed at the case-level or individual block-level.

The five-factor assessment framework considers block-level metrics like size and shape, as well as case-level road network data like density, connection, and closeness. This framework is used to analyse and describe the fundamental elements of the morphological DNA. The analysis-layout enables rapid and easy comparison of examples across five cases. The aerial views give a complete picture of the metropolitan layout, whereas the plotted factors reveal more particular case information. Subsequent analysis explains how examples cluster and spread within the territory, exposing identifiable patterns. Other attributes as cultural milieu, geographical circumstances, and architectural principles are used as additional variables to highlight case characteristics.

Using plug-ins like sDNA on a GIS platform can automate the process of developing morphological algorithms. However, it is worth noting that human judgement remains an essential part, vital to the morphological analytic process. The rigorous process of clearing, creating, editing, analysing, and formatting each case study reveals information that automated extraction overlooks.

CASES

Transitional Morphological Scales presents four cases specific to the Greater Bay Area and its morphological expression. The cases pertain to: Macau SAR, Guangzhou, Shenzhen and Zhuhai.

Case 1: Macau. Macau, a Special Administrative Region (SAR) in the Greater Bay Area, operates as a major gambling hub. Covering an area of 8,573 square meters. The city blends historic expansions with newly reclaimed swamp land, resulting in compact and small blocks. The road network is characterized by frequent angle changes, which reduce its proximity and connectivity indices. The closeness index is moderate to high at 1.547, while the betweenness index is in the higher percentile, reflecting its historical development. Macau has a shape index of 1.334. In morphological terms, Macau's block size index is the lowest among the four cases examined, typically falling within the 0 to 2,000 block size range. Although there are exceptions with some blocks reaching the 126,000 to 164,000 block range, most of Macau's blocks align with the 6,000 to 7,000 block index. This reflects a generally compact urban form, distinct from the larger block patterns observed in other cities. However, this is an exception within the block pattern, as most of Macau's blocks typically fall within the 6,000 to 7,000 block range.

Case 2: Guangzhou. Located in the northeastern part of the Greater Bay Area, Guangzhou spans 40,101.4 square meters. The city has evolved from an old town district into a modernized urban area. It boasts high overall connectivity and fair road density. The closeness indicator is in the higher percentile, while the betweenness index varies from middle to high. Guangzhou has a shape index of 1.314. Proximity tests suggest that the 15-minute walk concept is more feasible in the historic district than in modern developments. Guangzhou's block sizes are extremely large, ranking at the highest level on the matrix scale, with a dominant block size range of 126,000 to 164,000, setting the metrics for extensive sizes and variations to formal block dimensions specific to giga scale development.

Case 3: Shenzhen. Shenzhen, in the southeastern part of the Greater Bay Area, exemplifies hyper-industrialization and urban development over the past 50 years. Covering 29,337.33 square kilometres, it has a shape block size index of 1.278 and a road density of 11.796. The city features distorted rectangular megablocks influenced by the coastline and grid structures. Some megablocks are open on one side, with sub-roads providing connectivity. Proximity performance is medium-low, and block sizes are extremely large, though slightly smaller than Guangzhou's but larger than those in comparable Western cities.

Case 4: Zhuhai. Zhuhai, situated above Macau, covers 60,754.67 square meters and has experienced significant industrial growth over the past 20 years. The city features medium-sized rectangular blocks with insufficient road density, though connectivity and proximity in major areas are acceptable. The road density index is 7.771, and the connectivity index is 1.555. Morphologically, Zhuhai's block sizes align with Guangzhou's, falling within the block size range of 126,000 to 164,000. The betweenness index is middle-high, and the closeness index is in the higher percentile compared to other cases.

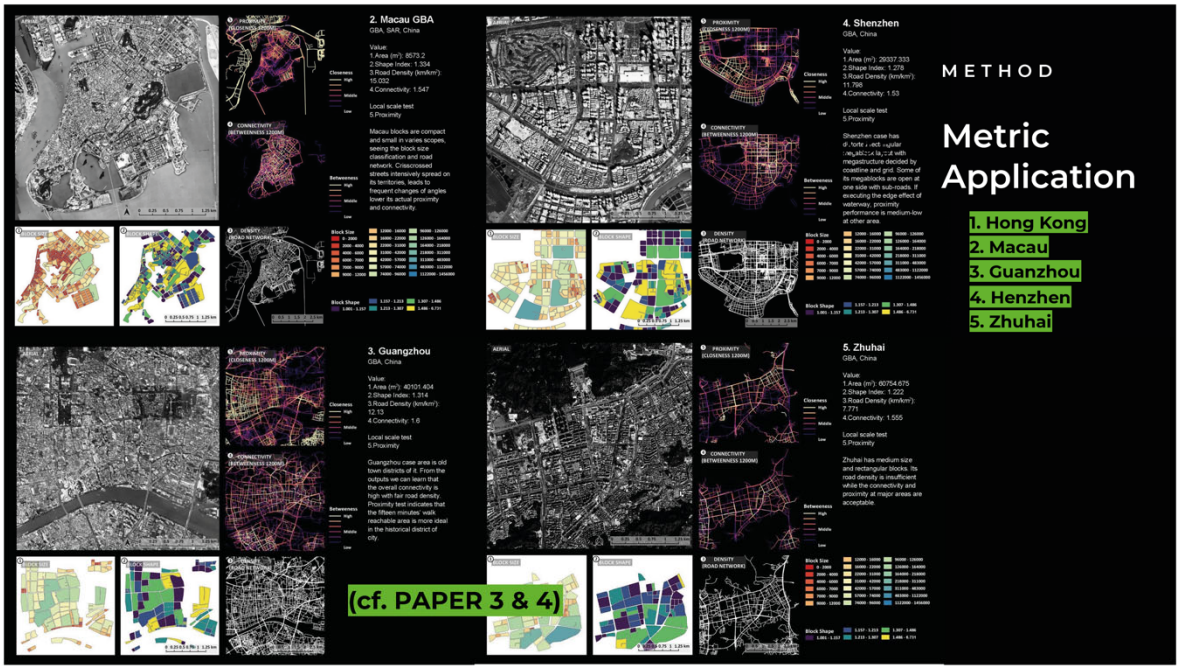

Figure 1. The collection of presented cases, capturing Macau, Shenzhen, Guangzhou, and Zhuhai, Mega City development part of the GBA. Credit: authors, 2024.

RESULTS AND DISCUSSIONS

Comparatively, the four cases shown highlights the diverse urban morphologies within the Greater Bay Area, each city reflecting unique developmental trajectories and planning strategies. From Macau's compact blocks to Shenzhen's megastructures, these cases provide insights into the region's dynamic urban landscape, and the upward shift in the morphological block formation scales.

Each case is exhibited utilising a consistent visual and data protocol as illustrated in image 1. The compilation of aerial photography, case particulars, and factor analysis collectively enhances the case overview. The physical attributes of each case, both collectively and individually, form the basis for subsequent morphological comparative analyses. The GIS plugin tool, Polygon Shape Indices (PSI),

automates the quantitative assessment of morphological properties, thereby streamlining the evaluation of polygon geometry and complexity. Polygon Shape Indices calculates over twenty distinct variables to characterise the dimensions, configuration, and complexity of spatial entities, including urban blocks and structures. These variables are employed to delineate the broader geographical entities.

Furthermore, the body of work builds upon the principles of Spatial Design Network Analysis (sDNA). This approach employs mathematical graph representations to model urban street networks, facilitating the assessment of their structure and connectivity (Barthelemy, 2011). In the sDNA framework, street segments are represented as graph edges, and intersections are illustrated as nodes. This facilitates the quantification of critical metrics, including the distribution of node degrees and the density of intersections (Porta et al., 2006).

Furthermore, advanced sDNA methodologies can assess integration, intelligibility, and synergy to evaluate the efficacy of spatial networks. sDNA employs graph theory to provide planners with vital mathematical metrics for analysing network structure and connectivity, essential for promoting dynamic and sustainable urban morphology.Moreover, the body of work enhances Spatial Design Network Analysis (sDNA). sDNA utilises mathematical graph representations to model urban street networks, facilitating the quantification of spatial structures and their interconnections (Barthelemy, 2011). In the sDNA architecture, street segments are regarded as graph edges, whereas junctions are depicted as nodes. This facilitates the assessment of critical metrics, including the distribution of node degrees and the density of intersections (Porta et al., 2006). Moreover, sophisticated sDNA methodologies can evaluate integration, intelligibility, and synergy to measure the efficacy of spatial networks. sDNA utilises graph theory to furnish planners with essential mathematical metrics for evaluating network structure and connectivity, which are critical for fostering dynamic and sustainable urban morphology.

Taking into account the 100 other cases examined by Peng (2024)—including Brasília, Manhattan in New York City, Old Irving Park in Chicago, and Melbourne—the cases demonstrate a shift in block scale order by an entire category. Evidence indicates that regular block sizes fall within the block size scale orders of 12,000 to 96,000, marking no fewer than eight scale categories (12,000–16,000, 16,000–22,000, 22,000–31,000, 31,000–42,000, 42,000–57,000, 57,000–74,000, 74,000–96,000 ranges). Transitional morphological scales indicate the consolidation of these categories into one full scale order up, (96,000–126,000, 126,000–164,000, 164,000–218,000, 218,000–311,000, 311,000–483,000, 483,000–1,122,000 and 1,122,000–1,456,000 block scale ranges).

Using this as evidence and, reflecting on De Jong and Rosenmann's 22 scale order, the argument for scale shifts is validated, where lower scale orders are subsumed by higher morphological scale orders, such as the sub-regional (scale order 16) and regional orders (scale order 17).

CONCLUSIONS

This paper has critically reflected on De Jong and Rosenmann's suggested scale order, examining its validity and contemporary relevance. The paper has also examined the empirical reality of urban blocks across four cases of the GBA, as evidence for the revision and implementation of new morphological scales that better reflect the GBA's current urbanization trends.

The findings of this paper underscore the need for both an awareness of scalar shifts as well as scalar revisions as part of the evolutionary development of urban morphology. The work conducted by geospatial sciences and the increasing influence of big city data is already showing evidence of assumed scalar shifts of morphological processing (Boeing, 2021).

Contextual and planning context in the GBA has greatly influenced the development scale and its literal choice of scale or morphological components. Still, the need to further advance the domain of urban morphology will facilitate future research in refining the possible scalar variations and scalar overlaps in the implications of introducing new scales to urban morphology as design instruments beyond mere analytic tools.

Understanding urban greenspace morphology: concepts, spatial attributes and application frameworks

Xiao-Jun WANG
[1] Department of Landscape Architecture, Faculty of Architecture, Southeast University, P R of China,
e-mail: wangxj@seu.edu.cn

ABSTRACT

Urban greenspaces are an indispensable component of the urban fabric. Although the research on urban greenspace is a much more unnoticed part in urban morphology, it is very necessary to pay attention to the urban greenspace morphology (UGM) because of its enormous potential application in both scientific research and planning practice. In this article, we intend to discuss the relationship between urban greenspace form (UGF) and urban form, the concept and definition of urban greenspace form, as well as the preliminary application and research framework, which mainly includes the following three parts. 1) The concept and definition of UGM were defined from the perspective of urban form, and then the temporal and synchronic characteristics of UGM as well as the relationship between urban greenspace form and artificial built form were explored. 2) The basic types and spatial attributes of UGM is the second part. The focus was on differentiating and describing the two major attribute forms of urban greenspace, namely the noumenon form and performance form. The noumenal form refers to the spatial attributes and characteristics of urban greenspaces. The performance form reflects the spatial utility characteristics of urban greenspaces, including recreational supply, environmental and ecological improvement. 3) The framework of synchronic approach for the planning application and research of UGF was based on the noumenal and performance forms in which a UGF analysis system was setup through form identification, classification, statistics, and indicator quantification. On this basis the planning application scope and related research fields of UGM were proposed.

Keywords: Urban morphology, Greenspaces, Framework, Noumenon form, Performance form

INTRODUCTION [Heading 1]

City is a spatial-explicit physical environment interweaving with man-made and natural elements, Urban greenspaces are an indispensable component of the urban fabric. A large number of studies have confirmed that urban greenspaces have many functions such as ecology, recreation, environment, aesthetics and so on(Kuo, 2015, Bastian et al., 2012, Lo and Jim, 2010, Markevych et al., 2017, Taylor and Hochuli, 2017). Urban ecological and environmental problems have attracted the attention of researchers in geography, ecology, environment science and other disciplines(Grimm et al., 2008, Wolch et al., 2014, Rupprecht and Byrne, 2014). As urban form is the most basic spatial attribute of urban physical environment, these studies consciously or unconsciously involve the relationship between urban form and ecological environment on various scales, in which greenspace

form is an important aspect. However, the research on urban greenspaces is a much more unnoticed part in urban morphology. Some studies have been published in Urban Morphology, but they are only carried out in limited fields such as urban fringe green belt, mostly in a historical and geographical perspective (Whitehand, 2019). There were also several papers on the ecological aspect (Marcus et al., 2019; Pont,2023), but there is still a lot of work to do in this direction. These studies have not paid attention to the urban greenspace form of different types, scales and spatial distribution, and the Urban Greenspaces Morphology (UGM) has not yet formed systematically. In this regard, J. W. R. Whitehand, former editor in chief of the journal, said that the elements of greenspace and open space are missing in the study of urban morphology (Whitehand, 2019). Peter Larkham proposed to conduct in-depth research on greenspace morphology (Larkham, 2022, 2024). So, how do we consider urban greenspace in the study of urban morphology? Are there morphological problems in urban greenspace? It is necessary to pay attention to the UGM due to its enormous potential application in both scientific researches and planning practice.

We pay attention to and think about the UGM because of the great changes brought about by the development of urban greenspace in China in the past 40 years. The status of China's urban greenspace development is very obvious and fast: the proportion of China's urban greenspace (greenspace area rate) has increased from less than 10% in the 1980s to 38.7% in 2023, and the park greenspace area per capita has increased from 1.5m2 to 15.29m2 (National Forestry and Grassland Administration, 2024). For most Chinese cities, the development of urban greenspaces during this period is also huge, for example, the urban greenspace area of Beijing city has increased from 27.5km2 to 835 km2 (Beijing Municipal Forestry and Parks Bureau, 2024), an increase of 30 times. The scale and volume of urban greenspace has become an indispensable part of urban development in China. There are two important driving factors for the development of urban greenspaces in China. First, Urban Greenspace System Planning in China is an important legal strategy document for the development and construction of urban greenspaces. It is not only a part of the legal content of the overall urban planning, but also a more in-depth special planning, including the detailed regulatory planning of the urban green line and biodiversity special planning. Another important driving force is the Garden City campaign, which is based on the selection of “Garden City” and “National Garden County” at national and provincial level by the Chinese Ministry of Construction in 1992 ((Ministry of Housing and Urban-Rural Development of the People's Republic of China, 2022), and “Ecological Garden City” by the Chinese Ministry of Housing and Urban Rural Development in 2004(Ministry of Housing and Urban-Rural Development of the People's Republic of China, 2004), which had been upgraded in 2016. The evaluation index system involved in the selection work has a large number of greenspace form requirements. Greenspaces form has become an increasingly important evaluation and analysis tool, for example, about two thirds of the evaluation indexes in the evaluation system of Ecological Garden City newly issued by the Chinese Ministry of Housing and Urban Rural Development in 2022 have different levels of greenspace form significance (Table 1), in the table, items 1-10 and 13 are indicators related to UGM.

Table 1. The evaluation index system of “Ecological Garden City” in China.

Goal	No.	Index	Details
Eco-friendly	1	Urban Greenspace Ratio（%）	①≥40%； ②≥ 28% for each urban district.

and Livable	2	Urban Green Coverage Rate（%）	①≥43%； ②the proportion of trees and shrubs should be≥70%.
	3	Per Capita Park Greenspace (m²/person)	①≥14.8m2/person； ②≥5.5 m²/person for each urban district.
	4	Coverage Rate of Park Activity Space Service Radius （%）	≥90%
	5	Coverage Rate of Urban Greenway Service Radius（%）	①the length of greenways per 10,000 people should be ≥1.2 km； ②the coverage rate of service radius should be≥70%
	6	Number of Comprehensive Parks per 100,000 People	≥1.5 parks/ per 100,000 people
	7	Compliance Rate of Urban Ecological Corridors（%）	100%
	8	Compliance Rate of Urban Biodiversity Conservation（%）	100%
Healthy and Comfortable	9	Urban tree-covered road Coverage Rate（%）	≥85%
	10	Compliance Rate of Urban Road Greening（%）	≥85%
	11	Implementation Rate of Vertical Greening（%）	≥15%
	12	Compliance Rate of Garden-style Residential Areas (units)（%）	≥60%
Safe and Resilient	13	Blue-Greenspace Ratio in Built-up Areas（%）	≥45%
	14	Compliance Rate of Disaster Prevention and Risk Avoidance Greenspace Facilities （%）	100%
	15	Implementation Rate of Urban Wetland Protection（%）	100%
Unique Features	16	Protection Rate of Parks with Historical Value （%）	100%
	17	Protection Rate of Ancient and Famous Trees and Reserve Resources（%）	100%
	18	Rate of Certified Landscaping Workers（%）	100%； Level 3 workers and above should be ≥20%.

THE RELATIONSHIP BETWEEN CITY FORM AND URBAN GREENSPACE FORM

What role does urban greenspace form play in urban morphology research? As an element of a complex urban system, can urban greenspace form be studied in morphology? Before discussing the concept of urban greenspace form, we first need to consider the relationship between artificial space and natural space in urban form.

City is a coupling system of artificial factors and natural factors, but it has two different driving mechanism logics. Urban artificial construction is the leader of urban spatial form. Its formation is driven by political, economic and social development (Turner, 2005). We can also call it " form-shaper". In the process of urban overall development and evolution, natural space is weakened in function, which is often occupied, blocked, cut and porous in space by artificial development and construction, showing the fragmentation of the overall pattern. These urban constructions are usually anti-natural processes (Forman and Godron, 1986). As the main carrier of urban natural space, the formation mechanism of urban greenspace is mostly the artificial restoration and reconstruction after

the destruction of its natural structure. The urban greenspace form has been restricted by the urban artificial construction, and the vast majority of urban greenspace form is " form-shaped" (Table 2). As a subsystem of the urban system, urban greenspace form is an integral part of the urban form, which is not only restricted by it, but also has its own distinctive characteristics (Neglia, 2024). First of all, because the natural attributes of urban greenspace determine the ecological and environmental function in urban spaces, it carries most of the natural processes and biological habitat functions in urban areas. The study of urban greenspace morphology should pay attention to its ecological and environmental mechanism and recreational function. Second, an important feature of the urban system is the deep and complex mosaic of fine-grained greenspace and artificial space (Forman, 2008). As a part of urban physical space, greenspaces are not completely independent, so it is necessary to consider urban greenspace form under the background of urban form. Third, the natural processes such as air circulation, water balance, heat balance and wildlife food chain occurred throughout the entire urban areas. In this sense, urban greenspace forms have more integrated characteristics and requirements.

Table 2. Comparison of urban natural space and artificial space

Factors	Artificial Space	Natural Space
Driving Factors	Human socio-economic development	Natural process; Human influence, interference or maintenance
Elements	Buildings, roads infrastructure, pavement	Forest, farmland, wetland, river, lake, park
Functions	Land use	Ecosystem services
Forming	Form-giving	Form-given and nature shaped
Feature	Hard	Soft
Shape	Geometrically regular	Naturally winding and humanly constrained

Morphological characteristics are one of the basic representations of urban spatial development, and also a means to reveal its spatial distribution law. The spatial distribution of urban greenspace itself can be explained in form. The various ecological, environmental and recreational functions of urban greenspaces also have clear spatial characteristics, which can be described and analysed in form. Therefore, morphological significance of urban greenspaces is clearly defined and worth studied.

THE CONCEPT AND DEFINITION OF UGM

Urban greenspace morphology (UGM) is a specialized discipline that studies the urban greenspaces form (UGF). In the absence of clear research in this area, how do we understand the form of urban greenspaces? We try to define it and divide all the contents related to UGF into two basic types: the Noumenon form and the Performance form. The basic types and spatial attributes of UGF is in depth discussion below.

The Noumenon form

The noumenon form refers to the spatial attributes and characteristics of urban greenspaces, including the overall descriptive or spatial characteristics of greenspaces such as classification of form types, statistics of quantity composition, and spatial distribution. Statistics can be made separately in terms of the General greenspace and the Special greenspace (Table 3).

1)The General Greenspace mainly reflects the overall level of a city on greenspaces development. 2)The Special Greenspace is a more specific refinement of various types of urban greenspaces, reflecting the quality of a city's greenspaces in recreational, ecological and environmental functions, and partly reflecting the level of greenspace service supply.

We can use a variety of measurement methods to carry out numerical statistics and spatial statistics in the noumenon form descriptions about the number and spatial distribution of greenspaces, which can be expressed in the overall or partial urban land use (Figure 1), and can also be expressed in different land use with the proportion of greenspace (Figure 2).

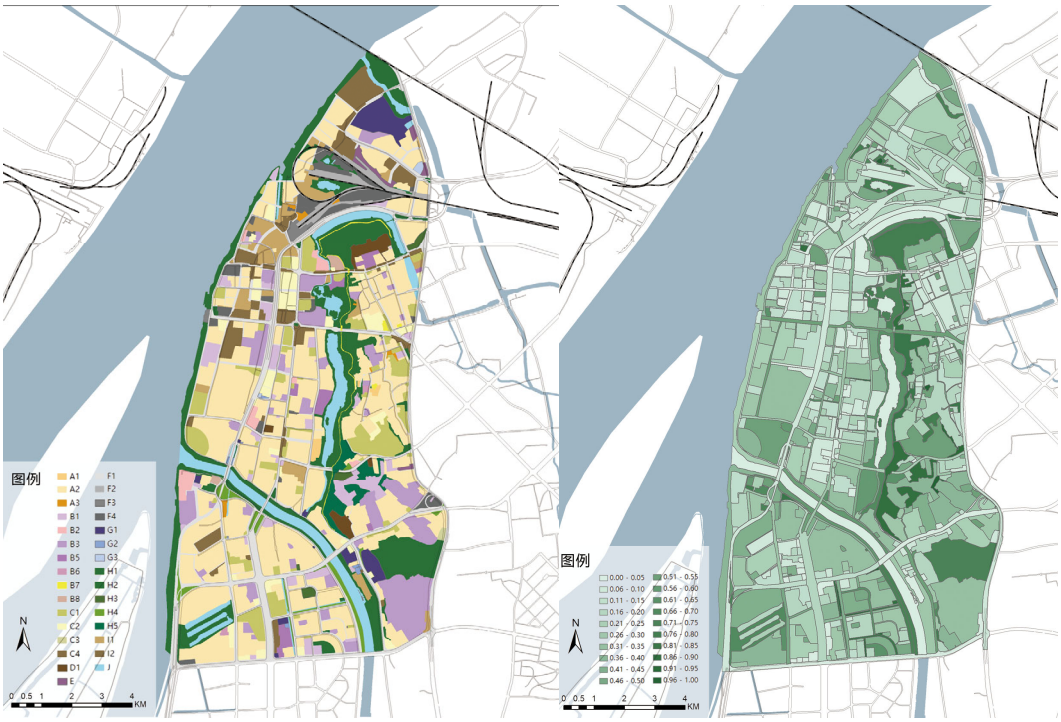

Figure 1. The spatial distribution of urban greenspaces

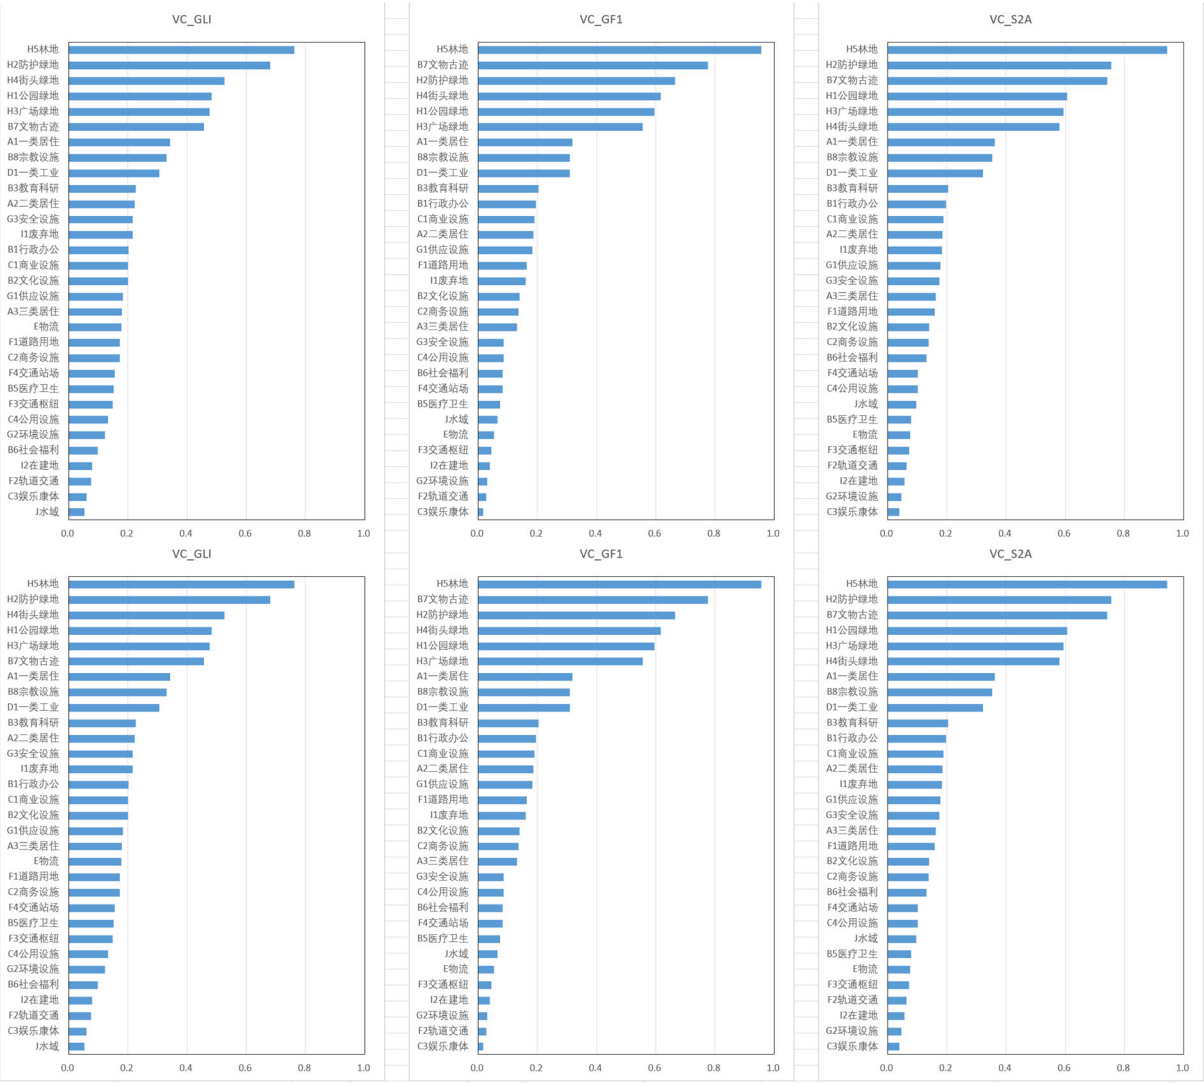

Figure 2. Quantity statistics of greenspace ratios in different land use

The Performance form

The Performance form reflects the spatial utility characteristics of urban greenspaces, including recreational service, quality of public space, ecological security, environment improvement, urban public safety and so on. Among them, recreational supply is dominant in traditional Urban Greenspace System Planning practice and involves the completeness of park recreational functions, the hierarchy of park system, and the accessibility of parks and greenways. Performance form and urban greenspace are related, but not a strict correspondence, and are affected by the urban environment as a whole. Performance form analysis should not be limited to the study of urban greenspace form. For example, the heat-island effect is a response to the overall heat state of the urban environment, but the “cold-lake effect”, which is opposite to the heat-island effect, is strongly related to the spatial distribution of urban greenspaces (Wang et al, 2015; Qian and Wang, 2016). Similarly, the accessibility of park greenspaces is also a type of performance form, which can comprehensively display the distribution of the service level of urban parks.

The relationship between the Noumenon form and the Performance form

Noumenon form is the foundation and the description of the basic state of urban greenspaces, however, the performance form is the application and the expression of urban greenspaces functional

performance (Figure 2). Noumenon form is the direct expression of urban greenspaces form, but the performance form is the extension of various functions of noumenon form and the indirect expression of urban greenspaces form. Noumenon form partly reflects the service level of urban greenspaces, but it cannot intimately reflect the ecological and environmental functions and service level of recreation and public space. Performance form can further supplement, describe and analyse the specific functions of Noumenon form from many aspects.

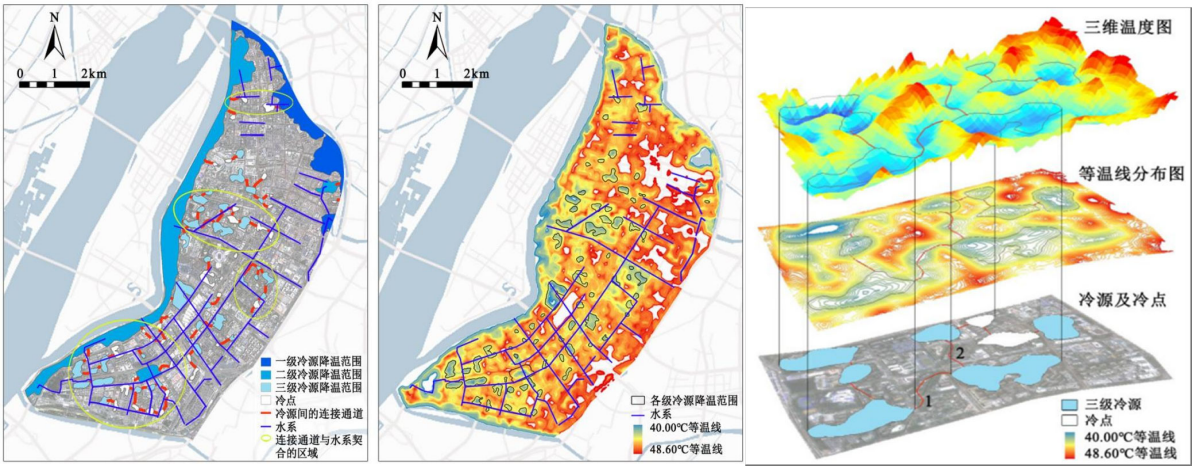

Figure 3. The relationship between the Noumenon form and the Performance form. Illustration of the relationship between the spatial distribution of urban greenspaces and the thermal pattern ofurban heat island the Noumenon form（本体形态） the Performance form（绩效形态）

A FRAMEWORK FOR PLANNING APPLICATION AND RESEARCH OF UGM

There are two basic approaches to the study of urban greenspace morphology, one is diachronic and the other is synchronic. The two approaches are different in terms of methodological framework.

Diachronic approaches to UGM

Diachronic approaches need to be studied from the perspective of greenspace evolution. In the diachronic approach, we usually do not care about the individual urban greenspace, which is usually the research object of history in landscape architecture. We are concerned about the overall development of urban greenspaces in a certain period of time at the city scale, which can be considered from three aspects as follows.

First, the construction of urban greenspace in different times should be adapted to the regional natural conditions and the level of social and economic development, showing the characteristics of the times. Second, the form of urban greenspace is generated in the timeline and is the result of the superposition of multiple times. Third, the policies and regulations, planning ideas and more detailed professional norms in different times have the greatest impact. These are usually from a historical and geographical perspective.

Synchronic approaches to UGM

The synchronic approach studies the current urban greenspace form. Based on the study of noumenon form and performance form, it solves various recreational, ecological, environmental and other problems closely related to urban greenspaces. The main goal of this approach is to achieve liveable

and sustainable environment. A basic research framework and its application strategy is as shown in the following figure (Figure 4), in which a UGF analysis system was setup through form identification, classification, statistics, and indicator quantification. On this basis the planning application scope and related research fields of UGM were proposed. UGM is one of the more scientific and rational foundations for various urban planning and design, and as a subsystem, it can also be effectively used to support the achievement of social development goals.

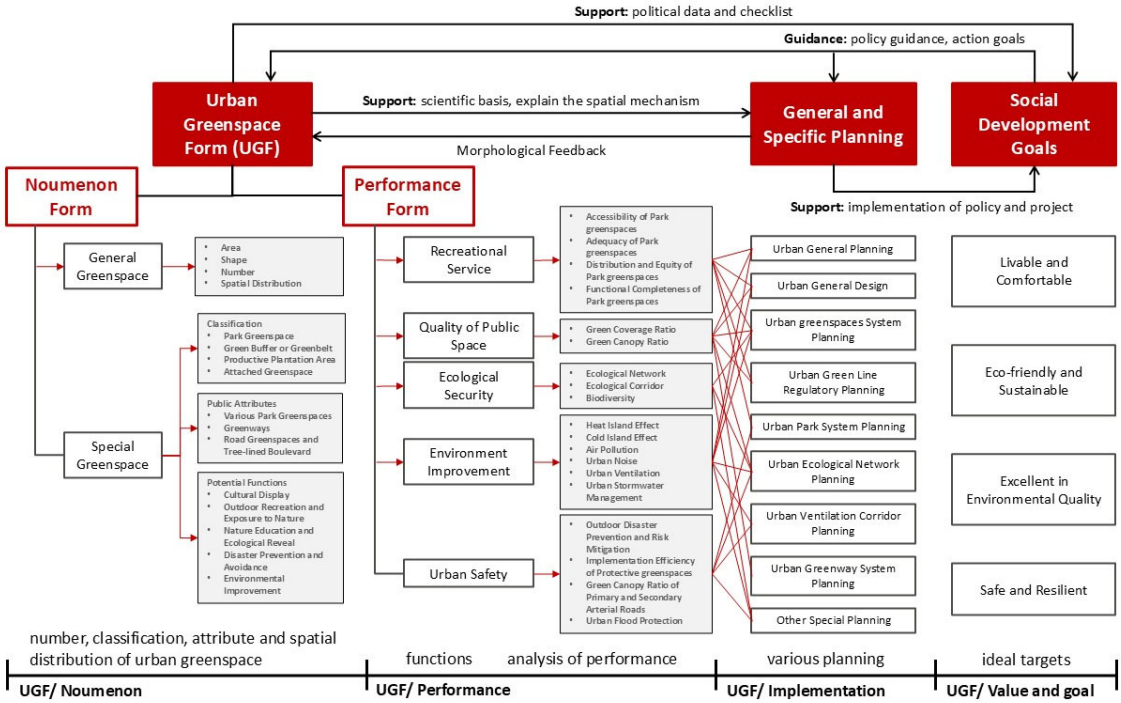

Figure 4. A preliminary research framework of synchronic approaches to UGM

SOME THOUGHTS AND PROSPECTS OF UGM

The purpose of understanding the urban greenspace form is to better understand the roles and functions of greenspace in the urban man-made environment. Although we have put forward the basic concept, definition and a preliminary work framework of UGM, there are still many problems worthy of further discussion.

How were urban greenspace forms shaped? What are the characteristics of them?

What kind of urban development mechanism leads to the formation of urban greenspace forms?

How effective are the urban greenspace forms of different cities in terms of recreational and ecological environment? Are there any advantages and disadvantages? How to evaluate?

How to operate and adjust urban greenspace forms in urban planning and greenspace system planning?

The answers to these questions are the knowledge basis for understanding urban greenspace morphology and further scientific research. Because when our research working group reviewed the progress of the field related to urban greenspace morphology, it found that the lack of this knowledge

basis was one of the main problems in the current related research (Wang et al,2020; Zou and Wang, 2021). Also, the answers to these questions are the basis for our application in planning and construction. Through policy planning, operation and construction, we can adjust and optimize the urban greenspace form to achieve the goal of sustainable development and liveable human environment reconstruction. It is especially beneficial for developing countries with more high-density urban environments all over the world.

Urban form and adaptive rules

Vaneska Paiva Henrique[1]
[1] PROPAR Research Programme Architecture, Faculty of Architecture, UFRGS Federal University of Rio Grande do Sul, Brazil, vaneska.henrique@ufrgs.br

ABSTRACT

Local identity adds value for urban development, attracting people and business, and, therefore, supporting cities both in engineering social and economic transformation. In the dynamic urban landscape, however, there is a tendency for standardised urban regulations, encompassing identical maximum and minimum heights, setbacks, floor area ratio, and other parameters. This homogenization represents a risk for the unique identity inherent in each neighbourhood over the course of time. This research endeavours to identify the distinctive spatial qualities in different neighbourhoods of Porto Alegre, Brazil. The main objective is to support urban regulations that better suit the specific characteristics of each scenario for the city, integrating local identity into the city´s forthcoming masterplan. Berghausen Pont and Haupt (2009) in Spacemate present a method to correlate density and form in order to identify different typologies through four parameters: GSI, FSI, OSR, and Height. This research applies GIS technology in order to use Spacemate to examine Porto Alegre´s block DNA, guiding alternative rules for urban design that can more efficiently recognize local identity and, therefore, design better cities. Through this exploration, we aim not only to recognize the inherent spatial patterns that contribute to defining local identity, but also to provide valuable insights for more adaptive and contextually relevant urban rules in the evolving urban fabric of the cities.

