Risk and disaster management: Due to environmental and social conditions, the main natural hazards result from hydrological, climatic and morphological phenomena, with floods being the most recurrent, followed by droughts and landslides.

CONCLUSIONS

From the bibliographical survey carried out, it is possible to observe that climate change has a significant impact on cities, in numerous ways. The natural effects resulting from changes in the climate, such as torrential rains, heat waves, droughts and forest fires, cause disasters and losses in different aspects, including environmental, social and economic, such as floods and floods, damage to buildings, impacts on public health with the spread of diseases and interference with the water supply, in addition to losses in agriculture and livestock.

It is also found that such effects can be mitigated through initiatives that involve the study and dissemination of information regarding climate and possible climate changes and urban planning, considering the implementation of blue and green infrastructure. In relation to the emergence and development of the capital of Sao Paulo, it is observed that the city of Sao Paulo was founded following the Portuguese model of urbanization at the time. Initially, the location between rivers was considered strategic, both for defense and transportation. However, the disorderly growth, and, therefore, the consequent precariousness of basic sanitation, which occurred due to the sudden population increase, resulted in the emergence of epidemics, associated with river floodplains.

Thus, during the period of implementation of the Avenues Plan in the city of Sao Paulo, watercourses were neglected when planning road works. This positioning results in recurring situations of floods and flooding, present to this day. In addition to issues related to the road system, it is also noteworthy

that, when replicating the Portuguese urban model, local climatic conditions were not considered, an aggravating factor for this problem. Therefore, to mitigate the effects caused by factors disregarded when the city was urbanized, the search for adaptation to the current situation through solutions to improve environmental quality, as well as the use and dissemination of climate information can be alternatives for management. strategy of urban space in the city of Sao Paulo.

With the analysis of actions taken in different locations around the world to combat the effects of extreme weather phenomena, it is possible to verify that the impacts of the urban heat island affect cities located in different regions and climates, as well as droughts and floods. It is also concluded that investment in green and blue infrastructure - implemented in Porto, Rotterdam, Hong Kong, Sydney and New York - may be the best alternative in the search for the resilience of cities in adapting to climate change. It is worth noting that this study did not consider unusual or non-existent extreme weather phenomena in the city of Sao Paulo, such as blizzards and sandstorms.

Furthermore, despite the geographical distance, similarities are observed between the city of Sao Paulo and the cities analyzed, especially in the impact factor of extreme weather phenomena. On the other hand, there is a significant divergence between Sao Paulo and cities such as Rotterdam, Hong Kong, Sydney and New York. As seen previously, they all suffer from flooding, however, these are coastal cities, while the capital of Sao Paulo is located on a plateau and approximately 80 kilometers from the coast. In this way, it is possible to affirm that the urbanization of the Brazilian metropolis, based on the plugging of rivers, resulted in negative impacts on the city that cause losses to this day. Furthermore, the actions taken in these cities can be alternatives to mitigate the risks of events caused by torrential rains in the city of Sao Paulo.

In relation to the dry period that occurred in 2014 and that eventually occurs during winter, the artificial rain solution adopted in Dubai can also be an example to be followed. It is possible to state that all the metropolises studied in this work have actions to seek to improve environmental quality, whether through intelligent, resilient or sustainable measures.

The management of urban afforestation and the revitalization of watercourses can be considered resilient and sustainable solutions, as their benefits help to mitigate the effects caused by extreme weather phenomena, demonstrating resilience, in addition to contributing to the improvement of environmental and economic aspects and social aspects of urban space, as they reduce the risk of flooding and consequently, avoid the respective losses, in addition to promoting the well-being of the population.

Rainwater management and risk and disaster management rely on intelligent, resilient and sustainable measures, as they mitigate the impacts of extreme events, add benefits in the social, economic and environmental spheres, in addition to including investment in technology, as was the case in Dubai. Specifically in this case, which can be an alternative for the city of Sao Paulo in times of drought, artificial rain could be strategically positioned in the most wooded regions of the city, as well as in parks and lakes, so that it would be possible to alleviate scarcity and avoid inconvenience simultaneously.

Regarding the SMS alert already implemented in the state of Sao Paulo and other regions of the country, despite being a preventive measure with investment in technology, it is worth highlighting

the need for digital inclusion of the most disadvantaged sections of the population, as mentioned previously.

Furthermore, considering that the management of urban afforestation is characterized as green infrastructure, and the revitalization of watercourses and rainwater management are characterized as blue infrastructure, it is possible to conclude that green and blue infrastructure are the most appropriate to seek measures that make the city more intelligent, resilient and sustainable.

Between borders: migrants, spaces, and socio-spatial relations in Cyprus

Ana Ricchiardi[1]
[1] SURFLab, Department of Architecture, University of Cyprus, Cyprus, aricch01@ucy.ac.cy

ABSTRACT

Migration plays an important role in shaping socio-spatial dynamics, especially in regions of political and territorial division. This paper introduces an ongoing study that investigates the socio-spatial impacts of migration in Cyprus, an island divided between the Republic of Cyprus and the largely un-recognized Turkish Republic of Northern Cyprus, separated by a UN-patrolled buffer zone. Focusing on migrant reception centres, urban neighbourhoods, and public spaces, the study explores how migrant communities navigate and transform urban environments. Through spatial and social data analysis, this research seeks to uncover patterns of spatial segregation and integration, emphasizing the agency of migrants in urban transformations. This study contributes to the understanding of how migration processes in divided contexts can influence urban policy and social inclusion. The paper introduces current events in the island that influence the way discourses have shaped narratives on migration and the spaces being used by migrant communities. The methods to be applied in the research relate to the analysis of specific case studies in the Island. The study seeks to uncover insights into spatial and social segregation/integration in these areas, and their impact on the living conditions of migrants populations. As migrant communities influence established spatial hierarchies, the research underscores their role in shaping space making processes and urban transformations. Ultimately, this work emphasizes the importance of viewing such spaces as dynamic assemblages of individuals, groups, and institutions, and understanding spatiality not just as physical infrastructure but as a lens through which to examine the everyday politics and material practices of communities.

Keywords: migration, cyprus, social and physical infrastructures, urban transformations, spatial segregation/integration

INTRODUCTION

Migration has become a critical factor in shaping the socio-spatial dynamics of cities, influencing patterns of integration, exclusion, and urban transformation (McAuliffe and Triandafyllidou, 2021). As societies increasingly need to accommodate diverse populations, understanding the socio-spatial ramifications of migration is essential to creating just and inclusive cities. In Cyprus, migration plays a critical role, shaped by the island's complex history, geographical position, and divided status. Cyprus, a geographically and politically divided island, has become both a transit point and destination for migrants. The island’s particular socio-political context, with the Republic of Cyprus (RoC) in the south

and the largely unrecognised state Turkish Republic of Northern Cyprus (TRNC) in the north, separated by a UN-patrolled buffer zone, offers a compelling case for analysing how migration reshapes urban spaces and social relations.

This paper is part of an ongoing three-year project that aims to examine the interplay between migration flows and socio-spatial relations in Cyprus, considering the historical, political, and cultural contexts that shape these interactions. By exploring the experiences of migrants and the spaces where these communities, inhabit, work and resist in, the study seeks to contribute to a better comprehension of the socio-spatial transformations occurring in Cyprus. The paper presents an initial overview of the current situation in the island and highlights possible paths for the ongoing project. This work contributes to ongoing discussions on migration and urban spatiality, framing these spaces as essential sites for observing the agency of migrants as cities are reshaped by those who inhabit them.

The paper is organized as outlined: The first section briefly reviews the relation of migration with urban space, contextualises Cyprus particular condition as bridge and border for Europe and highlights recent events around migration and rising tensions in the island. The second section introduces a three-part methodology for the project, focusing on spatial and social data analysis through case studies. The results section presents three potential thematic cases where migrant space-making practices are significant, followed by a discussion of the broader implications of studying such spaces. The conclusion reflects on the study's potential contribution to the field.

Migration and space-making

Migration involves more than just the movement of individuals, it plays a fundamental role in the everyday production of urban spaces. Drawing from diverse methodological approaches, disciplines, and perspectives, the work wants to situate migrant space-making practices within a broader discussion of urban transformation. Migrants actively participate in shaping the “city as a thing in the making” (Simone, 2010:3) where people’s everyday actions cumulatively reshape urban environments, even amidst exclusionary state policies. The theoretical framework of the project draws from migration and refugee studies, urban spatial theory, and critical perspectives on architecture and urban space. It aims to align with critics on conventional architectural and policy responses to migration, which often focus on crisis management and materialize in refugee camps (Awan, 2024), while also challenging the colonial, patriarchal, and racist underpinnings of the concept of integration (Astolfo et al., 2021).

Space-making practices refer to the processes by which physical, social, and symbolic spaces are created, contested, and negotiated by various actors in society. These practices involve not only the construction of physical environments but also the ways in which individuals and groups shape spaces through social interactions, cultural practices, and political activities. Space-making practices related to migration are processes through which people on the move actively reshape and negotiate their physical and non-physical environments (Boccagni, 2017; Trimikliniotis et al., 2015; Miellet, 2021), both in host countries and in transient spaces (Maqusi, 2021). These practices involve an interplay between physical adaptations, social networks, and cultural expression, as migrants and refugees carve out spaces for survival, identity, and community. Space-making is closely linked to the idea that spaces are not passive containers but actively shaped by human agency, power dynamics, and societal

structures (Lefebvre, 1991). By focusing on the layered production of space the study points to understanding how migrants not only inhabit urban spaces but also actively produce them. This transformation extends beyond the physical; it involves the formation of subject-citizens in neighbourhoods, where relations of conviviality and conflict shape urban landscapes.

Cyprus: bridge and border

Cyprus holds a particular position as a member state of the European Union, geographically separated from mainland Europe by hundreds of kilometres. The island is situated closer to Turkey, its often contentious northern neighbour, and the unstable Middle Eastern region—Syria, Lebanon, Palestine, and Israel. The historical backdrop of Cyprus is marked by a legacy of conflict and division (Hitchens 1997). Since Turkey's occupation of its northern region in 1974 and the declaration of the Turkish Republic of Northern Cyprus (TRNC), the island has remained divided with the Republic of Cyprus (RoC), an European Union member state, governing the south of the island. Between the two regions lies the United Nations Buffer Zone, also referred to as the Green Line, a demilitarized area patrolled by the United Nations Peacekeeping Force since 1964.

Cyprus's geographical and geopolitical position has made it a strategic location. It has long been a site of both emigration and immigration, resulting in a complex multi-diasporic landscape (Teerling & King, 2011). Cyprus had historically been an exporter of migrants. As a former colony British colony, various Cypriots moved to the UK, Australia, US and South Africa (Anthias, 1992). Post-1974, Cyprus became part of the Southern European model of immigration, attracting labour migrants, refugees, and expatriates from various regions (Trimikliniotis, 1999). More recently, regarded as a gatekeeper of the EU (Mainwaring, 2014), Cyprus serves as both a bridge and a border between Europe, the Middle East, and Africa. As one might expect, living between borders profoundly influences the lives of those who inhabit these areas and those who navigate and challenge these boundaries. Migrants frequently face significant challenges in the island, including exploitation, limited access to social services, and legal barriers to integration (Trimikliniotis et al., 2015). These difficulties are compounded by the island's division, leading to divergent migration policies and administrative practices in the south and north of the island (Achiri and Klem 2024). Despite these challenges, the presence of migrants has contributed to the island's cultural and demographic diversity, particularly in urban centres where migrant communities form distinct socio-spatial enclaves (Philippou, 2008).

Following the economic challenges brought by the war and partition, Cyprus experienced significant growth in the 1980s, driven by the expansion of the service sector, tourism, and investments. Greek Cypriots, displaced from the north provided cheap labour force that contributed to this economic recovery (Trimikliniotis and Demetriou, 2005). During this time, the RoC maintained restrictive immigration policies, as there was little demand for foreign labour. However, by the late 1980s, sustained economic growth created labour shortages, prompting to the implementation of a guest-worker system in 1990. This system issued temporary work permits, typically in low-skilled sectors such as domestic work, agriculture, and construction. These permits, renewable annually, were tied to specific employers, limiting workers' job mobility (Trimikliniotis, 2001). The policy successfully attracted foreign labour but also led to a rise in irregular immigration. International events, such as the collapse of the Soviet Union, the Gulf War, and the conflicts in Palestine and in the Balkans, contributed to this influx.

The historical context of Cyprus has greatly influenced contemporary discussions on migration, Mainwaring (2012a) notes that this has happened particularly through two main factors: first, the island's militarization and second, concerns over demographic security. Military presence on the island is highly visible, with Turkish troops stationed in the TRNC and local conscripts serving in the Turkish Cypriot Security Forces, patrolling the northern side of the Green Line. Meanwhile, the RoC's National Guard patrols the southern side, and compulsory military service remains in place in the Republic of Cyprus for all male citizens. What is more, British colonial legacy persists in the form of two active sovereign base areas, Akrotiri and Dhekelia (Clogg, 2015). The second point of tension in discussions on migration involves demographics. Turkish immigration to Northern Cyprus following the 1974 partition had heightened Greek Cypriot concerns over the population makeup (Mainwaring, 2012a). The RoC government views these immigrants as 'illegal settlers', claiming that their numbers surpass those of the Turkish Cypriot population (Miltiadou, 2006). Academics argue that the demographic situation is more complex, with large numbers of temporary residents, including students, migrant workers, long-term settlers, and their children—some of whom have acquired TRNC citizenship (Hatay, 2005). Demographic concerns are persistently raised, with politicians and leaders of the Orthodox Church of Cyprus—a highly influential stakeholder in the context—amplifying fears of a demographic shift in the country (Gomez, 2024). Nationalism, fuelled by both militarization and demographic concerns, remains strong. Within this framework, foreigners—particularly low-paid migrants, asylum seekers and refugees—are often viewed with suspicion, while wealthier expatriates, like British retirees and tourists, are more easily integrated due to their economic positions (UNHCR, 2023). These debates highlight an unwillingness to accept that Cyprus's multicultural society has been shaped by many waves of immigration and emigration.

In the last decades, Cyprus has experienced a significant rise in arrivals of asylum seekers, placing pressure on the island's reception facilities (UNHCR, 2024). The Syrian civil war and instability in neighbouring regions have contributed to the influx, with asylum applications increasing dramatically (UNHCR, 2024b) (see figure 1). As noted by Mainwaring (2012b; 2014). Cyprus has leveraged its position as a southern European frontier state to secure greater influence within the EU. By framing migration as a crisis and emphasizing the disproportionate burden on its resources, Cyprus has managed to lobby for greater EU 'solidarity' in the form of financial assistance, refugee relocation programs and policy reforms. This approach has only reinforced a securitized view of migration, where border control and asylum restrictions take precedence over humanitarian considerations. Cyprus has struggled with the reception and integration of migrants, many of whom face overcrowded reception centres, limited employment opportunities, and social marginalization (Fischer, 2024).

Rising tensions

Media and political discourses surrounding migration in Cyprus reflect patterns similar to those observed in many European Union countries, where immigration and migrant groups are frequently portrayed in a negative light. The language used to describe (irregular) migration across the Mediterranean often distorts power dynamics (Mainwaring, 2012a) depicting migrants as invaders, while framing wealthy European nations as vulnerable and defenceless. This narrative overlooks the vast economic inequalities between the countries on the northern and southern shores of the Mediterranean and neglects the legacy of European colonialism, which continues to shape migration patterns and influence the political, economic, and social realities of these regions (Mayblin and Turner, 2021). Furthermore, it fails to acknowledge the ongoing economic exploitation and power

imbalances in the global system that perpetuate migration. The conflict-driven coverage in European media can fuel anti-immigrant sentiment and influence voting behaviour among audiences (Eberl et al., 2019).