Keywords: urban center; masterplan; urban plan.

INTRODUCTION

From the dawn of human settlements to the rise of contemporary megacities, the preservation of local identity has been a central theme in debates on urban development. On the one hand, it is necessary to ensure urban development by adding new structures to the pre-existing fabric that keep pace with the dynamics of social transformations. On the other hand, there is a need to ensure that certain environmental qualities are preserved in this process of transformation. In the 1960s, Kevin Lynch, in his seminal work *The Image of the City* (1960), laid the foundation for discussions on how the perception of cities by their inhabitants is shaped by physical and symbolic elements that confer identity to these spaces. Lynch introduced concepts that would become fundamental in the following decades, such as "urban image" and "legibility," which are essential to understanding how citizens perceive and connect with the urban environment.

Building on Lynch's pioneering work, other authors such as Jane Jacobs (1961), Aldo Rossi (1966), Edward Relph (1976), Manuel Castells (1997), and David Harvey (2012) continued to emphasize the importance of considering the existing context when planning urban growth. Currently, there seems to be a certain consensus among scholars on the subject that local identity should not only be preserved but also serve as a guide for formulating rules and parameters that direct the development of urban areas. From this reality emerges the challenge of reconciling the need to recognize the constitutive patterns of what is called local identity with specific regulations so that new constructions fit into the existing fabric.

In 2009, Berghausen Pont and Haupt proposed a series of metrics in their book Space, Density and Urban Form that seek to describe, through urban planning parameters commonly applied in urban planning—indices, quotas, zones, and other prescriptions—the morphological type occupation of consolidated urban fabrics. In 2019, Henrique and Turkienicz explored the application of this methodology in the Brazilian context as a way of predicting strategies for ensuring that the parameters for constructing new structures within the existing fabric can draw from existing patterns in their design.

The present work, which uses the method proposed by Henrique and Turkienicz as a basis for proposing alternative urban planning parameters for the new Master Plan of Porto Alegre, is structured into three (3) parts: (i) method, which describes the input data as well as the procedures for identifying the morphological type patterns found in the territory of Porto Alegre; (ii) results and discussions, presenting the results obtained in identifying the city's morphological type patterns and the possible interpretation of results in a comparative analysis with other studies; and (iii) conclusion, presenting the main conclusions on the subject as well as directions and recommendations for future work.

METHOD

Case Study: Porto Alegre, RS, Brazil

The municipality of Porto Alegre is located in the southern part of Brazil, serving as the capital of the state of Rio Grande do Sul. With approximately 1.5 million inhabitants and over 250 years of history, the city is recognized for its tradition in urban planning, a title it earned due to its practice and innovation in the field, being the first capital in the country to have a Master Plan (PORTO ALEGRE, 1999). Despite this position at the forefront of Brazilian planning, what is noticeable today in the capital is a clear homogeneity in the new constructions that emerge in the city. The identity of neighbourhoods is suppressed by buildings that do not recognize the local characteristics, a direct result of the application of the current Master Plan's regulations.

Figure 1. Location of Porto Alegre in Brazil.

Currently, Porto Alegre is in the process of revising its Master Plan, which is why it was deemed appropriate to develop a specific study aimed at addressing the problems identified in the application of the current Master Plan. Since the Master Plan is a law that organizes the development of the entire municipal territory, the area selected for the application of the methodology involved the assessment of parameters across the entire territorial extent of the municipality, covering its 94 (ninety-four) neighborhoods.

To systematize the data from the different components of the urban space, the model proposed by Berghausen Pont and Haupt (2009) was applied, as presented below.

Space, density and urban form

Berghauser Pont and Haupt (2010) present a model capable of associating densities with built forms, allowing the identification of typological patterns associated with different building densities through the Spacemate graph.

The various variables for measuring urban density proposed in the study are derived from the combination of four (4) BASIC MEASURES: Base Land Area (A); Network Length (l); Gross Floor Area (F); and Built-up area, or footprint (B). These basic parameters are correlated to generate three (3) BASIC INDICATORS: Network Density (N); Building Intensity (FSI); and Coverage (GSI). The Basic Indicators, in turn, are correlated to generate what the authors call DERIVED INDICATORS: Building Height (L); Spaciousness (OSR); Tare (T); and Mesh and Profile Width (w and b).

Among these indicators, four (4) are correlated to create the basis of the Spacemate graph: FSI, GSI, OSR, and L. Based on the graph generated, the authors identify zones within the graph that can be used as a basis for identifying specific morphological type patterns, as shown in the figure below.

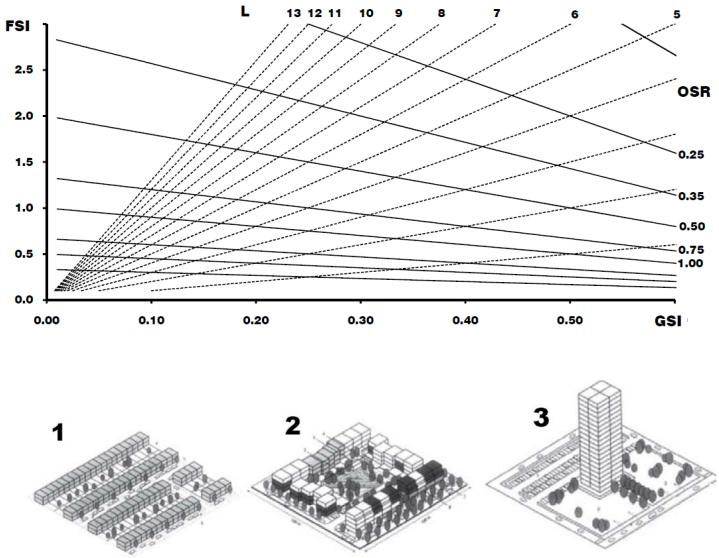

Figure 2. Spacemate. BERGHAUSER PONT e HAUPT, 2009.

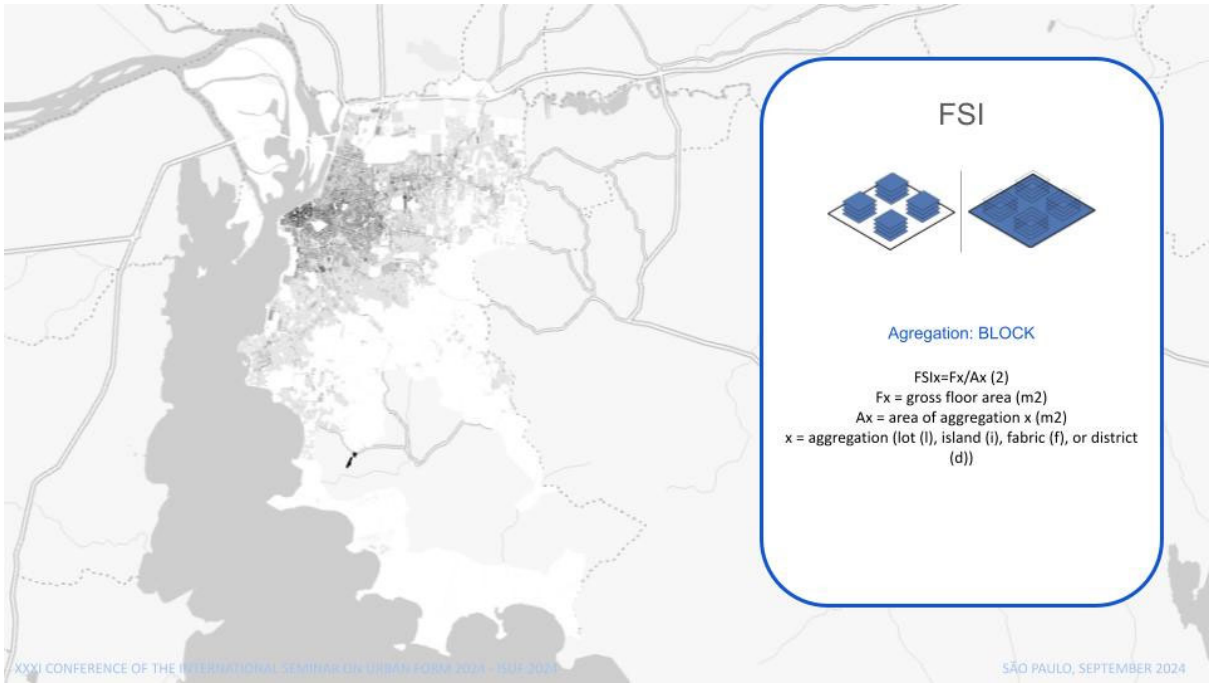
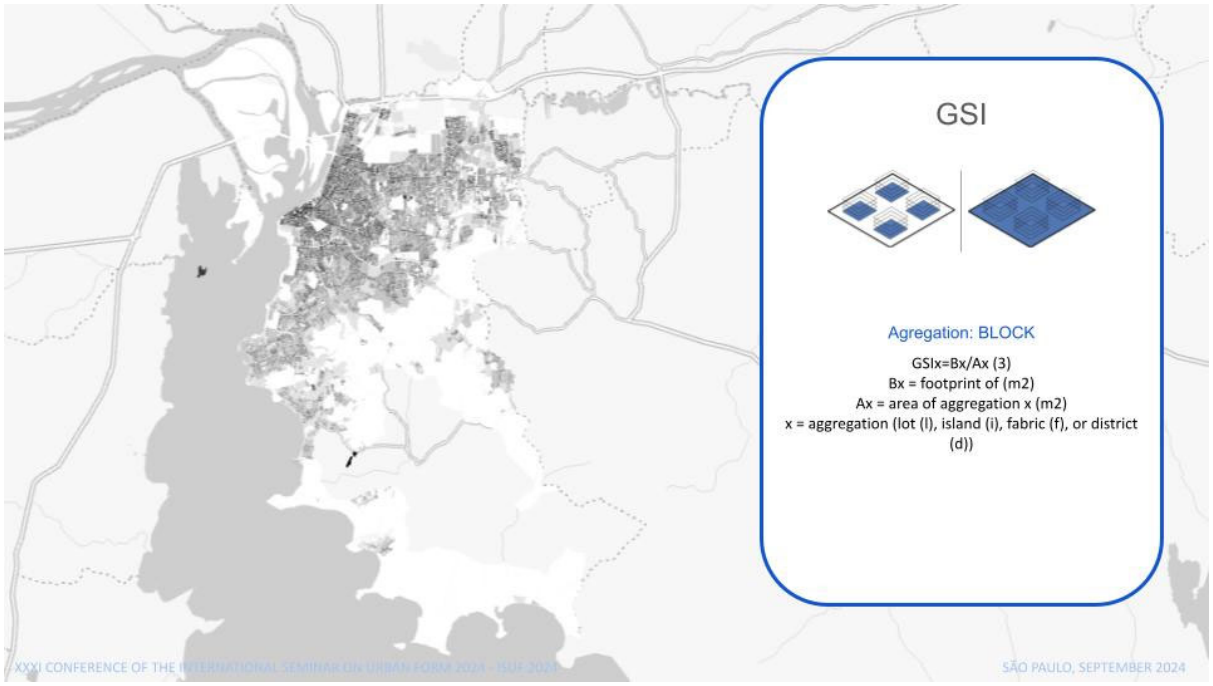
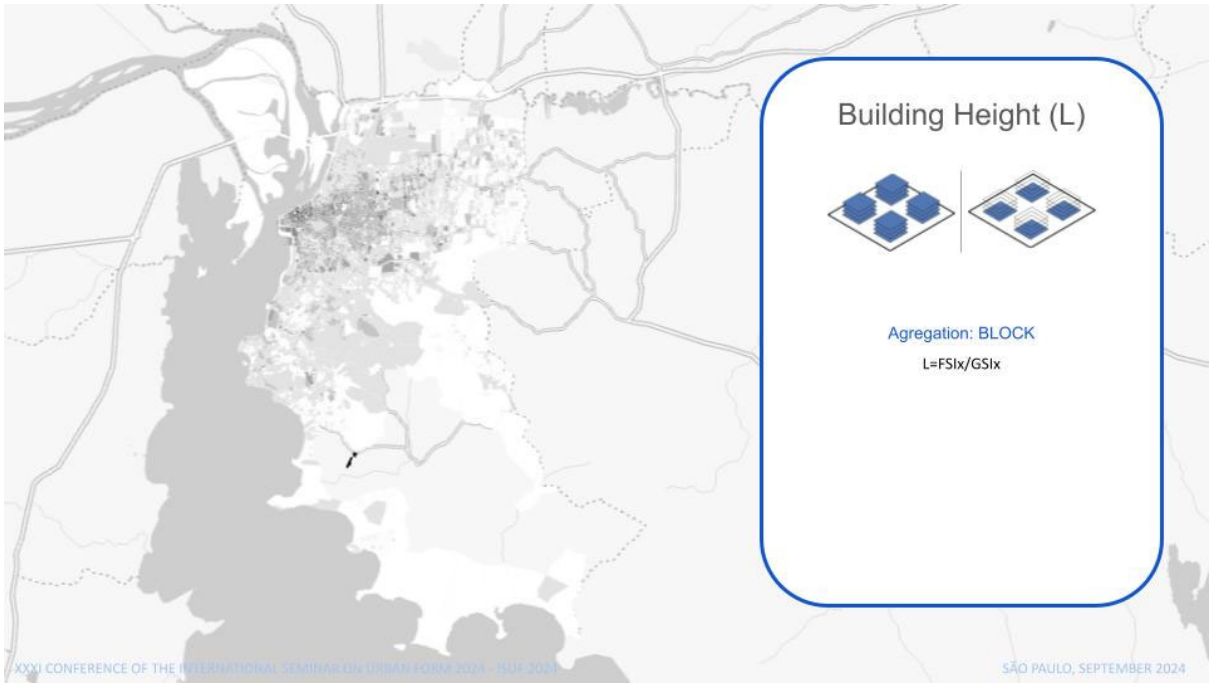
Application of the model to the case of Porto Alegre

The description of morphological type patterns in the urban fabric of Porto Alegre initially involved the construction of the four selected indicators from the Spacemate for the territory. For this construction, the aggregation scale chosen was the neighborhood boundaries as the general scale and the urban blocks as the detailed scale.

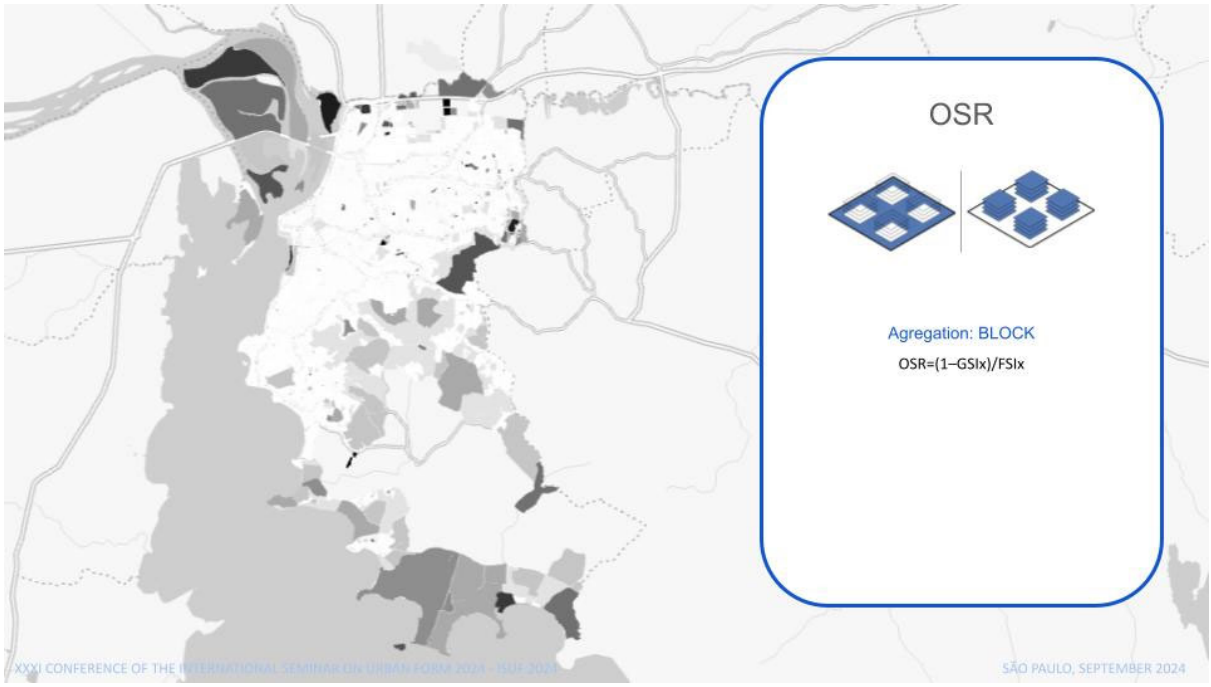




GSI
Agregation: BLOCK
GSIx=Bx/Ax (3)
Bx = footprint of (m2)
Ax = area of aggregation x (m2)
x = aggregation (lot (l), island (i), fabric (f), or district (d))
XXXI CONFERENCE OF THE INTERNATIONAL SEMINAR ON URBAN FORM 2024 - ISUF 2024
SÃO PAULO, SEPTEMBER 2024



Building Height (L)
Agregation: BLOCK
L=FSIx/GSIx
XXXI CONFERENCE OF THE INTERNATIONAL SEMINAR ON URBAN FORM 2024 - ISUF 2024
SÃO PAULO, SEPTEMBER 2024



From the results, the aim was to identify clusters based on calibration performed using the Spacemate graph interface to indicate morphological type trends of the blocks in different neighborhoods of the city.

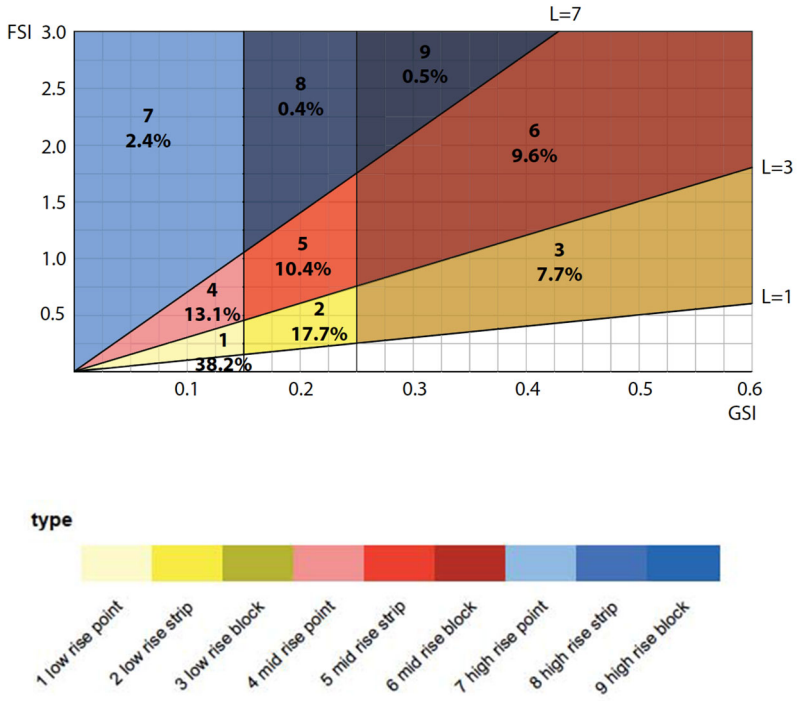


Figure 1. Spacemate. BERGHAUSER PONT e HAUPT, 2009.

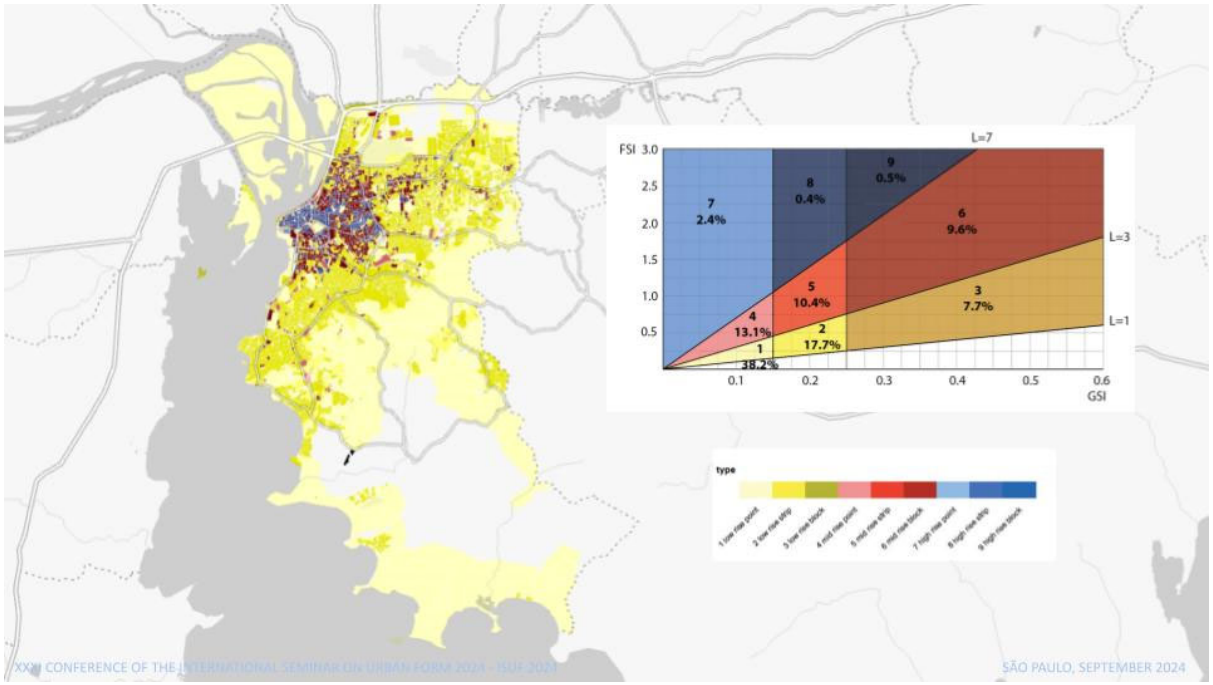
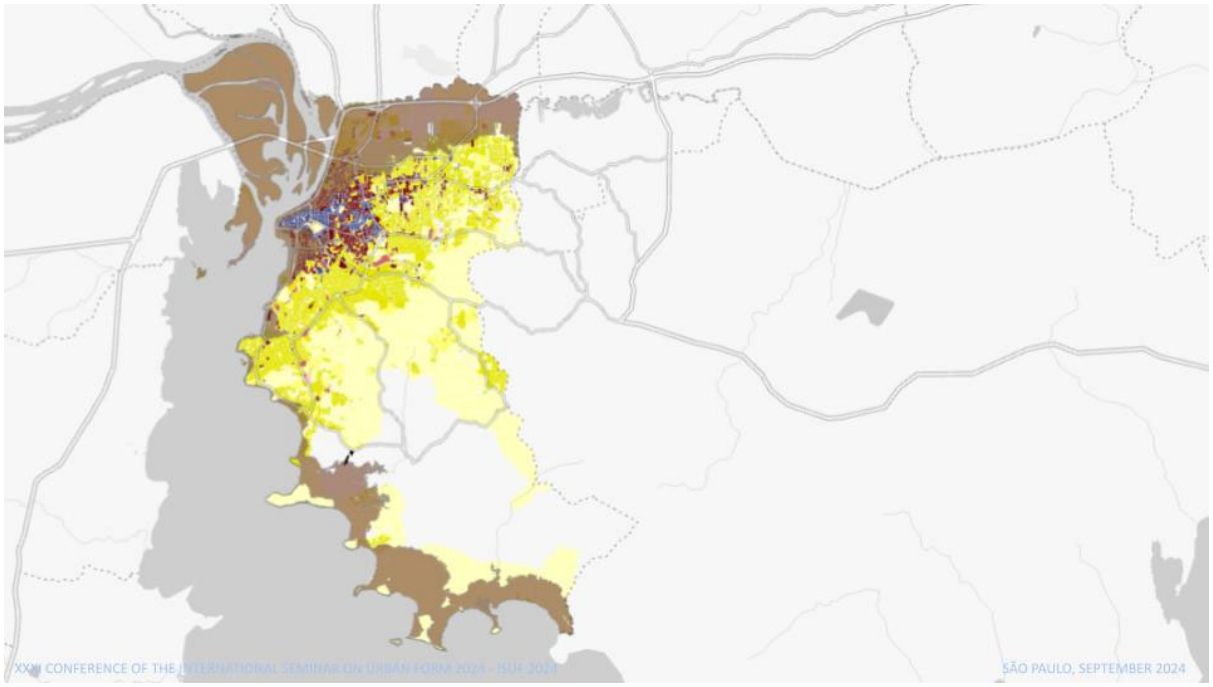
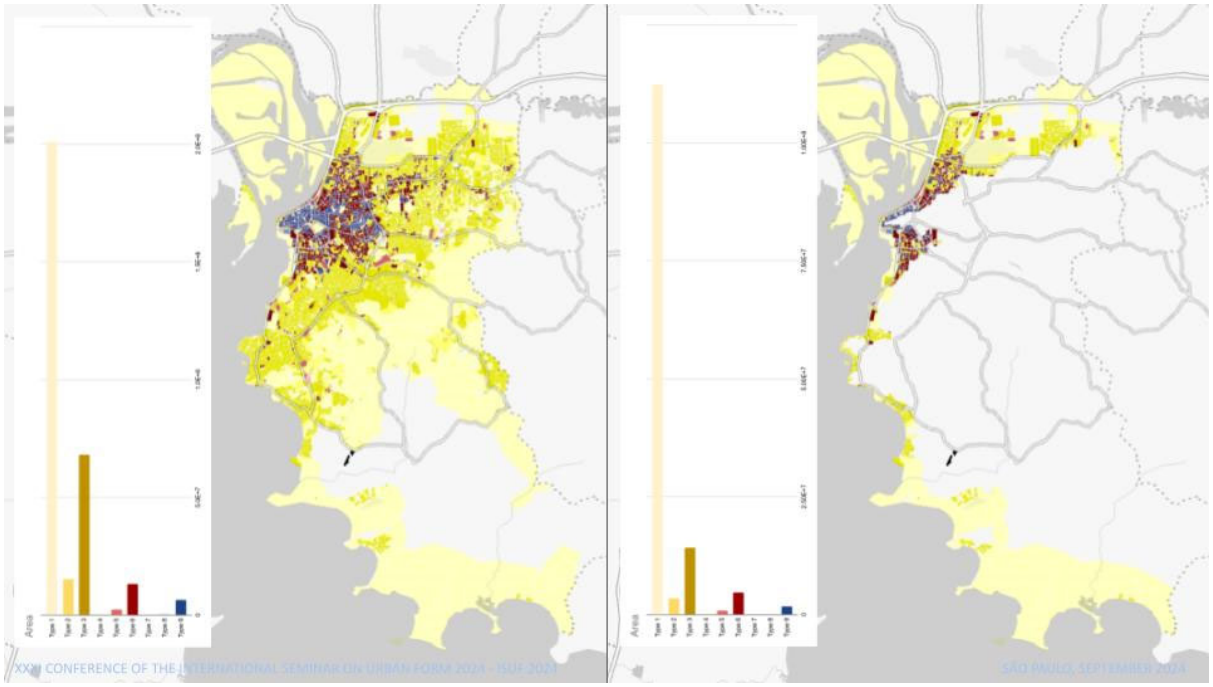


RESULTS AND DISCUSSIONS

The morphological type segmentation of the neighborhoods enabled the identification of distinct urban typologies across the city. In May 2024, Porto Alegre experienced its worst climate-related disaster, with 30% of the territory impacted by severe flooding. As the city continues to recover, it becomes evident that any future urban planning efforts must fully integrate flood risk into land occupation regulations. To address this, we conducted a preliminary selection of affected areas from our previous analysis, establishing a baseline for comparison with earlier models. This comparison aims to better understand the existing typologies and define appropriate planning parameters for various regions. Even though this is an initial mapping, the results show that the flooding impacted different typomorphological configurations within the territory, underscoring the need for tailored resilience strategies that respond to the specific characteristics of each urban area.





CONCLUSIONS

The proposed modeling for identifying morphological type characteristics at the neighborhood and block levels in Porto Alegre, although still in the testing phase, has demonstrated its effectiveness for data processing. This approach shows great promise for informing the development of urban parameters that are better aligned with the current conditions of the city. In particular, it offers valuable insights for addressing the specific challenges posed by areas affected by the 2024 floods. By integrating these findings into urban planning, it will be possible to establish more resilient, context-sensitive regulations that account for both the existing typologies and the vulnerabilities exposed by the recent disaster.

ABSTRACT

Like other urban nuclei, the Itapina district in Espírito Santo, a Brazilian southeast state, is experiencing exogenous actions impacts from economic processes and, since 2015, contamination consequences from Doce River waters that border it. However, the local economic decline was already manifesting itself in contrast to the first 20th century decades golden times, when Itapina promoted the coffee production flow via railways and the river. On the one hand, the road network logic contributed to changing its central position, leading the town to an economic and populational decline. However, on the other hand, economic dynamics reduction discouraged changes. It allowed the maintenance of the urban form, the prominence of its unique landscape, the permanence of a significant architectural complex; an imposing unfinished bridge, reflecting this transition moment. Such a condition reinforces a dichotomy: Itapina stands out as one of the seven historical sites listed by the state, maintaining its access via the river and the operating railway; however, many buildings are closed. So, this article aims to analyze the historical routes reorganization process associated with economic processes that generated erasures and permanence in Itapina urban form. The methodology involves bibliographical research, cartography survey and examination, and photographs and graphic production that allows the interpretation of the data. The study verified the relationship between the genesis of the urban form in Itapina and the flows that gave it centrality, as well as its economic decline following the rise of new road connections. Therefore, the article unveils the relationship between routes, economic dynamics, and urban form throughout Itapina's history, aiming to highlight possibilities for maintaining its heritage and reversing the current decline.

Keywords: historical routes, economic processes, permanence, Itapina

INTRODUCTION [Heading 1]

Economic dynamics shape the history of occupation and social formation in various brazilian cities. The colonization process, characterized by extractivism and the exploitation of indigenous people and nature, is followed by other economic and social cycles, such as agriculture, initially associated with slavery and immigration, as well as mining and industrial activities, which spurred internal migration processes, promoting the rural-to-urban movement and the formulation of new labor relations.

These processes were accompanied by the expansion of territorial occupation, particularly along routes connecting areas of economic exploitation and ports (interior-coast), resulting in a new organization of roads and transportation, along with changes in preexisting activities and routes. The evolution of these routes, which initially utilized natural waterways and paths that transformed into roads and highways, impacted various settlements, villages, and cities formed along rivers, trails, and pathways, harking back to an earlier period (Tesch, 2018). Primitive road routes were replaced by faster systems with greater load capacity, consolidating new forms of occupation around productive chains and nodes of road networks, resulting in the re-signification of pathways, as well as fluvial and terrestrial routes, alongside human settlements.

Another characteristic of these functional arrangements is the exclusion of previously occupied and prosperous territories from the new routes, which, on one hand, it lead to depopulation and economic decline and, on the other, to the preservation of a significant urban ensemble— a condition evident in the historic sites of São Mateus, Santa Leopoldina, Muqui, São Pedro do Itabapoana, and Itapina, which are protected in the state of Espírito Santo (Lordello, 2018).

In this context, the district of Itapina, which is part of the municipality of Colatina, Espírito Santo, Brazil (Figure 1), underwent a reconfiguration of its access routes and its role as a connector of the coffee territory, due to the impacts of national and regional economic restructuring projects. An important cargo hub in the first half of the 20th century, its occupation intensified with the establishment of the Vitória-Minas Railway (EFVM) in 1907, reaching its peak between 1920 and 1960 (Bona and Almeida, 2019). Starting in 1920, there was a significant movement of coffee production inland to the north of the Doce River, accompanied by the expansion of the road network at the regional and state levels.

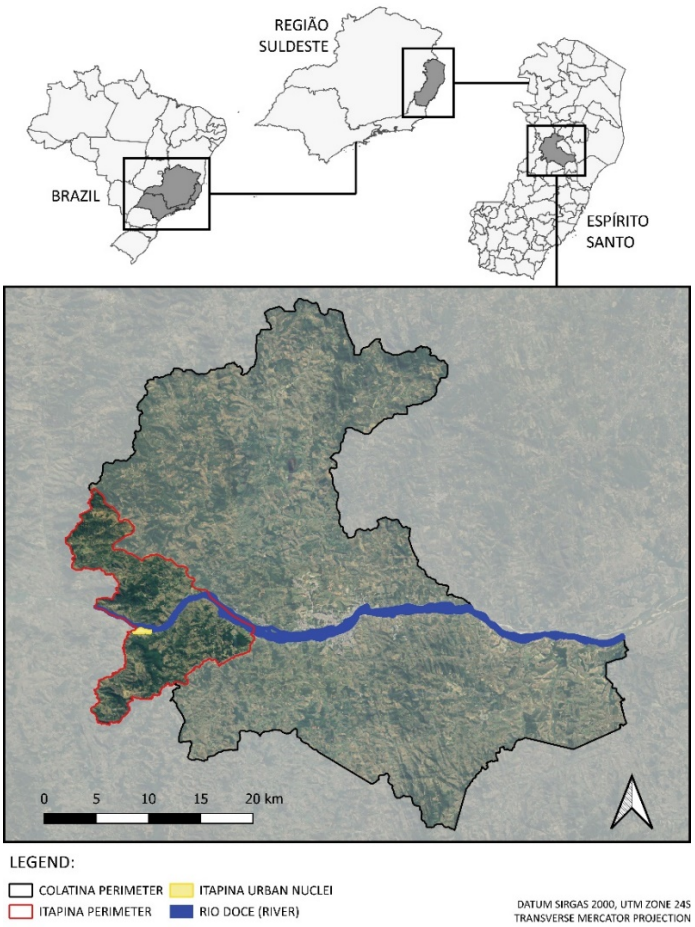

Figure 1. Location of Itapina in Colatina. Fonte: Produced from the Qgis base

Starting in 1950, the national road system was added to this rearrangement, which reconfigured connections and promoted new links through more attractive bridges and highways along new routes, fostering fronts of urban growth. Understanding the morphological processes and the driving forces that operate on the origin and abandonment of agglomerations becomes essential for obtaining an overview of their dynamic character, while also serving as a generic analytical tool that can be applied in other urban contexts (Panerai, 2014).

In the case studied, both state and federal works aimed for greater economic efficiency and the expansion of productive areas. In other words, the primary objective was not to integrate villages and settlements along their routes, which led to a marked decline with the eradication of coffee in Brazil between 1962 and 1967, strongly impacting Espírito Santo after 1967 (Daré, 2010).

Conditions like these, mediated by decisions and actions of the State, are also influenced by the market and affect urban form (Lamas, 2011). Furthermore, evolutionary periods are based on the innovations introduced in the urban landscape, which reflect economic, social, political, and cultural aspects, revealing the rise and fall of certain formal characteristics (Gimmler Netto, Pereira Costa, and Lima, 2014). By analyzing the relationship between form and time, associated with the actions of agents in each period, it is possible to understand urban processes, identifying the reasons for transformations, continuities, and the resulting form (Pereira Costa and Gimmler Netto, 2015).

Thus, this article aims to analyze the process of reorganization of routes associated with economic processes that generated erasures of flows and continuities in the urban form of Itapina, seeking to unveil the historical contexts in which these processes are embedded. It is understood that by examining the impacts of economic cycles and the routes linked to them in Itapina and its surroundings, it is possible to identify processes common to other cities and towns that also experienced decline and economic stagnation but had their urban forms preserved. This procedure also allows for the identification that the erasure of flows resulted in the persistence of elements of historical and landscape value, a condition that can serve as a starting point for the preservation and cultural appreciation in public policies and projects. Thus, over time, in the face of transformations, the persistence can be identified, analyzed, and selected, with the aim of preserving its cultural and environmental value (Pereira Costa and Gimmler Netto, 2015).

Seeking to understand the economic processes that associate access, road configurations, and transportation with the occupation and subsequent depopulation of the region, the article is structured along a timeline marked by three main periods that overlap at certain moments and delineate morphological processes in the Doce River and its surroundings. The first period is characterized by military and tax barriers, along with the exploration expeditions of nature and Indigenous people by the bandeirantes, approximately from 1574 to 1889. The second period encompasses the settlement and clearing of forests for the establishment of coffee agriculture, the improvement of navigation, the arrival of immigrants, the introduction of the railway, and the formation of villages and urban nucleai, covering the interval from 1879 to 1950. The third period is marked by the increasing process of mineral extraction in Minas Gerais, the eradication of coffee plantations, industrialization in Espírito Santo, and emigration, including the opening and infrastructure of land routes and highways starting in 1934.

METHOD

The methodology involves bibliographic research, cartographic surveys and analysis, as well as photographs and graphic production that allow for the interpretation of data. The maps, photographs, and historical data were obtained from institutional collections, while historical information was investigated in books and specialized websites. Theses, dissertations, and articles related to the history of the occupation of the Doce River region were also consulted, seeking the spatiality of the information. The theoretical foundation is based on authors in the field of urban morphology, considering perspectives from different periods, such as Lamas (2011), Lynch (2011), Panerai (2014), and Pereira Costa and Gimmler Netto (2015), the latter being grounded in the English school of morphology. The overlap of the times and elements investigated is synthesized in maps, aiming to understand the relationships between historical routes, road and transport infrastructure, economic processes, erasures, and continuities. In the process, drawings on images and figures were created in Photoshop, in addition to map production using the Qgis program.

RESULTS AND DISCUSSIONS

Origen: security barrier and settlement

During the colonial period, the river routes and precarious roads served the purpose of delineating borders and controlling smuggling. According to the earliest records, access to the Doce River, from its mouth to the region of Baixo Guandu, near the Escadinha Waterfall (now the Mascarenhas

hydroelectric plant), was achieved in 1572 by invading bandeirantes, who reported the presence of stones and precious metals, resulting in the capture of Indigenous people (Teixeira, 1974). Starting in 1786, the occupation of areas around the river was authorized with the granting of sesmarias. However, the growing exploitation in the mining region intensified colonial control over the Doce River beginning in 1798, when the exploration of mines and the establishment of settlement nuclei along its banks were prohibited. This restriction was maintained through the installation of barracks, military posts, and fiscal stations, which later gave rise to villages and, eventually, cities, such as Porto de Souza, in the present-day municipality of Baixo Guandu (Teixeira, 1974).

During the imperial period, the river and the precarious roads took on the role of territorial integration, tax collection, production control, and the flow of goods (Albergaria, 2023). In this context, navigation on the Doce River was reestablished, accompanied by the granting of lands to navigation companies (Teixeira, 1974). In 1835, a decree granted the exclusive right to explore navigation on the Doce River and in the capitals of the empire to the Companhia de Navegação, Comércio e Colonização do Rio Doce. One of the objectives of the decree was to populate and occupy the region. Among the rights granted to the navigation operator were the donation of public lands for the construction of roads, ports, and docks, as well as the freedom to set freight and toll rates. Among the obligations, the granted lands had to be occupied by at least 60 couples of settlers within a seven-year period (Teixeira, 1974).

Within these terms, the Companhia operated steam navigation between 1836 and 1841, revealing the intention to populate the region, especially the northern part of the Doce River, with a view to expanding coffee production and agriculture. Around 1850, a settlement was established in Mutum by Frei Bubbio, aiming to pacify and colonize the Indigenous people of the region (Marinato, 2007). In 1857, 46 immigrant settlers arrived in the region of Franscilvânia (now the municipality of Colatina), to the north of the Doce River, between the Pancas and São João rivers. Between 1861 and 1865, 400 North American settlers disembarked in the region of Baixo Guandu; however, these settlements failed, leading this population to migrate to other areas (Teixeira, 1974). Marinato (2007) associates the failure of attempts to advance settlement in the northern Doce River region with the presence and resistance of the Indigenous peoples, the Botocudos, to the invasion of their territories. In parallel, during this period, there was significant interest on the part of the province of Minas Gerais in expanding and improving connections to the Atlantic. Espírito Santo, particularly the lands near the Doce River, was considered strategic in this connectivity relationship, as Minas Gerais engaged in import and export activities through Rio de Janeiro and Bahia (Cravo, 2013).

Thus, the incursions for the exploration of nature and Indigenous peoples, the establishment of defense mechanisms by invading colonizers, and the attempts to settle immigrants and implement agriculture indicate an overlap with Indigenous territories along the banks of the Doce River until the imperial period. However, to the west of Itapina, the occupation of the Baixo Guandu region for agricultural production was established in 1889, promoted by Francisco Carvalho Milagres, who brought Italian immigrants to work on the plantations. Although land transportation was configured by rudimentary ancestral paths and trails opened by bandeirantes and drovers, navigation ensured the connection with other regions along the banks of the Doce River (Sartorio, 1996). This period is notable for the importance of rivers in human location and movement, as demonstrated in Figure 2

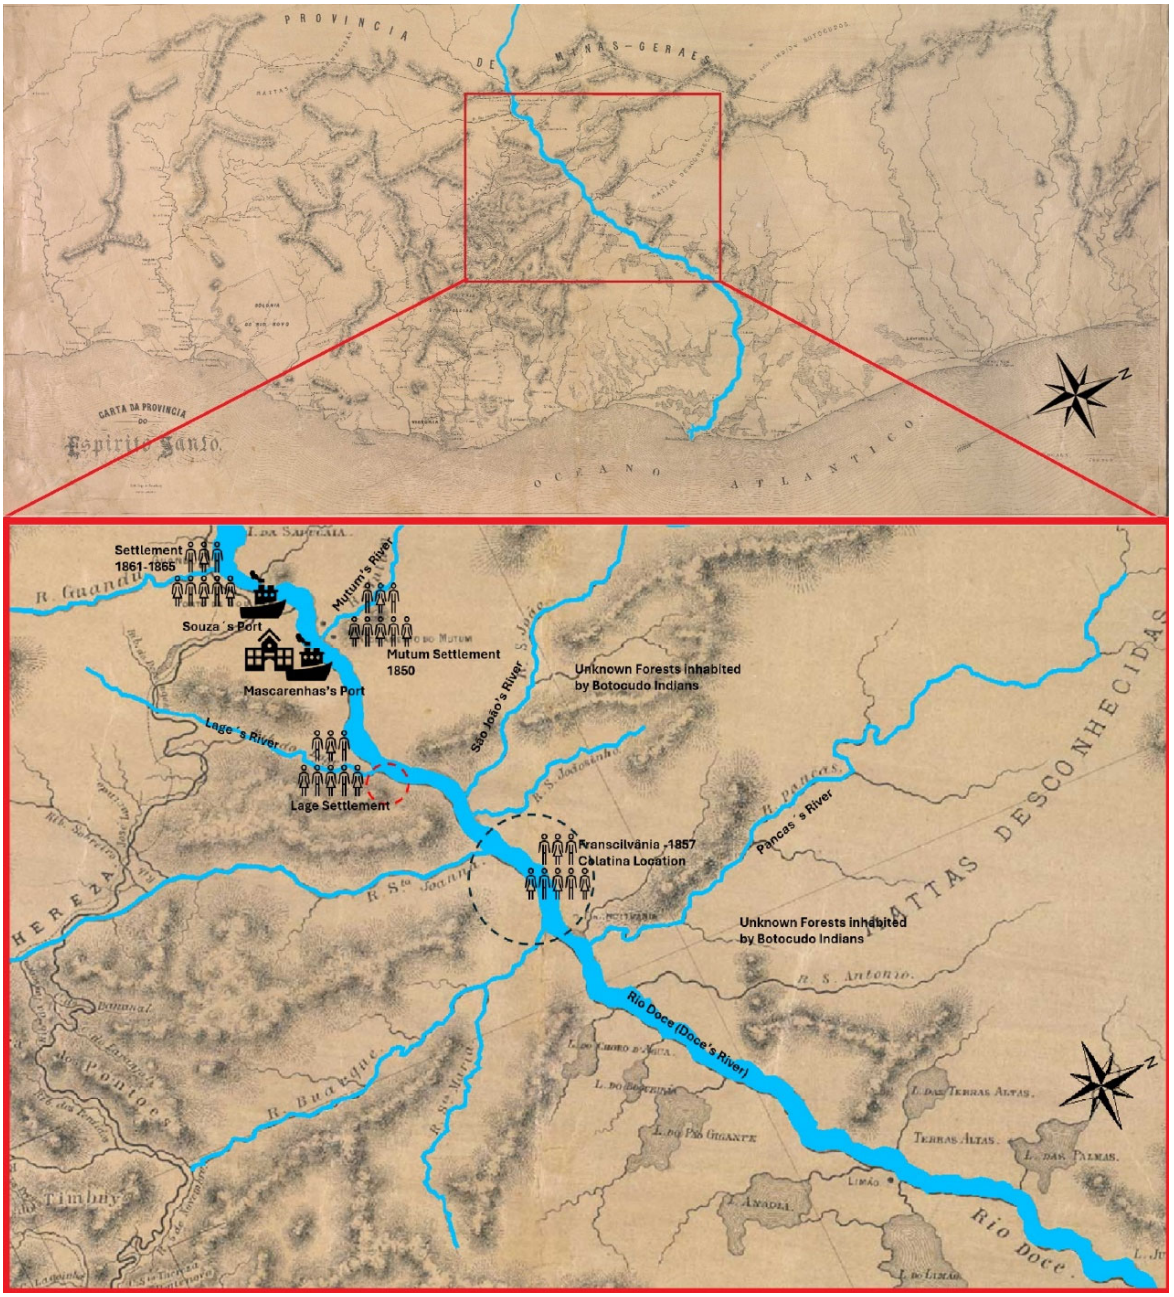

Figure 2. Excerpt from the Doce River with the location of settlements and ports in the 19th century. Source: Adapted from Biblioteca digital luso-brasileira, 2024.

The exact date of the founding of the Aldeamento de Lage, now known as Itapina, is unknown. It is known that it was located near the confluence of the Ribeirão Lage with the Doce River, as described by the inspector of the Indian Protection Service (SPI) in Espírito Santo, Lieutenant Antônio Estigarribia, in 1912. In his account, he mentions that the settlement consisted of a farm with chickens and pigs, and that there were "six huts made of straw and wood, one of which was the granary, where a large quantity of corn was stored [...]. Along the banks of the Ribeirão Lage, there was a settlement inhabited by the Munhageruns and Nac-Nanucs, who settled there in the second half of the 19th century and remained there into the early decades of the 20th century" (Tesch, 2018: 66-70 – our translation). These tribes were monitored by the SPI, and later, their remnants were taken to the Aldeamento de Pancas, eventually being transferred in 1940 to the Krenak reservation in Minas Gerais.

Growth and expansion of occupation with the coffee economy

According to Tesch (2018), the territorial formation of the current district of Itapina occurred with the arrival of immigrants from Cantagalo in Rio de Janeiro to the Ribeirão Lage region, south of the Doce River, where a sesmaria was demarcated and the headquarters of a coffee-producing farm was built. Navigation on the Doce River was only permitted at the end of the 18th century when Silva Pontes assumed the governorship of the captaincy of Espírito Santo. The steam navigation service between the Porto de Souza and Porto de Regência was granted in 1890. This navigability condition favored the migratory process of settlers from various origins starting in 1892, attracted by the possibility of obtaining lots and land for the cultivation of subsistence crops and coffee.

Itapina became a connection point, a way station between the rudimentary roads and the Doce River, interconnected with a steam navigation system that facilitated the movement of people and the flow of coffee produced on the farms south of the Doce River (Tesch, 2018). In addition to coffee, other products also circulated through the region, described by Jurandyr Pires Ferreira, then president of IBGE in 1959, as a river of great economic potential due to its smooth navigable access to the territory of Minas Gerais (IBGE, 1959).

The commercial village developed in the late 19th and early 20th centuries, thanks to its strategic location in relation to the Doce River. Initially, access to the village was achieved through both land transport, using animals, and river transport along the Doce River (Lordello, 2018).

In addition to the flow of coffee production and the receipt of various cargoes, another determining factor for the development of Itapina was the implementation of the Vitória-Minas Railway in 1907, which reinforced the longitudinal axis of development in the southern Doce River region. The railway line, created for the transport of cargo between Minas Gerais and the capital Vitória on the coast of Espírito Santo, boosted the local economy, facilitated the movement of people, and established connections between the village and neighboring urban and rural areas, such as Aymorés, Baixo Guandu, and Colatina.

This condition promoted Itapina as a commercial hub in the first half of the 20th century, even with the construction of roads and bridges in the Colatina and Baixo Guandu region (Tesch, 2018). The village was emancipated in 1923, receiving the name Distrito de Lage and being annexed to the recently emancipated municipality of Colatina (1921). In 1943, it was renamed Itapina (Tesch, 2018).

To the south, a primitive road connected Itapina to Figueira de Santa Joana, Lagoa, and Afonso Cláudio (now the ES-164 road). From the perspective of connecting productive areas and cargo flow points, a private truck was incorporated into the route in 1926, expanding cargo transport from Lagoa to the Santa Leopoldina region, totaling approximately 100 km to the south of Itapina (Sartório, 1996).

Complementing this infrastructure, the Companhia Vale do Rio Doce, established in the 1940s, implemented a road-rail connection with its own trucks and bus stations in Afonso Cláudio, Lagoa, and Figueira de Santa Joana. These stations facilitated and encouraged the use of road-rail transport, creating a constant flow of various cargoes, such as pigs, beans, and corn, with coffee being the main product. The company also promoted the transport of imported goods in the opposite direction, such as industrialized products, kerosene, and salt (Sartório, 1996).

These activities directly impacted the improvement of the road infrastructure between Afonso Cláudio and Itapina, which, although not paved, had wooden bridges and trestles replaced to accommodate motorized transport with greater load capacity, replacing animal traction.

Until 1928, a large part of the road network in Espírito Santo was concentrated in the southern portion of the Doce River. This characteristic began to change with the establishment of the Companhia Territorial de Colonização, which implemented a project aimed at building bridges and roads in the northern region of the Doce River (Sartório, 1996). Another relevant feature was the pathways and automobile road that connected Afonso Cláudio to Itapina, passing through settlements in Itaguaçu, as illustrated in the 1935 map (Figure 3).

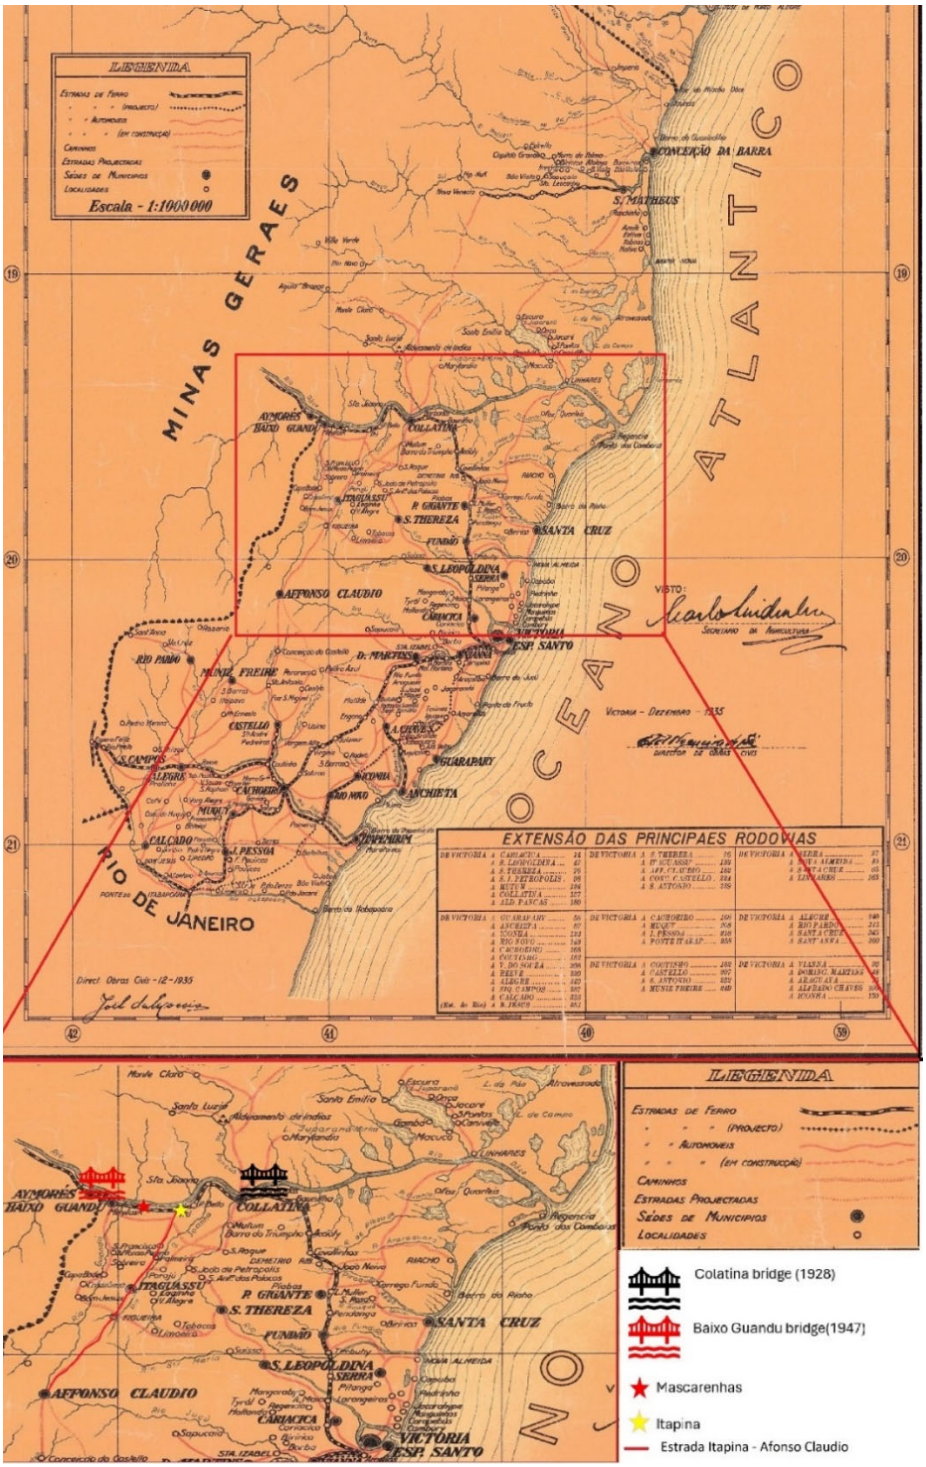

Figure 3. Map showing the main roads of Espírito Santo in 1935, highlighting the location of Mascarenhas, Itapina, and the bridges connecting the northern and southern banks of the Doce River near Itapina. Source: Adapted from Agências Postais, 2004.

In Brazil, the first paved roads were created to expedite the flow of coffee to the ports, dating back to the imperial period (Albergaria, 2023). The first railroads also emerged during this same period (IPHAN, 2014). However, it was in the first half of the 20th century, with the introduction of concrete and asphalt technologies, that there was a more intense expansion of the road system. Itapina, however, reached its peak before the arrival of the highways associated with this developmental

period. The convergence of paths, trails, and roads in Itapina, along with its close relationship with the Doce River and the Vitória-Minas Railway (EFVM), favored its development and economic rise until 1950 (Tesch, 2018).

Before the construction of the bridge in Baixo Guandu in 1947 (7.8 km to the north), Itapina's connection with the northern bank of the river was limited to river transport or road crossing at Colatina, where a bridge had been built in 1928 (25.7 km to the south). The new bridge in Baixo Guandu reorganized transportation flows and opened new fronts for investment in road infrastructure, such as the connection between Itapina and Mascarenhas, as well as the road in the Vale do Mutum on the northern bank. This situation persisted until 1979 when the bridge was destroyed by the force of a river flood (Sartório, 1996).

The bridges were catalysts for the occupation of the northern portion of the Doce River. In Colatina, the Florentino Avidos Bridge, inaugurated in 1928, also enabled the formation and densification of new neighborhoods and promoted improvements in access roads to the north, such as the establishment of the route between Colatina and Nova Venécia (1928-1930), which later consolidated the axis of the state highway ES-080 (Sartório, 1996).

Despite the improvements to the north of the Doce River, Itapina remained an important commercial hub, which justified the investment in a new bridge, initiated in 1956, in the center of its urban area. This new structure aimed to facilitate the crossing of the Doce River and connect productive areas to the storage and distribution facilities of the district (Tesch, 2018). The main connections in the region reflected the chain of coffee production and distribution until the eradication of coffee plantations occurred between 1962 and 1967, devastating 53% of the plantations in Espírito Santo (Partelli and Pereira, 2021).

New economic directions: eradication of coffee plantations and industrialization

Starting in 1956, national transportation policies directed investments and external financing toward the road sector, resulting in significant growth in Brazil between 1960 and 1970 (Sartório, 1996). This decision impacted the railway network, which, in 1959, extended 37,120 km. From 1962 onwards, several railways began to be decommissioned or replaced. Over a period of seven years, 1,595.10 km of railways were replaced by roads, of which 321.1 km were paved. By 1968, the railway network had been reduced to 32,054 km, a decrease marked by the replacement of railways with roads utilizing the same bed. Some exceptions occurred, such as the EFVM, which incorporated an additional 64 km during this period (Brasil, 1970).

In Espírito Santo, in 1959, there were 3,225 km of state highways, with only 20 km paved. This length of highways remained unchanged until 1966, and by the end of that period, 152 km were paved (Brasil, 1970). On one hand, state investments in highways focused on paving existing segments; on the other, President Juscelino Kubitschek's Metas Plan included Espírito Santo in the national connection project, significantly impacting the Itapina region, particularly through the implementation of the federal highway BR259. Initiated in the 1960s, BR259 facilitated the east-west connection between João Neiva in Espírito Santo and Felixlândia, a city near Governador Valadares in Minas Gerais (Orrico et al., 2005). The segment between João Neiva and Baixo Guandu, on the border with Minas Gerais, dates to 1968. In the stretch between Colatina and Baixo Guandu, BR259 runs north of the river before returning to the southern bank, approximately 7 km west of Itapina (Brasil, 1970).

This period coincides with the eradication of coffee plantations and changes in the economic base of Espírito Santo, which intensified the process of industrialization. Despite the completion of BR259 and the full operation of EFVM, the bridge that would connect Itapina to the northern bank of the Doce River, started in 1956, was not completed (Figure 4). From 1960 onwards, the local population began to decline, and the region underwent a process of stagnation, attributed by some authors to the redirection of flows and the unfinished bridge (Tesch, 2018). The economic decline of the following years, especially between 1962 and 1967 — the period of coffee eradication — also marks the process of industrialization in the state, with a strong presence of steelmaking on the coast of Espírito Santo, migration from rural to urban areas, and the predominance of investments in road transport

Figure 4. Doce River, Itapina, photo credit: Willian Henrique, 2019

This context is reflected in the population decline of Itapina, which recorded a 53% reduction over a period of 50 years. In 1960, the population reached 5,350 inhabitants, with significant drops in the following decades (IBGE, cited by Tesch, 2018, p. 128). The period between 1960 and 1970 was also marked by a population decrease in Colatina, which experienced a reduction of 27.86% during the same period. As a result, there were impacts on job availability both in rural and urban areas, as well as repercussions in commerce and transportation. The concentration of the population in urban areas led to migratory processes towards new economic areas, such as the steel industry in the capital, Vitória (Tesch, 2018).

Since 1947, improvements in the road connections crossing the Doce River, in the north-south direction, were directed towards Baixo Guandu and the headquarters of Colatina, with bridges and paving integrated into the route of BR259, which was completed in the 1980s (Orrico et al., 2005). By linking with the Fontelle and Florentino Avidos bridges, and more recently, the Sérgio Ceotto Bridge, BR259 diverted the routes that came from the south and passed through Itapina, generating the district's isolation from the main flows.

In 1986, the ES446 road and part of the ES164, between Baixo Guandu and Itaguaçu, were paved (Sartório, 1996). In 2018, paving began on the ES446, from Colatina to Itaguaçu (DER, 2018), a project that was completed in 2021 (DER, 2021). The roads connecting Itapina to urban centers and rural areas remained as unpaved local roads (Figure 5).

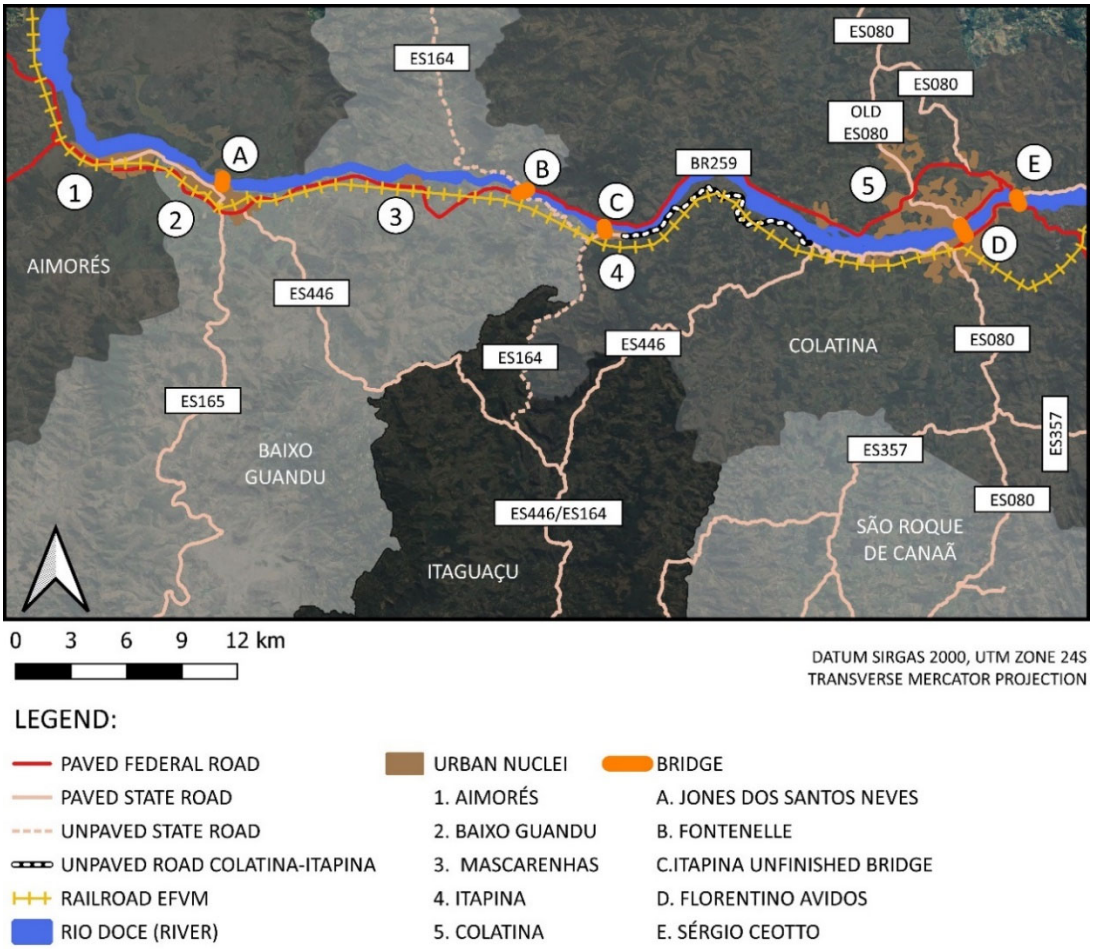

Figure 5. Current map of the road infrastructure and location of urban areas. Source: Adapted from the Qgis database, 2024.

Throughout the process of exploration and occupation of the Doce River, the riverbed and its banks have been modified and impacted by urbanization, transport networks and infrastructure, extractive activities, coffee cultivation, and the clearing of pastures. These actions not only suppressed native vegetation but also affected water resources, resulting in pollution and siltation, which caused environmental, social, and economic damage over time (Orrico et al., 2005). Additionally, this problem is compounded by the impacts of exogenous agents, such as mineral exploration, which peaked with the destruction caused by the collapse of the Samarco tailings dam in Mariana, Minas Gerais. This environmental crime occurred on November 5th 2015, and contaminated the Doce River all the way to its mouth (Organon, 2015).

Transformations and permanences

The road and transport context surrounding Itapina reveals a gradual loss of connectivity between the urban center and other areas, as well as with important trade and cargo transport routes. The Colatina-Itapina road, which runs along the southern bank of the Doce River, and the current ES164—an important north-south link that connected the area to Afonso Cláudio during the height of coffee production—still exist but no longer serve the same function. These roads are characterized by narrow, unpaved sections and are isolated from the ongoing improvements in road infrastructure and land transport routes. The ferry facilitates the crossing for people between the historic site of Itapina

and BR259; however, the reduction in population, along with the siltation and contamination of the river, has made trips less frequent.

This scenario is also related to the logics of morphological processes inscribed in the territory, which clarify the reasons for its current form, as pointed out by Panerai (2014). The driving forces of the improved highways direct and organize the agglomerations. The layouts are associated with the phenomena related to their creation, such as decisions and forces from the state or the market, marking the urban form and promoting order, symbolic stability, control, power, access, exclusion, economic function, or cultural values (Lamas, 2011). When routes are redirected, the exclusion of this territory from the context of new economic fronts promotes a stabilization of changes in its form.

When analyzing the spatial configurations, it can be observed that, in the first half of the 20th century, Itapina was an important nodal point in a vast region, serving as a point of arrival, departure, and modal transfer for journeys between productive rural areas and markets. The railway, the waterway, and the roads converged in the district, characterizing it as a local commercial, social, and cultural reference. The routes connecting rural areas to the urban center, configured by paths and roads running north-south along the river, as well as the railway, were associated with a rural landscape and the Doce River. Although the river is an important natural attribute for the emergence of the urban center, it also constituted a barrier to the growth and connection of Itapina with productive expansion to the north.

The economic and infrastructural changes in the region led to a process of hollowing out of activities in Itapina, resulting in population decline and abandonment of properties in the town. However, aspects related to the permanence of local attributes are observed, such as the urban form, built heritage, landscape, and cultural characteristics of the village formed until the 1950s (Bona and Almeida, 2019). This recognition materialized in the listing of the Historical and Landscape Ensemble of Itapina in June 2013 by the Secretaria de Cultura do Espírito Santo (Espírito Santo, 2013).

The periods identified from the road connections are associated with public policies and historical transitions, based on innovations introduced in the field of transportation that are exogenous to the locality. As demonstrated by Gimmler Netto, Pereira Costa, and Lima (2014: 32 – our translation), "[...] the evolutionary periods are based on innovations introduced into the urban landscape, which reflect economic, social, political, and cultural aspects of the rise and decline of certain forms [...] represent the synthesis between historical facts and innovations materialized in the urban landscape, determining formal characteristics."

The gradual consolidation of external road flows passing through Itapina and the secondary hierarchy of the highways providing access to the town contributed to the preservation of its architecture and urban layout. This contrasts with what occurred in neighboring cities, such as Colatina and Baixo Guandu, which were crossed by road transport for medium and long distances. Thus, in the context of urban centers near the Doce River, the crossing of road flows promotes more frequent formal changes than other modalities. Indeed, the railway and the operational river crossings did not bring about significant changes in the urban structure and landscape of Itapina after 1960.

Another condition that contributes to understanding the continuities in Itapina is the configuration of growth lines, characterized as "support for growth that occurs in a specific direction" (Panerai,

2014:60 – our translation). These lines can be represented by a road, a river, or a railway along which the agglomeration grows, taking into account the physical site and the poles it connects. The economic periods are reflected in the growth line of Itapina, which has been linked to the paths of invaders, the Doce River, and the EFVM railway, later becoming connected by an extensive road network.

The attempt to connect with the north through the Itapina Bridge failed, and its unfinished structure became a visual landmark of the town. The perception of the historical urban core as an important sector arises not only from the presence of a temporal segment but also from the typological similarity outlined in its preservation process.

On one hand, the economic stagnation and relative isolation of Itapina are associated with rearrangements of regional flows, aligned with economic development policies exogenous to the locality, which resulted in the transfer of important access points and connections to other cities. On the other hand, local groups maintained their relationship with space, preserving the conditions of the urban landscape. In the words of Panerai (2014), continuities activate a system of landmarks and references, facilitating everyday life and reinforcing local culture.

CONCLUSIONS

As Pereira Costa and Gimmler Netto (2015) explains, that historic urban landscapes are an important cultural asset, with a significance that transcends the community they are part of. The relation between routes, economic dynamics, and urban form points to a time span that preserved the landscape and elements revealing its origin, such as the river and train transport. Integration by water and the persistence of terrestrial routes indicate possibilities for maintaining its historical path. These factors, combined with its scenic and architectural heritage and the culture preserved by its residents, suggest the potential for reversing the current decline.

ABSTRACT

Urban greenspaces have multiple functions and provide different ecosystem services for cities. The high-quality development requires an optimization in terms of layout and planning of urban greenspaces, leading to a widespread attention of urban greenspace morphology in recent years. The development of urban greenspaces is based on the Urban Greenspace System Planning (UGSP) in China, but how effective are the constructions of single greenspace and urban greenspace system under the top-down guidance of UGSP? Is UGSP the only factor which influence the construction of urban greenspace? From the perspective of urban greenspace morphology, this study aims to address this problem based on three rounds of UGSP and the corresponding construction situations of park system in Quanzhou, China. Firstly, we construct a database containing basic information of both planned and constructed park greenspaces in different periods, then, combine UGSP and satellite images, extract and measure morphological factors from the individual and system levels in three periods respectively. Secondly, we form our framework by selecting and reclassifying possible driving factors other than UGSP according to the regional history and relevant research. Finally, by evaluating and analyzing the greenspace morphology of planned and constructed parks, we identify driving factors and interpreter the evolution process of Quanzhou's park system. The results show that, from 1995 to 2020, there were 28.24% of parks development were influenced by the UGSP, morphological factors of planned parks, in terms of area (r=0.658**), shape (r=0.501**), type (r=0.331**), location (r=0.512**) and layout (r=0.204**) were positively highly significantly correlated with those of constructed park. While, the other morphological factors of parks are comprehensively influenced by various driving factors in urban space, which should be vital references for the future development of urban green space systems.

Keywords: urban greenspace, urban morphology, park system, driving factor

INTRODUCTION

As an important part of urban planning and development, the urban greenspaces (UGSs) contribute to the improvement of urban ecosystem and human well-beings. The Urban Greenspace System Planning (UGSP) provides a top-down guidance in the development process of UGSs in China. In 1992, China's state council issued the Urban Greening Ordinance, which stipulated the local city council assumed the responsibility to compile UGSP, while, in the Standard of Landscape Garden City, the compiling of UGSP became one of the evaluating indicator, both emphasized the vital role of UGSP.

With the constant publication of relevant policy and standard, the compilation and implementation of UGSP tend to be matured. In this process, experts and scholars have done a lot of research on UGSP in various aspects including policy (Liu and Wang, 2009), tool (He, Ye and Chen, 2015; Liu and Wang, 2009), theory and management (Zhang, Zhou and Yang, 2009; Li et al., 2016; Song and Zhang, 2016; Xiao, Cao and Li, 2020; Yang et al., 2010; Liu and Jiang, 2002; Yang, Li and Ye, 2019; Zhang, Guan and Li, 2018; Wu and Chen, 2000; Tan, 2005), which ensure the scientific and sustainable development of UGSP in the process of compilation and implementation. However, there is no study which focus in the influence of UGSP and its relation with the morphological evolution of UGSs. With the establishment of the National Territory Spatial Planning, a new round of UGSP is about to start. How to correctly understand the relation between UGSP and UGSs? How effective is the guidance provided to the construction of UGSs by UGSP? What factors may influence the guidance efficiency of UGSP? Which are crucial questions.

The identification of urban morphology can contribute to understand the laws and characteristics of urban development and predict future trends. Since the first International Seminar on Urban Form (ISUF) in 1997, different groups have come to agree that cities can be interpreted and analysed by three basic physical elements: buildings and their related open spaces, plots and lots, and streets. However, current research mainly focuses on the buildings, and lacking understanding of UGSs, which is an important part of urban open spaces (Zhu and Shi, 2021). Form, resolution and time are three basic elements of urban morphological research (Moudon, 1997). While UGSP controlling the form of UGSs in various scales in different phases of urban development, which means UGSP is a fundament of UGS morphological research in China. Therefore, urban morphology provides a theoretical framework for the questions mentioned earlier.

From the perspective of urban morphology, this study was based on Park Green Spaces (PGSs) in 3 rounds of Quanzhou's UGSP, constructed an evaluating framework for UGSs under the guidance of UGSP through correlation analysis, revealed the relation between UGSP and UGSs, then identified the driving factors which may influence the implementation of UGSP in urban space. The result may provide reference and guidance for compilation and implementation of UGSP in the future.