An analysis by Trimithiotis and Voniati (2023) of media coverage specific to Cyprus reveals that sensationalist reporting, coupled with the portrayal of migrants as threats, reinforces xenophobic political narratives that advocate for even stricter migration control policies. Media representations of migrants in Cyprus - including refugees and asylum-seekers- primarily depict them as a threat to security, the local economy and the nation's existence and culture (Kadianaki et al., 2018; Avraamidou et al., 2019).

Recent events highlight rising tensions. In August and September 2023, racialized individuals, - including migrants and refugees - experienced violent, pogrom-like attacks in Limassol and Chloraka (Al Jazeera, 2023). Shops owned by migrants were targeted, resulting in injuries to several people. Racist incidents have become increasingly common in these areas, with delivery workers often facing racially motivated assaults (Mantzipa, 2023). NGOs supporting migrants have also faced significant challenges. In early 2024, the headquarters of KISA (Action for Equality, Support, Antiracism) was attacked with a makeshift explosive device, highlighting serious safety concerns for human rights advocates (Amnesty International, 2024).

Public demonstrations in streets and public spaces have become common. In April 2024, hundreds gathered in Nicosia to advocate for equal rights for all migrants in Cyprus. This protest honoured Anisur Rahman, a Bangladeshi man who died while attempting to flee a police raid in Limassol. Protesters demanded equal healthcare access and an end to the dehumanization of third-country nationals (Kades, 2024). The experiences of migrants in Cyprus highlight how the nation's restrictive asylum policies often obscure the everyday realities and agency of migrants (Fischer, 2020). The ongoing tension between fulfilling international obligations to protect refugees and managing national resources is becoming increasingly apparent in current debates. As the instability in the Middle East worsens, concerns have grown over the potential impact on migration flows to Cyprus (France24, 2024).

The worsening of the situation for migrants and asylum seekers in the island in recent years has to do with political developments and policy responses. The Cypriot government has been lobbying the EU to designate certain areas in Syria as safe (Al Jazeera, 2024). In April of 2024, declaring that 'the flows are unmanageable' (Stamouli, 2024), Cyprus suspended asylum applications from Syrians without specifying how long the measure would last. In September 2024, Human Rights Watch (HRW) accused Lebanon and Cyprus of collaborating to prevent Syrian refugees from reaching Europe and forcibly deporting them back to danger in Syria, citing pushbacks by the Cypriot Coast Guard (Human Rights Watch, 2024).

Migration patterns, debates and issues are further complicated by Cyprus's division. Irregular migrants often arrive in the TRNC via ferry routes before crossing the Green Line into the RoC. Some also enter the RoC on legal visas but overstay or violate visa terms (Baldwin-Edwards & Kraler, 2009). Many migrants and refugees travel in stages from countries such as Turkey, Syria, or Lebanon, eventually crossing the Green Line to reach the Republic of Cyprus and apply for asylum (Trimikliniotis & Demetriou, 2005). A result of such movements is the situation of individuals who remain trapped in

the UN-patrolled buffer zone, caught in limbo between a government refusing to accept them due to their entry from the northern part of the island, and the UN, which insists that Cyprus is bound by international law to provide protection (Al Jazeera, 2024; Smith, 2024).

For those who manage to apply for asylum and have their claims reviewed, the situation remains far from simple. As of April 2024, over 26,000 asylum applications remain pending (UNHCR, 2024b) , further highlighting the strain on the asylum system. Long processing times have worsened the challenges faced by newly arrived migrants (UNHCR, 2024a). Additionally, Cyprus experiences stark disparities in the treatment of asylum applications from different regions, with certain nationalities facing higher rejection rates, as seen in Table 1 (AIDA, 2024; Fischer, 2024). With around 96% of asylum applications denied, Cyprus ranks among the leading European countries in terms of deportations, proportionate to the number of asylum seekers in the country (see Figure 1 and Table 1).

Bangladesh	99.4%	0.57%	0%
Iraq	52.38%	10.95%	16.6%

India	100%	0%	0%

METHOD

This section highlights the methodological intentions for the three year project. The study adopts a multi-scalar approach, analysing migrant spaces across various urban environments in Cyprus. Key case studies include reception centres, migrant neighbourhoods in Nicosia, and public spaces that have become sites of migrant resistance. Spatial data will be collected through open-source databases and field observations, while social data will be gathered through engagement with NGOs. This dual approach will potentially allow for the analysis of how space is negotiated in these contexts. The research will adopt a mixed-methods approach to analyse the socio-spatial dynamics of migration in Cyprus, focusing on how migrants navigate and transform urban spaces. The methodology unfolds in three interconnected stages, allowing for a multi-scalar analysis that incorporates policy review, spatial change analysis, and the lived experiences of migrants. Table 2 summarizes the Stages and methodological approach proposed for the research.

Multi-Scalar Analysis of Migration on the Island

This phase focuses on understanding the broader migratory policies and infrastructures in place for migrant reception and integration. The stage envisions three main routes of methodological approach:

- Literature and Policy Review: entails a review of academic literature and government documents concerning migration policies in the EU and Cyprus, especially those related to the reception and integration of asylum seekers and refugees.
- Site Visits: Visits to key locations, such as refugee reception centres will help contextualize the policies within their spatial environments.
- Semi-Structured Interviews with Experts and Policymakers: Conducting interviews with key stakeholders, such as government officials, policymakers, and NGO representatives, will offer valuable insights into the execution and challenges associated with migration policies in Cyprus.

Spatial Analysis of Change in the Case Studies

This stage focuses on analysing how and if migration flows have physically altered urban environments in key case study areas.

- Diachronic Mapping: Historical and contemporary maps will be used to examine spatial changes in the urban fabric over time.
- Urban Morphological Analysis: A detailed analysis of the spatial layout, land use, and building typologies in migrant-inhabited areas will be conducted.

Lived Experiences Related to Space-Making Practices by Migrants

This phase will focus on capturing the everyday spatial practices and experiences of migrants, particularly in how they navigate, shape, and make space within Cypriot cities.

- Observations Through Activities with NGOs: Participant observation will be conducted during activities organized by NGOs.

- Semi-Structured Interviews: Interviews with migrants will be conducted to gather personal narratives about lived experiences, focusing on how urban environments are navigated and contested.

Table 2. Stages and methodological approach proposed for the research

	Main Focus	**Methodological approach**
Multi-Scalar Analysis of Migration on the Island	Understanding the broader migratory policies and infrastructures in place for migrant reception and integration. Recognition and Selection of cases to be analysed	Literature and Policy Review Semi-Structured Interviews
Spatial Analysis of Change in the Case Studies	Analysing how migration has physically altered urban environments in key case study areas	Diachronic Mapping Site Visits Urban Morphological Analysis
Lived Experiences Related to Space-Making Practices by Migrants	Capturing the everyday spatial practices and experiences of migrants, particularly in how they navigate, shape, and "make" space	Observations Through Activities with NGOs Semi-Structured Interviews

Data Analysis: The qualitative data gathered through interviews, participant observation, and site visits will be analysed through thematic coding. This will involve identifying recurring themes and patterns related to migration governance, spatial segregation, resistance, and community formation. Special attention will be given to the ways in which migrants engage in everyday acts of spatial negotiation, adapting to and reshaping their environments despite the constraints imposed by policy and socio-political exclusion. Additionally, the spatial data collected through GIS mapping will be integrated with qualitative findings to provide a multi-layered analysis of the physical and social dimensions of migrant spaces in Cyprus.