METHOD

Study Area

Quanzhou (24° 30′ -25° 56′ N, 117° 25′ -119° 05′ E) is a coastal city eastern China, bordered by Putian to the north, Xiamen to the south, and Taiwan to the east. It belongs to a subtropical maritime monsoon climate with superior climatic conditions. As of the end of 2022, the city's permanent population is 8.879 million. Since 1995, Quanzhou has carried out three rounds of UGSP. Quanzhou has achieved certain results in the construction of UGSs, in 2003, it was selected as the International Awards for Liveable Communities, then, in 2005, it was selected as a National Landscape Garden City. This study mainly focuses on the central area of Quanzhou city which divided by railways and natural water bodies. The study area is bounded by the Fuxia Railway on the north side, Jin River on the southwest side, and Luoyang River on the east side, including the central cluster, Beifeng cluster, Donghai cluster, and Chengdong- cluster, with a total area of approximately 156.19km2 (Figure 1).

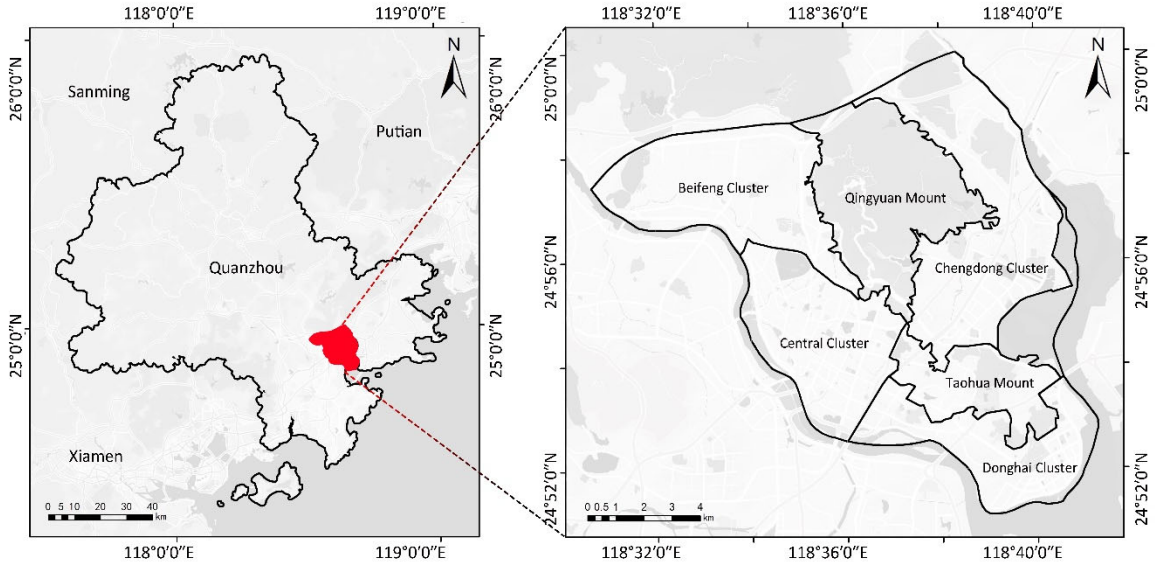

Figure 1. Study Area, satellite map source: https://www.google.com/maps/

Data Source

Currently, there were 3 rounds of UGSP in Quanzhou, which were respectively compiled in 1995, 2005 and 2010. Although both short-term and long-term planning target are compiled in UGSP, commonly a new round of UGSP would start before the achievement of long-term target because of the rapid urban development. The relations of different round of UGSP shown as Figure 2. Thus, this study selected clear and cloudless Landsat data in 1995, 2005 ,2010 and 2021 respectively (Table 1), which sourced from USGS (https://glovis.usgu.gov/), after data acquisition, preprocessing is carried out, including geometric correction, radiometric calibration, atmospheric correction, etc. Based on the UGSP documents and the interpretation results, we established a database of planned and constructed PGSs of Quanzhou on the ArcGIS platform.

Table 1. Data Source

c	Compilation Year	Data Source for Planned PGS	Implementation Year	Data Source for Constructed PGS
1995	1995	Landsat 4/5	2005	Landsat 7
2005	2005	Landsat 7	2010	Landsat 7
2010	2010	Landsat 7	2021	Landsat 8/9

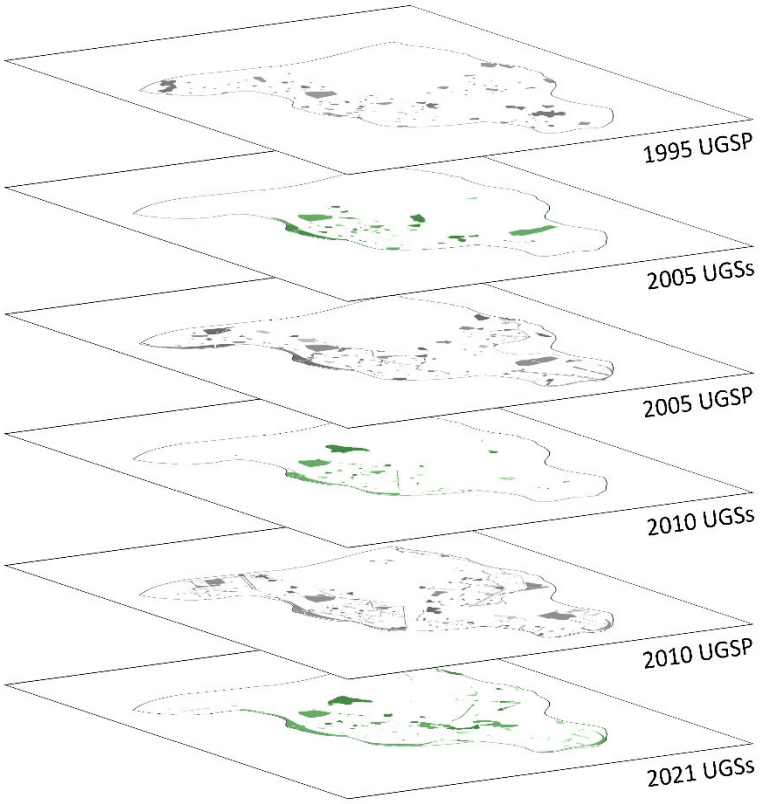

Figure 2. Relation of UGSs Development and UGSPs' Guidance

UPG Reclassification

There is a relatively long period between the compiling of three UGSPs, and the relevant regulations and standards are constantly changing, resulting in differences in the classification standards for UGSs. According to current classification standard named the Standard for Classification of Urban Green Space (CJJT 85-2002, detail shown in Table 2), this study sorted out the urban green regulations and historical materials of Quanzhou City reclassified the types of PGSs of different rounds of UGSP, in terms of their definition and functions, providing the same standard for research.

Table 2. Standard for Classification of Urban Green Space (CJJT 85-2002)

Category	Subcategory	Description
Park Greenspace	Comprehensive Park	Greenspaces with rich content, suitable for various outdoor activities, and complete recreational and supporting management service facilities.
	Community Park	Greenspaces with an independent area of land that features basic recreational and service facilities, primarily serving the local residents within a certain community for daily leisure activities.
	Theme Park	Greenspaces with specific content or form, equipped with corresponding recreational and service facilities.
	Small Park	Greenspace with an independent area of land that is smaller in scale or varied in shape, convenient for nearby residents to access, and possesses certain recreational functions apart from the other type of greenspace mentioned above.
Protective Greenspace	—	Greenspace with an independent area of land with functions of sanitation, isolation, safety, and ecological protection, which is not suitable for public access.
Square Greenspace	—	Urban public activity spaces primarily for recreation, commemoration, gatherings, and emergency shelter.

Affiliated Greenspace	Affiliated Greenspace of Residential Land	Greenspaces attached to various types of urban construction land.
	Affiliated Greenspace of Administration and Public Services Land	
	Affiliated Greenspace of Commercial and Business facilities Land	
	Affiliated Greenspace of Industrial and Manufacturing Land	
	Affiliated Greenspace of Logistics and Warehouse Land	
	Affiliated Greenspace of Road, Street and transportation Land	
	Affiliated Greenspace of Municipal Utilities Land	
Regional Greenspace	Landscape and Recreational Greenspace	Greenspace with good natural environment, open to the public, primarily serving functions such as leisure and recreation, tourism, entertainment and fitness, and scientific research, equipped with recreational and service facilities.
	Ecological Conversation Greenspace	Greenspace dedicated to ensuring urban and rural ecological security, improving landscape quality, and undertaking protection, restoration, and resource cultivation.
	Regional Facilities Protective Greenspace	Greenspace around regional transportation facilities and regional public facilities that serves functions of safety, protection, sanitation, and isolation.
	Production Greenspace	Nurseries, flower beds, and grass beds used for the production, cultivation, and trial introduction of various seedlings, flowers, grasses, and seeds for urban and rural greening and beautification.

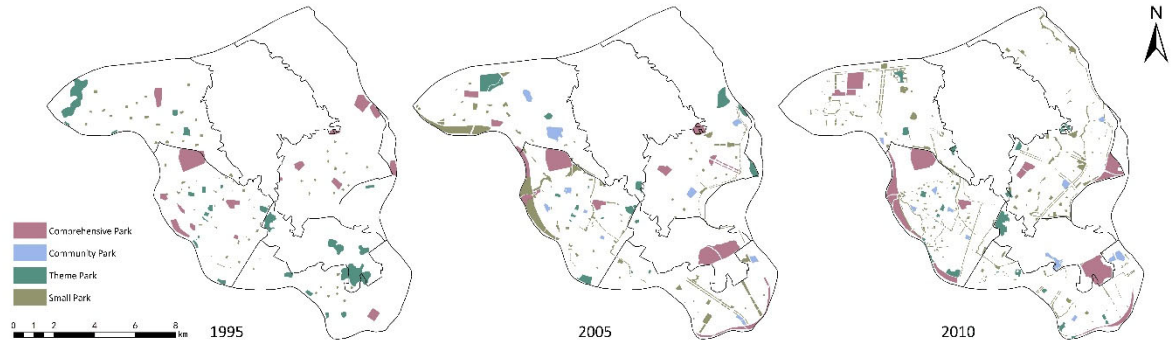

Figure 3. Planned PGSs in UGSPs

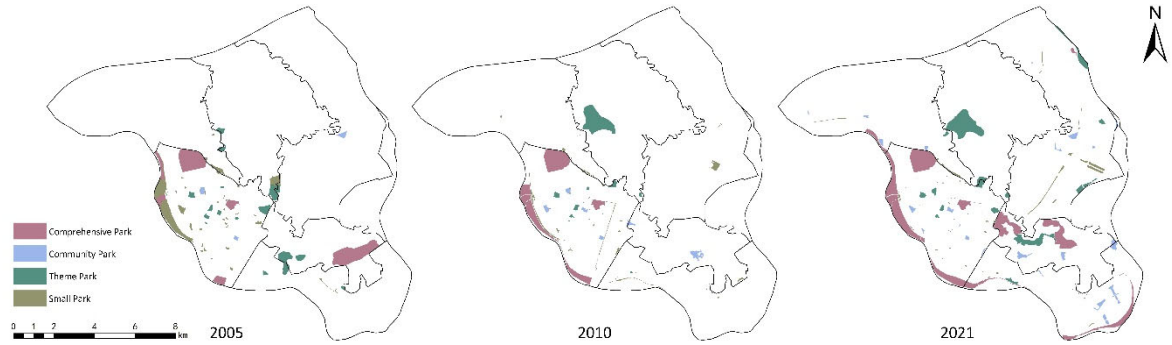

Figure 4. Constructed PGSs in Implemenatation Years of UGSPs

Morphological Factor Identification

Firstly, we overlapped planned PGSs and constructed PGSs of three rounds of UGSPs based on the Spatial Joint tool in ArcGIS, and selected the planned PGSs which were spatially connected with constructed PGSs. Then, through literature review and relevant research, the main morphological factors of UGS were pre-selected, including area, perimeter, shape, type, number of patches, location, etc. (Chen, Yang and Dai, 2023; Wu et al., 2023; Du, 2022; Guo, Hou and Shi, 2024; Yang et al., 2023; Sun et al., 2024; Yang and Xue, 2006; Ma and Lu, 2010; Gui, Wei and Huang, 2019). Finaly, we calculated the pre-selected UGS morphological factors of the planned and constructed UGSs mentioned above in FRAGSTATS and ArcGIS platforms, and conducted correlation analysis on SPSS platform.

RESULTS AND DISCUSSIONS

A Guidance Efficiency Indicator of UGSP

The correlation analysis results show that the planned PGSs is significantly positively correlated with the constructed PGSs in five morphological factors including area, shape, type, number of patches, and completion rate, indicating that UGSP provide guidance for the construction of PGSs in terms of morphological factors mentioned above (Table 3), and which were selected to evaluate the guidance of UGSP in this study.

Table 3. Correlation Analysis Result of Morphological Factors

Factors	Correlation Coefficient	P-value	Description
Area (AREA)	0.658**	0.000	Area of the PGS.
Shape Index (SHAPE)	0.501**	0.000	Standardization results of the area and perimeter of the PGS, describing its complexity.
Classification	0.331**	0.000	Types of parks and green spaces under current classification standards
Number of Patches (NP)	0.204**	0.007	The number of green patches a PGS divided by other urban land use
Built Area	0.512**	0.000	The area of the overlapping part of the planned PGS and its spatially connected constructed PGS
Perimeter (PERIM)	0.103	0.179	Perimeter of the PGS
Nearest Distance (NEAR)	0.013	0.864	The distance between the PGS and its nearest PGS

Based on the PGS morphological factors mentioned earlier, various evaluation indicators are constructed to quantify and analyse the guidance effectiveness of the PGSs in the three rounds of UGSP, and the technology roadmap is shown in Figure 5. We calculated the planned PGSs and the corresponding constructed PGSs with relation of spatial connectivity:

1) Area Ratio (AR), the area ratio of the planned PGS to the corresponding constructed PGS, indicating the guidance of UGSP in terms of area, which can be expressed as follows:

$$AR = \left| \frac{AREA_P - AREA_e}{AREA_p} \right| \quad (1)$$

where, AR is area ratio, $AREA_p$ is the area of planned PGS, $AREA_c$ is the area of corresponding constructed PGS.

2) Shape Ratio (SR), the SHAPE index ratio of the planned PGS to the corresponding constructed PGS, indicating the guidance of UGSP in terms of shape, which can be expressed as follows:

$$SR = \left| \frac{SHAPE_p - SHAPE_e}{SHAPE_p} \right| \quad (2)$$

where, SR is shape ratio, $SHAPE_p$ is the SHAPE value of planned PGS, $SHAPE_c$ is the SHAPE value of corresponding constructed PGS.

3) Built Ratio (BR), the ratio of overlapped area after Spatial Joint to the area of corresponding planned PGS, indicating the guidance of UGSP in terms of built accuracy, which can be expressed as follow:

$$BR = 1 - \frac{AREA_b}{AREA_p} \quad (3)$$

where, BR is built ratio, $AREA_b$ is the overlapped area, $AREA_p$ is the area of planned PGS.

4) Classification Accuracy (CA) is applied to determine the type consistency of planned PGS and corresponding constructed PGS. If the types are consistent, assign a value of 0; if not, assign a value of 1.

5) Patch Number Accuracy (NA) is applied to determine the patch number of planned PGS and corresponding constructed PGS, If the numbers are consistent, assign a value of 0; if not, assign a value of 1.

6) An efficiency indicator (EI) is constructed by integrating these morphological factors, and the lower the value, the smaller variation between the planned PGS and the constructed PGS, indicating that the better guidance effectiveness of UGSP; the higher the value, the greater variation between the planned PGS and the constructed PGS, indicating that the poorer guidance effectiveness of UGSP. The calculation formula is as follows:

$$EI = AR + SR + BR + CA + NA \quad (4)$$

where, EI is the efficiency indicator of UGSP; AR is area ratio; SR is shape ratio, BR is built ratio; CA is classification accuracy; NA is patch number accuracy.

EI of 576 planned PGSs have been calculated, then we employed Jenks Natural Breaks in ArcGIS, the calculating result is classified into two clusters with significant consistency. In the study area, if EI falls below or equals 3.25, the planned PGS is well guided by UGSP. Conversely, if EI exceeds 3.25, the PGS is poorly-guided by UGSP. Based on the calculating and clustering result above, we employed the quantity ratio of the well-guided PGSs to planned PGSs, indicating the guidance efficiency of certain PGS cluster. The calculation formula is as follows:

$$WGR = \frac{N_w}{N_p} \times 100\% \quad (5)$$

where, WGR is well-guided ratio; N_w is the number of well-guided PGSs; N_p is the number Planned PGSs.

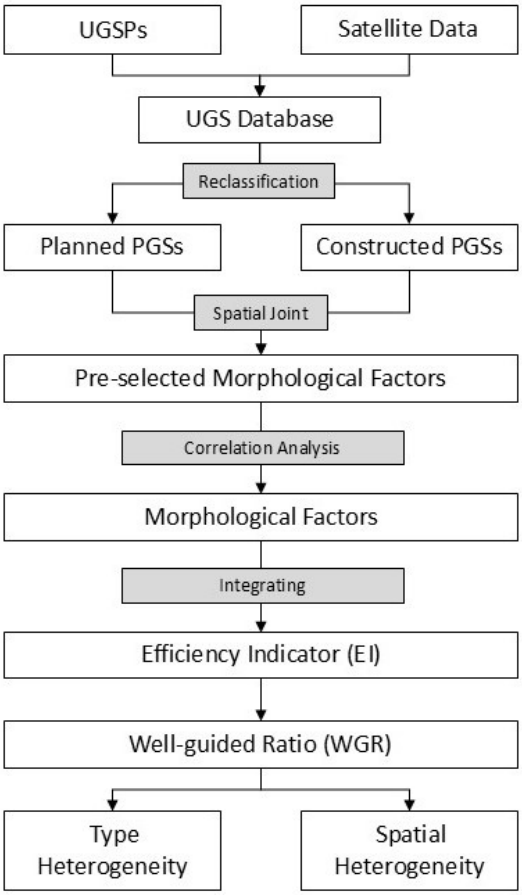

Figure 5. Technology Roadmap

WGR Heterogeneity of UGSP

There are 104 PGSs were well guided by UGSPs, the WGR of 576 planned PGSs in Quanzhou is 19.56%. Based on WGR calculations, the WGR of UGSPs exhibits heterogeneity in various aspects, which we will discuss in the following sections.

Type Heterogeneity

WGR of different types of PGSs in the three rounds of UGSP is shown in Figure 6. The community parks exhibit the highest guidance efficiency, while the small parks show the lowest. Overall, the WGR of community parks stands at 45.45%, the highest among the four types of PGS, indicating the best guidance efficiency of UGSP. Comprehensive parks and theme parks follow, with WGRs of 41.46% and 35.38%, respectively. Small parks have the lowest WGR at 12.25%, indicating the poorest guidance efficiency of UGSP. Due to the relatively large number of small parks, they significantly impact the overall WGR.

The high WGR of community parks can be attributed to their advantages in construction and management, as well as the increasing demand for public greenspaces at the community level by urban residents. Compared to comprehensive parks, community parks are smaller in scale, have shorter construction periods (Luo and Fu, 2016), and are easier to manage; compared to small parks, community parks have more comprehensive functions and higher recreational value. Additionally,

community parks are usually located near densely populated urban residential areas, closely integrated with the daily lives of urban residents. This proximity allows for better oversight of land use and construction quality by the surrounding community.

Theme parks maintain relatively high WGR, which is largely due to Quanzhou's emphasis on cultural heritage protection. Heritage parks make up a significant proportion of theme parks in the three rounds of UGSP in Quanzhou. As early as the 1995 UGSP, key national cultural relics such as Qingjing Mosque, Kaiyuan Temple, and Tianhou Palace were incorporated into the UGSP as theme parks. Due to the high historical and cultural value of these park green spaces, their form, quantity, and scale are strictly controlled and managed, making them less susceptible to other urban factors, thereby resulting in higher guidance efficiency.

The WGR of small parks is significantly lower than the other three types of PGS. This is because, in the 1995 UGSP, small parks were used as a "tool" to meet greenspace indicators, distributed as isolated points throughout the urban space without considering the rationality of greenspace construction. Both the 2005 and 2010 UGSP included plans for large numbers of linear small parks along main urban roads, again without considering the suitability of greenspace construction. In actual urban greenspace construction, these small parks, due to their small scale and unclear land ownership, either were not realized or became part of road affiliated greenspaces or protective greenspaces.

Related studies suggest that while amusement parks cannot replace the important role of large parks, they can optimize urban biodiversity (Gan, Guo and Yao, 2019), enhance community and social equity (Ye et al., 2023), promote the physical and mental health of nearby residents (Xu, Shi and Li, 2023), and improve urban microclimates (Peschardt and Stigsdotter, 2013). Therefore, the issue of their insufficient guidance should not be overlooked, as it has significant implications for the optimization of urban green space hierarchies.

Figure 6. WGR of different types of PGS

Spatial Heterogeneity

WGR of PGS in different urban clusters in the Three Rounds of UGSP (Figure 7). The central cluster demonstrates the highest WGR, with a more complete park system and similar spatial distribution characteristics across the three rounds of UGSP. Overall, the WGR of the central cluster is 36.12%, the highest among the four clusters, indicating the best guidance efficiency. The Beifeng cluster has the lowest WGR, both overall and in each individual round of UGSP, among the four clusters. Although the total planned PGSs in the Donghai and Chengdong clusters has been continuously increasing, the number of constructed PGSs is only in the single digits. The WGRs of these two clusters differ significantly from that of the central cluster. As shown in Figure 8, in the 2010, the park system within the central cluster is largely established, while constructed PGSs in the other clusters are more dispersed.

In the Beifeng cluster, although PGSs have been planned across the three rounds of UGSP, only three small park green spaces have been constructed in actual construction (Figure 8). The main reason for this is that, apart from the area around West Lake Park which is located at the border with the central cluster, the Beifeng cluster primarily consists of village construction land and agricultural and forestry land, which means this cluster is still in the early stages of urban development. Consequently, the demand for PGSs from the surrounding residents is relatively low.

The Chengdong and Donghai clusters are influenced by the nearby Qingyuan Mountain Scenic Area, and the Taohua Mountain greenspace which share the same mountain range. This reduces the recreational demand within the clusters. Numerous studies have confirmed that urban scenic areas have public and communal functions (Chen and Chen, 2018; Li, 2015), providing recreational, spiritual, and cultural benefits. This results in the planned PGSs near the mountain edges within these clusters remaining largely unconstructed. In contrast, most of the constructed PGSs in these two clusters are distributed along natural water bodies. Research indicates that waterfront areas are popular spots for visitors, offering unique recreational experiences to urban residents (Zhai and Wu, 2020).

This study illustrates that the guidance efficiency of PGSs is influenced by urban land use and landscape patterns. Therefore, it is essential to prioritize these areas mentioned above during the compilation and implementation of UGSP.

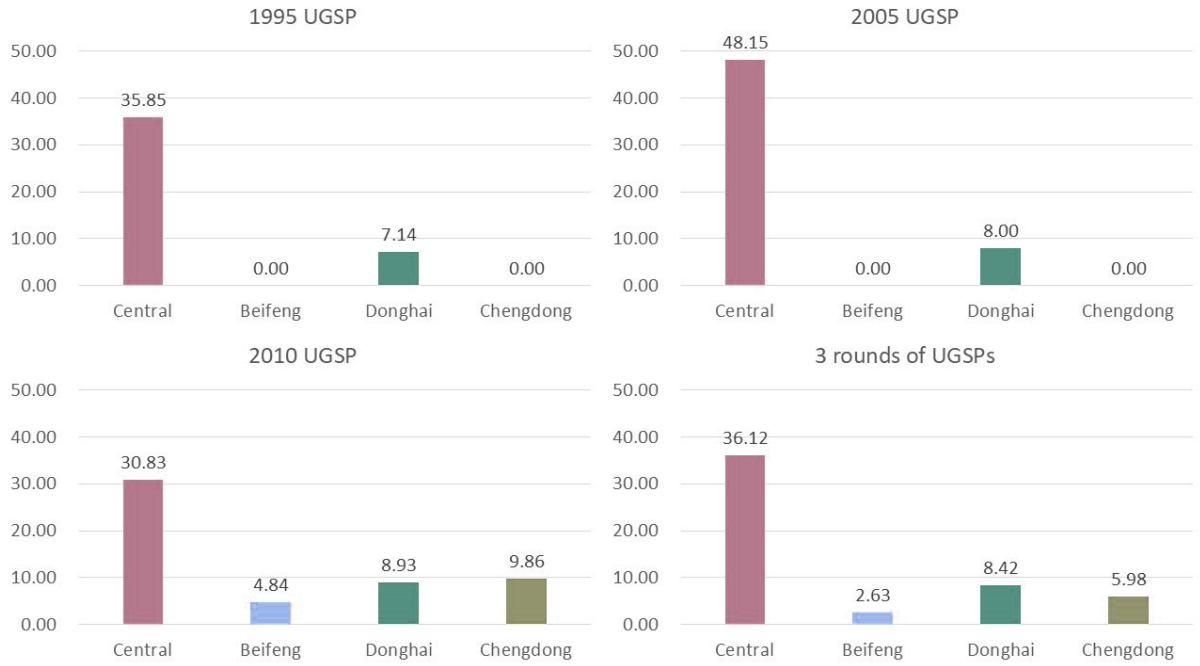

Figure 7. WGR of different clusters of PGS

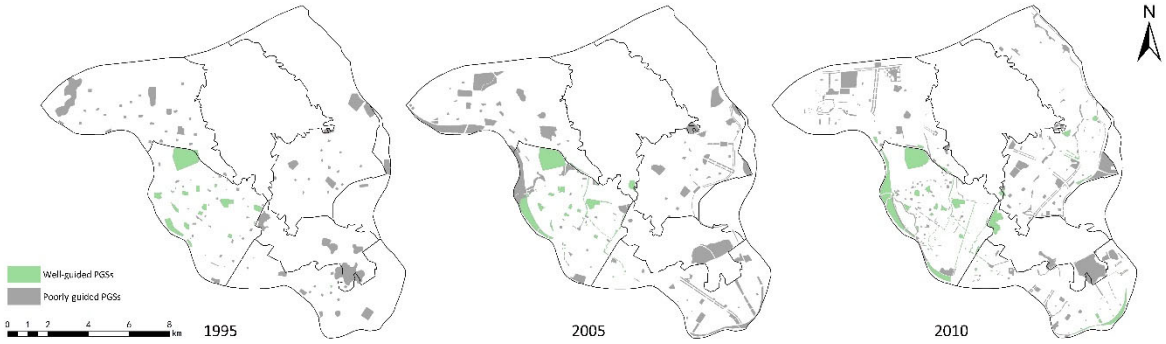

Figure 8. Well-guided PGSs and Poorly-guided PGSs of UGSPs

CONCLUSIONS

This study develops an evaluation indicator for the guidance efficiency of UGSP and identifies driving factors affecting the guidance efficiency of UGSP. Focusing on the PGSs in the three rounds of UGSPs in Quanzhou, the study measures and analyses guidance efficiency with the following results: From the perspective of UGSP, the guidance efficiency show heterogeneity. Regarding the types of PGS, community parks exhibit the highest guidance efficiency, while small parks show the lowest. In terms of spatial distribution, the central cluster has the highest guidance efficiency, featuring a more complete park system within the cluster.

Overall, the guidance efficiency of UGSP is influenced by various factors. Throughout the UGSs development process or within a specific round of urban green system planning, the guidance efficiency of different types of park green spaces varies. This variation is related to the robustness of relevant regulations and standards, the demands of residents around the UGS, the scale and value of the UGS, and the management and protection by relevant departments. Land use properties and landscape patterns also affect guidance efficiency. PGS in riverside areas have better guidance

efficiency, while those near regional greenspaces have lower efficiency. These research findings provide valuable insights for the compilation and implementation of UGSP. The evaluation method for guidance efficiency proposed in this paper also introduces a new research perspective in this field.

However, there are some limitations in this study. For instance, it only considers PGS with independent spatial connections between planned and constructed PGS. There may be cases where a small portion of the planned PGS is divided into multiple greenspaces during implementation, or constructed green spaces were originally planned as multiple greenspaces. Additionally, due to the small sample size of planned and constructed community greenspaces, the findings might not comprehensively explain its guidance efficiency. This paper primarily focuses on PGSs within UGSs, aiming to clarify the impact of UGSP on PGSs construction. While, UGSs include other types of greenspaces that are closely related to the living environment. Future research will expand on this methodology to the entire urban green system, identifying different guidance efficiency factors for various greenspace types. This will be done both longitudinally by increasing the temporal scope and horizontally by expanding the research scale, providing a foundational basis for the future compilation and implementation of UGSPs.

ABSTRACT

This article presents a methodology for analyzing the content of Urban Mobility Plans proposed by Machado in 2019, verifying the alignment of the minimum content required by Law nº 12.587/2012 and the Support Booklet, proposing a search codification for the minimum content for evaluating plans of small municipalities. Based on the methodology presented by Machado (2019) and using data from the Survey on the Status of Urban Mobility Plans made available by the Ministry of Cities as a source, the research sample was defined, delimiting, from all the municipalities, the Brazilian region to be studied and the UMPs of the municipalities to be analyzed. After defining the codes and search elements, based on the Support Booklet provided by the federal government and the coding proposed by Machado (2019), the codes were entered into qualitative data analysis software to obtain, process and organize the results. It should be noted that the lack of uniformity in the presentation of the plans was a limiting factor for the tool used in the content analysis methodology, as they could not be read by the MAXQDA software because they were files identified as images and not text. In order to optimize the validation of compliance with the minimum criteria required by law and what was presented by the municipality, it is important to calibrate the search elements to include words and terms similar to those searched for. Calibration can be carried out after the data processing stage, including the terms similar to the corresponding codes, re-running the search for each code and processing the data before starting the process of categorizing and counting the number of occurrences.

Keywords: methodology,municipality, categorize, evaluation.

INTRODUCTION

The National Urban Mobility Policy (PNMU), established by Law nº12.587/2012, is an instrument of urban development policy that aims to integrate different modes of transport and guarantee universal accessibility and mobility of people and cargo throughout the municipal territory (BRAZIL, 2012). Before Law nº12.587/2012, municipalities sought to implement standards and actions aimed at improving urban mobility only when financing or receiving resources from the Federal Government was involved. The promulgation of the Law highlights the obligation of urban mobility objectives that

are related to the municipality's territorial and urban planning and these objectives must produce satisfactory benefits consistent with the resources used (BRASIL, 2013).

The compliance of the objectives, principles and guidelines of the PNMU must be carried out with the Urban Mobility Plans (PMU) and are mandatory for municipalities with more than twenty thousand inhabitants, members of metropolitan regions, integrated economic development regions and urban agglomerations with a total population of more than one million inhabitants and members of areas of tourist interest (BRASIL, 2012). While the minimum content of the PMU is characterized in article 24 of Law nº12.587/2012through eleven topics that guide the implementation of the PNMU in Brazilian territory. The regulations and responsibilities are assigned to the three spheres of government: the Union is responsible for offering technical and financial assistance to the states, Federal District and municipalities, in addition to promoting the development of technologies and scientific knowledge that meet the principles and guidelines of the Law and, continuously, aligned with states and municipalities, promote the training of people linked to the PNMU. The states are responsible for providing urban intermunicipal public transport services or delegating the function to municipalities through a consortium or cooperation agreement; ensure the support and promotion of services that go beyond municipal territorial limits and propose tax and incentive policies for their implementation.

The responsibility of municipalities is to plan, execute and evaluate the PNMU, provide urban public transport services, train people and develop institutions linked to the PNMU and regulate urban transport services in their territory. For Oliveira (2012), the regulation may seem simple, but it proves to be innovative by stating that mobility must be considered when building cities and by reaffirming that planning should not be carried out only in the central regions of cities but throughout the entire city. Its territory, including territorial relations between municipalities and their districts. Carried out by the Ministry of Cities (MCID - BRASIL, 2023), the survey of the situation of Urban Mobility Plans shows that around 1,865 municipalities are required to develop and approve the PMU and, of this total, 1,582 cities have less than 100 thousand inhabitants.

Observing the difficulty faced by municipalities with up to 100,000 inhabitants in preparing their plans, the federal government, from 2019 onwards, began offering specific technical support for the development of PMUs in these municipalities with the Support Booklet and the digital system for preparing the initial version of the plan. However, this is not the only option for these municipalities, in the literature there are also specific scripts and strategies for cities that aim to develop their PMU (PIRES, 2020; WRI BRASIL, 2017; COSTA and MARTORELLI, 2016; BRASIL, 2007).

This article aims to validate the PMU content analysis methodology proposed by Machado in 2019, using as a search basis for analysis the content of the Booklet to support the development of urban mobility plans for municipalities with up to 100 thousand inhabitants developed by federal government. It is necessary to verify the alignment of the minimum content required by Law No. nº12.587/2012 and the Support Booklet and propose a search coding for the minimum content for evaluating PMUs in small municipalities.

The criteria established by IBGE for population arrangements will be adopted: small size for municipalities with up to 100 thousand inhabitants, medium size between 100 and 750 thousand inhabitants and large size for municipalities with more than 750 thousand inhabitants (IBGE, 2017a).

To achieve the proposed objectives, research classified as descriptive was carried out, as it proposed to describe the characteristics of a given event (GIL, 1991 apud SILVIA and MENEZES, 2005).

METHOD

As one of the Union's obligations described in the PNMU is to offer technical and financial assistance to the States, Federal District and municipalities, programs, events and tools were promoted with the aim of stimulating the knowledge and training of public managers for the development of the PMU jointly or not with the transfer of income to achieve the plan's goals. Below, some of the instruments made available by the Union will be presented.

The National Cities Training Program (PNCC or Capabilities) provides technical training to help cities execute regional and urban development programs and projects and build a fairer and more democratic society (BRASIL, 2020). Starting in 2013, as part of Capabilities, the National Secretariat for Urban Mobility (SEMOB) began to hold in-person Awareness Seminars for the Urban Mobility Policy and Plan to promote Law nº12.587/2012 and workshops for the preparation of the PMU. The purpose of the activities is to provide a moment for reflection, projection and exchange of experiences about urban mobility within the organization of each participating municipality (BRASIL, 2022).

The Reference Booklet for the Preparation of the Urban Mobility Plan was the support material released by the federal government in 2007 to guide municipalities with populations above 500 thousand inhabitants in the construction of their Transport and Mobility Master Plans (PDTM), item mandatory with the promulgation of Law nº12.587/2012 (BRASIL, 2007). The document was republished in 2015 after a technical review to add the new principles, guidelines and obligations required by Law nº12.587/2012 (ITDP Brasil, 2015).

These Reference informs that the itineraries and suggestions brought are generalizations constructed from the average characteristics of Brazilian cities, however the Notebook and the PNMU show inconsistencies by not considering the themes of promoting public transport and discussing cargo transport for municipalities small.

The municipalities with a population of up to 100 thousand inhabitants have, in addition to the Reference Booklet, three exclusive instruments made available by the federal government to assist in the preparation of their PMU: the Support Booklet, the Support System for the Preparation of Urban Mobility Plans and the video tutorial “Support Program for Mobility Plans”, available on TV Portal CNM’s YouTube channel. According to Brasil (2022), the support system is a computerized system that aggregates the information described by municipal managers and generates a preliminary version of the PMU with the minimum content required by the PNMU.

The methodology presented in the Support Booklet suggests a 14-item structure for the PMU, with the first three items being an introduction to the plan with presentation, history and characterization of the municipality and the remaining eleven items must deal with each minimum content described in Art. 24 of Law nº12.587/2012 (BRAZIL, 2019). Unlike the Reference Booklet, the Booklet indicates only four steps for the development of items referring to the minimum content foreseen in the PMU: diagnosis, objectives, goals and strategic actions. This instrument presents a description of each

mandatory topic, suggested material for diagnosing the situation and examples of objectives, goals and strategic actions.

The methodology proposed by the Booklet recommends the institution of the PMU in the form of a municipal law, even though Law nº12.587/2012 does not oblige the municipality to take this action. According to Martorelli in the video tutorial on TV Portal CNM (2020), approval in the form of a municipal law offers a guarantee for compliance and continuity beyond municipal management.

Metholodologies for PMU Analysis

The Law nº12.587/2012links the approval of plans with the release of federal resources for activities related to urban mobility in municipalities. As there is no obligation to establish the PMU through a Law or municipal decree, there is a decrease in the power of supervision by any citizen and a lack of guarantees in relation to the execution of the objectives and actions described in the PMU by subsequent administrations.

Carneiro (2018) proposed a qualitative analysis of PMUs from a traffic safety perspective using inductive, comparative and observational methods. With the proposal to analyze the conception and applicability of the PNMU, Machado (2019) proposed a PMU content analysis methodology different from that presented previously.

Machado (2019) analyzes the applicability of each PMU, checking the coherence between plan and theory, plan and Law and effectiveness of the actions proposed in the plan. To compose its analysis sample, the following criteria are adopted: approval of municipal legislation, complete PMU (text contains the phases of diagnosis, prognosis, action plan and means of financing and monitoring) and completion after approval of Law nº12.587/2012 until 2018 (research preparation period). Moraes (2021) sought to analyze the content of municipalities' PMUs from the perspective of active mobility, establishing as criteria PMUs developed after 2012 (law nº12.587/2012), the availability of the plan on municipal administration digital platforms and documentary sufficiency , defined in four items: objectives for active mobility, guidelines, strategies and action plans and mapping of proposals.

However, unlike Machado (2019) who analyzes the data obtained through frequency measurement, Moraes (2021) uses the word cloud tool to examine and discuss the assertiveness of the proposals for active mobility of the PMUs in his sample. The discussion is carried out on the cloud composed of the recurrence of all grouped categories, followed by the isolated clouds for each city studied. As it is not intended to obtain data on attributes of the PMU analyzed and the objective is to identify the minimum content required in the PNMU, without bias towards a theme, we chose Machado (2019) does not require the full reading of the PMU and verification of the content is identified based on the existence or absence of search elements, without the interference of the examiner's understanding of the text read.

Based on the methodology presented by Machado in 2019 and using data from the Survey on the situation of Urban Mobility Plans made available by the Ministry of Cities as a source, the methodology of this research is divided into four stages. First, to define the research sample, delimiting, from all municipalities, the Brazilian region to be studied and, subsequently, the PMUs of the municipalities to be analyzed. Next, the codes and search elements are defined, based on the Support Booklet provided by the federal government and the coding proposed by Machado (2019). Based on these definitions,

the PMU and codes are inserted into qualitative data analysis software to obtain, process and organize the results, making up steps three and four of the methodology.

To define the sample municipalities, data from the Survey on the status of Urban Mobility Plans made available by the federal government through the Ministry of Cities website was used. The MDR informs that the survey on the status of the preparation of PMUs is carried out through the responses of municipalities to a letter sent by SEMOB to representatives of city halls, with the last sending being carried out in February 2019, and emphasizes that it does not carry out any assessment of the content of PMUs, with municipalities having full responsibility for the information passed on to the federal government (BRASIL, 2023).

The files used for data processing are called Status of preparation of urban mobility plans in municipalities with up to 250 thousand inhabitants and List of municipalities required to prepare the urban mobility plan, which will be treated as Status 250 and List of municipalities, respectively, from this point. The spreadsheets used in this work were downloaded in May 2023.

The information contained in the Status 250 spreadsheet is arranged in columns called municipal code - IBGE, Region, UF, Municipality, Has an Urban Mobility Plan, Year of preparation, Approved by law or normative act, Legal Instrument, Law No. and Date of Law. In List of municipalities, the information is municipal code - IBGE, Region, Federative Unit, Municipality, RIDE, RM, Urban Agglomeration (AU) - IBGE 2021 and Population - 2010 Census (IBGE), also arranged in columns.

To find the status of preparation of PMUs in municipalities with up to 100 thousand inhabitants, the Population column - 2010 Census (IBGE) of the Municipality List spreadsheet was added to the Status 250 spreadsheet. For this purpose, the Excel PROCV search formula was used, using as value searched in both spreadsheets for the municipality code – IBGE. After obtaining the list, the Excel Dynamic Spreadsheet tool was used in the resulting spreadsheet, with the Region field in the lines area and Population - 2010 Census (IBGE) and Municipalities in the values area.

It was found that there are 1,582 cities with less than 100,000 inhabitants required to prepare the PMU and as the first selection to define the municipalities in the sample, the Brazilian region with the largest number of small municipalities required to prepare the PMU was used. As the Northeast region has the largest number of small municipalities required to prepare the PMU, 576 in total, this was the region selected to obtain the PMU for analysis. For the next step in composing the research sample, a filter was carried out in the Region column to select municipalities in the northeast region in the list with the status of PMUs of all municipalities required to prepare with a population equal to or less than 100 thousand inhabitants. The selection was copied to another spreadsheet to create a new dynamic table formed by the Has Urban Mobility Plan fields in the lines and values areas.

RESULTS AND DISCUSSIONS

It was found that 575 small municipalities in the northeast region received the letter sent by SEMOB, the exception was the city of Bom Jesus (RN) and there are no records of explanations from SEMOB or MCID for what happened. 315 cities declared that they did not have a PMU, 237 did not respond to the question and 23 declared that they had a PMU.

From the 23 municipalities that declared that they had a PMU to the federal government, two criteria were applied to compose the analysis material: 1) the preparation of the PMU after the year 2012 (Law nº12.587/2012 is in effect) until 2023 (the year the research was carried out); and 2) the availability of the plan in electronic form. The municipalities of Sento Sé in Bahia and Bonito, Pesqueira, São Bento do Una and Surubim in Pernambuco were excluded from the PMU search, as they declared the preparation and approval of the PMU before 2012, between the years 2006 and 2011 and did not declare to the federal government have updated their plans.

With the remaining eighteen municipalities, the plans were searched for through city hall websites and, when this search failed, an email was sent to the city hall or the municipal ombudsman's office and the request of the PMU through e-SIC of each municipality. The mobility plans for Santa Maria da Vitória, Tabuleiro do Norte, Santa Inês, Bananeiras and Ipojuca were not found on the websites of their respective city halls. The request was then made via email and e-SIC.

The municipality of Santa Maria da Vitória, Bahia, indicated Municipal Law nº12.587/2012 to the MDR as the law regulating its PMU, however this law establishes the municipality's Master Plan, which in turn does not mention the words mobility, vehicles, pedestrian once. , transport, bus or bicycle. Using the law and decree search tool made available by the municipality of Tabuleiro do Norte, Ceará, we found Complementary Law 002/2018, reported to the MDR as responsible for establishing the PMU in the municipality, but we are directed to the file of Municipal Law nº 998 /2018 that grants the title of Tabuleirense citizen to Mr. Antônio Pinheiro Granja. The request for information about the mobility plan was registered under protocol 20221122-0025 on the municipality's e-SIC portal and there was no response.

The request for access to Municipal Law nº101/2015 informed by the municipality of Santa Inês, Maranhão, to the MDR as a regulatory law for the PMU was made only through the Ombudsman's Office page available on the municipality's website, as there is no field for registration and requesting documents. No protocol number was provided to accompany the request, nor was the request returned until the completion of this work.

The municipalities of Bananeiras, Paraíba, and Ipojuca, Pernambuco, did not provide a number of laws or decrees to sanction their PMUs. The request made to the Bananeiras e-SIC did not generate a protocol number for monitoring, while the Ipojuca request was made through protocol 00010.000039/2022-60. As in the cases mentioned above, there was no response from the municipalities in these cases.

The remaining thirteen mobility plans were located on city hall websites using the transparency portal, search in the search bar using the number of the regulatory law or the words mobility plan or official gazette of the municipalities. The files were downloaded and renamed with the name of the municipality and state for insertion into the data analysis software . However, after including the files and each search code in the software, it was found that five files were not read, as they are printed documents that were scanned and, even though they had the .PDF extension like the other files, these they behaved like image files and not like text files, preventing the search for words by the MAXQDA software. For this reason, only the PMUs of Aracati, Currais Novos, Entre Rios, Limoeiro do Norte, Paulo Ramos, Serra Talhada, Vitória do Mearim and Zé Doca remained part of the research sample.

Definition of Codes and Search Elements

The definition of codes and search elements used was generated by combining the content of the Support Booklet for municipalities with up to 100 thousand inhabitants and the categories used by Machado (2019) in his content analysis. The codes were defined based on the eleven topics described as mandatory by Article 24 of Law nº12.587/2012, which was presented in chapter 2.2. and are also the basis of the Support Booklet's simplified methodology. In this way, the entire content of the Support Booklet was read and words related to the content of each topic were extracted to form the list of search elements.

It was found that the categories Road Safety, Infrastructure, Social Groups, Integration, Circulation Regulation and TPC Regulation by Machado (2019) can be directly related to topics II to VIII and X of the obligations required by the PNMU, thus their elements were added to the code elements extracted from the Support Booklet.

The 1176 elements from the data processing stage were counted and are distributed with: 169 occurrences for Public Transport; 233 in Road Circulation; 322 in Infrastructure; 91 in Accessibility; 20 in Modal Integration; 31 in Cargo Transport; 9 in Generator Pole; 173 in Parking Lots; 4 in Access and Circulation; 67 in Financing Mechanisms and Instruments and 57 occurrences for Assessment and Update. To verify whether the PMUs in each municipality meet the minimum requirements stipulated in Law nº12.587/2012, the results obtained were organized by municipality and corresponding code and are presented in Table 1.

Table 1 - Number of Occurrence: Code x Municipality. Source: author (2023).

	Aracati (CE)	**Currais Novos (RN)**	**Entre Rios (BA)**	**Limoeiro do Norte (CE)**	**Paulo Ramos (MA)**	**Serra Talhada (PE)**	**Vitória do Mearim (MA)**	**Zé Doca (MA)**
Public Transport	80	6	12	20	2	17	3	29
Road Circulation	92	6	13	52	10	32	2	26
Parking lots	97	4	3	26	10	17	1	15
Infrastructure	198	6	7	64	7	23	2	15
Cargo Transport	2	1	3	5	-	8	1	11
Financing Mechanisms and Instruments	51	1	4	1	2	1	1	6
Assessment and Update	25	1	11	12	-	6	-	2
Accessibility	29	3	9	17	4	23	4	2
Generator Pole	2	-	2	2	-	1	-	2
Modal integration	10	1	-	1	1	6	-	1
Access and Circulation	-	-	2	-	-	2	-	-

The codes Accessibility, Road Circulation, Parking, Infrastructure and Financing Mechanisms and Instruments were recorded in all plans analyzed. Cargo Transport was not registered only in the PMU of the city of Paulo Ramos. Assessment and Update and Modal Integration was not present in the plan of two municipalities and no Generator Pole element was not registered in three plans in the sample.

The Access and Circulation code was the least recorded in the research, being present only in the PMUs of the municipalities of Entre Rios and Serra Talhada, with two occurrences in each plan.

The analyzes carried out in this work are not intended to establish statistical correlations between the codes and elements sought, but to offer aspects, clues and trends that can guide future research on the topic. As only the PMU in the municipality of Serra Talhada, Pernambuco, presented at least one occurrence of all the codes sought, it is concluded that only this municipality addresses all the minimum content required in Law nº12.587/2012 in light of the proposed methodology.

Regarding the methodology presented by the Support Booklet, only the municipality of Aracati presents the four suggested stages: diagnosis, objectives, goals and strategic actions. The plans for Currais Novos, Entre Rios, Limoeiro do Norte and Paulo Ramos mention the need to carry out the diagnostic stage to achieve the proposed objectives, but do not provide or inform how to obtain data from this stage. Although not mandatory, the Support Booklet and other instruments made available by the federal government suggest the establishment of the PMU through some legal instrument such as a law or municipal decree and only the municipalities of Aracati and Vitória do Mearim did not comply with this suggestion. Table 2.

Table 2 – Characterization of the cities in the sample. Source: Author (2023) based on the IBGE 2022 Census.

UF	Municipality	Population	Territory [km²]	PMU pages	Returned Elements
BA	Entre Rios	38,098	1,187.77	19	66
CE	Aracati	75,112	1,227.20	498	586
CE	Limoeiro do Norte	59,560	744.53	44	200
MA	Paulo Ramos	20,341	1,168.61	36	36
MA	Vitória do Mearim	30,805	716.72	3	14
MA	Zé Doca	40,801	2,140.11	11	109
PE	Serra Talhada	92,228	2,980.01	17	136
RN	Currais Novos	41,318	864.35	5	29

The city of Aracati (CE) presented 586 occurrences, being the highest number of results in the search. Next we have the municipalities of Limoeiro do Norte (CE) and Serra Talhada (PE) with 200 and 136 occurrences, respectively. Regarding the number of PMU pages, the city of Aracati (CE) also has the largest plan, with 498 pages. The difference between the plans for the next two cities is more than 450 pages, with Limoeiro do Norte (CE) having 44 pages and Entre Rios (BA) having 19 pages.

The large difference between the number of pages of the plans analyzed can be explained by Aracati and Limoeiro do Norte having benefited from the Urban Development Program for Regional Poles of Ceará, promoted by the Secretariat of Cities of the States of Ceará, which allowed the obtaining of

financial resources for hiring consultancies and consortia to prepare the PMU (CEARÁ, 2023). The PMU in the city of Aracati was carried out by IDOM Consultoria Ltda. hired in 2016 by the Secretariat of Cities of the State of Ceará to advise the municipalities of Sobral, Coreaú, Forquilha and Aracati in the preparation of their plans (CEARÁ, 2016).

The city of Limoeiro do Norte had its PMU updated by the Prodeurb Ceará Consortium, made up of the companies Tecnotran Engenheiros Consultores Ltda., Instituto da Mobilidade Sustentável – Rua Viva and Cadaval Arquitetura e Urbanismos Ltda, contracted by the government of the state of Ceará through contract nº.028/CITIES/2016 to assist in the preparation and updating of PMUs in the municipalities of Jaguaruana, Quixeré, Massapê, Santana do Acaraú, Irauçuba, Russas, Morada Nova, Limoeiro do Norte, Tabuleiro do Norte and Jaguaribe (CEARÁ, 2018).

The cities of Paulo Ramos (MA) and Vitória do Mearim (MA) are the cities with the PMUs with the lowest number of pages, 4 and 3 respectively, and with the smallest population, approximately 20 and 31 thousand inhabitants. Vitória do Mearim is also the city with the fewest results, with only 14 words divided between seven of the eleven codes searched.

CONCLUSIONS

As around 1,865 municipalities are required to develop and approve the PMU (BRASIL, 2023), the full reading of its texts to verify the content and adequacy to the requirements of Law nº12.587/2012 appears to be an unexecutable form by the government, as it would require a lot of reading and analysis time for a team, in addition to allowing subjectivity in the examiner's interpretation because, as we have seen throughout this work, the plans do not have a uniform structure, presentation or number of pages.

The content analysis methodology proposed by Machado (2019) and used in this work presented itself as a valid option for verifying PMU content in a massive and impersonal way. By searching for words throughout the text using qualitative data analysis software , full reading of the plans is not necessary and allows the analysis of many pages in a few hours.

In this work, more than 600 pages from eight different mobility plans were analyzed in less than eight hours, considering the stage of processing the results obtained, excluding terms that did not fit the expected context. Among the words most returned by the MAXQDA software we have sidewalk with 201 returns, parking with 157 and public transport with 87 results. The word sidewalk belongs to the Infrastructure code, which was the most cited among all the plans in the sample, 322 occurrences.

However, during the research, the need to include a code calibration step was identified to include synonymous terms that were not considered in the first search because they were not cited in the Support Booklet or in the work of Machado (2019), such as bicycle parking in the same direction as the bicycle rack and traffic restrictions in the same direction as the circulation restriction.

It is worth noting that the lack of uniformity in the presentation of plans was a limitation for the tool used in the content analysis methodology. As explained in chapter 3.1. and 3.3. five PMU located were not read by the MAXQDA software because they were files identified as images and not text.

The establishment of the PNMU through Law No. 12,587/2012 was a milestone for Brazilian urban mobility. Following its sanction, municipalities now have legal support to prioritize non-motorized transport over motorized transport and public transport over individual transport, potentially reversing years of investment and prioritization of individual motorized transport in urban centers.

As the Ministry of Regional Development informs that it does not carry out any evaluation of the content of the PMU, the results presented in the survey on the situation of the Urban Mobility Plans are merely a compilation of the information sent by city halls through letters sent by SEMOB (BRASIL, 2022), The present work proposed as its objective to validate the PMU content analysis methodology proposed by Machado in 2019, using as a search basis for analysis the content of the Booklet to support the development of urban mobility plans for municipalities with up to 100 thousand inhabitants developed by the federal government. To validate the methodology, one of the specific objectives was to verify the alignment of the minimum content required by Law nº12.587/2012 and the Support Booklet.

As the Support Booklet presents the eleven topics described as mandatory by Article 24 of Law nº12.587/2012 and a simplified four-step methodology (diagnosis, objectives, goals and strategic actions) it was verified that this tool made available by the federal government and the PNMU requirements are aligned.

It was found that the coding proposed in this work to search for the minimum content of PMUs and presented in Table 3 proved to be an initial reference for evaluating the content of PMUs in small municipalities, as the use of words and synonymous terms that were not present in the Support Booklet or in the coding proposed by Machado (2019).

The methodology proposed by Machado (2019) proved to be efficient for identifying the minimum content required by Law nº12.587/2012 since a calibration step of the search codes was added to add synonyms for the searched terms.

Therefore, it is proposed as a suggestion for future work the inclusion of the calibration stage of the search elements to include words and terms similar to those already searched, with the calibration being able to be performed more than once after the data processing stage, including the terms analogous to the corresponding codes, running the search again for each code and processing the data once again before starting the process of categorizing and counting the number of occurrences.

ABSTRACT

Vienna's present municipal territory covers over 150 historic villages with medieval and early modern origin; the majority of these can be categorized as linear settlement types, mostly Straßen- or Angerdörfer. While some of these villages have been completely absorbed by the city, others are still clearly recognizable in their original form. Although the degree and type of transformation varied, their functional role within the urban texture is fairly comparable: they currently either serve as an urban sub-centre or a development axis.

The study aims to investigate these historic settlement sites in various regions of Vienna, ranging from the Vienna Woods' foothills and valleys to the plains of Transdanubia. The analysis includes villages that have manged to structurally survive on the fringes of the city, villages that have been integrated into the urban street network while maintaining their unique structural and functional characteristics, as well as the highly urbanized and assimilated assemblies. The focus hereby lies on the comparison of several parameters, including historical farmhouse types, property cadastre information and the different village layouts. The evolution or persistence of these features over the last 200 years is traced using map sequencing in four selected time frames.

The papers' intention is to illustrate how these structures have changed over centuries and to reveal potentials for their further development. It is crucial to have a fundamental understanding of these villages, their forms and functions, and how they have been incorporated into the urban texture; especially in the context of ever-growing cities, that are expanding beyond their historical borders and continuing to absorb rural structures into their fabric. The development in recent (international) urban history emphasises the high relevance of urban morphological knowledge; not least because of this we are deeply convinced, that this insight ultimately will help determine a course of action for the discussed historic structures' structural and functional activation as well as their climate-friendly adaption.

Keywords: Vienna, linear settlement, rural settlement, urban fringe/periphery, permanence & persistence, cultural heritage

INTRODUCTION

Vienna is defined by a compact and dense urban structure, which mainly results from urban development processes in the 19th century. Especially in the second half of the 19th century, the urban area west to the Danube, where the city centre is located, underwent two significant major urban expansions (Stadterweiterungen), in the years 1850 and 1890, which still define today's cityscape in terms of urban layout and architecture. These urban expansions correlated with a rapid increase in the population, and made Vienna one of the largest metropolises in the world with over 2 million inhabitants around 1910. In the course of these urban developments, pre-established historic suburbs (Vorstädte) and agricultural villages (Vororte) of the former hinterland, were incorporated and gradually remodelled over time.

With the regulation of the Danube (1870-1875) – which until then had been a highly unpredictable and therefore dangerous river, meandering relatively erratically through the hinterland, constantly changing its course and regularly flooding the surrounding area – and the subsequent construction of new bridges, the city was able to expand beyond the former topographical and hydrographical lines and to incorporate the land to the east. Thus, although the first urban agglomerations had already emerged in this part of the city around 1900, the area east of the Danube mainly developed in the 20th Century.

The originally rural areas around Vienna were characterised by linear settlement structures that were later incorporated as the city grew outwards. The analysis of the preconditions for the development of these linear settlements has been performed in Vienna (Tobisch/Loeschenbrand/Psenner 2023) as well as in the nearby Pannonian Basin (Loeschenbrand/Tobisch/Psenner 2023) in earlier works. Thereby, the significance of socio-political processes in colonisation, as well as the significance of geographical factors such as topography, proximity to water, and prevalent wind direction could be demonstrated.

Figure 1. Typical linear Settlement with farmsteads along a main street, the Gründerzeit developments in the background indicate the approaching urbanisation. Ottakringerstraße (Stauda 1903, ONB: data.onb.ac.at/rep/BAG_1903875)

For the in-depth morphogenetic analysis of the linear settlements, a historico-geographical approach is employed, which consists of the analysis of these villages through time using a chronological sequence of maps. (Kropf 2017:18) This process is illustrated on the basis of 6 villages[49] using four selected time frames. Next to the current perspective, the following time frames were considered: Franziszeische Kataster[50] 1817-1829, Franzisko-Josephinische Landesaufnahme[51] 1869-1887, Generalstadtplan[52] 1912. These time periods were selected because the corresponding map material is based on reliable national surveys and was recorded with sufficient accuracy. Up to now, the study primarily focuses on the developments of the 19th century; later time frames from the 20th century will be included. Especially interesting insights to the genesis of the built structure are expected with the analysis of the plans of the second half of the 20th century, when with the beginning of a general motorisation the increasing number of cars brought about a major urban transformation.

[49] The six villages discussed in this paper are examples from the east and northwest of Vienna. To complete the overall study, Vienna's south will be analysed in the winter term of 2024/25, keeping the methodology and the research-led teaching approach identical. Nonetheless, the research conducted thus far offers initial results on the morphogenetic development of Vienna's linear settlements as well as on the typological genesis of rural building typologies in an urban context.

[50] Historical cadastral map decreed in 1817 by emperor Franz 1st for the purpose of enabling uniform taxation based on land and building ownership in Cisleithania, the cadastre was finished in 1861.

[51] The third military survey of the Habsburg monarchy was conducted 1869-1887, it was initiated by emperor Franz Joseph 1st and portrayed the entirety of Austria-Hungary.

[52] The general city plan, portraying the entirety of the municipal area of Vienna at that time.

Figure 2. Overview of Vienna with district boundaries and the investigated villages. ©Loeschenbrand/Tobisch/ Psenner.

Following Conzens categorisation of the urban form, the selected settlements are considered in their basic elements: The streets and the resulting network, the plots and their configuration into blocks, and the buildings themselves. (Conzen 1960) The development of these elements, their preservation, their change or their disappearance over time is traced documented in the analysis. In line with the authors of the *Atlas du Territoire Genevois* (1993), we use the following terms – originally French – in relation to the precise definition of the preservation of historical structures: *structural permanence* and *structural persistence*. The atlas provides a precise definition and differentiation of the two terms:

The six villages discussed in this paper are examples from the east and northwest of Vienna. To complete the overall study, Vienna's south will be analysed in the winter term of 2024/25, keeping the methodology and the research-led teaching approach identical. Nonetheless, the research conducted thus far offers initial results on the morphogenetic development of Vienna's linear settlements as well as on the typological genesis of rural building typologies in an urban context.

Historical cadastral map decreed in 1817 by emperor Franz 1st for the purpose of enabling uniform taxation based on land and building ownership in Cisleithania, the cadastre was finished in 1861.

The third military survey of the Habsburg monarchy was conducted 1869-1887, it was initiated by emperor Franz Joseph 1st and portrayed the entirety of Austria-Hungary.

The general city plan, portraying the entirety of the municipal area of Vienna at that time.

Permanence is defined by the "invariable character of an element" (Léveillé et al. 1993: 10), when cadastral lines precisely overlap and elements have the same position, form, and size.

Persistence is determined more by change. The Atlas gives the following examples on the subject of persistence: elements that replace and take over the position in a property; cadastral lines that roughly match but are neither permanent nor disappearing; a trail that becomes a street or road but still stays on the same path/route; a sequence of plot-lines that, for example, depicts a canalized watercourse (ibid.: 10).

The transformation of the street network has already been of earlier studies, which demonstrate that a majority of the historically relevant links are characterised by either permanence or persistent and can therefore still be identified in today's street network. (Loeschenbrand et al. 2024)

When it comes to a typological analysis the chosen examples of Vienna's linear settlements can be broadly categorized as either the type Angerdorf or the type Straßendorf. The paper does not cover detailed definitions and explanations, nor does it encompass every subtype description. However, both kinds depict compact village structures, which are additionally distinguished by a degree of linearity. While the main street serves as the spine of a Straßendorf, a centrally positioned open area surrounded by side streets forms the core of an Angerdorf – e.g. Leopoldau, Fig. 5 ,The plot or building structures are identical in both settlement types.

Research Project

The paper looks at the specifics of the different incorporation processes, the typological changes that occurred within the villages in terms of architecture, and the morphological remnants that may be observed in the current property parcelling. The study on which this text is based is carried out as part of the international DUT research project *EMC2 - The Evolutive Meshed and Compact City*[53], which – on a national level – is addressing the spatial development of Vienna's periphery and urban fringes (Loeschenbrand et al. 2024, Tobisch et al. 2024). From an urban morphological perspective, it is obvious that in order to anticipate future developments it is necessary to know the history and evolution of urban structures in detail. Therefore, an in-depth knowledge of the morphogenetic processes and the spatial development of these zones is required; for this reason, the paper provides

BACKGROUND

Dynamics in 19th century Vienna

The primary observation period for the map sequencing with four-time frames is the 19th century. In this period, Vienna experienced a number of notable social, economic and spatial transformations, that continue to strongly influence the cityscape and urban layout today. Especially in the second half of the 19th century a rapid increase in population led to over 2 million inhabitants by 1910, which made Vienna one of the largest cities in the world at the turn of the century (Psenner 2023, 36f). This was connected to major urban development interventions and essential infrastructural initiatives, such as several bridge and railway projects and the regulation of the Danube in the early 1870s and the levelling of the entire terrain (Psenner 2018 and Psenner 2023, 38f). The newly developed areas *(Stadterweiterungsgebiete)* on the outskirts of the city followed a radially-concentric logic. Within just four decades the two city fortifications – the inner city-wall and the outer wall *(Linienwall)* – were

[53] In the transnational research project *EMC2 - The Evolutive Meshed and Compact City*, we are working together with partners from France, Italy and Sweden on the feasibility of translating Carlos Moreno's 15-minute city concept to the urban periphery. The urban fringes in Gothenburg, Nice, Lille and Vienna are being analysed, as well as the *Zwischenstadt* landscape on the Ligurian coastal strip between Massa and Viareggio. At the national level, we are working on a deeper understanding of Vienna's peripheral zone by means of specific morphological studies and analyses. The national team is based at the Institute of Urban Design and Landscape Architecture, at TU Wien and is working on the issue of the "evolutive mesh" around Vienna under the lead of Angelika Psenner: https://urbanism-tuwien.at/forschung/projekt/emc2 und https://emc2-dut.org[53] Some of the used data and material was produced as part of research-led teaching at the Institute of Urban Design and Landscape Architecture at TU Wien. The taught and applied working methods are explained in detail in the methods chapter.

demolished and prestigious projects such as the *Ringstraße* – which was not so much a street as a ring-shaped urban development area with a central, all public buildings embracing boulevard around the inner city-centre – were realized. Horse-drawn and later on electrified trams and railways were introduced. This new public transport system was constantly improved by increasing the speed and the manageability of greater distances and thus promoting the expansion of the city.

These developments had an increasing impact on the surrounding linear settlements discussed here. With regard to their agricultural use the geographers Hans Bobek and Elisabeth Lichtenberger in their fundamental work on Vienna's "bauliche Gestalt und Entwicklung" distinguish between *Weinhauer-dörfer* (villages with vineyards) in the west (Bobek/Lichtenberger 1978: 67) and *Ackerbaudörfer* (villages with arable fields) in the south and east (ibid.: 254). The regions to the west and east of the city are relevant to this paper. Around 1840 there were two different types of linear settlements in the west of today's city area:

Villages that were located closer to the former city limits of Vienna, that had already shifted away from wine to increased milk production in the 18th century and developed into early holiday destinations for the summer. Subsequently, these villages experienced intense densification and commercial enterprises often settled there – such as the linear settlement *Penzing*.

A number of Linear settlements in a more peripheral location near the Viennese woodlands, which were also characterised by an increased dairy farming. They were often used as summer resorts for the bourgeois and aristocratic class, their urbanisation is therefore mainly dominated by country houses (ibid.: 67).

In general, various urbanization processes with different typologies can be observed in the context of the linear settlements in the 19th century, from the progress of grid structures, e.g., in the surroundings of *Ottakring* (ibid.: 99ff) to groups of villas and row houses (ibid.: 102ff).

With the new eastbound bridges and the regulation of the Danube in the 1870s, the city of Vienna was finally set to expand to the east. Some of the historical linear settlements, such as *Stadlau*, were used as bridge-heads, where urbanization processes started and industry settled (Bobek/Lichtenberger 1978: 102ff). The linear settlements in peripheral location were expanded with lower densities and with row houses (ibid.: 103); over some time, they largely retained their rural character.

Building types in Vienna's linear settlements

Originally, linear settlements were made up of mostly single-storey farm buildings, which were lined up in a regular pattern left and right of the central street. The special shape of the distinctively deep and narrow plots was formative for the architectural form of the buildings and their spatial configuration. In the 6 linear settlements analysed in the study, plot widths of 13m, 15m, 20m, and 30m were identified.

Although the Straßendorf could theoretically be extended relatively easily in length, the majority of plots – which originally measured a relatively uniform 30-35 metres in width (Dungl 1988: 44ff) – were divided, particularly in the estate process: they were often halved or quartered in length. Thus, in the second half of the 15th century the province of Lower Austria, which surrounds the City of Vienna was dominated by such *Viertellehen* and *Halblehen* (Grüneisen 1979: 90, cited in Dungl 1988: 44). Over the centuries, armed conflicts, fire and several major floods led to repeated destructions within the linear

settlements in the Vienna basin, but in most cases, they were constantly rebuilt or occasionally newly laid out (Hinkel 1994: 13).

First relevant studies on the classification and typologization of the here discussed Lower Austrian village structures and the corresponding farm-building types were carried out in the 20th century. The work of Adalbert Klaar with the "Siedlungsformenkarte" (1942) and the book "Die Siedlungsformen Wiens" (1971) provides a significant foundation for the Austrian context. With further work by other scientists, multiple definitions of individual farm house types emerged. As for example, Klaar defines the building footprint of the *Zwerchhof* as a C-shape (Klaar, 1942: 27), whereas the architect Klaus-Jürgen Bauer, describes it as being a L-shape (Bauer, 2023: 161). Regional differences in understanding; e.g., the aspect of whether a cross-standing barn is still counted as part of the main building footprint, can be explanations for different interpretations. Bauer also often describes the Zwerchhof as the result of a later expansion of a former *Streckhof* (Bauer, 2023: 161), which addresses the aspect of the structural adaptation and genesis of building structures and farm types.

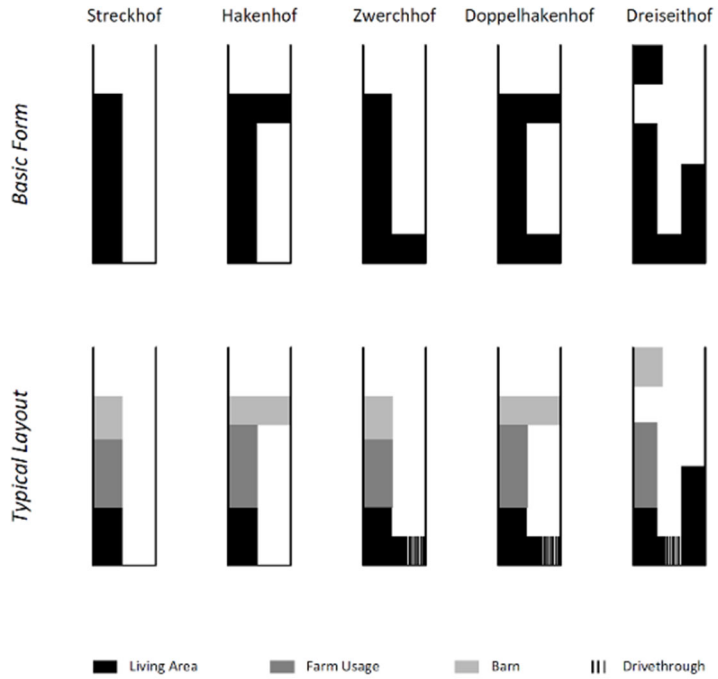

Figure 3. Basic form and configuration of the typical farmstead types ©Loeschenbrand/Tobisch/Psenner.

The following building types determined the characteristic farm houses in the chosen research field in and around Vienna: Streckhof, Hakenhof, Zwerchhof, Doppelhakenhof, Dreiseithof. The aim of this study was to carry out a simplified typological categorisation of the farmstead types present in the case studies on the basis of the respective building floor plans. This requires a clear definition of the types, which, however, often cannot fully take into account the complexity of ground plans and their genesis or the precise but sometimes differing definitions of Klaar, Bauer or Kräftner (1987). In our research we use the following list of structural building types; with the corresponding catalogue of features:

The Streckhof is a narrow, rather elongated building, with a living area oriented towards the street front; with an agricultural usage behind this and the stables extending parallel to it – always in the same alignment.

The *Hakenhof* type results when the barn is rotated by 90° thus creating an L-shape ground floor plan.

Bauer's definition is adopted for the *Zwerchhof*: a Streckhof that is extended to the street side with a transverse building – again an L-shape, but mirrored.

The *Doppelhakenhof* means that there is a transverse building on the street side as well as in the backyard, thus resulting in a C-shape.

The *Dreiseithof* type also forms a C-shape. According to Klaar (1942: 26) and Kräftner (1987: 116), his courtyard opens up towards the main street and is closed by a gate. The examples in our research area, however, show a mirrored situation, where an attached building is positioned along the streets, with two further side-buildings extending into the interior of the plot.

Other renowned building types related to linear settlements such as the *Gassenfronthaus* or the *Weinhauerhaus,* were not taken into consideration individually because their floorplan layout does not differ significantly from the farm types already described. The Weinhauerhaus comes in various forms and – according to Kräftner – lacks a clearly set arrangement (Kräftner 1987: 140). Kräftner describes the Gassenfronthaus as being the "latest organic farm house type to be progressively developed, where traditional building types have been merged with new ideals and requirements to a new symbiosis" (ibid.: 132; translated by paper authors). Here the living area is oriented towards the street side. After 1850 the Gassenfronthaus increasingly replaced existing farm types, such as the Streckhof, Hakenhof or Zwerchhof (ibid.:132ff).

The Viennese farmstead types

Building typology studies on farmstead types such as the Streckhof or Zwerchhof generally focus on rural areas in the surrounding of Vienna, primarily in the provinces of Lower Austria or Burgenland. Although these studies can also be applied to Vienna – since historically speaking the linear settlements in today's Vienna urban area were located in Lower Austria until the end of the 19th century – an explicit Vienna-related discussion on the villages and their building types is missing. For this reason, in-depth research was necessary, in which we analysed a selection of 20 buildings in detail in the 6 villages covered here. The relevant planning documents were retrieved from the building authority archives – this alone being a rather time-consuming task – and their genesis analysed in detail. The aim was to gain an understanding of the specific local building configurations and floor plans in comparison to the prototypical floor plans (Fig.3, Fig.4), to obtain an overview of morphogenetic developments of Viennese farmstead types and in this way to gain a relevant initial assessment of those special building types for the main study.