Ethical Considerations: Conducting research with vulnerable populations, such as asylum seekers and refugees, requires careful attention to ethical considerations, particularly regarding consent, reciprocity, representation, and flexibility (Darling, 2014). While policy experts and NGOs may provide information with less personal sensitivity, interviewing migrants and refugees presents more significant ethical challenges. Ensuring informed consent will be a central priority in all interviews and interactions. This entails clearly communicating the research purpose, explaining how the information will be utilized, and ensuring that participation remains completely voluntary. The author is also mindful of the dynamic nature of fieldwork, where unforeseen changes may arise. Even though such changes cannot always be anticipated, a commitment to a reflexive approach will be maintained, acknowledging the positions of power and privilege held by the researcher throughout the process.

The proposed methodological framework is a work in progress, but it is hoped that it will enable a multi-scalar understanding of migration in Cyprus, linking macro-level policies to micro-level spatial and social practices. The combination of policy analysis, spatial mapping, and lived experience research can potentially offer an approach to exploring the socio-spatial dynamics of migration in the context.

RESULTS AND DISCUSSIONS

As mentioned, the spatial dynamics of migration in Cyprus are shaped by the complex intersections of political division, socio-economic precarity, and the island's unique position as a gatekeeper to Europe. The project hypothesis argues that Migrant communities have an impact on Cypriot cities, both in terms of physical infrastructure and social integration. This section presents three key spatial categories where the presence of migrants is particularly evident as areas of possible exploration for the case studies to be selected for the research. These include reception centres, migrant neighbourhoods, and public spaces. These spaces are not merely containers of people and activities but are actively reshaped by peoples' daily practices and interactions with the urban environment.

Reception Centres: Pournara as a Site of Isolation and Control

The Pournara First Reception Centre, located on the outskirts of Nicosia, provides a stark example of the socio-spatial exclusion faced by migrants upon their arrival in Cyprus. Originally intended as a temporary facility for newly arrived asylum seekers, Pournara has expanded significantly in recent years to accommodate the growing number of migrants arriving on the island (UNHCR, 2024b). The physical isolation of Pournara, surrounded by fields and industrial zones, not only limits migrants' access to the broader urban fabric but also reinforces their exclusion from Cypriot society. Accounts on experiences in the camp highlight dire conditions (Fischer, 2024). While the reception centre was originally designed to house 350 people for 72 hours, its capacity has since grown to over 1,000 residents, with many asylum seekers staying for months at a time (UNHCR, 2024a).

Migrant Neighbourhoods: Spaces of Integration and Ghettoization

Beyond the reception centres, many migrants who manage to secure a more permanent status in Cyprus settle in specific urban neighbourhoods. These neighbourhoods have become vibrant but contested spaces, where issues of integration, economic survival, and social marginalization are at play (Philippou, 2008). While communities create trans-local networks, establishing businesses and forming social connections, they are often framed by public discourse as ghettos—spaces of exclusion and racialized difference. The creation of migrant enclaves in Cypriot cities reflects broader patterns of socio-spatial segregation, where economic precarity and racial discrimination limit migrants' ability to integrate into the mainstream urban fabric. These neighbourhoods are often under-resourced and stigmatized, both by local authorities and the media, which tends to sensationalize the presence of migrant communities as a threat to social cohesion. Cases in the city centre of Nicosia will be explored in the project.

Public Spaces: Resistance and Visibility in the Urban

Public spaces in Cypriot cities, such as parks, squares, and streets, have also become important sites for migrant visibility and resistance. Migrants use these spaces not only for leisure or economic activities but also as platforms for asserting their presence and rights within the city. Public spaces can become arenas for political contestation, where migrants engage in acts of resistance against their exclusion from mainstream society. In Nicosia, public spaces being used to challenge the state's treatment of migrants and to demand better living conditions and legal rights will be explored. Acts of resistance highlight the agency of migrants in shaping the urban, despite the restrictive policies that govern their presence. By occupying public spaces, migrants disrupt the spatial hierarchies that seek to confine them to the margins of the city.

The transformation of urban spaces in Cyprus materialised in reception centres like Pournara, migrant neighbourhoods in cities like Nicosia, and public spaces used for resistance and visibility all illustrate

the interplay between migrant agency and state control. These spaces, while often framed by exclusionary policies and socio-political marginalization, are actively reshaped by the practices and struggles of communities. Understanding these spaces as sites of negotiation, contestation, and adaptation can bring to light the need for the development of more inclusive policies that acknowledge the contributions of migrants to the urban and social fabric of Cyprus.

CONCLUSIONS

The hope is that the findings of the study will highlight the significant socio-spatial transformations driven by people on the move in Cyprus. Two key implications are anticipated: the role of migrants in challenging spatial exclusion and the potential of exposing the violence embedded in migration and integration management within this context.

Although the research does not aim to offer concrete solutions, it seeks to encourage reflection on the current situation. The findings may have significant implications for urban policy in Cyprus, particularly in terms of migrant integration and spatial justice. This study will explore the socio-spatial dynamics of migration in Cyprus, focusing on how migrant communities both shape and are shaped by the urban environments they inhabit. By examining the unique political and spatial context of Cyprus—a divided island with a history of colonialism and contested sovereignty—the research will reveal that migrants are not passive recipients of state policies, but active agents who transform urban spaces through their everyday practices and acts of resistance. The study will emphasize the importance of viewing urban spaces not merely as static infrastructures but as dynamic, contested arenas where migrant agency, state control, and socio-political struggles intersect.

ABSTRACT

This article investigates the intersection of memories, existences, and affections in the Alto da Serra neighborhood in Petrópolis after the 2022 floods, highlighting the social, cultural, and emotional dimensions of urban landscapes in contexts of socio-environmental vulnerability. Utilizing the cartography of affections, the research explores the emotional and spatial dynamics that shape the identity and resilience of the community, revealing the symbolic layers of the territory and the formation of local symbols based on the residents' experiences. The analysis is based on Raffestin's (1995) tetraglossia, which encompasses the territories of the everyday, exchanges, reference, and the sacred, highlighting the intersection of environmental injustice, vulnerability, and community resilience. The active methodology of the "Viver Cidades+, inclusion and urban diversity" group captured the voices of the residents through the game-device "A cidade que eu vivo," promoting an inclusive dialogue sensitive to the material and emotional needs of the residents. The 2022 tragedy underscored the urgency of inclusive public policies that promote socio-environmental justice and community participation.

Keywords: social memory, socio-environmental vulnerability, cartography of affects, community resilience, urban landscapes

INTRODUCTION

Landscapes: between memories, existences, and resistances

According to Jean-Marc Besse (2006), the landscape is everything that the eye can see, understood not only through the act of observing but also by participating in the experience, being perceived as the objective place of existence. This essay explores how different landscapes generate varied feelings in the individuals who inhabit them, highlighting the importance of mapping contemporary issues through landscapes that reflect social, economic, and political practices and values. Contemporary disruptions, such as climate change and migration, further complicate these dynamics.

Neil Brenner (2019) reinforces that urban transformations often result in unequal environmental impacts, with marginalized communities suffering more intensely. This amplifies the need for resilience and adaptation. Anne Tsing (2019) adds that global landscapes, though filled with ruins, can still generate new forms of life and existence, taking advantage of disturbances to create resilient environments. Tsing argues that "feral life" emerges from human disturbances in unpredictable ways, creating new interactions and forms of existence.

Tsing's narrative intersects with Ailton Krenak's (2019), who views the "end of the world" not as a singular event but as a continuous experience, particularly for indigenous peoples who face the destruction of their cultural ties and connections with nature due to colonial infrastructures. Both highlight resilience and the capacity for regeneration in the face of human disturbances. While Tsing discusses "ferality" as a natural response to human interference, Krenak emphasizes the continuity of indigenous resistance. Together, they invite us to rethink the relationship between humans and non-humans, recognizing that life persists and transforms, challenging the notion of total control and pointing to a resilient coevolution in a constantly changing world.