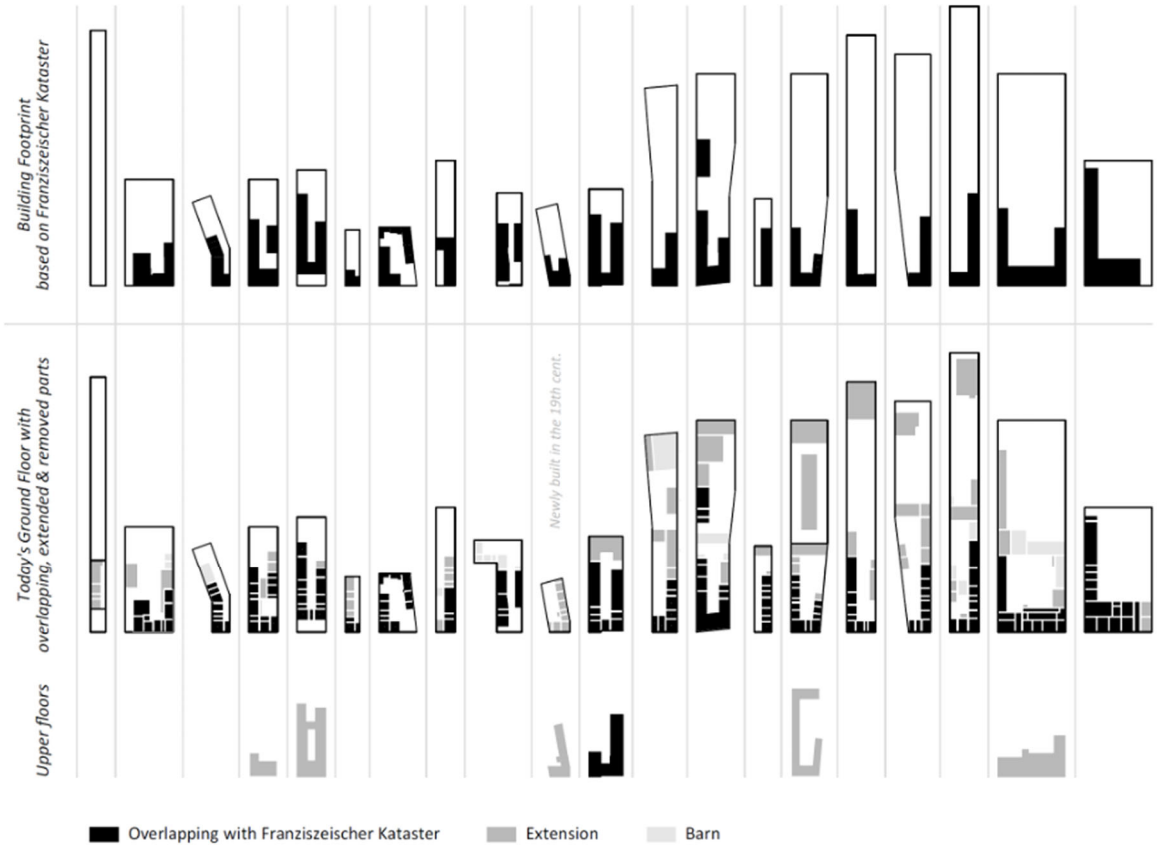

Figure 4. Illustration of the building genesis in relation to the Franziszeische Kataster; based on the 20 selected building examples in our 6 case studies. ©Loeschenbrand/Tobisch/Psenner.

The entire archive file repertoire of over 20 objects was taken into consideration and the individual conversions, extensions and modifications that emerged from this analysis were examined. The oldest planning documents still available date from to the 1870s, with plans from a *Gassenfronthaus*. Other than that, plans of conversions in the 19th or 20th century, often including sewer plans for the respective properties[54], provided insights into the organisation of the floor plan. This procedure made the individual development stages of the buildings visible; and ultimately abstracted and schematic floors plans were created on the basis of those findings (Fig.4).

Since original planning documents or drawings of the respective buildings were not available, because of the distinctly rural character of the original settlements – far away from the meticulous administrative power of the capital – the schematic floor plans were compared to the building footprint based on the Franziszeische Kataster (1817-1829). The black regions in our illustration (Fig. 4) represent the floor plan sections that overlap with the Franziszeische Kataster, the dark grey areas represent the building parts that were added later, and the light grey colour code indicates the parts of the building that were removed (being mostly the wooden barns). This micro-level investigation and analysis reflects the variability and complexity within the farmstead types and provides initial insights into the morpho-genesis of the individual plots and farm structures. Even though this background research is not further part of the paper, it shows the potential for further research, e.g.,

[54] Especially as they localise the connection of the house sewer to the public sewer and thus allow conclusions to be drawn about the overall organisation of the building.

METHOD

Village morphology & building types

The morpho-genetic development of the selected historical linear village structures is analysed on the basis of four observation periods: beside the current state, 3 historical states were selected: Franziszeische Kataster 1817-1829, Franzisko-Josephinische Landesaufnahme 1869-1887, Generalstadtplan 1912. On a quantitative level, the mere extent of the preserved historic building structures and farmstead types – or parts thereof – was recorded. In addition, a qualitative evaluation was made of how the historical buildings have developed typologically, i.e. not least in terms of utilisation structure, with a focus on the farm types (in the sense of building typology).

The paper describes a work in progress: the investigations carried out so far cover the linear settlements in the east and north-west of Vienna. Surveys of those in the south of Vienna are currently being prepared and will be carried out in autumn – for this reason, the latter are not yet the subject of this text. Three villages each from the northwest and east were selected – NW: Untersievering, Ottakring and Penzing; E: Großjedlersdorf, Leopoldau and Stadlau. In order to present a comprehensive picture, the selected linear settlements were to reflect as many different conditions as possible, from a strongly preserved village character to heavily transformed and urbanized structure.

The analysis of the villages was carried out together with students from the TU Wien: in a seminar designed as research-led-teaching, each student analysed one linear settlement.

For this research activity a common standard with plural work steps were defined: the teaching supervisors (us researchers) predetermined this standardised method in advance in a corresponding pre-test. The students' work was continuously checked and corrected if necessary. The aim was to identify historical buildings and farmstead types on the basis of the building footprints. Due to the inaccuracy of the original map material, a certain bias (interpretation errors and imperfections) is to be tolerated in individual cases in this approximation.

In a first step, the linear settlements were vectorized on the basis of the *Franziszeische Kataster* and the individual farmsteads and buildings were assigned typologically due to their building footprint: Streckhof, Zwerchhof, Hakenhof, Doppelhakenhof, Dreiseithof, other, special objects, outerbuildings and context. In order to narrow down the observation area of the individual linear settlements, a 15-minute catchment area was determined using the demo version of the Travel Time web application (Fig.5). The category *other* was set in order to indicate buildings with footprints that cannot be clearly assigned. The category ‘special objects’ represent churches, monasteries, vicarages or castles.

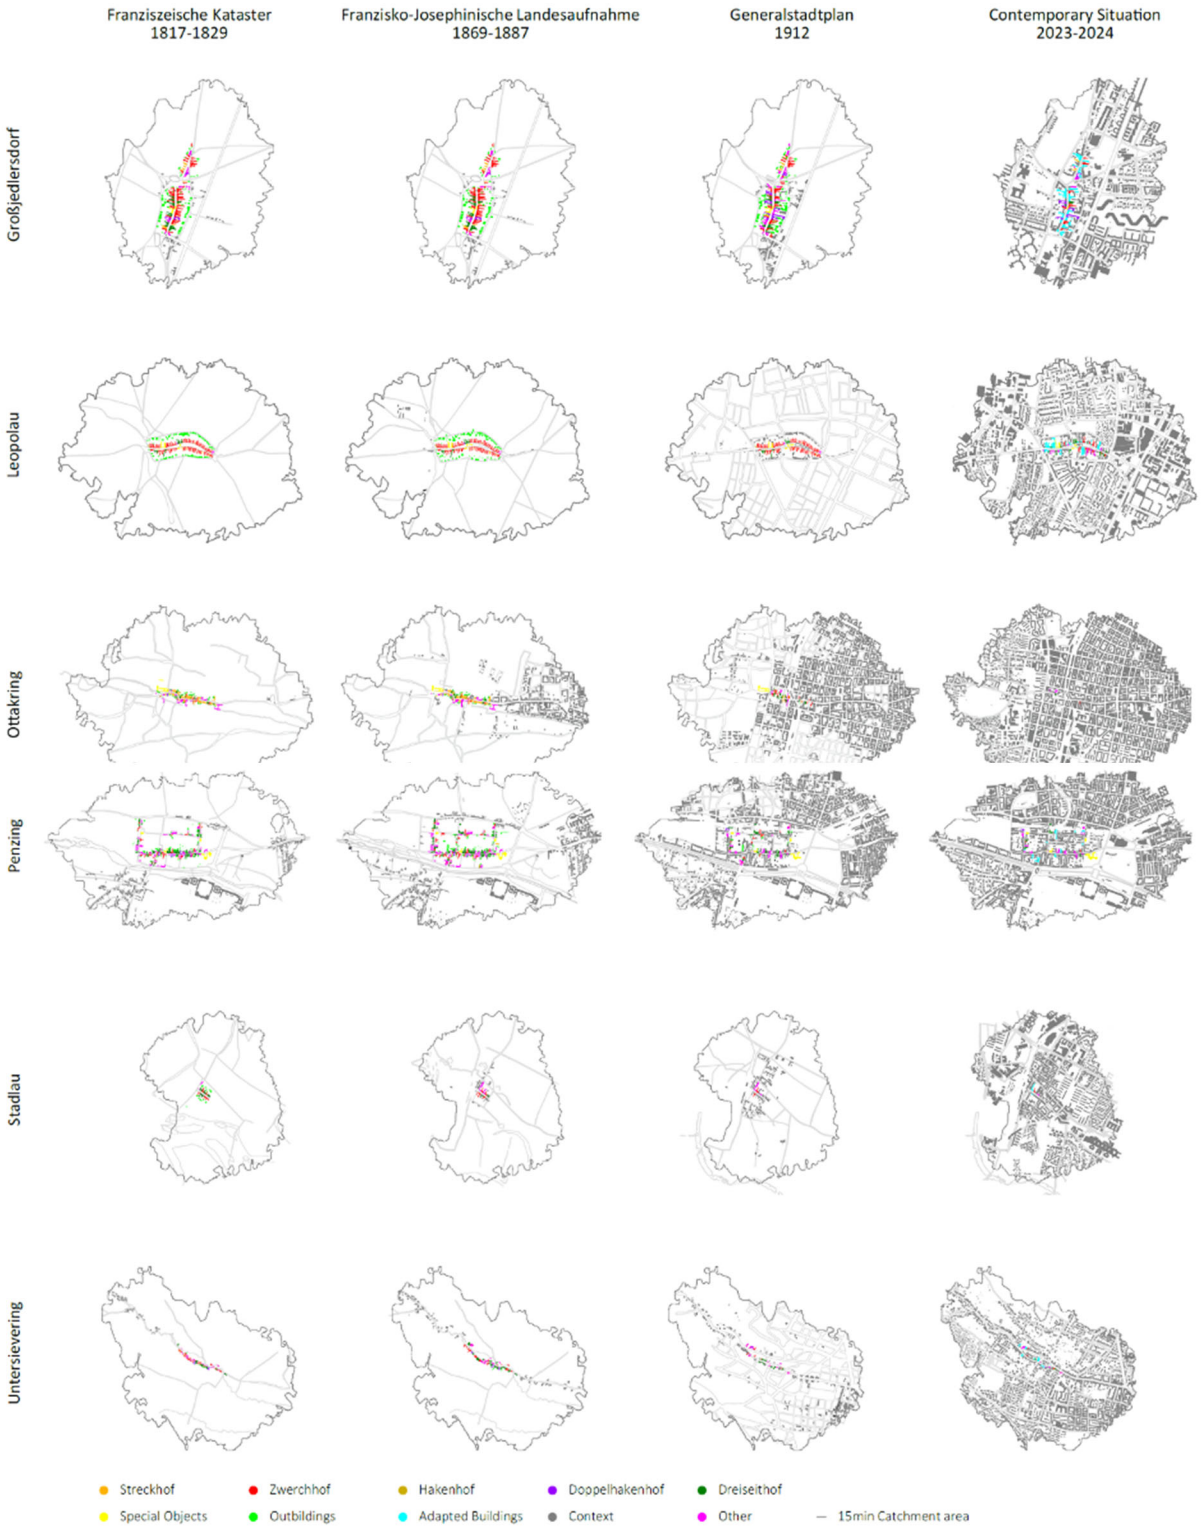

Figure 5. The graphic representation of the 6 linear settlements in the four periods analysed with their respective typological classifications. ©Loeschenbrand/Tobisch/Psenner.

This categorisation was followed by a comparison with the *Franzisko-Josephinische Landesaufnahme* (1869-1887) and the new vectorization and typological classification. This principle was repeated in the next two time frames. For the final analysis, the current state in the 2020s, the category *adapted* was added. The intention was to identify farmstead types which, despite their historical components,

have changed so much in the course of conversions or extensions in the 20th and 21st century that they can no longer be regarded as original. On-site surveys and digital map services were used to determine the category *adapted* (Fig.6).

Figure 6. Evaluation of the collected data for the six linear settlements. *©Loeschenbrand/Tobisch/Psenner.*

Structural permanence respectively persistence on a plot-level

In the second phase of the analysis, the overlaying of plans was used to determine the extent to which historical layouts of plots and parcels in the immediate surroundings of historical linear settlements can still be found in today's cadastral plan. For this purpose, the vectorized version of the *Franziszeische Kataster* was overlaid with the current land cadastral plan of the City of Vienna[55], and compared with each other.

A rectangle of 1500 x 1000 m (150 ha) was defined around the 6 selected villages as observation area. Two levels were examined: Firstly, the extent to which plots and properties have been preserved and are still characteristic – shown as a framed area. Secondly, the extent to which today's paths or roads can already be found in the *Franziszeische Kataster* as paths, roads or plot boundaries – shown with a dashed line.

RESULTS AND DISCUSSIONS

Village morphology & building types

The linear settlements surveyed in their historical form vary in terms of size and scope: Leopoldau and Ottakring consist of about 100 buildings. Großjedlersdorf and Untersievering are half the size with about 50 objects. Penzing – with 150 buildings – is a special case, as there are additional buildings along the cross streets in the direction of the main road running parallel to the north, whereby the settlement centre (running west-east) corresponds in size and length to a linear settlement with 100 buildings. Stadlau, as a second special case, represents a small linear settlement structure with 12 farm buildings.

In order to investigate the question of permanence or persistence and to clarify the extent to which historical building patterns and typologies are still reflected in the cityscape, two parameters were determined. Firstly, what is the percentage of historical buildings in today's streetscape?[56]. For the

[55] They are both available on the website of the City of Vienna at https://www.wien.gv.at/kulturportal/public/ and https://www.wien.gv.at/flaechenwidmung/public/.

[56] The survey is carried out once with and once without taking into account the category *adapted.*

evaluations, only the buildings along the main street within the historic village boundaries were taken into account. Including the category *adapted*, Großjedlersdorf with 87% and Leopoldau with 72% are still strongly characterized by historical buildings and patterns. without the *adapted* category, the value for these villages is 40-50%, which indicates a comparatively high proportion of historic buildings with a building footprint similar to the original farmstead types. The example of Ottakring illustrates how, in the course of new urban development processes in the 19th and 20th centuries a historic linear settlement structure has almost completely disappeared, with only individual properties creating relevant points of reference. If it was not for the large residential buildings in Ottakring, which count as one object in the statistics, the figures - now 11% and 6% – would be even lower. Penzing, Stadlau and Untersievering are still characterized by about a third of historical structures, if the adaptions are taken into account – without the value being around 20%.

Secondly, the number of historical buildings excluding adaptions and the *context* category was compared with the building stock of the period 1817-1829. The results roughly correspond to the assessment of the percentage of historical buildings (excl. adapted ones) in today's streetscape. However, the aforementioned aspect of the influence of large residential structures in Ottakring is recognizable here – this value is now 2%.

With regard to the development curves in the individual linear structures, it can be stated that the linear settlements of Großjedlersdorf and Leopoldau, which retained their historical character the most, also show little structural development in the 19th century, with the major changes only taking place in the 20th century. For the most part, steady declines can be observed in the other village structures.

When looking at all six villages together, the Zwerchhof is by far the most prevalent style during the four time frames examined here. Many buildings of the category *other* have been found in Penzing and Sievering, making buildings of this category the second most common. The proportion of building layouts similar to the Dreiseithof, is also significantly high. There are hardly any Hackenhöfe in the 6 case studies. The percentage of significantly extended or transformed historical farmstead types, which was summed up in the *adapted* category, differs greatly in the six linear settlements.

Structural permanence respectively persistence on a plot-level

The evaluation of the overlay of the cadastral maps requires a more differentiated analysis. (Fig. 7) The high proportion of historical properties in Großjedlersdorf and Leopoldau is also reflected in the fact that the characteristically narrow elongated plot division – which is in no way comparable with the Gründerzeit plot grid – has been permanently inscribed in the city map. However, the original already narrow long plots were often divided into two or more plots, as described above. In this way, the former rear-sides of the linear settlements became new front-sides. In addition, there are plots and fields – most of which still agriculturally used – in the directly neighbouring areas of the respective observation areas of Großjedlersdorf and Leopoldau that still correspond to the parcels of 1829. Similarly, a large number of paths and streets around Großjedlersdorf and Leopoldau correspond pretty much exactly to the historic situation.

Figure 7. Overlay of the Franziszeische Kataster with the current cadastral map in the respective linear settlement. ©Loeschenbrand/Tobisch/Psenner.

The disappearance of Ottakring shows that most of the plots and properties in the area under consideration now represent other urban systems; which in the Ottakring case are increasingly

organized in (Gründerzeit) grid structures. Penzing still has some areas that can be compared with the state of 1829. As in Großjedlersdorf and Leopoldau, the longitudinal plots have been halved or divided in some other way. With the addition of new streets, the original linear settlement of Penzing also increasingly developed into a grid system. The original plot structure of the linear settlement of Stadlau is still recognizable today, although here too the long parcels have been divided into several plots. The geographical or topographical conditions in Untersievering and a comparatively low population density result in paths and parcelling largely matching the situation of the *Franziszeische Kataster*. Particularly in the peripheral Untersievering, for example, large parts of the parcels and paths or streets correspond to the situation in the *Franziszeische Kataster*.

CONCLUSIONS

As already stated, the research presented in this paper is part of an ongoing wider study. As part of this comprehensive research project, the first convincing representations of the morphogenetic processes were generated using the building footprint-based map evaluation procedure. The two-dimensional map analysis carried out here and the evaluation of the building floor plans (building heights were not taken into account, as the relevant data is missing) enabled an approximation of the actual building stock. However, the extent to which the architectural structures actually still correspond to historical building types, and whether they are permanent or persistent, requires further qualitative assessments, including those based on site inspections. The category *adapted* was therefore introduced as part of the map analysis.

We see the need to incorporate more qualitative aspects into the study, thus, the results of the background research concerning the Viennese farmstead types offer potential. In any case, this type-focused background research will also be carried out for the south of Vienna and thus expanded further. Irrespective of this, the first influencing factors and parameters that determine the level of transformation of linear settlement structures in Vienna have already crystallised:

- the geographical location,
- the spatial proximity to centres,
- the direct connection respectively the historic main road as part of today's primary network

appear to be decisive parameters for the degree of change and transformation of the villages studied. The overlay of the historical and current cadastral maps revealed initial findings and patterns, but certainly requires further investigation.

Despite various transformations, the linear settlements in Vienna continue to strongly characterize the cityscape of the outskirts and suburbs. They represent important facets of social identification in today's urban fabric. Therefore, when it comes to the spatial development of the urban fringes, these villages should be integrated in the best possible way without trying to preserve them in a purely visual heritage-like manner, but rather by maintaining or (re)strengthening their spatial qualities and their distinctive identity-building character.

This paper and the ongoing research contribute to recognizing and understanding the fundamental qualities of linear settlements.

Acknowledgements

The emc2 project is funded by ANR (France), FFG (Austria), MUR (Italy) and Vinnova (Sweden) under the Driving Urban Transition Partnership, which has been co-funded by the European Commission.

The authors would also like to thank the students participating in the four courses in question: Design studios 'Band—Netz—Stadt: Siedlungsstruktur und Linearität in Transdanubien' and 'Tal—Schluss—Stadt' and the seminars 'Kern—Band—Netz: Wiener Dörfer in Transdanubien ' and ‚Wiener Täler'. With special thanks to the students who vectorised the map sequences of the selected villages, namely: Luise Deumer (Großjedlersdorf), Maximilian Minihofer (Leopoldau), Bernhard Weiss (Ottakring), Ilai Debazi (Penzing), Maja Munck (Stadlau) and Cansu Dogru (Untersievering).

ABSTRACT

The Refugee Pattern Language for 'Palestine refugees and internally displaced people' IDP is an outgrowth of a larger project called: 'The Sugar in the Milk – A Refugee Pattern Language RPL.' While we are working on a generic (design, planning, and building) pattern language that addresses nine - twelve refugee domains with 12 patterns each, we are also conducting particular case projects with their own domains, such as patterns for Palestine and its displaced people. In this context, we found it necessary to explore and investigate beyond the refugee problem, just to understand this case in its historic, geopolitical, land, and peoplehood dimensions.

Starting with the assumption that the world would be a better place if made up of 'Independent Regions' or small countries with 5-20 million population, because larger countries tend to dominate smaller countries or they use smaller countries to serve their own larger geo-political interest. With the Palestine-Israel conflict, we have a highly complicated and complex socio-spatial case of almost biblical proportions, that urgently needs to be resolved, after a hundred years of war on Palestine, with hidden qualities such as the colonial settler system, supremacy, and apartheid as a system of control and domination of another group of people, thereby creating countless refugees. An emerging world order, as well as regional transformation within the Middle East, is considered a new promising tendency for finding a way towards the formation of an Independent Palestine. In this emerging configuration, Israel could be seen as an important 'Independent Region' by itself in transformation. This paper works with five patterns in the Pattern Language Method to start to address some of these problems: INDEPENDENT REGIONS - THE INDEPENDENT REGION OF PALESTINE - THE COLONIZATION AND OCCUPATION OF THE PALESTINIAN TERRITORIES - REFUGEES IN PALESTINE, THE WEST BANK, GAZA AND ADJACENT COUNTRIES – A HOUSE IS NOT A HOME.

The following guidelines provide instructions to format your full paper, specifically on the way how text should be formatted, table and figures captioned, and references cited. The conference proceedings will be published in an electronic format. The paper should be submitted in a Word document (.doc or .docx) and shall be written in accordance with instructions of Urban Morphology Paper Submission Guidelines.

Keywords: refugees, pattern language (pl), palestine-israel, independent regions, land and peoplehood

INTRODUCTION

We are thankful to the Sao Paolo ISUF conference organizers that they have acknowledged the notion of disruption as a major conference theme in addition to the three themes of continuity, expansion and reverberation. Disruption is referred to with the following sub-themes:

"1. Disruption: climate change, global warming, heat island, rising sea levels, pandemic, healthy cities, migrations, conflicts, etc." (ISUF Program, Sao Paulo, https://isuf2024.org/)

Destabilization, disruption and conflict need to be recognized at all levels of scale in the social-spatial world from global to local and including different modes and relevant causes and kinds of conflicts for different socio-spatial situations and events. While disruption has become a major issue on many fronts, it may be best understood in two categories, natural disruption, and man-made disruption, whereby disruption in nature is more often than not connected to man-made causes.

For the last 70-75 years, one lifetime, most parts of the world enjoyed the longest time of peace and prosperity. Over the last decade, this peace has come into question with the transitional process of an emerging multi-polar world, and accompanying conflicts and discrepancies. We must acknowledge that the world is in a period of transformation and restructuring, that shows up in many places on the surface of the earth, as well as the space above, and possibly hidden in the waters below. And we need to study these new transformations. https://www.youtube.com/watch?v=t-edUqSmkoI

Study and research: Overall, in our research and plans, we study spatial, social, and related life giving regions and cities, towns and neighbourhoods, building clusters, houses for refugees, gardens, and communities, as well as streets, parks, and public buildings. Furthermore, we focus on the processes that create and form these physical social and spatial urban settlement, with the pragmatic objective to create or recreate healthy urban and regional places for all, including refugees.

Preface

For the complex and complicated pattern language case 'The Palestine-Independent Region' PaIR, it seems appropriate to lay out foundations that place this research in a proper context of relevant subthemes, background, and premise.

1. Refugees: This paper is part of a larger enterprise of refugee pattern language research, that started seven years ago. The Refugee Pattern Language for 'Palestine's refugees and internally displaced people' is an outgrowth of an extensive project: 'The Sugar in the Milk – A Refugee Pattern Language RPL' with deeply humanistic aspirations. This paper includes limited history of the production of refugees in Palestine since 1948 and its unusual distribution into huge camps in the surrounding countries that required basic unpacking. (See Figure 7)

2. Investigation: The consequent investigation into the backgrounds of refugees and the ongoing base conflict revealed more and more facts, that have created a very difficult if not disturbing picture of a situation that needs to be corrected almost immediately. Here, eminent Jewish and Palestinian scholars, in particular, were indeed very helpful in revealing hidden or subdued dimensions, that are going unresolved since more than 80 years such as colonial settlement and its perils that one scholar calls an 'outdated business model.' (Richard D. Wolf)

3. Revealing Events: The events in Gaza with 39,000 people unnecessarily killed (July 25, 2024), had a particularly strong impact because they helped to slowly reveal a terrible amoral system of war crimes, genocidal tendencies, and brutal killings that anybody who followed the full view of events in Gaza and in the Westbank on tv and online, could evaluate and make up his own mind.

4. Furthermore, my background (HN) first as a German and later also as a US citizen have affected particular views that needed adjustments on several accounts since the Student Revolt 1966-74):

- German and US restrictive laws on criticizing Israel (i.e. artificial standards and laws).
- Student protests in Germany and the US for inner and outer liberation and freedom.

5. My hope for the new generation today, in particular the students in the two countries US and Germany, who have suffered from police and counter protesters physical violence, to keep a clear head and open mind, with an understanding of the double standard and hypocrisy of outdated laws, and ideological behaviour against free speech, freedom and liberation. It is the new generation of students who understand the big problems in the world with a fresh outlook on conflict, economic, and ecological issues. They want to solve outdated problems expediently to have time to deal with the real larger issues for survival on earth.

Disclosure

Our work in the last seven years on the ever-increasing and worsening problem of refugees worldwide has confronted us with new challenges, particularly in the complex Palestine-Israel case, starting with finding large refugee camps in Palestine and larger camps in surrounding countries of Israel-Palestine, since 1948. This fact alone has started to hint at a number of hidden dimensions that need unravelling beyond the challenge of refugees. Why are millions of Palestinian people still living in camp cities for 75 years in surrounding countries and occupied territories? Other facts that needed unpacking relate to Zionism, colonialism, as well as apartheid, landgrab and peoplehood (Finkelstein, N. 2024).

Here again, my background as a German citizen, is relevant, with moral and legal obligation to Jewish people and the Israel State, personally, and by ‘raison d’etat’ of the German Constitution, and other kinds of laws that are supposed to protect Jewish population against antisemitism and worse. While I have followed these rules freely since high school, recent questions that Germany’s official law in the constitution may not be the right way of addressing the problem of Palestine’s subjugation by Israel, culminated in the accusation of Germany’s complicity of ethnic cleansing and genocidal tendencies by Israel, is coming to the fore, at the international court of Justice ICJ in Den Haag. (Sharp, A. 2024)

As a citizen of the United States (HN,) I have more freedom, and access to pursue questions on the Palestine conflict than in Germany. But even here, there are various forces and players that try to hide their activities or try to create more laws to prevent open discourse that also needs unravelling i.e. some kind of McCarthyism tendencies. It became more and more important to shed light on these tendencies and ongoing events that have followed me since my childhood, some without proper answers. In contrast to Germany, however, the US provides more openness to pursue and discuss these issues, in large part because of Jewish and Palestine scholarship. Still, the biggest issue to be unravelled is the killing of 42,000 Palestinians as of October 25, 2024 in front of the world’s eyes and justifying this atrocity with the right of Israel security to defend themselves. How about Palestine?

Finally, I also have to ask how my primary interest as an architect and city planner in creating beautiful and peaceful places, buildings, parks and neighbourhoods, fits together with my interest in social justice and peace, well-being, health, prosperity, especially in extremely difficult socio-spatial situations such as the Israel-Palestine conflict. The quick answer to myself is that going from unjust to just, from destructive to peaceful is for me a continuum and equal to creating beauty in an ugly world.

METHOD

For much of the research on refugees the Pattern Language method is applied, largely because it is action-oriented in its base format of Problem – Discussion – Solution. In other words, if you do not have a solution or at least a suggestion, you do not have an action pattern. In addition, patterns are connected by links to create a larger format of supporting and connecting elements and efficiency to a connected Pattern Language, helping to deal with the complexity at hand.

The research on the individual patterns uses quantitative and qualitative methods as well as the critical dialectic method in the form of discovering hidden dimensions of difficult and complex situations. Especially helpful material is provided by eminent scholars that help to understand the history, as well as social and power relations, such as Zionism, apartheid, and colonial settlement… (Finkelstein, Wolf, Said, Harari, Hedges, Khalidi, Pappe, et al). The terrible attack by Hamas on October 7, 2023 and the disastrous genocidal attacks by Israel on Gaza were followed in the news and online media and had a significant impact on what is called the Gaza conflict (also called a war by Israel) which consequently affected the forming of this paper including the adjustment of the term pattern.

In addition to social and spatial aspects, there is a strong underlying quality that we may describe here as a humanizing quality or humanistic pragmatic-approach. The focus is on refugees, migration, and the conflicts that create them, that is on the extensive man-made disruption side which includes, war, terrorism, destruction, forced displacements, etc. that rightfully might be considered Anti-Patterns. But the overall objective, of course, is to find ways to reach the positive side of Good-Patterns, that is, patterns for peace, wholeness, healthy cities and independent regions, living neighbourhoods, vibrant streets and buildings, and beautiful parks and organic gardens… and healthy prospering people.

Next Steps	**Palestine and Israel as two Independent Regions** Outlook

Note: The Refugee Pattern Language for 'Palestine's refugees and internally displaced people' PaPL is an outgrowth of a larger project called: 'The Sugar in the Milk – A Refugee Pattern Language RPL.' In this case study paper we have only space for five patterns from Cluster One and Two, marked with black points in table above.

RESULTS AND DISCUSSIONS

Cluster one:
The independent region of Palestine pattern

Independent Regions (IR) are more suitable for providing a better, more peaceful, and more orderly world than the recent and current system of large hegemonial countries; this is supported by several characteristics of an IR such as a limited size of up to 20mio population and the nature and limits of human government, and others. A WORLD OF THOUSANDS INDEPENDENT REGIONS follows as a proposal of a structure for governing and cooperating in a world of smaller countries or Independent Regions that collaborate with each other, without dominating or attacking each other.

The need and opportunity to build up Palestine as a new Independent Region is emphasized by using data from its disturbing history with the Zionist Colonization and the forced upon misery with the unilateral formation of Israel in 1948 and its subsequent subjugation and occupations since that time. Embedding the new State and Independent Region of Palestine within the Mid-East World Region is a major objective for Palestine with Israel as another Independent and cooperating Region 'in spe.'

INDEPENDENT REGIONS (Pattern APL 1)

Illustration 1: Bird flying freely in the Sky Neis

***Metropolitan areas* and larger regions *will not come to balance until each one is small and autonomous enough to be an independent sphere of culture,* autonomous state, and land.**

There are four separate arguments which have led us to this conclusion:

1. *The nature and limits of human government.*
2. *Equity among regions in a world community.*
3. *Regional Planning Considerations.*
4. *Support for the intensity and diversity of human cultures.*

Therefore: Whenever possible, work toward the evolution of independent regions in the world, each with a population of 2and 10 million (1977); each with its own natural and geographic boundaries; each with its own economy; each one autonomous and self-governing, each one with a seat in a world government, without the intervening power of larger states or countries.

Figure 1. A short summary version of Pattern 1. 'Independent Regions'. APL, 1977 in the Problem::Discussion::Solution format (non-original text in straight letters).

First Response from Palestine:

- The total population of Palestine is estimated at 5-7.5mio people (depending on internal and external counting in surrounding countries and Israel). The number fits well into the concept of IR population size between 3-15 or 5-20 million people.
- Palestine does not have its own natural and geographic boundaries.
- They do not have their own economy.
- They also do not have an autonomous and self-governing administration.
- They do not have a full seat in the UN, but they enjoy a limited associate member status;
- They rely and depend on various intervening powers of larger states and countries (mostly Israel as occupying power) in controlling their internal and external affairs.
- In fact, the Palestine Region is not independent at all, has no state, and is no country in 2024, even though they were promised statehood already in 1947, 77 years ago, while, at the same time, they had to give up large parts of their land for the birth of another country.
- But recently they have huge amounts of international support and growing recognition.
- Based on strong international support and promise of an Independent Region and a political neutral state, they can provide a convincing case for their own State.
- In addition to having no full state, the largest problems for Palestine are two: a. The continuous loss of land from Israel (from 100% - about 22%) and the issue of a second class peoplehood.
- Overall, we can say, that Palestine was crippled, economically, politically, even physically, religiously, culturally, robbed of their land, degraded of being full and whole people, and placed into an ever ongoing subjugation of various forms.

Links: Create THE INDEPENDENT REGION OF PALESTINE as quickly as possible so that Palestine emerges and contributes to A WORLD OF THOUSAND INDEPENDENTT REGIONS. *Within each region encourage the population to distribute itself as widely as possible across the region THE DISTRIBUTION OF TOWNS (APL 2) with POLITICAL NEUTRALITY as a safeguard for Israel.*

THE INDEPENDENT REGION OF PALESTINE (Pattern)

Problem: After 75 years of Submission, Occupation, and war on Palestine, the Palestinian People need their own Independent Region, Country and State – Now.

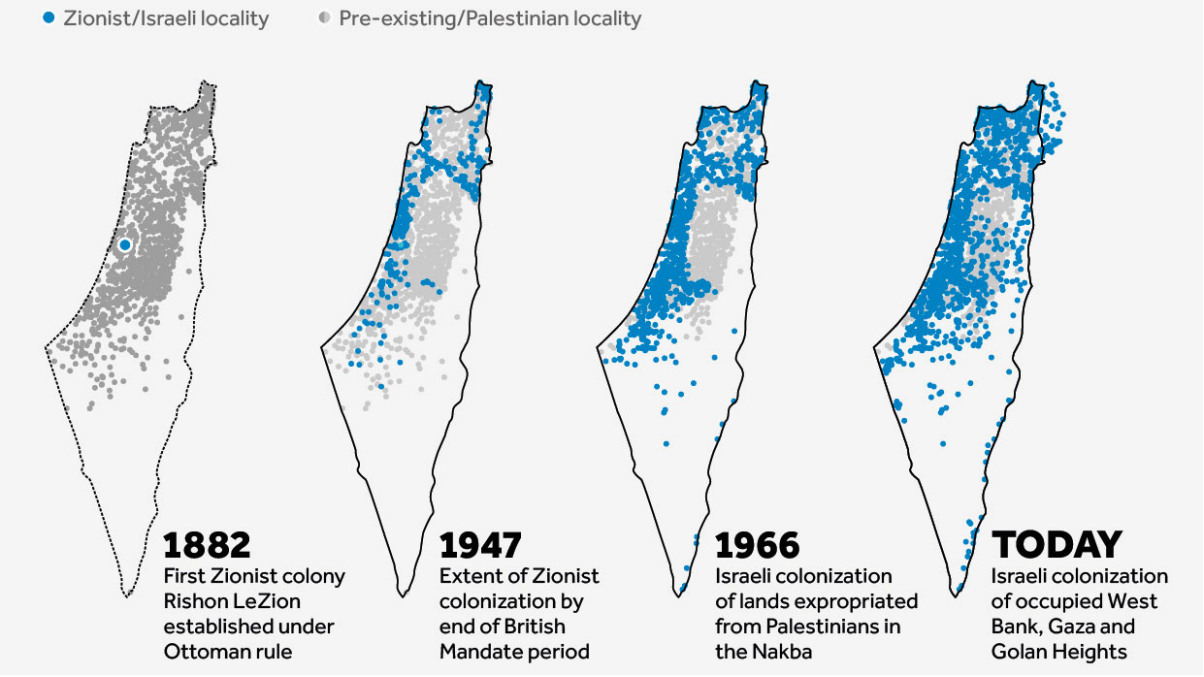

Figure 2. The Zionist Colonization of Palestine. Source: visualingpalestine.org (2019); Data source: bit.ly/vp101data

Discussion: Since the 1948 violent expulsion from their Homeland in Palestine, known as Nakba (Chaos) accompanied by atrocities, with about 750,00 million people expelled and part of them killed, the Palestinians have been chased out of their homeland, with less and less land over the years, to the point that very little is left, and more and more is taken violently even today because Palestinians have very few rights to oppose.

Given the terrifying history of Palestinian people and refugees over the last 75 years, culminating in the total physical destruction of Gaza in 2024, it is high time to establish a Palestinian country, state, and if possible also as an Independent Region with liberating strength and forces that includes liberty, freedom and beauty, and paths and processes to achieve some of those as Franz Fanon taught us already for Algeria. (Fanon, 1961)

The fundamental option that urgently needs to be put into place is a country on its own, a place that has been defined in Pattern 1. Independent Region, and 2. A world of Independent Regions, with less than 20 million people, with its own democratic system and its own culture and regional spatial system. Various options that are being discussed include:

2. The two-state solution: the approach to the two-state solution has been part of the discussion from the very beginning of the establishment of the Israelian Zionist state, in principle, but also as part of the overall arrangement and possibly compensation for being expelled in the Nakba. However, this solution has been opposed and practically almost made impossible, by Israel and its Western allies, in particular the US and Europe (including Germany). It seems therefore appropriate to focus on the formation of a Palestine country and independent region first and then try to bring the two, Israel and Palestine, together as neighbours.

3. The one-state solution: The way this is currently being discussed, is not focusing on Palestine as the original population needing a region, a state, but it is discussed as a framework, where

the whole region becomes one state together with the Israeli and Palestine population. But while this sounds innocent, it has meant for 75 years so far that the Israeli government has subjugated the Palestinians in a form of what is known as a apartheid, which means that the Palestinians are all treated as second-class citizens. Given this history, it may be understandable that the Palestinian population has little trust in such a solution. However, the Jewish scholar Ilhan Pape considers a combined democratic state as a serious option in the long run. This is relevant because for Palestine Israel is not a democratic state, it is a Jewish democratic state. Its Arab citizens do not have the same rights. First, Israel would have to become a democracy to give this proposal even a starting consideration.

However, a more sophisticated pragmatic solution could certainly entail two countries, or independent regions, where Palestinians who happen to live in the new Israel, have the option to continue to live there, and Israelis who happen or are willing to live in the new Palestine state, also have the choice to continue to live there. This wise progressive proposal was told to me by my colleague Professor Howard Davis. While this proposal is welcome, here we want to emphasize first, what the Palestinians need, and proceed from there. And right now they need their own state and their own Independent Region based on the 1967 borders. What is worrisome in this context, is the secret and continuous planning and building by Israel in the occupied territories with new colonial setlements as part of one larger Israel from the river to the sea as Noam Chomsky so eloquently pointed to already in his 2014 presentation to the UN. (Chomsky, 2014)

Consideration/Solution: The cruel events surrounding the Israel – Palestine Conflict in the spring of 2024, with 35,000 or more Palestinians killed, 75,000 wounded and crippled and over a thousand Israelis killed, it is critical to find a solution to this ever-increasing conflict, and establish a Palestinian Independent Region with immediate statehood right after the end of this war in 2024. This region needs to become truly independent, without any continuing apartheid control and subjugation of Palestinians by Israelis. While New Palestine needs liberation and freedom, Israel needs security and safety for all its citizens as a central element in place.

Cluster Two: (Patterns and Anti-Patterns)
Destabilization, refugees, and the architecture and planning of occupation

This cluster emphasizes the destabilization of Palestine society and environment as a long planned and organized process in a deliberate way by Zionist supremacy, colonialism, apartheid, physical destruction of buildings and infrastructure and the elimination of people, through the means of ethnical cleansing and indeterminate killing. Regional and Urban colonial Planning as well as the architecture of occupation played a dominant role in the destabilization with the creation of multifaceted (multi-times refugees) within their own territories from which they could not escape.

- The Colonization and Occupation of the Palestinian Territories
- Refugees in Palestine the West Bank, Gaza and adjacent Countries
- A House is not a Home: (includes ChatGPT, Lookx)

The colonization and occupation of the palestinian territories pattern

Problem: Israel as a Zionist and colonist society which is using the occupied Palestine Territories at their will since at least 1948, and 1967, violating numerous international laws on the way, destroying buildings and infrastructure, hiding the facts, killing Palestinians, and expropriating and stealing houses in East Jerusalem in an organized and systematic fashion.

Today, the Palestinian territory encompasses Gaza Strip, the West Bank with the Jordan River, and East Jerusalem. The area has been occupied, controlled, and exploited by Israel since the 1967 war, leaving less and less space for Palestinians accompanied by less and less peoplehood for Palestinians.

Rashid Khalidi in his book 'The Hundred Years' War on Palestine – A History of Settler Colonialism and Resistance, 1917-2017,' describes this period from the Palestine perspective and its people's horrendous experiences, starting with a letter by Theodor Herzl one of the early main Zionist leaders. "He had already begun to give thought to some of the issues involved in the colonization of Palestine, writing in 1895."(Khalidi, 2020, p.4)

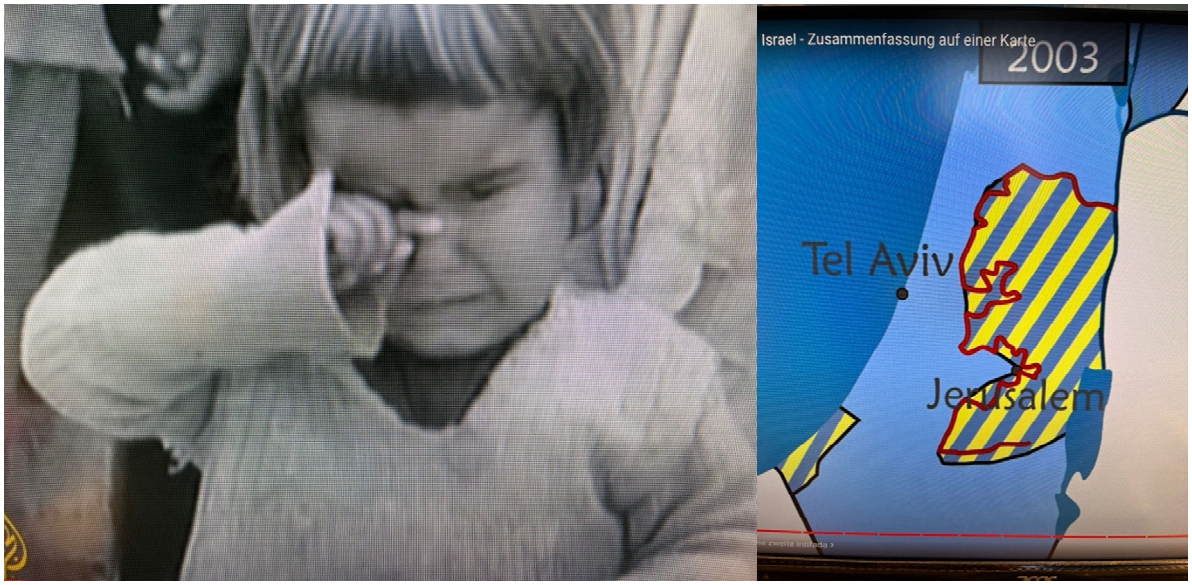

Figure 3. (Left) Palestine refugees 1948 Nakba (Source: unknown),Right: Ariel Sharon's building of a wall grabbing more land from Palestine 2003 (https://www.youtube.com/watch?v=W51ENoykVN4 Geo-Geschichte 2024)

> *We must appropriate gently the private property on the states assigned to us. We shall try to spirit the penniless population across the border by procuring employment for it in the transit countries, while denying it employment in our own country. The property owners will come over to our side. Both the process of expropriation and the removal of the poor must be carried out discretely and circumspectly. (Khalidi, p.6) (see also Herzl, 1960).*

What has been written more than hundred years ago, as an instructive suggestion, demonstrates the power of an idea that became true showing the reality of Zionism. With the proclamation of Israel as a Jewish State 1948, David Ben Gurion, Head of the World Zionist Organization, the fate of Palestine took a deep hit, from which it did not recover until today. The 1948 expulsion of almost all Palestinians (Nakba) created huge refugee camps in the surrounding countries, only the people in Gaza stayed until today, becoming refugees in their own country because Egypt refused to take them in.

> *"By the summer of 1949, the Palestinian polity had been devastated… Some 80 percent of the Arab population, that at war's end became the new state of Israel had been forced from their homes and lost their land and property. At least 720,000 of the 1.3 million Palestinians were made refugees… Israel controlled 78 percent of the territory of former Mandatory Palestine, and ruled over 160,000 Arab Palestinians…" (Khalidi 2020, p. 58)*

Khalidi refers to the Nakba as grounded in the defeat (1936-1939 great revolt) and willed by the Zionist state-in-waiting as well as foreign interferences and fierce inter-Arab rivalries. For him, the Nakba was only made possible by massive global changes during and after World War II. The 1947 UN committee agreed to the partition of Palestine. Arabs did not agree but Zionists did, the first time officially recognized with their own territory. Hostilities started between Arabs and Zionists. (Figure 4a)

1948 FIRST ISRAEL ARAB WAR AND NAKBA: Zionists prepare for war with the help of Europe with weapons, financial, and practical support. Golda Meir receives 30 million US Dollars from the Jewish community in America for starting the civil war. Plan Dalet by Ben Gurion. Hagana conquers the street from Tel Aviv to Jerusalem and destroys villages along the way plus a massacre in Deir Yasin. May 14, 1948 Ben Gurion declares Israel as an independent state and starts war against the Arabs. June 11, UN formed a peace treaty that benefits Israel with additional weapons from Russia and Check Republic. After a fire pause, in only 10 days, Israel pushes the Arabs to the East.

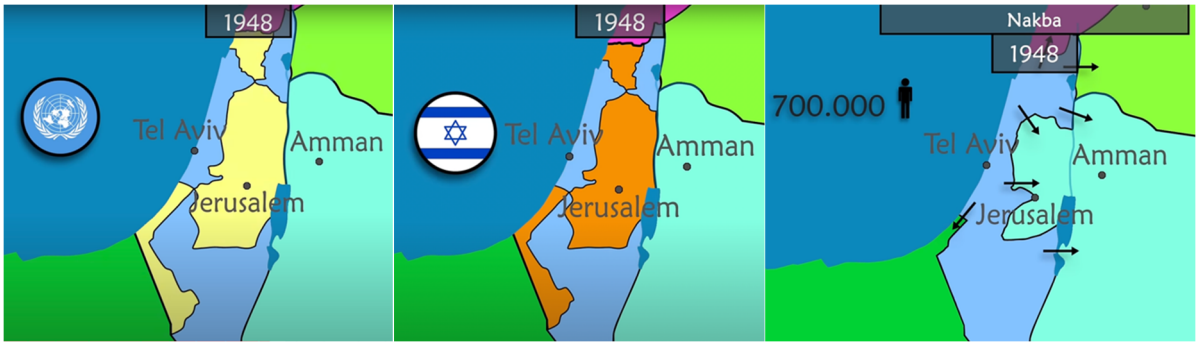

Figure 4: Die Geschichte von Palestina und Israel – Zusammenfassung auf einer Landkarte : 4a The land partition by UK and UN; b) Formation of Israel State and Government within their allocated area in blue; 4c loss of huge amount of lands taken away from Palestine by Israel, Jordan and Egypt. The Nakba Catastrophe original sin. (https://www.youtube.com/watch?v=W51ENoykVN4 Geo-Geschichte 2024)

A Palestinian government is formed in the Gaza strip, supported by the Arab states with the exception of Jordan, which wants to annex the area. (Figure 4b) Various peace treatises are worked out in which Palestine loses additional large amounts of land to Israel including West Jerusalem. Gaza is allocated to Egypt, and the West Bank is allocated to Jordan (Figure 4c). More than 750,000 Palestinians were expelled, killed, or massacred in what is known today as the Nakba or Catastrophe, and Israel is born with its own original sin. Large Refugee camps are established in Gaza, West Bank, and the surrounding countries. Israel refuses the return of these refugees to their home country in now Israel-occupied territory until today. Only 150,000 Arabs still live in Israel at that time.

1949 Israel opens up for their own refugees and immigrants, especially from Yemen and Iraq.1952 In only three years the Israel population doubles to 1,400,000.The causes of the 1967 war, apparently, are less clear, but what is clear is that Israel defeated the armies of three States, Egypt, Jordan and Syria, decisively, by destroying their warplanes on the ground before the war even started. Egypt's moves in the Sinai apparently created incitement in Israel that provided the casus belli and allowed

Israel military to launch a long planned, US supported, pre-emptive first strike; "…one that smashed the Airforce of three armies and changed the face of the Middle East." (Khalili 2020, p.98)

A new US-Israel axis resulted in Security Council Resolution SC 242, 1967, drafted by the US, and interpreted by Israel as keeping all the occupied territories they gained in the war, and colonize and use them until today. All of this against international law and the world community. The resolution "treated the issue as a state to state matter between the Arab countries and Israel, eliminating the presence of Palestinians." (Khalili, 2020 p.106) This diplomatic trick resulted in the fact that Palestinians had no more rights since they 'did not exist.' Most important, in terms of land grabbing "242 effectively legitimized the 1949 armistice line as Israel's de facto boundaries, thereby indirectly consenting to its conquest of most of Palestine in the 1948 war." "…a whole new layer of forgetting, of erasure and myth-making, was added to the induced amnesia that obscured the colonial origins of the conflict between Palestinians and the Zionist settlers." (Khalili, 2020)

Although most land expropriation by Israel and its settlers was accomplished after the 1967 war, more expropriation continued, i.e. by Arial Sharon, forming a new land-grabbing wall around the West Bank including Jerusalem (Figure 3b), and this is still going on today with settlers, who are used to the long established colonial system, taking what they want and displacing Palestinians at the same time. The goal was always about expropriating land and denying peoplehood, as Herzl advised long time ago

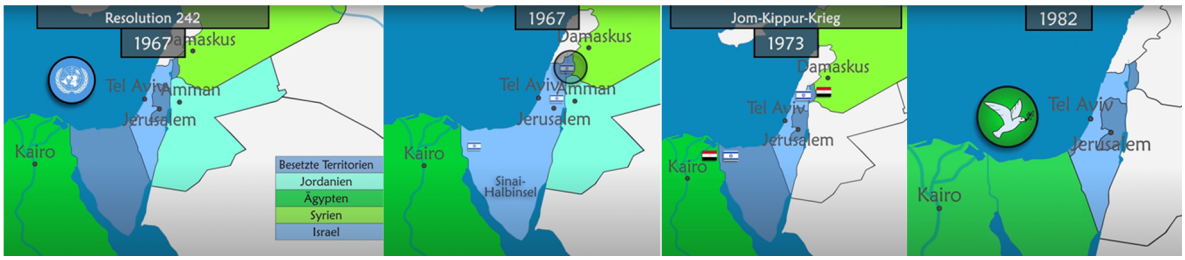

Figure 5: Die Geschichte von Palestinien und Israel – Zusammenfassung auf einer Landkarte. a. b. In the third war 1967 more land was expropriated by Israel (Resolution 242) and c. In the Ramadan War of 1973 Arab countries tried to recover lost areas. In 1982 Israel invaded Southern Lebanon attacking Palestinian Refugee Camps. (https://www.youtube.com/watch?v=W51ENoykVN4 Geo-Geschichte 2024)

even though several rulings by the International Court of Justice, as well as reprimands by the UN (i.e. the current ICJ preliminary ruling on the Gaza genocide case), have determined land grabbing behaviour as illegal, and against international law. However, this system has continued for over 100 years, so that there are now 600,000 colonizers living in the Westbank with new Israeli settlements, houses, land, gardens, and beautiful agricultural land with olive trees, all stolen from the Palestinians.

Therefore: It is hard to believe that this gruesome history was going on all along in our modern times, long after WWII, without being openly discussed or even acknowledged. It is time to directly confront these facts. Today, the internet and other sophisticated recording and communication systems help us to get a better view of this hidden history, and still ongoing practices, bring the truth to the front, and correct this illegal situation. The international community needs to grant statehood for Palestine as an Independent Palestine IR during already during the Gaza 24 conflict. It would help, to establish solid guarantees for Israel's own security, with Palestine neutrality and integration in the Middle East Region and with cooperation, mutual help, and co-existence. https://www.youtube.com/watch?v=W51ENoykVN4 (second Intifada 2000-2003)

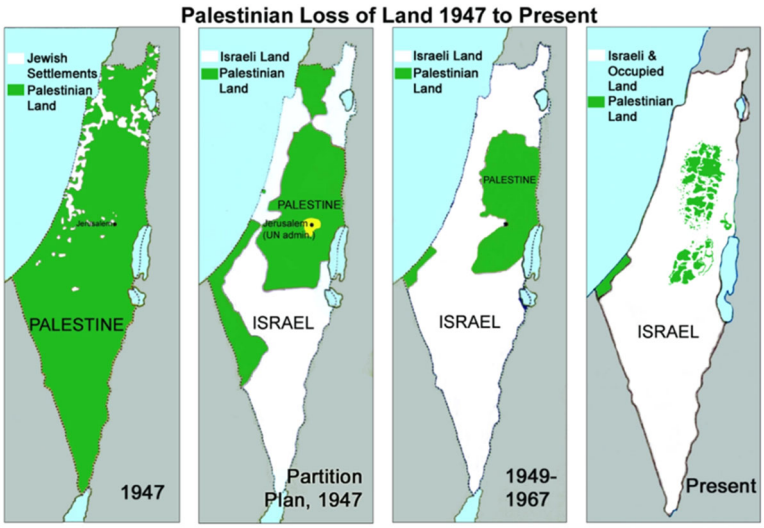

Figure 6a: Palestine land reduction over time from 100% to 22% with imminent danger of nihilation of Palestine. It is critical, that occupied territories since 1967, are returned to Palestine as the base land for a new Independent Region of Palestine and the advance to new peoplehood in Palestine in a new independent state with equal rights for all. 6b. Safa Khalib:"Telling the Battle of the Nakba story is a battle against time." Midleeasteynet.net. https://s10probus.co.uk/israel-palestine-the-background-by-david-worth-24th-may-2021/

Links: IRREVERSIBLE NEXT STEPS: The Formal Recognition of Palestine as a State and the Formation of the Independent Region of Palestine (see cluster 4, p.4)

Refugees in Palestine, the west bank, Gaza and adjacent countries pattern

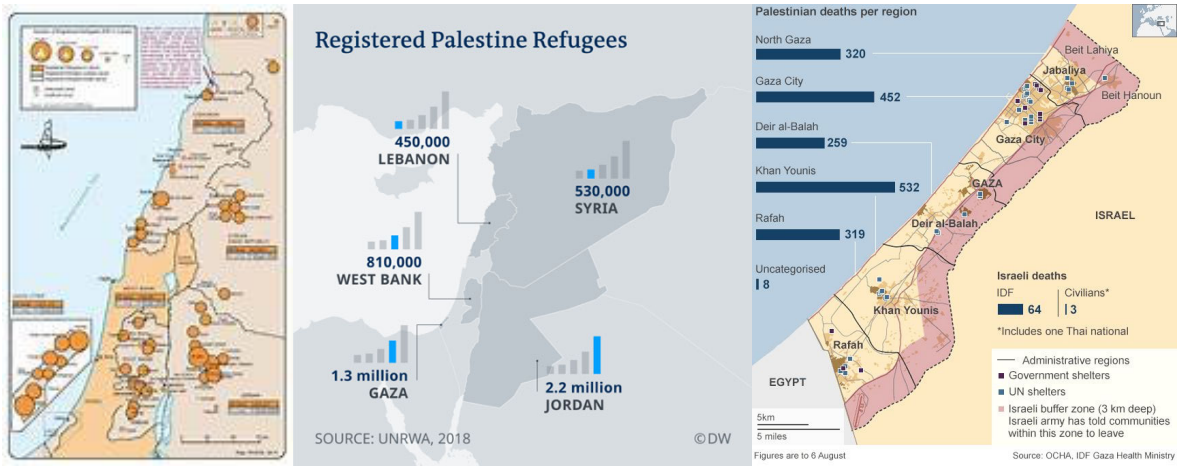

Figure 7. Distribution of Refugee camps in West Bank, Gaza and adjacent Countries (Source: a) Passia http://www.passia.org/maps/view/72) b) DW UNRWRA 2018; c) OCHA, IDF GAZA HEALTH MINISTRY, 2024.

Problem: Millions of Palestinian refugees and their children and grandchildren refugees are living in camps in the West Bank, Gaza, as well as Jordan, Syria, Lebanon and other places. They want to return to their lawful homes, gardens, and land in Israel and the occupied territories. Some of them wait since 1948, and want to return home and die at home.

Refugees and refugee camps in Palestine and adjacent countries started out as a reminder of Israel 's original sin to expel almost a million people from their home and land after the 1948 birth of Israel, with no country and state for Palestine as originally promised and intended in the UN resolution.

Displacement is all too familiar to Palestinians. Many fled their homes during the 1948 Arab-Israeli war in a forced migration, and catastrophe. After the establishment of Israel, many sought temporary shelter in the Jordan-controlled West Bank and the Egypt-controlled Gaza Strip. Thousands fled once again after the 1967 Six-Day War, in which Israel captured control of the territories, and currently in 2024, millions are fleeing from one place to another within Gaza as refugees with no place to go and open for being killed in front of our eyes. Trying to make the killing of Palestinians a new normal, is certainly one of Israels' most serious miscalculations that needs serious correction.

As we can see from sources like the UNWRA map above, the majority of Palestinians – over 5 million – are refugees. About one third of the Palestinian refugee population are spread out across 58 UNWRA-administered refugee camps in the Occupied Palestinian Territories (OPT), Jordan, Lebanon, and Syria. In addition, there are an estimated 10,000 unregistered refugees in Iraq, and a further 50,000 in Egypt." United Nations Relief and Works Agency in the Near East (UNWRA, 2018 and 2024)

Therefore: After living more than 75 years in Palestinian refugee camps distributed into more than six countries, it is time to bring all refugees and their families back to home, in a new independent region, country and state of Palestine. It is time to not only formulate a clear path to Independent Palestine but also to take practical actions to bring refugees back in to their home land. And do not fill up Gaza with new Israeli colonizing settlers or other new Israeli Occupation Plans.

A house is not a home pattern

Problem: A house is not a home when you are forced to rebuilt it every few years.

It is not unusual that in areas of natural disasters, such as earthquakes, flooding, firestorms, and other disasters by "the hand of god," houses may be partially or fully destroyed and need repair or total rebuilding from the ground up, in extreme cases 2-3 times in the lifetime of a family, father and mother. Rebuilding might be a matter of resilience and necessity, be it partial repair or total new building altogether. But if the force of nature destroys one's house too often, as might happen because of the effects of climate change in our times, the house will start to lose its quality of a permanent home, one might start to consider to rebuild in another safer area and create a house that one can also call a reliable and safe home.

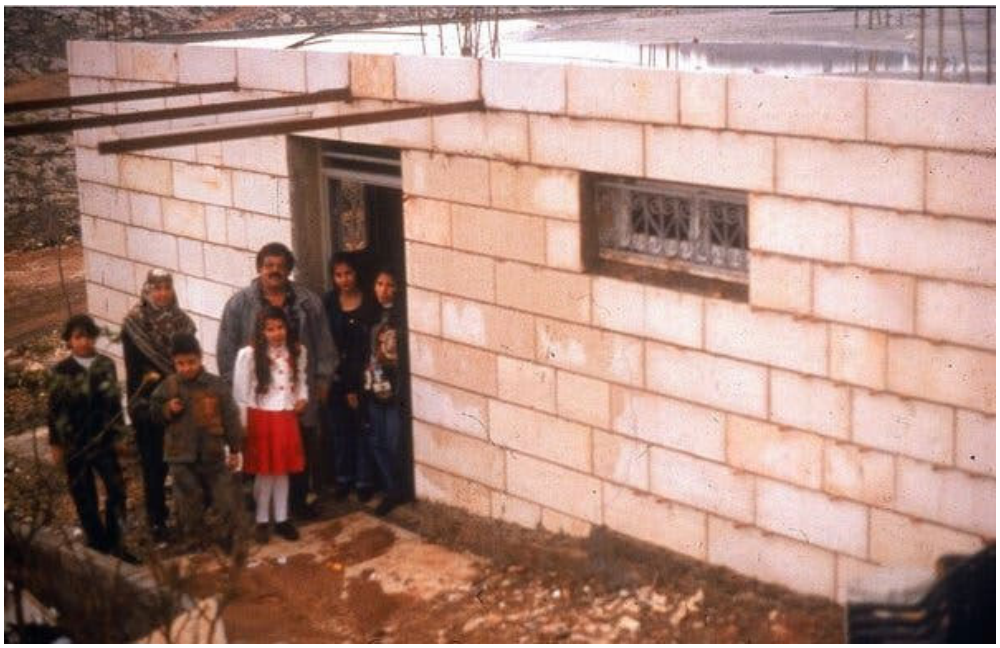

Figure 8. Palestinian Refugee House (Courtesy of Jeff Halper) in NYT, March 25, 2024

Links: INDEPENDENT REGIONS – OCCUPATION AND COLONIZATION OF THE PALESTINIAN TERRITORIES (ORIGINAL SIN) - REFUGEES IN PALESTINE THE WEST BANK, GAZA AND ADJACENT COUNTRIES

If the house is destroyed by war, like in WW I, one can rebuild it; and if it is destroyed a second time by war, as might have happened in WW II, one still can rebuild it a second time, hopefully without losing too much of the quality of home, and withstand the wish or tendency of trying to abandon and look for a house and home at another place.

However, if the house is intentionally destroyed by state terrorists every few years, one might definitely try to look for a better place of a house elsewhere, unless one has no other place to go, and can muster the fierce determination to keep a house alive that still might contain a few qualities of home by rebuilding and rebuilding. This is what happened 'pars pro toto' to a Palestinian family reported by Imam Fayad, who is a member of this family. NY Times, March 25, 2024.

> *"On July 9,1998 a small house in Anata, a village Northeast of Jerusalem, was destroyed for the first time. Home to the Shawamreh, a Palestinian family of nine, the house was built four years earlier in a part of the West Bank over which Israel military has control. House demolitions occur routinely in this territory, where Palestinians like Arabiya and Salim Shawamreh are denied building permits on land that they have purchased and rightfully own. NYT, March 25, 2024*
>
> *This house became a target for repeated demolitions because the family refused to leave. Each time Israeli authorities razed it, the family rebuild it, alongside volunteers from the Israeli Committee Against House Demolitions. Now known as Beit Arabiya, the house has become a symbol of resilience." NYT, March 25, 2024*

But one also has to consider the Sisyphus moment, when the rebuilding of the house becomes a continuous alternating process of building, destruction and rebuilding, as an eternal process. In Greek mythology this is what happened to Sisyphus, who was punished by the gods for some crime, to forever roll a heavy stone up the hill, only to have the stone roll back to the base of the hill, and then start the process again forever and forever. But while the Sisyphus moment can be seen a serious

consideration totally changing the spirit of the rebuilding. it is also the wrong solution to the problem in such a precarious situation of Palestine life and society. It is a means of ethnical cleansing and a violation of international law as well as a crime against humanity.

Suggestion/Solution: The slightly bitter solution to the problem is more along the lines of "A house can be temporary, but the home is permanent." And while this may be a useful temporary solution of such a foundational problem of keeping a home, in the end, you still want to create, design, and build a house that is also a home with a garden, a view, and a prospect of a good future.

Below, we have tried to work with an Alternative History of development for the Shawamreh family house by modelling possible histories, based on the original house to the left in 2023).

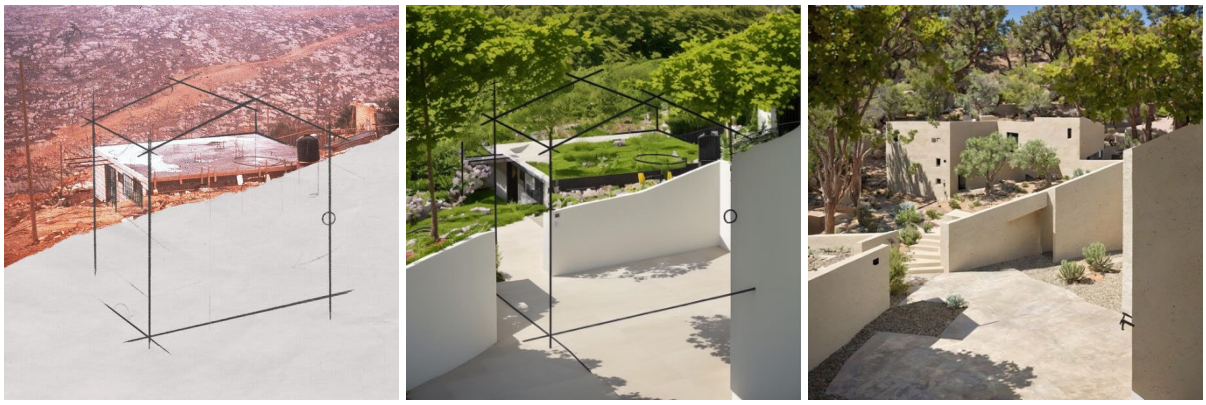

Figure 9. (Left) Building in 2023 (NYT) Shoshana Schultz, (Middle) Alternative history with AI (Hajo Neis and Zayla Jacobson, 2024) (Right) Alternative history with AI (Hajo Neis and Zayla Jacobson, 2024)

Links: INDEPENDENT REGIONS - MODERN TECHNOLOGY, SOCIAL MEDIA, AND THE OPENING OF THE WORLD'S EYES

CONCLUSIONS

The investigation into the refugee situation and Palestine as an Independent Region, has led to larger issues that needed to be understood first to come closer to our objective and support the immediate formation of a Palestine State as an Independent Region to solve the refugee problem as well as unpacking other serious problems such as Apartheid, Zionism, neocolonialism, and supremacy of one ethnic group over another ethnic group.

In essence this epic 100 year conflict seems to be about land, with one ethnic group invading another ethnic group to grab as much land as they can and also try to eliminate or neutralize the indigenous people in different ways, and start their own new state, not as an independent region, but as a region that can live only with the support of large powers such as first France, Britain and since the end of WWII the United States. This conflict has produced large number of refugees, millions in fact, many living in camps since 1948 in surrounding countries, Gaza and the Westbank. They want to come back.

There also seems to be a strong fire wall for the creation of an independent Palestine State or Region, directly or indirectly. Most Israelis are currently not interested, and Netanyahu has and will do almost anything to avoid a Palestinian State. Example: On July 17, 2024 the Israel Parliament voted again against an Palestine State, as they have done many times before. (Public TV News Report in Germany)

From more liberal voices, you will hear most often "Palestinians deserve their own state." But then after a pause it goes "I believe the time is not now." And this is how it goes since 75 years. They will

also claim that the Palestinian people do not want their own state, because they want to destroy Israel and recover the land from the river to the sea, while de facto it is Israel that does everything to grab all space between the river and the sea. Zionism ideology and Palestinian life are two different things.

In fact, we see it the exact opposite of creating a Palestine state right now, especially because of the terrible disaster that is going on in Gaza. Nevertheless, after such a cataclysmic event, there is a very good chance to try just that, create new state for Palestine supported by the international community and the emergence of a new world order demanded by the global South. It is important for Palestine, to be a real 'Independent Region" with neutrality and cooperation with its neighbour Israel, and without being dominated. Given 100 years of war on Palestine, this time is as good as any. And with it, we see the release of the refugees who are sitting in their refugee camps in the surrounding countries, the Westbank and Gaza, and be able to return to their new independent region, and homes.

But as Noam Chomsky in his speech to the United Nations in 2014 very ominously warned us: While all these negotiations and political moves are going on, the Palestinian Territories are subject to further killing and land appropriation by settlers and the Israel Government, and that is the real event, that is going on all the time as the main Israel hidden policy and activity without anybody even talking about, as a slow and decisive death and the elimination of Palestine. And as we can observe now in front of our eyes, it only got worse. https://www.youtube.com/watch?v=1f1wXGKd9Ss . Consequently, "it may be necessary for the international community to formally impose the new Palestinian state on Israel." (Sachs, J. 2024) https://www.youtube.com/watch?v=Rchfx5qGdtg . We will continue to work on this huge problem with more research, fresh ideas, and pattern formation.

Acknowledgements

Thanks to Sara Ishikawa for providing books that made this work richer. I also want to thank the "stateless" Motasem Amleh from Palestine, who studied electrical engineering in Ukraine only to escape from war with his Ukrainian wife and two children to a small German Town, where I met him. Furthermore, I need to thank my student colleague Achmed from Palestine, and I acknowledge the student Taheri, whom we tried to help prevent extradition to Iran at the University of Frankfurt 1969.

Adapting urban forms to rising sea levels: sustainable design and resilience in Guayaquil's delta context

Christian Corral Burau[1]
[1] Territorial Design and Urban Planning, Architecture and Landscape, Leibniz University Hannover, Germany, Postgraduate Program, Architecture and Urbanism, Mackenzie Presbyterian University, Brazil, christian.corral.burau@stud.uni-hannover.de

ABSTRACT

This study addresses the pressing need for cities situated in deltas to adapt their urban morphology and strategies in response to rising sea levels, a challenge further intensified by climate change. The case study focuses on Guayaquil, the second-largest city in Ecuador, situated in the Guayas River estuary. The research highlights the city's significant socio-economic and geographical segregation issues, along with an increasing vulnerability to coastal flooding. The study emphasises the integration of water into the urban design of precarious areas, proposing the transformation of public spaces, architecture, and daily life to shift the perception of water from a mere threat or economic resource to a central element in sustainable urban planning. The study analyses Isla Trinitaria, one of Guayaquil's most vulnerable localities affected by rising sea levels, in order to explore adaptation strategies that promote adaptability and integration with the aquatic environment across disciplines. The investigation employs a hybrid interdisciplinary methodological approach that integrates qualitative analyses with empirical explorations in a cross-scale and cross-layer articulation. The study proposes the development of an innovative multidisciplinary framework for climate adaptation. This approach not only contributes to Guayaquil's resilience in the face of climate change but also provides scalable, sustainable urban development models for delta cities worldwide. The significance of this study lies in its contribution to the field of urban design, promoting sustainable development and urban design strategies to confront the impacts of rising sea levels.

Keywords: delta cities, urban adaptation, rising sea levels, climate change, Guayaquil

INTRODUCTION

This investigation aims to develop strategies for the current dynamics and evolving challenges of climate change, with a particular focus on enhancing resilience and adaptability in deltaic and coastal cities across three scales: regional, urban, and architectural. Central to this strategy is the evaluation of water not merely as a threat but as a potential dimension within the morphological and planning dimensions of cities.

The current research questions the urbanisation processes and operational behaviours in cities. According to Graaf (2012), cities exhibit linear resource flows characterised by parasitic behaviour.

They consume resources from nearby and distant areas while expanding into adjacent ecosystems. These resources are converted into waste materials, CO2, heat, and wastewater, which are not utilised productively but discarded, negatively impacting local surrounding regions. This condition results in resource depletion and adverse urbanisation effects on the land.

Urban planning and design strategies in delta regions are undergoing a significant reassessment of how we design with nature, climate, and cities for mutual benefits (Lo, 2016; MacHarg, 1969; Meyer & Nijhuis, 2013). This perspective challenges the traditional view of cities as static entities focused solely on survival. Instead, it proposes that cities are evolving complex systems in the local and regional context. According to Alongi (2008), change is an intrinsic characteristic of Earth's ecosystems, with organisms constantly adapting to spatial and temporal conditions due to climate and other physical factors-" To exist is to change... []"(Bergson, 1922, p. 22). These ecological and biological transformations, driven by natural and anthropogenic disturbances, play a vital role in introducing and testing adaptive strategies within ecosystems (Odum & Barrett, 2005).

This research aims to explore a multi-scale and multi-layered framework and develop tools that help articulate different strategies within the urban context, contributing to the city's adaptability and resilience. The investigation hypothesis is that adaptability can only be achieved when different scales and layers are articulated with each other, enabling them to respond effectively to climatic imperatives.

The research is structured as follows: The first section explores the global and local situation, as well as its implications for the city of Guayaquil in the face of climate change and sea level rise. The following section explores interdisciplinary concepts and tools to enable cities to adapt and be resilient, predominantly for coastal and deltaic cities. The following section explores the implementation of the concepts and patterns explored in the qualitative section to build the framework for adaptation at the regional, urban and architectural scales.

Background and context

Since the 16th century, the water-land environments have been transformed, dredge, and expand to benefit humans (Meyer & Nijhuis, 2014). The world's largest cities are situated in coastal and delta regions. Due to climate-related conditions, these urban environments are particularly susceptible to the increasing risk of extreme weather events and sea level rise. The current situation has already begun to affect millions of people (C 40 Cities, 2022).

The Intergovernmental Panel on Climate Change (IPCC) (2021) provides conclusive evidence that human activities have led to global warming. As stated by the IPCC (2022), climate change is causing pervasive and potentially irreversible damage to ecosystems, urban areas, and human health. There is evidence that species are migrating to higher latitudes and elevations, with many ecosystems facing irreversible impacts. Furthermore, the intensification of heat waves contributes to the retreat of glaciers, which in turn affects the functioning of hydrological systems. The report identifies significant adverse effects on global physical and mental health, including increased mortality from extreme heat, an elevated incidence of climate-related diseases, and the expansion of vector-borne diseases. Similarly, exposure to wildfire smoke, dust, and allergens has been linked to an increased prevalence of cardiovascular and respiratory issues.

The population exposed to a 100-year coastal flood could increase by approximately 20% with a 0.15 m rise in global mean sea level relative to 2020, doubling at a 0.75 m rise and tripling at 1.4 m in the absence of additional adaptation measures. The increase in sea level represents an existential threat to some small islands and low-lying cities. The report suggests that by 2100, global assets at risk in coastal floodplains could be valued between US$7.9 and US$14.2 trillion. The costs associated with maintaining and reconstructing urban infrastructure are set to rise significantly, with considerable disruption anticipated, particularly in areas with permafrost and along coastlines (IPCC, 2022). As sea levels rise, the functionality and safety of coastal infrastructure, including ports and freshwater resources, will be increasingly compromised. Sea level rise is contributing to the salinisation of coastal aquifers and sedimentation (Meyer & Nijhuis, 2016).