Social memory, existence, and resistance in transforming landscapes

The dialogue between Tsing (2019) and Krenak (2019) suggests that the end of the world, rather than being catastrophic, is an ongoing experience. Landscapes constantly transform through sociocultural processes and human and non-human actions, dismantling community bonds and connections with nature due to modernity. Krenak (2019) argues that modernization displaces people from rural and forest areas to favelas and peripheries, erasing identities and memories, replacing them with a homogeneous vision of humanity.

These perspectives lead to a discussion on how social memories are shaped by human actions and resilient responses from non-humans. Social memory, in the context of environmental disasters, becomes a field of resistance. Recalling and retelling traumatic stories is crucial in constructing a collective identity that challenges marginalization. Farias and Pinto (2016) question whether those who endure traumatic experiences can narrate their lives when facing death or the dissolution of subjective arrangements. This inquiry underscores the importance of testimony as a form of resistance and identity recovery.

For marginalized communities, survival mechanisms are born out of adversity, forming resilience against marginalization and a reclamation of landscapes through memories. Actions in landscapes, in response to fear of uncertainty, unite communities to face daily challenges. Marginalized communities

suffer from stigmas and stereotypes, resisting the lack of recognition of their practices. In this context, Spivak (2010) argues that the subaltern, excluded from political and legal representation, faces significant challenges in representing themselves autonomously. This struggle preserves their identities, asserting their place as rights-bearing subjects. It is crucial to create spaces where these voices can be spontaneously expressed as manifestations of memory.

This brings forth the concept of social memory. Jô Gondar (2016) views social memory as transdisciplinary, ethical, and political. Memory is produced in the present to reflect on the past with a view toward the desired future. Social memory is always connected to ethics and politics. Another essential perspective is the significance of forgetting in maintaining identity, which can be challenged and shaped by different forms of forgetting, such as segregation and historical silence. Memory is not reduced to representation since collective representations cannot fully capture society's dynamic nature. Social memory is influenced by emotions, sensations, creation, innovation, beliefs, and desires (Gondar, 2016).

In this light, reflection arises on the role of social memory in traumatic events, alongside efforts to document and resist forgetting. There is a paradox between erasing perceptions of lived traumas and giving voice to these experiences. However, such initiatives build a collective memory that transcends individual suffering, fostering solidarity and promoting resistance against marginalization and social amnesia. It is crucial to recognize that, while silence may be a survival strategy, testimony seeks meaning amid trauma, transforming memory into resistance. This introspection of experiences shapes the identity and resilience of vulnerable communities.

Socio-environmental vulnerability and environmental injustice

The concept of socio-environmental vulnerability addresses the intersection between social and environmental conditions, highlighting how these influence communities' ability to deal with threats and climate change. Vulnerability involves exposure to social, environmental, political, or economic risks (Braga, Oliveira & Givisiez, 2006). Its three main components are: risk exposure, reaction capacity, and degree of adaptation (Esteves, 2011).

When discussing landscapes and memories, we explore the ability of marginalized communities to adapt and resist environmental and social disruptions. Conceptualizing socio-environmental vulnerability also requires considering environmental justice. Low-income communities often accept risks to obtain better opportunities, exposing themselves to significant dangers (Zhouri & Oliveira, 2012). Environmental injustices stem from a developmental perspective that neglects social, cultural, and ecological issues.

Thus, understanding socio-environmental vulnerabilities requires a multidimensional approach that considers the interactions between social, economic, and environmental factors (Rammê, 2012). Fair and effective public policies must recognize and value the resilience of marginalized communities, promoting environmental justice that proposes an adequate redistribution of social goods to correct inequalities, values community participation, equity in resource distribution, and sustainability to address contemporary socio-environmental dynamics (Rammê, 2012).

Henri Acselrad, Cecília Campello Amaral Mello, and Gustavo das Neves Bezerra highlight that environmental injustices disproportionately affect vulnerable social groups, reflecting historical and geographical asymmetries (Acselrad et al., 2009). Similarly, Ricardo Abramovay argues that sustainability must be integrated into development strategies, promoting a more just and regenerative social metabolism (Abramovay, 2012). Based on this, we argue that recognizing the intersection between environmental injustice and socio-environmental vulnerability enables the development of more inclusive and effective approaches that promote socio-environmental justice and community resilience.

This entire debate seeks to affirm that landscape analysis reveals a complex web of interactions shaping territories and community identities, intertwining social memory, existence, and resistance to socio-environmental vulnerabilities through the fight for environmental justice. From this perspective, the landscape becomes a dynamic, interconnected space, a palimpsest of memories, existences, and resistances that manifest in a continuous effort of adaptation and survival, challenging power structures and promoting a more equitable understanding of human-environment relations.

CARTOGRAPHY OF AFFECTS AND ITS MULTIDIMENSIONAL INSTRUMENTS

Social cartography is an action-oriented concept that challenges the state's monopoly on map-making, advocating for the inclusion of marginalized social groups in the cartography of their own territories (Acselrad, 2009). This concept redefines cartographic practice, allowing communities to map their own territories and specific issues, using cartography as a tool of resistance against hegemonic spatial domination (Santos, 2011).

Suely Rolnik (2016) introduces "sentimental cartography," focusing on the emotional dimension of cartography. This approach emphasizes the importance of capturing emotional dynamics that influence individuals' relationships with their territories, offering a sensitive reading of human landscapes. It maps psychosocial landscapes, tracking transformations and the formation of new worlds to express contemporary emotions (Rolnik, 1989).

This methodological approach transcends the mere physical representation of spaces, enabling a deeper understanding of subjective and emotional experiences in the constitution of landscapes. Affective cartography allows for mapping not only objective structures but also affective ties, memories, and resistances that define communities' relationships with their environments, revealing the emotional and social dynamics that shape the resilience and collective identity of marginalized communities.

To apply this theory in field analysis with an ethnographic perspective, we draw on Raffestin (1995), who establishes an intrinsic relationship between language and territory through a fourfold schema for reading the landscape: everyday territory, exchange territory, reference territory, and sacred territory. Everyday territory is perceived through discontinuity and encompasses safety, love, and belonging. Exchange territory is in constant flux, based on power relations. Reference territory is linked to individual and collective memory and history, while sacred territory is associated with religion and the construction of the sacred (Raffestin, 1995).

Analyzing the territory of Alto da Serra through this territorial language and emotional framework is essential, especially following the 2022 flood disaster that claimed over 240 lives and transformed the

local landscape. Understanding the territory and the practices that constitute the Alto da Serra landscape requires empathetic dialogue with residents, considering their traumas, fears, and insecurities, and recognizing urban spaces as human and non-human relationships imbued with emotional dimensions.

The concept of "emotion city" suggests that urban space gains significance through our relationship with the world, shaped by both perceptual processes and sociocultural meanings (Coelho, 2015). This concept enables us to study a collective view of the city, understanding how collective identity is formed and highlighting the emotional dimension in the significance of public spaces, improving collective urban experiences.

Raffestin (1995) further distinguishes between the **Language of Landscape** and the **Language of Territoriality**, enabling us to understand spaces or agents as either structural or symbolic. The Language of Landscape refers to the visible, physical structure of a place—**the seeing**—while the Language of Territoriality pertains to the cultural and social meanings—**the living**. In our analysis, this approach allows us to comprehend the dynamics of the territory and the formation of collective identity, analyzing both the structural and symbolic elements of the landscape.

Our fieldwork strategies incorporated a multidimensional reading of the territory, initiated through the game “The City I Live In”, which captured residents' perceptions of Alto da Serra, revealing the potentialities and tensions in constructing the local landscape amidst memories, existences, and resistances shaped by socio-environmental vulnerabilities. The organization of results and discussions is structured around the narrative of Alto da Serra in Petrópolis, memories and vulnerability contexts, the game “The City I Live In”, and the landscapes of Alto da Serra—existences and emotions.

THE PLACE ALTO DA SERRA IN PETRÓPOLIS, MEMORIES, AND CONTEXTS OF VULNERABILITIES

Considered one of Brazil's first planned cities, Petrópolis (Figure 1) had its urban design commissioned by Emperor D. Pedro II and developed by Major Júlio Frederico Koeler in 1846 (Figure 2). One of the main directives at the time was that the city should be settled only along river courses. However, this design strategy proved ineffective over time, as territorial expansion became necessary in areas closer to the city center, where life technically unfolds (Alvarenga, Blaudt, & Garin, 2023).

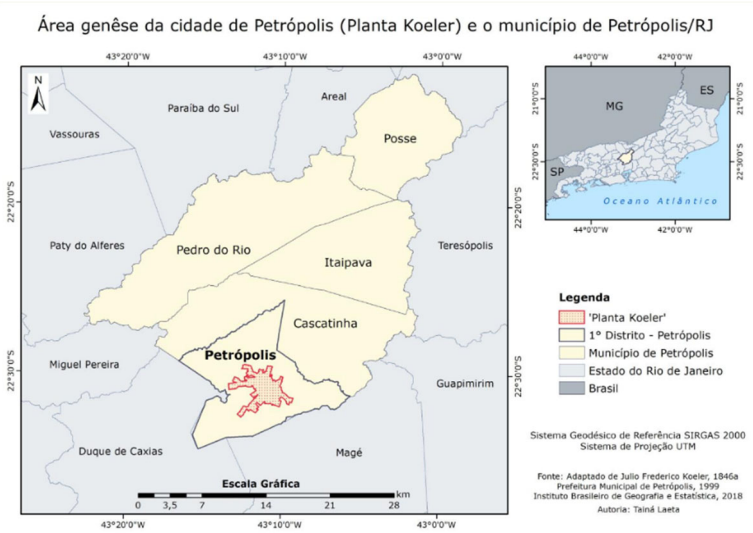

Figure 1. Boundaries of the Petrópolis area - "Koeler Plan". Source: Laeta, Fernandes & Fernandes (2022).

Initially, the city was designed to serve D. Pedro II's court. However, its proximity to Rio de Janeiro and the construction of the BR 040 highway in 1928 increased demographic density. The establishment of industries, particularly textile factories, attracted a working population to nearby areas, leading to settlements on the slopes surrounding the originally planned sectors (Alvarenga, Blaudt, & Garin, 2023).

The Alto da Serra neighborhood, previously known as Villa Theresa (Figure 2), exemplifies this process of demographic intensification. The neighborhood's development was driven by the inauguration of the train station and the arrival of the railway (Figure 3) in 1883, with its last operation in 1964 (Diário de Petrópolis, 2010). The establishment of factories, such as the Dona Isabel Textile Factory (1889) and the Cometa Textile Factory (1903), made the neighborhood a central hub of industrial activity (Reis, 2021).

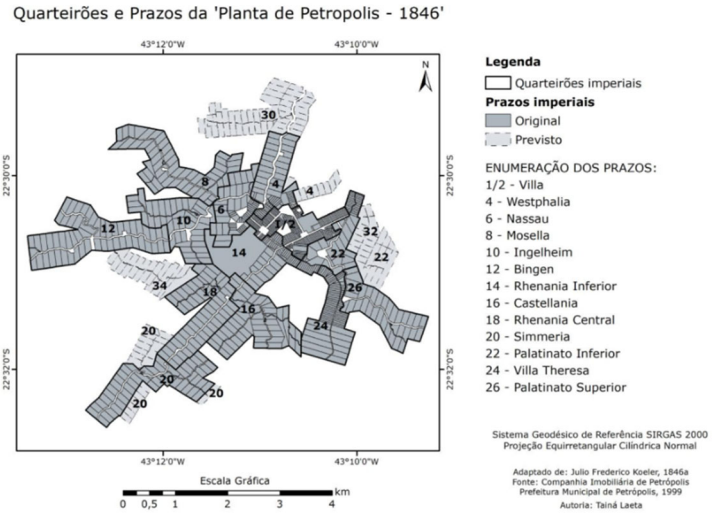

Figure 2. Imperial blocks and land grants on the Koeler Plan – 1846. Source: Laeta, Fernandes & Fernandes (2022).

In addition to its commercial dynamics, the former Villa Theresa — now Rua Teresa, part of the Alto da Serra neighborhood — was, in the 19th century, the only possible route for those coming from Rio de Janeiro to the center of Petrópolis. During this time, the street served both residential and

commercial purposes. However, by the 1970s, due to the city's geographical challenges that hindered expansion, the factories in the neighborhood went bankrupt, leading former workers to establish clothing businesses along the street and in nearby areas. This shift shaped the current dynamics of Rua Teresa, now considered the largest open-air shopping area in Latin America (Sou Petrópolis, 2023).

Figure 3: Freight train leaving Alto da Serra, passing in front of Rua Chile towards the station in the city center. Source: Personal collection of Mr. Walmir, n.d.

The unassisted urbanization in the neighborhood led to the removal of vegetation and the impermeabilization of the soil, causing the extinction and pollution of water sources and an increase in erosion processes, commonly associated with housing disasters (Lopes apud Campos & Parola, 2022). Petrópolis, located in the Serra do Mar, has rugged terrain and a tropical altitude climate, resulting in torrential rains (Campos & Parola, 2022).

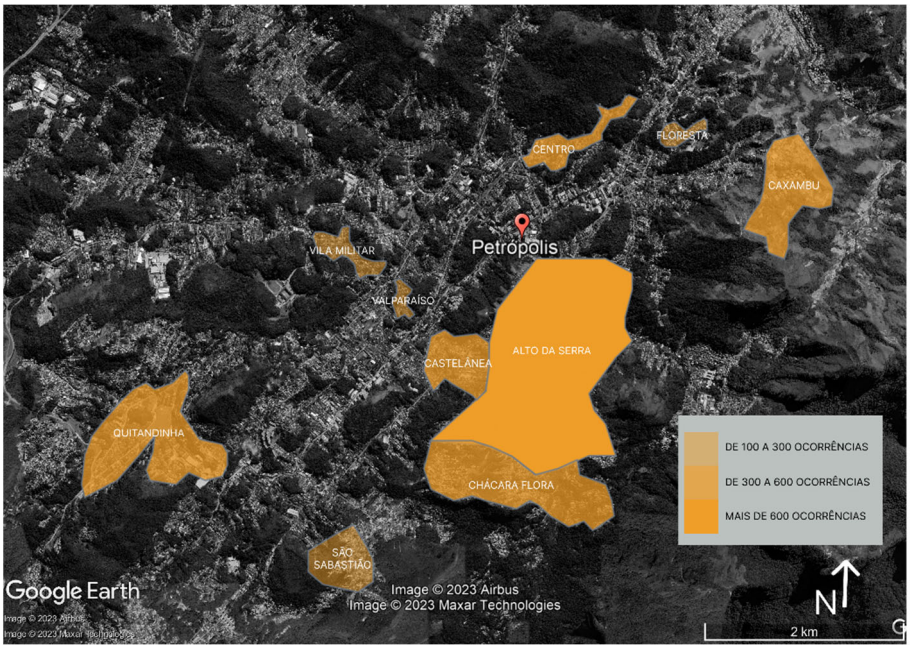

Figure 4: Map of incidents recorded by neighborhood on the day of the tragedy by region. Source: Author, with data from the Petrópolis Civil Defense, 2024.