UN-Habitat (2016; 2017) emphasises the urgent need to regenerate and adapt urban ecosystems, particularly in Latin American cities, where a significant portion of the population resides in low-lying coastal areas. The New Urban Agenda stresses the urgent need for climate change adaptation in coastal cities, noting that the cost of inaction could lead to severe economic consequences, with potential damages exceeding one trillion dollars annually by 2050 due to rising sea levels and other climate-related events. Additionally, climate-related extreme weather events in Latin America and the Caribbean have shown a marked increase, with economic damages surpassing 120 billion dollars during the 2001-2005 and 2011-2015 periods (United Nations, 2017, p. 66).

The last century has been marked by considerable urbanisation processes all over the globe (UN-Habitat, 2020). Deltas have seen substantial transformations in the landscape and the coastlines since the Industrial Revolution. Today, nearly 44% of the global population lives within 150 km of coastlines (Meyer et al., 2010; UN Atlas of the Oceans, 2010). On a global scale, half of the population resides in urban areas (New Urban Agenda, 2016; United Nations, 2014). Cities are often the first locations to experience the impacts of climate change and face rising temperatures, increased flooding, storms, and other complications driven by anthropogenic activities (IPCC, 2022). In this context, climate change and sea level rise could displace up to one billion people by 2050, disproportionately impacting low-income populations. Informal communities are often the most affected by the non-democratic distribution of resources (IPCC, 2023; United Nations, 2017).

The challenges introduced by climate change are inherently dependent on the developmental stage and geographic context of the area of study (Mirza, 2011). Extreme weather events related to climate change in Latin America and the Caribbean show an increasing trend, with economic impacts surpassing 120 billion dollars in both the 2001-2005 and 2011-2015 periods (United Nations, 2017). Deltaic areas present a duality of being strategically positioned for commerce and rich in fertile soils for agriculture while also being extremely vulnerable to climate change due to the proximity of the territory to extensive water systems and the ocean. These regions are critical to the global economy and are valuable ecosystems. Given that over 80% of global trade in high-volume goods is conducted by sea, the economic repercussions on international trade and the economies of affected nations could be substantial (World Bank, 2023).

Deltas often accommodate large populations in sensitive environments dominated by water. As such, urbanising deltas are particularly susceptible to threats from climate change and rapid urbanisation, including increased flood risks and the loss of ecological and socio-cultural values (Garner et al., 2021;

IPCC, 2022; Meyer, 2014). Transforming urbanising deltas into resilient and productive entities is essential for sustainable development and climate adaptation. The collective interactions and relationships of geographic localisation, coupled with unchecked urbanisation processes and extractive economic-centred activities, have significantly contributed to a non-resilient transformation for delta environments. The situation poses substantial threats to this environment in the face of rising sea levels. Delta regions worldwide are currently facing significant land-use transformations. A primary shift, driven by globalisation and technological advancements, involves the expansion of ports and port-related industries (Meyer, 2014; Meyer & Nijhuis, 2014; Saeijs, 2006).

Natural barriers and dynamic ecosystems in delta regions have undergone significant natural changes over time. However, these systems are experiencing degradation due to human interventions, leading to a decline in their ecological integrity. According to Alongi (2008), while climate change could lead to a global loss of 10-15% of mangrove forests, the immediate concern is the ongoing deforestation rate of 1-2% annually. The current distribution of mangrove forests is primarily influenced by historical sea-level changes dating back to the Holocene era (Saintilan et al., 2020). Mangroves possess inherent features to help against sea-level rise and storm damage but also mitigate the impact of extreme weather events like hurricanes, cyclones, and tsunamis. Various studies have demonstrated that mangrove forests effectively attenuate wave energy, reducing wave height significantly as waves travel through them, with attenuation rates ranging from 63.7% to 94.7% (Brinkman, 2006).

In the 20th century, Latin America saw a massive demographic shift due to deteriorating rural conditions and industrialisation, leading to extensive urban migration; in the same form, these demographic shifts were replicated at the national level (Carpio Vintimilla et al., 1987; Milton & Villavicencio, 1988). This migration has resulted in concentrated urban populations and rapid spatial expansion, particularly in urban cores and fringes. Currently, about 84% of the Latin American population resides in urban areas, making it one of the most urbanised continents globally. Despite this expansion, Latin American cities still maintain higher densities than those in developed regions. Latin American cities' urban development patterns, reflected in Guayaquil's urban growth, as described by Borsdorf and Dattwyler (2009), exhibit fragmented urban patterns shaped by profound socioeconomic challenges and disparities. These dynamics have led to urban landscapes characterised by widespread and decaying housing, a product of the gradual impoverishment of the labour force under a neoliberal model that prioritises profit maximisation and uneven wealth concentration.

Guayaquil, Ecuador's second-largest city, located in the lowlands along the Pacific coast, faces critical water challenges, including flooding and water scarcity. Much of the city's development has taken place on plains, floodplains, and areas that previously consisted of mangroves and salty estuaries (CAF, 2017). Despite being surrounded by water, seven out of ten residents have access to contaminated drinking water, and 12% of households in the poorest southern areas lack adequate sewage systems. Furthermore, over 80% of industrial wastewater, rich in organic pollutants, is discharged untreated into the sewage system or directly into rivers, exacerbating the city's environmental and public health issues (World Bank, 2019). Guayaquil spans 34,449 hectares, with 92% of its area urbanised, while the remaining land consists of water bodies like the Guayas River and Salado Estuary. The city supports a population of approximately 2.75 million. The city's economy is predominantly informal, with about 46% of economic activities occurring in this sector, resulting in high levels of underemployment (42.9%) and unemployment (9.6%) (INEC, 2010). The rapid urbanisation and ecological degradation in the territory have increased its vulnerability to climate change, particularly to flooding from rivers,

sea, and rainfall. This is exacerbated by the El Niño-Southern Oscillation (ENSO) and heavy rain concentrated between January and April (CAF, 2000, 2017). It is defined as the fourth city in the world most vulnerable to sea-level rise, with economic damage projections under high-end and RCP 8.5 sea-level rise scenarios potentially reaching $546.5 billion by 2100 (Abadie et al., 2020).

Urban transformation processes have historically resulted in the parallelisation of the city's structure, where the dichotomies of the formal and informal collectively shaped the urban landscape. Formal structures are those intentionally planned within the urban fabric, whereas informal structures arise spontaneously, driven by the population's initiatives, often without formal construction knowledge and using substandard materials (Davis, 2006). According to the United Nations (2017), Informal settlements are particularly vulnerable to climate change, as it disproportionately impacts impoverished communities.

In Guayaquil, approximately 70% of the city is within some level of the informality spectrum (INEC, 2010). The shortage of affordable housing has led to the emergence of informal settlements in areas such as Isla Trinitaria (1980s), Guasmo (1960s), Monte Sinai (1970s), Los Esteros (1980s), Bastión (1990s), and La Alborada (2000s) (Carpio Vintimilla et al., 1987; Delgado, 2013). Isla Trinitaria, located in southern Guayaquil within the Ximena parish. The island covers 860 hectares, with 455 hectares of urbanised informal settlements and a 395-hectare natural reserve. Urbanisation began in the 1980s following the construction of the Perimetral Road, leading to rapid informal development driven by rural-to-urban migration. Initially occupying estuarine locations, most homes now sit on solid ground due to landfills. The island, with a population of approximately 120,000, is organised into around fifty cooperatives.

In addition to rainfall-induced flooding, floods from rising tides and increased river discharge will significantly affect areas near water bodies, including mangroves and rivers. Many informal settlements in Guayaquil, established during the city's rapid expansion since the 1960s, are in these vulnerable zones. The Andean Development Corporation (CAF) has identified these settlements as particularly susceptible to heavy rainfall. Due to inadequate construction methods, these areas lack the necessary measures to cope with current climatic conditions. With rising temperatures, heavy rainfall events will become more frequent, disproportionately impacting these vulnerable populations. The risk of landslides, exacerbated by heavy rainfall, poses a significant threat to both life and infrastructure, especially in the city's peripheral areas with pronounced topography. According to CAF (2017), 53.4% of Tarqui parish, 49.4% of Pascuales, 35.3% of Febres Cordero, and Monte Sinai 68.75% are susceptible to landslides.

Figure 1. SLR 2030 RCP 8.5, return of 100 years. Blue: Water Bodies, Pink: Inundation. Data from: coastal.climatecentral.org. Created by the author.

Figure 1 illustrates the impact of a sea-level rise under the RCP 8.5 scenario with a 100-year return period, highlighting significant risks to large areas of the island, particularly the natural reserve, southern regions, including the port, residential zones, and northern regions near the estuary. A one-meter rise indicates substantial damage, while a two-meter rise suggests widespread inundation. This underscores the urgent need for strategies to enhance Isla Trinitaria's resilience. Current research inadequately addresses the specific vulnerabilities of informal settlements like Isla Trinitaria.

Key concepts and theoretical framework

The section is structured around tools and their potential applications and articulations across different scales: regional, urban, and architectural, as well as key concepts and terminologies related to climate change adaptation strategies. To approach the challenges posed by climate change and sea-level rise in cities demands a multidisciplinary approach. Based on a qualitative interdisciplinary analysis, the following four concepts have been identified as essential current and future scenarios adoption: 1) Mitigation, which is defined as the potential to reduce the adverse effects of physical hazards, including those of human origin, by decreasing threat levels, exposure and vulnerability (IPCC, 2022); 2) Adaptation, which involves altering infrastructure and systems to reduce societal vulnerability to climate impacts. The term also refers to the capacity of individuals or groups within a system to influence and enhance resilience; 3) Resilience is defined as the ability of a system to absorb disturbances and recover effectively; and 4) Transformability that addresses the system's ability to undergo fundamental changes in response to significant forces (Kabisch et al., 2017; Walker et al., 2004).

Due to the island's informal configuration, various intervention mechanisms have been explored to find bottom-up and top-down approaches that facilitate the transition to a more resilient model. Harvey (2013) argues that the neoliberal approach to urban development often exacerbates social inequalities and environmental degradation-“The right to the city is far more than the individual liberty to access urban resources: it is a right to change ourselves by changing the city.’’(Harvey, 2008, p. 1). Similarly, Davis (2006) highlights the precarious conditions in which millions live and how environmental changes worsen these conditions.

At the architectural scale, adapting the urban morphology of Isla Trinitaria presents an opportunity to create jobs, promote sustainability, and build resilience, integrating circular design and participatory design principles in the process. Building on this foundation, we argue that the true nature of

architecture is inherently participatory, as proposed by Katoppo and Sudradjat (2015). They contend that participatory design is integral to architectural practice, fostering engagement and collaboration among all stakeholders. Moreover, Roth (1999) emphasised that human-centred design research must involve those who will ultimately use the product. The author advocated for participatory processes within design, arguing that they facilitate rapid development and result in more effective and user-centred outcomes.

Given the complexity of informal settlements and their precarious situation, project interventions must be carried out in a very bottom-up manner, involving the inhabitants in workshops both to approach and inform about the problem, as well as in the creative and design process, and in the creation of more flexible guidelines for the population, which are not strictly governed by norms but by the availability of material, social, and implementation resources. Carroll (2006) emphasised the importance of incorporating an active participatory process throughout the entire design phase, where users are directly involved in setting design goals and planning prototypes. This approach contrasts with traditional methods that engage users only after the primary concepts and prototypes have been established. Many projects fail to be adequately implemented due to the theoretical and practical disconnection from reality of the informal dimension.

In the current context, the global construction industry is responsible for approximately 39% of global CO2 emissions (UN, 2019), with cement production generating 1 kg of CO2 per kg of cement produced, compared to bamboo's significantly lower CO2 footprint of -14,89 kg of CO2 per kg (Gu et al., 2019). The excess production of CO2 compels a re-evaluation of materials that can capture CO2, their implementation and recycling, and the new employment opportunities they can offer. The study of vernacular architecture offers critical insights into the logical responses to local climatic conditions by utilising available resources (González Couret, 2018). Camino Solórzano (1999) posits that the traditional three-room stilt house, prevalent since the colonial period, has persisted in rural regions with minimal alterations. This architectural form is particularly well-suited to the imperatives of the coastal climate. Bamboo and wood have been prominent materials used in the construction of Ecuador's coastal region. It has been used in the vernacular typologies of coastal areas in the country, significantly differing from the typologies of the Andean highlands in terms of morphology. These structures are elevated from the ground to adapt to the changing conditions of rivers and rainfall in their locations. However, according to Gonzales Couret (2018) these typologies have gradually disappeared in the country due to the integration of cement and models not being adapted to the context.

At the regional and urban scales, both planning and implementation tools are suggested as being of equal importance. Assessment mapping and scenario mapping emerge as critical tools for developing city planning strategies (Salewski, 2013). Geoinformation systems (GIS) tools, along with social, environmental, climatic, and urban data, are used to create maps that highlight areas of intervention (Berchtold, 2016).

Given the multi-actor and multi-component nature of cities, they cannot be seen as isolated entities in the landscape. Cities have influences on the local, regional and global scale (Gausa, 2022a; Sassen, 2001; Schröder & Maddalena, 2019). According to Gausa (2022a), this transition has led to the emergence of the "Metapolis," a multifaceted and interconnected system where diverse elements

coexist and interact simultaneously. They operate as multi-layered systems where various factors interact and sometimes conflict with each other. According to Meyer (2010), the “Layer Approach” can be constructed based on the following components: 1) The foundational layer (land, soil, water, and rock), 2) The infrastructural layer (transportation and utilities networks), and 3) The top layer (human activities and urban patterns). Furthermore, Gausa (2022b) and Schröder et al. (Schröder & Maddalena, 2019) emphasise the need for an integrated environmental framework that connects urban areas with natural landscapes, merging ecological and technological elements to create resilient and interconnected urban environments. Barker and Cutts (2016) present a multi-scale framework for urban climate adaptation, focusing on resilience at regional, urban, neighbourhood, and building levels. At the regional scale, they highlight tools such as forest infiltration, flood insurance, and wetland restoration. Urban strategies involve implementing blue-green infrastructure, including flood storage areas and parks. For neighbourhoods, they recommend reed bed systems, permeable surfaces, and rain gardens. At the building level, the strategies include rainwater harvesting, green roofs, energy efficiency measures, and typological adaptations like amphibious, elevated, and waterproof buildings to improve flood resilience.

McHarg, in his pioneering work Design with Nature (1969), contributed to landscape architecture by integrating ecological principles into planning and design. In this context, a multi-functional landscape can be intentionally designed to incorporate environmental processes and human needs into a cohesive framework (Fry, 2001; Wiggering et al., 2002). Despite advancements in landscape ecology, particularly in the analysis of landscape patterns and their interactions, landscape management decisions remain limited (Nassauer & Opdam, 2008). The success of landscape projects is critically dependent on the effective integration of ecosystem services—such as biodiversity conservation, resource provision, waste management, and cultural value enhancement—within the design and planning processes (Lovell & Johnston, 2009).

The following strategies have been identified as the most effective strategies during the literature research for flood adaption: ecosystem-based adaptation (EbA), ecosystem-based disaster risk reduction (Eco-DRR), nature-based solutions (NbS), green-blue infrastructure (GBI), green infrastructure (GI), and sponge cities. The ecosystem approach is a strategy that supports the sustainable management of land, water, and living resources with the objective of promoting conservation. The Millennium Ecosystem Assessment (2005) defined ecosystem services provide essential support, regulation, and promotion of human well-being. EbA is a strategy that focuses on leveraging biodiversity to build resilience, while Eco-DRR is a strategy that aims to reduce disaster risks through sustainable ecosystem management (Lo, 2016). Sustainable Land and Water Management (SLWM) is an approach that seeks to balance economic and social gains with the preservation of ecological functions. Strategies such as EbA and Eco-DRR also enhance carbon sequestration. It provides opportunities for ecosystem restoration, which in turn supports livelihoods and contributes to overall environmental resilience (Lo, 2016; Millennium Ecosystem Assessment, 2005).

NbS are strategies inspired by natural processes to enhance resilience and climate change adaptation in cities and natural environments. NbS employs reforestation, blue-green infrastructure, and urban green infrastructure to improve carbon storage and mitigate flooding. Sponge cities, inside the spectrum of NbS, represent innovative, sustainable approaches to urban water management and ecosystemic restoration for water-land territories, coastlines and inner territories adjacent to water bodies. The Chinese "Sponge City Program" (SCP), which was launched in 2013 and implemented in

30 pilot cities, is focused on developing innovative solutions to address urban flood risk, improve stormwater purification, and enhance water storage for future use (Qi et al., 2020). The Sponge City concept involves a multifunction that helps the resilience of the city while serving as a recreational space and positively influencing the lack of green areas in large metropolises in China.

The Industrial Revolution and new technologies systematically transformed the land with slogans such as "fighting against the water." Today, it is undergoing significant changes, and such slogans are obsolete. This new perspective represents an approach that embraces the concept of "working with nature" (Meyer et al., 2010, p. 23), "Room for the river" (Deltares, 2007), and "making space for water" (Barker & Coutts, 2016, p. 57), along with Nature-based solutions, and ecosystem interventions. The "Room for the River", initiated in 2007 in the Netherlands, is a resilient approach that integrates periodic flooding while aiming to balance its impacts and benefits. The project involves restoring natural floodplains in less vulnerable areas to protect more critical zones. By 2015, the project had lowered and broadened floodplains, restored wetlands, enhanced natural water storage, biodiversity, and recreational spaces, created river diversions, and established temporary water storage areas with a cost of 2,3 Billion euro (Deltares, 2007; The Minister & of Infrastructure and the Environment, 2007). Urban flood management strategies that integrate the environment and the city have emerged in response to the changing paradigm of urban environments and climate change. The "LifE" (Long Term Initiatives for Flood-risk Environments) project, funded in 2007 by the UK government's Department for Environment, Food and Rural Affairs, promotes sustainable practices for flood integration without relying on structural defences (Barker & Coutts, 2016, p. 57). The strategy emphasises enhancing the environment's natural capacity to absorb water, creating multifunctional spaces that serve as reservoirs, energy sources, and recreational areas. Initial master plans and case studies were developed for Hackbridge, Peterborough, and Littlehampton, focusing on non-defensive, adaptive approaches to urban inundation scenarios (Barker & Coutts, 2016; Waterstudio & Baca, 2009).

Lundy and Wade (2011) affirm that effective water management in urban areas requires a multidisciplinary approach that recognises the benefits of multi-functional green-blue infrastructure in urban environments. The authors argued that to adapt to rising sea levels, cities must adopt an integrated approach to land use and water systems in cities. Furthermore, the research suggests that a collaborative process with communities and stakeholders is essential for the exploration and implementation of the project. We must consider stormwater and groundwater management and land subsidence in relation to sea level rise. We must also take into account water balance, including freshwater supply and protection. The authors also suggest that in the case of disaster, we must adopt a multi-risk approach and use priority budgeting and creative financing to ensure long-term security (C 40 Cities, 2022).

A multidisciplinary report by Molenaar (Molenaar et al., 2018) addresses the specific flood risks in Guayaquil, particularly during periods of intense rainfall. The project focuses on mitigating coastal and pluvial flooding through the strategic placement of semi-permanent structures designed to manage water storage within recreational and underground spaces. Swyngedouw (1997) uses Guayaquil as a case study to explore water management within the "policy ecology of power," arguing that the urbanisation of water reflects a broader economic model that integrates society and nature into a system that benefits a select few while marginalising others. This model reinforces the extractive use of natural resources, particularly in the context of agro exports. Carofilis Cedeño (2018) provide a

historical analysis of the transformation of the Guayas River, examining the interaction between urban development and ecosystems. Their study highlights the complex relationship between Guayaquil's urbanisation and its territorial appropriation, offering insights into the interdependencies between urban growth and environmental change.

METHOD

The research comprehensively explored interdisciplinary literature and reference cases in the context of cities, climate adaptation and flooding using the following databases: Google Scholar, Elsevier, JSTOR and ResearchGate, selected for their comprehensive collections of peer-reviewed research, and books in the fields of ecology, urban and regional planning and architecture. The qualitative approach aimed to identify key strategies and concepts to develop a cross-scale climate adaptation framework for deltaic and coastal cities. The framework integrates adaptation strategies into urban morphology, providing guidelines for addressing climate change in cities. The research declares that adaptability is achievable only when different scales are effectively articulated. The concepts from the literature were synthesised into a framework (see Figure 2) to facilitate the articulation of the tools across the various disciplines, scales and layers.

RESULTS AND DISCUSSIONS

This research acknowledges the complexity of cities in their various dimensions and the intricate interactions among all contributing factors. It posits that cities cannot be viewed as isolated from nature but must be understood as dynamic entities shaped by social, natural, and morphological contexts. The study suggests that interventions must be grounded in a thorough qualitative and quantitative analysis of the context, integrating tools like assessment and scenario mapping to explore the vulnerabilities of the city and its inhabitants. The goal is to develop strategies that accommodate changing climate conditions and the dynamic nature of urban environments, leading to more resilient, sustainable, and equitable outcomes.

A multi-scale and multi-layer framework (see Figure 2) is proposed for urban adaptation in deltaic and coastal regions, focusing on integrating flood management within urban morphology, planning, and climate adaptation. The framework divides urban environments into three scales: regional, urban, and architectural. This research proposes that the city and the territory are constructed of three interconnected layers: Bottom (ecosystems, land, soil, and water), Middle (infrastructure and urban form), and Top (human activities). These layers are closely articulated, with interactions often surpassing individual dimensions, necessitating a flexible methodology that guides planning without being confined by rigid definitions. This approach fosters continuity across layers, enabling tools and concepts to adapt and function cross-scale, cross-layer, and discipline. Apart from the layers briefly discussed, due to new intangible dimensions, space must be analysed, including the informational dimension (digital) within city planning.

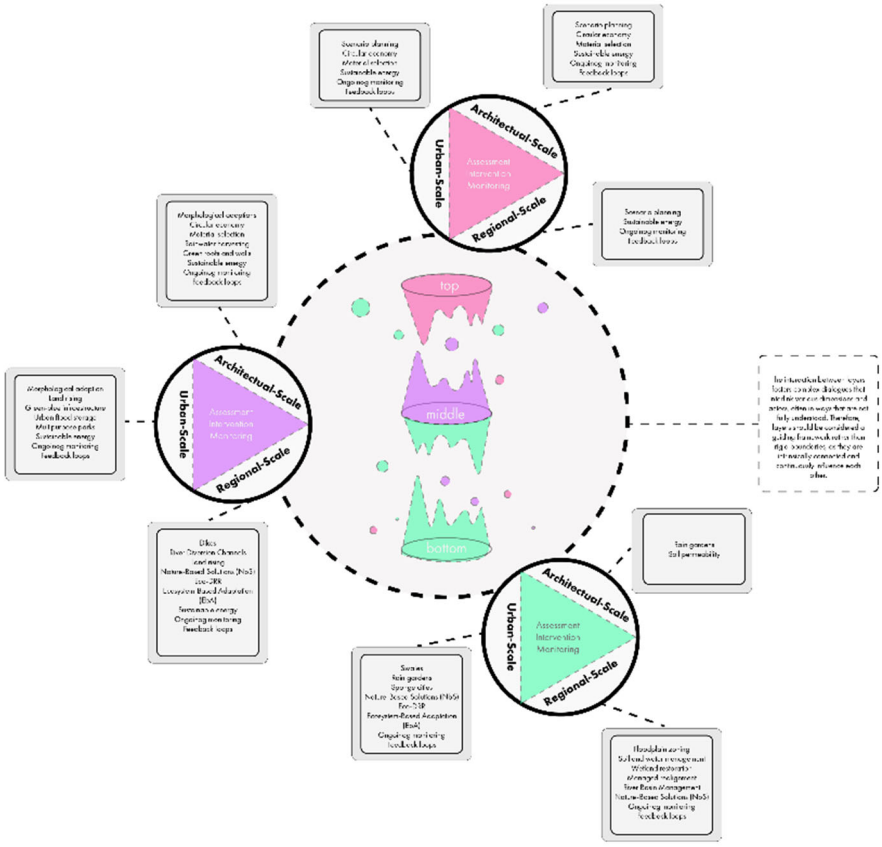

Figure 2. Adaptation Framework: Integrating Cross-Scale and Cross-Layer Approaches. Created by the author.

CONCLUSIONS

Cities are in a period of readjustment, in which the adaptation of the current and future state will dictate the urban morphology and how these will adapt to the outcomes imposed by climate change. The current research suggests that cooperation with the environment across different scales is a potential route to more sustainable and resilient models in the face of changing climate conditions and their existing vulnerabilities. Guayaquil's current situation reflects a deteriorated city, where the urban impact is noticeable on the environment. This situation reflects capitalism's urban development, supported by extractive practices, on land, water, and people. The socio-urban construct shows the consequences of inefficient resource repartition and poor infrastructure.

The research proposes a framework that articulates strategies across scales and layers (see Figure 2), emphasising the integration of water within cities' physicality and the acceptance of flooding as a natural part of urban life. The research indicates the necessity of creating more frameworks for interdisciplinary studies for scenario planning and possible adaptation strategies that harmonise the differences between actors, scales, and layers of a territory, as well as the repercussions of these strategies in urban morphology. The research underscores the importance of a multi-scalar approach in achieving effective urban interventions, starting at the architectural scale with an integration of bottom-up and top-down processes. The strategy aims to cultivate collective resilience by reintegrating overlooked typologies and employing a cross-layer, cross-scale integration of tools. By embracing an interdisciplinary methodology, this approach leverages diverse techniques across various layers and scales, ultimately fostering a cohesive and resilient urban model.

Cities can enhance their social and spatial resilience by adapting their morphology to the natural flow of water. However, the research suggests that these strategies are not universal and must be adapted to the specific climatic, social, political, economic, and ecological conditions of each project. The research offers a potential framework for future interdisciplinary and multi-scale strategies for coastal and deltaic cities. The aim is to create more sustainable, adaptive, and resilient urban environments and better understand the natural process and the implications of cities beyond administrative borders. The investigation suggests that an articulated, multi-scale, and cross-disciplinary approach could be beneficial, where the interventions at one scale reinforce and complement those at other.

ABSTRACT

Cities are socio-ecological systems that constantly face challenges, one of which is the impact generated by climate change. The characteristics of heat islands are also known. The urbanization process changes the urban landscape and, consequently, the microclimate. The city of Sao Paulo emerged on top of a hill surrounded by the Tamanduatei and Anhangabau rivers, a strategic location for defense and transportation. With the disorderly growth of railways, canalization and confinement of water courses resulted in valley bottom avenues. This practice proved to be a factor in worsening flooding problems in the city. Extreme weather phenomena can be defined as occurrences of floods, storms, heat waves and prolonged droughts. Sao Paulo also suffers, in addition to the impacts of the El Niño and La Niña effects, from the effects caused by the urban heat island and climate change, conditions that directly affect the rainfall regime in the city. To mitigate such impacts, the search for adaptation and resilience must be constant. Solutions were adopted in different locations around the world and those can be alternatives to mitigate risks of events caused by extreme effects in the city of Sao Paulo, considering the concepts of smart, resilient and sustainable cities. Environmental concerns have transformed the recovery of urban rivers into a global trend. Specifically, the city of Sao Paulo contains even greater challenges in this aspect, considering its historical and geographical characteristics. It is possible to conclude that green and blue infrastructures are the most suitable for seeking measures that make a city more intelligent, resilient and sustainable.

Keywords: climate change, smart, sustainable cities

INTRODUCTION

Water is essential for the occupation of territories and maintenance of life (Bacci and Pataca, 2008). However, sustainable management of this resource is necessary in urban spaces. Projections indicate that the city of São Paulo, together with the metropolitan region, will continue to grow until 2030 (Nobre et al., 2010). To make matters worse, studies indicate that climate change can significantly affect the planet, especially in climate extremes and in developing countries located in the tropical region (Marengo, 2008).

Justification and objectives

- Climate change;
- Impacts on the urban space;
- The applicability in the city of Sao Paulo, considering its characteristics;
- Report the experience of several locations that have suffered or are suffering from extreme weather phenomena;
- To evaluate the applicability of the related actions in the context of the city of Sao Paulo;
- Discuss the adoption of measures related to blue and green infrastructures as alternatives to improve the environmental quality of the urban environment

Hypothesis

"The implementation of measures related to blue and green infrastructure in urban space can improve environmental quality and contribute to the city of Sao Paulo becoming smarter, more resilient and more sustainable."

METHOD

This research can be considered qualitative in nature, with characteristics of an exploratory case study depending on the perspective adopted. Eisenhardt (1989) stated that case studies can collect data using multiple sources of evidence, such as documentary analysis, data collection and observations. To prepare this work, a bibliographical survey was carried out based on national and international articles and publications. The keywords used were related to the topic of climate change, the respective impacts on the urban environment, the urbanization of the city of São Paulo, and alternatives for improving environmental quality in cities.

RESULTS AND DISCUSSIONS

Considering the latest generation of climate models, the probability of major heat waves occurring in the coming years is significantly high. Studies show that climate scenarios point to a tendency for the global average temperature to increase, as well as extreme events such as heat waves, droughts, forest fires, floods and also increased levels of atmospheric pollution (Geirinhas et al., 2018). The impacts of climate change are expected to have serious consequences in the coming decades. In cities, the effects will be more severe (Rafael et al., 2017). Studies have shown that climate changes occur in regions where there is human intervention (Hingane, 1996). On the other hand, the existence of climate fluctuations independent of human action was also verified (Alcoforado, 1999). The increase in the global average temperature can result in drastic changes in rainfall patterns, such as a significant increase in rainfall and frequent floods in specific areas, simultaneously accompanied by a significant reduction in rainfall and severe droughts in other regions (Campbell et al., 2009).

Furthermore, the combination of global climate change and increased urbanization results in environmental problems, such as extreme weather and poor air quality. The phenomenon of heat islands is also known: urban areas have higher temperatures compared to adjacent rural areas

(Borrego et al., 2014). The intensity of the heat island is related to urban morphology and also to the size of the city. The urbanization process is the result of the transformation of natural surfaces, altering the urban landscape and consequently, the microclimate. Some factors that impact this process and enhance such thermal anomalies are vegetation, water and pollution (Romero et al., 2019). An aggravating factor in this scenario is that, in Brazil, cities' Master Plans, in general, do not include preventive actions for extreme events or climate change (Giulio et al., 2019). Scientific evidence has shown that climate change poses a serious risk to water resources in Brazil.

Furthermore, the impact caused to the national economy due to climate variability in past years is also considerable (Marengo, 2008). In parallel, it was found that the use of environmental information can play a strategic role for urban management (Côrtes et al., 2015). Sao Paulo de Piratininga was founded on a hilltop, just like the references of its colonizers, the village was similar to Portuguese cities (Oliveira, 2008). At that time, the periodic floods of the Tamanduatei and Anhangabau rivers were considered positive, as the hill was transformed into a peninsula, guaranteeing safety in the summer months. Furthermore, the establishment of commercial relations in the town of Sao Paulo was due to the navigation potential of the Tamanduatei River, which served to transport products from more distant farms or the coast (Gouveia, 2016). Population growth came together with the evils of civilization: Sao Paulo had precarious basic sanitation and preventive hygiene was moving at a slow pace. Swamps and floods tormented the population with a high rate of infant mortality (Mota, 2003).

Therefore, the city center was undergoing urban reforms and regulations, while the city expanded. With the aim of minimizing intense traffic in the city center, “Plano de Avenidas” consisted of the implementation of three avenues, outlined in a “Y” system: Avenida Anhangabau Inferior – currently Av. Prestes Maia – and Avenidas Nove de Julho and Itororo – current May 23rd. The Y system is the natural route of the Anhangabau stream and its main tributaries: the Saracura and Itororo, or Bexiga, streams. Then began the widespread practice of channeling and confinement of water courses, which gave way to valley bottom avenues. The practice proved to be a factor in worsening flooding problems in the city, as the waters continued to follow their original route, however, the percolation in the soil was replaced by the waterproofed surfaces of the avenues (Gouveia, 2016).

Extreme climate phenomena can be defined as occurrences of floods, storms, frosts, heat waves and prolonged droughts. In Brazil, a historical pattern of regularity in the climatic effects of the El Niño and La Niña phenomena was observed (Araújo, 2012), which, respectively, are characterized by the warming and cooling of the surface of the Tropical Pacific Ocean. Such occurrences interfere with meteorological conditions, especially the wind regime in the equatorial and subtropical zones, influencing precipitation and temperature in different locations around the world (Pereira et al, 2011). El Niño results in increased precipitation in the southern region of Brazil and reduced rainfall in the north and northeast. The opposite situation is observed during La Niña, with droughts in the South and increased rainfall in the Northeast. Such climate changes cause events that directly impact economic issues (Araújo, 2012), in addition to social, urban and public health issues. Studies have shown that endemic vector-borne infectious diseases (also called arboviruses) and waterborne diseases are sensitive to climate variations (Confalonieri, 2003).

Next, solutions adopted in different locations around the world will be presented to mitigate or reverse the effects caused by extreme weather phenomena. Porto, Portugal, suffers the effects of the urban heat island (Lopes et al., 2021). In order to reverse this situation and also to combat climate change, the Municipal Plan for Afforestation of Porto (PMAP) was prepared, which defines the implementation strategy based on pedestrian safety, identification of roads subject to afforestation and identification of suitable species. The Plan aims to plant trees in 200 kilometers of streets in Porto and improve the hydrological cycle in floods that occur in winter, protection as barriers to winds and reduce air pollution (Gonçalves, 2023).

About Rotterdam, the Netherlands has 25% of its territory below sea level. Delta Works is the largest and most elaborate flood defense (Alcoforado, 2022). The project has approximately 30 kilometers of dams that close the estuaries of three rivers and connect five islands, resulting in freshwater lakes that do not suffer from the tides (Petruzzello, 2022). In addition, there are projects for lakes, garages, parks and plazas that have an additional function: water reservoirs at times when the seas and rivers overflow.

In Dubai, the region's desert climate has high temperatures throughout the year and low rainfall (Guitarrara, 2021), as the water droplets formed by the clouds evaporate before reaching the ground, resulting in a shortage of rainfall. Investment in technology was used, starting with the launch of drones that measured temperature, humidity, and electrical charge within a cloud, to then make the droplets large enough to reach the surface (Neumam, 2021). The result was the torrential rain that occurred in Ras al Khaimah, located north of Dubai. The artificial storm was stimulated by four drones (Carvalho, 2021).

Located in Southeast Asia, Hong Kong has a subtropical climate (Chan et al., 2009) and a large part of its territory with mountainous relief (Simões, 2018). During the rainy season, the city is threatened by intense storms, especially in the months of May and June. Four rainwater drainage tunnels were built, in addition to 360 kilometers of river channels and 2400 kilometers of drainage pipes to transport rainwater, according to the Rainwater Drainage Manual (Beckers et al., 2012). The fifth version of the Manual, published in 2018, includes considerations on climate change as well as the concepts of blue and green infrastructure.

Even surrounded by the sea, Australia is part of the driest inhabited continent in the world. Between 1995 and 2012, the country suffered from the Millennium Drought. As a result, the New South Wales (NSW) government has implemented a number of measures to improve the health of the state's rivers, including the Sydney Metropolitan Water Plan (Anderson, 2006). As a measure to improve rainwater collection, the city implemented rain gardens, that slow down runoff (Rosa, 2018). In contrast to the dry season, 2022 was the wettest year in Sydney's history, as a result of the effects of La Niña (Rosenthal and Miller, 2022).

New York suffers from the effects of the urban heat island (Green, 2021), in addition to floods and vulnerability in relation to sea level rise (Neves, 2023). Two plans were launched: Cool Neighborhoods, in 2017, and East Side Coastal Resiliency, in 2020. The first aims to combat extreme heat, with the investment in green infrastructure and planting trees in high-risk neighborhoods, in addition to painting roofs white to reflect heat (Green, 2021). The second one began after Hurricane Sandy, in 2012. The resilience plan consists of raising the waterfront around Wall Street, by planting trees to

drain rainwater, reinforcing the sanitary sewage system, 4 kilometers of elevated parks and protective walls, and is scheduled for completion in 2026, with the installation of floodgates to contain high tides.

Some solutions to improve urban environmental quality in the city of Sao Paulo are:

Urban forestry management: The increase of permeable areas in the city is essential, as they allow the infiltration of water and contribute to the reduction of the flow speed. Trees also preserve watersheds and help improve the quality and quantity of drinking water (Meneguetti, 2007). Despite the benefits, urban afforestation needs investment and maintenance, or results in the risk of causing problems in the environment;

Revitalization of watercourses: Attempts to clean Pinheiros and Tiete rivers are recurrent. The new project to clean Tiete River is expected to be completed in 2026 (Maes, 2023). Regarding Pinheiros River, the interventions remain in progress within the initial schedule. There has already been an improvement in water quality (Fonseca, 2023).

Stormwater management: The city of Sao Paulo has a Decree that regulates the environmental quota, under the terms of Law No. 16.402. The environmental quota is a set of occupation rules that aims to make each lot contribute to the improvement of environmental quality (Prefeitura de São Paulo, 2016).