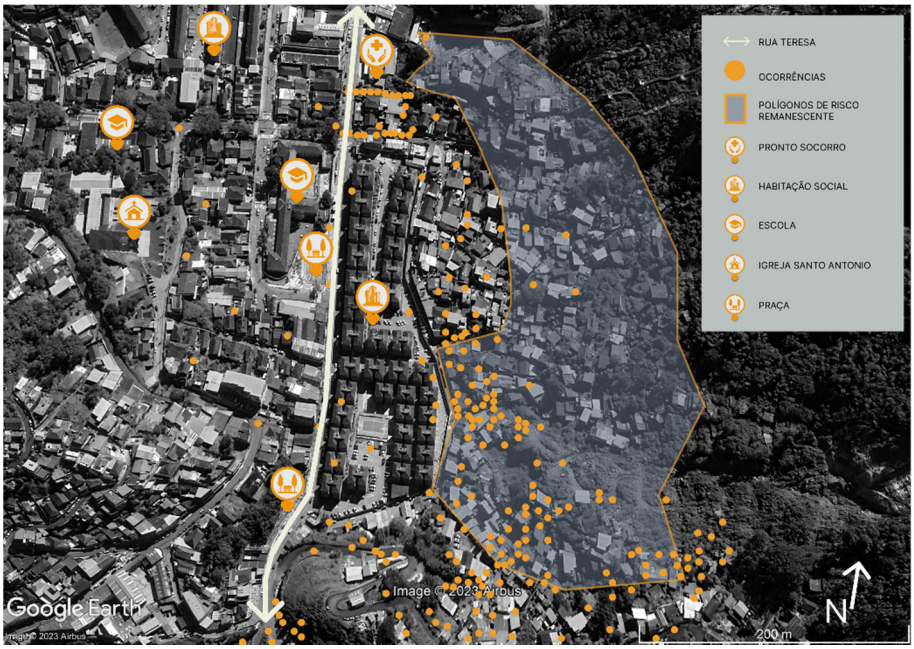

Figure 5: Revised map of the Morro da Oficina region with the location of recorded incidents and remaining risk polygon. Source: Disaster in Petrópolis in the summer of 2022: general aspects and Civil Defense data (Blaudt, Alvarenga, & Garin, 2023).

The combination of irregular urbanization with Petrópolis' natural conditions leads to tragic events, such as the one on February 15, 2022. A storm accumulated 259 mm of rain in six hours, severely impacting the Alto da Serra neighborhood, with 2,407 incidents reported (Figures 4 and 5). The most severe landslide occurred in Frei Leão Pathway and Ferroviários Street, destroying approximately 90 homes and causing the deaths of around 80 people (Alvarenga, Blaudt, & Garin, 2023).

Access to dignified housing and a balanced environment is a right, but many face precarious housing conditions without adequate infrastructure, resulting in environmental and social impacts. The public authorities' omission is evident, as no one would choose to live in a high-risk area (Campos & Parola, 2022). The city reflects the structural problems of societies, where economically dominant classes select the best territories, leaving minority groups with the remaining areas.

It is worth noting that Petrópolis was conceived as an agricultural colony with clear social and spatial segregation since the Koeler Plan. The 1st and 2nd class land grants (Figure 6) were reserved for nobility and artists, concentrating activities in the city center, while the 3rd and 4th class grants were assigned to artists less involved in agriculture and to farmers, respectively (Laeta et al., 2022). The Alto da Serra neighborhood, formerly known as Villa Theresa, carries the stigma of socioeconomic marginalization, demonstrating social segregation since the city's foundation. The territorial structure, conditioned by land use, perpetuated inequalities that persist in Petrópolis today, highlighting the need for inclusive and effective approaches that connect historical elements to contemporary dynamics of unassisted urbanization and environmental vulnerabilities.

We emphasize that promoting socio-environmental justice and community resilience requires public policies that value community participation, ensure equitable resource distribution, and foster sustainability. With a sensitive approach to community involvement, this research aimed to understand the physical and symbolic dimensions of Alto da Serra through the game that maps the memories and emotions of Petrópolis residents—"The City I Live In."

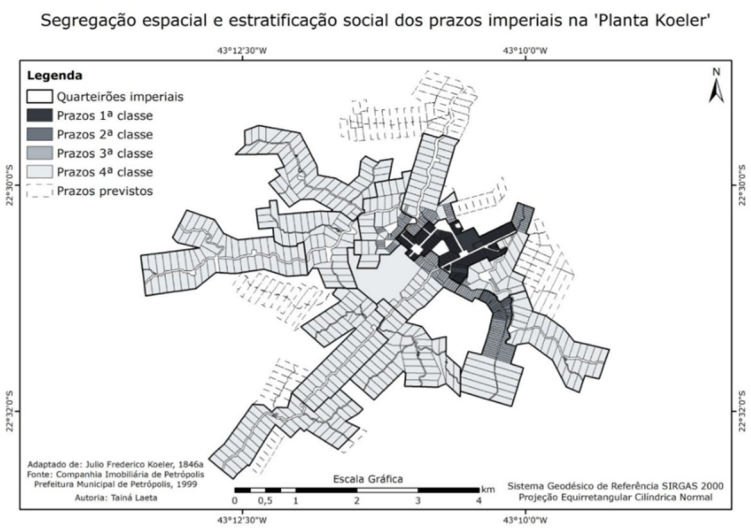

Figure 6: Imperial land grants and class division, following the occupancy guidelines of the provincial report. Source: Laeta et al., 2022.

The game, "The City I Live In"

To understand the multiple dimensions of socio-environmental vulnerability and community resilience in Alto da Serra, a methodology was adopted that captured the physical, social, and emotional experiences of the residents. The cartography of affections emerged as an essential tool, allowing for the mapping of memories and emotions that shape the lived landscape. The research group "Viver Cidades+, inclusion and urban diversity" used the conversational device "The Cite I Live In" (Figure 7) to promote a sensitive and inclusive dialogue, reflecting the residents' perceptions of the territory and their future aspirations.

On June 17, 2023, a cartographic activity was conducted in the event hall of the St. Anthony's Church, aiming to capture the physical, environmental, and social issues of the communities affected by the February 2022 floods. Based on the theory of Szaniecki and Anastassakis (2023), the activity engaged participants using a vector map of the neighborhood with reference points and questions about their relationship with Alto da Serra.

Participants included long-time residents of the neighborhood, some of whom were directly affected by the 2022 tragedy, and members of the St. Anthony's Church choir, who demonstrated a strong connection to the community and religious value to the region. In total, nine people participated, representing a wide age range and revealing the complex relationship between the community and its territory. The discussions highlighted the affection and belonging to the neighborhood, as well as the traumas and challenges faced. This approach captured the memories and affections that form the collective identity of Alto da Serra. Additionally, the analysis of the discussions, based on Raffestin's (1995) tetraglossia, will explore how the landscapes, existences, and affections of the residents intertwine, revealing layers of meaning that permeate the territory.

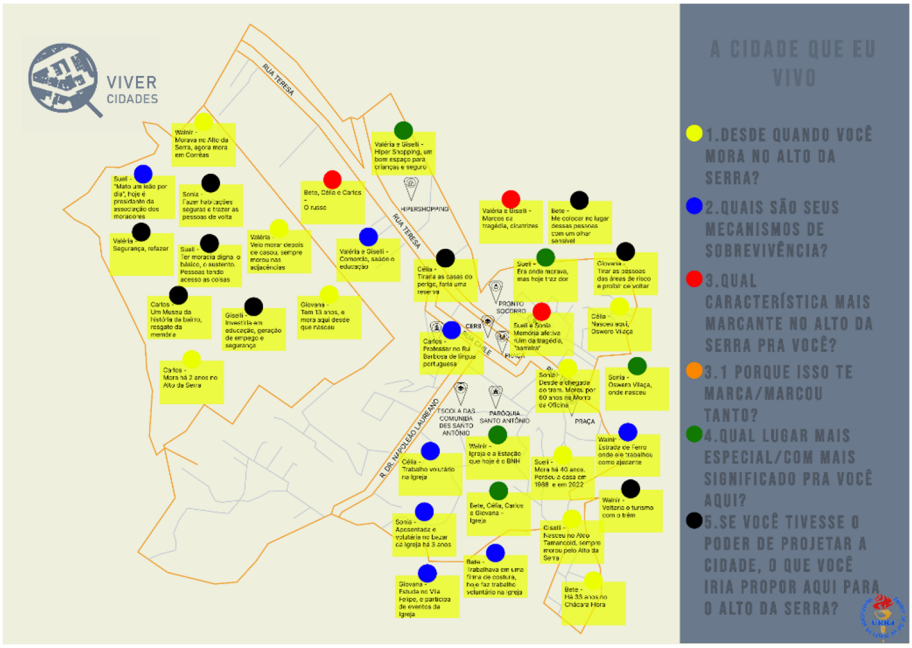

Figure 7: Game based on the social cartography methodology "The City I Live In." Each question has a corresponding color, with the responses being linked to the colors during the session, using post-it notes to record the main issues raised by the participants. Source: Viver Cidades+, 2023.

The landscapes of alto da serra, existences, and affections

Based on the field notes, we conducted a detailed analysis of the participants' statements, focusing on understanding the territory and its multiple dimensions. Using Raffestin's (1995) tetraglossia — everyday territory, exchange territory, reference territory, and sacred territory — we identified how these dimensions emerge in the residents' narratives, revealing emotional and symbolic layers that constitute the place. This approach articulated the concepts of the cartography of affections and the complex relationships between memory, existence, and resistance, highlighting the intersection between environmental injustice, socio-environmental vulnerability, and community resilience practices in Alto da Serra.

A statement that exemplifies the everyday territory well is from Resident B, where a contradiction becomes apparent after she praises her neighborhood:

> *[sic] Resident B: "So, everything here is good. Alto da Serra is a good neighborhood to live in for me. We have everything, we have a good emergency room, a pharmacy, we have everything we need here in Alto da Serra. So, Alto da Serra is a good neighborhood. Does it need improvement? Yes, it does. Our transportation is very bad, it is. So, these are things that, now, after last February's tragedy, made our situation much worse. So, we need to improve our neighborhood again, to try to bring it back to what it was, not what it was in the old days, but what it was just a short time ago, because we need many improvements." (Field Notes, June 17, 2023, emphasis added).*

Resident B begins by praising the neighborhood, highlighting its positive aspects, but soon reflects on the deficient infrastructure, especially urban mobility. This discrepancy highlights socio-spatial vulnerability, where the right to the city is unequally distributed. Despite the lack of infrastructure and the tragedy, she cannot imagine living anywhere else, reflecting a strong sense of belonging and attachment to the territory.

Another statement by Resident B reinforces this point:

> *[sic] Glauci [Researcher Viver Cidades+]: So, you live in Alto da Serra?*
>
> *[sic] Resident B: My life is in Alto da Serra. [...]. I can't imagine living anywhere else, okay? I can't see myself outside of here (Field Notes, June 17, 2023).*

Through this statement, we observe Resident B's positive affection for the place, as well as the strong sense of identification and belonging to the neighborhood where she grew up. Despite the lack of infrastructure and the recent tragedy, Resident B cannot envision living elsewhere. This feeling of belonging and attachment to the territory echoes the emotional and affective dimension discussed in the cartography of affections (Kastrup & Passos, 2013). Everyday life in Alto da Serra is shaped by the need for security, love, and belonging—fundamental elements in the construction of the everyday territory, as proposed by Raffestin (1995).

The analysis of these accounts reveals that the everyday territory in Alto da Serra is composed of both structural and emotional elements. While urban mobility and basic infrastructure are critical to the residents' quality of life, the way they are emotionally impacted by their daily routines is equally important. The cartography of affections has mapped these dimensions, offering a profound understanding of the social and emotional dynamics that shape the Alto da Serra community. Residents recognize both the available resources and the structural shortcomings they face. This highlights the urgent need for public policies that ensure the equitable distribution of urban resources, thus promoting socio-environmental justice and fostering community resilience. To achieve socio-environmental justice in Alto da Serra, it is essential for public policies to address both the material needs and the affective and emotional bonds of the residents.

An analysis of the territory of exchanges further reveals how economic and social interactions shape the lives of residents, especially within contexts of socio-environmental vulnerability. A statement from Resident A, regarding "housing allowance", a financial aid provided by the Federal Government to the population affected by the tragedy, sheds light on these dynamics:

> *[sic] Resident A: I said it because, thank God, I pay my bills. I don't need anyone to pay for me; I work for that. But it's complicated. And they target the weakest point. Ah. For people, that point is money. Unfortunately, right?*
>
> *[sic] Glauci [Researcher, Viver Cidades+]: It's the money, right?*
>
> *[sic] Resident A: Yes. Because not everyone has it, right? Unfortunately, now with this situation, any money that comes in is a gain for many, unfortunately.*
>
> *[...]*
>
> *[sic] Resident A: It's a bargain. It's a bargain. Unfortunately. It's complicated. The poor face a lot of complications. (Field Notes, June 17, 2023).*

This dialogue highlights the power of money in the lives of affected residents. In a vulnerable situation, the government opts for short-term, palliative solutions, as noted by Brenner (2019), who emphasizes

how urban transformations result in unequal impacts, with marginalized communities suffering the most. Financial aid exposes the fragility of public policies that should equitably ensure the right to the city. Zhouri and Oliveira (2012) stress that low-income communities accept significant risks in exchange for better opportunities, exposing themselves to considerable dangers. Thus, the territory of exchanges in Alto da Serra is shaped by the interdependence between the residents' economic needs and public authority actions. Palliative solutions, like “housing allowance”, while aiming to mitigate the immediate effects of the tragedy, perpetuate a cycle of vulnerability, underscoring the urgency for more inclusive and sustainable approaches that uphold the dignity and autonomy of affected communities.

In the territory of reference, the memory and ancestry of residents play a crucial role in shaping space and constructing collective identity. Moradora B’s statement highlights the importance of old memories of the neighborhood and the perceived changes over time:

> *[sic] Juliana Baur [Viver Cidades+ Researcher]: Moradora B. So you’ve been living here, as you mentioned to us, right?*
>
> *[sic] Moradora B: Yes, I’ve lived here forever. I’m from the time when we still had the train in Alto da Serra. Eh eh, there were almost no buses because sixty-five years ago there was none of this, none of what the other Serra is today. Back in my time, we knew everyone, but now we hardly know anyone, of course, only the very old ones. I, I was born here. Back then it was called Morro da Oficina (Field Notebook, June 17, 2023).*

Moradora B reveals a strong emotional connection to the neighborhood and a nostalgia for a past when the community was more cohesive and integrated. This sense of belonging, along with the reference to the train (Figure 3) that once existed in Alto da Serra, highlights the intrinsic relationship between collective memory and the territory. According to Raffestin (1995), the analysis of the territory of reference involves the historical and ancestral connection of the residents to the place, influencing their perceptions and interactions, marked by the memory of a more integrated social dynamic. Gondar (2016) emphasizes the role of social memory in constructing collective identity and resisting marginalization, as seen in Moradora B’s efforts to preserve the community’s memories and identity amidst urban transformations. Tsing (2019) and Krenak (2019) explore the resilience and adaptation of communities to environmental and social disruptions, illustrating how the memory of old landscapes serves as an anchor for the residents. Thus, the territory of reference in Alto da Serra becomes a palimpsest of memories and experiences, forming a collective identity that resists change and preserves the essence of the place. The residents' narratives reveal how social memory and collective identity are shaped by urban and socio-environmental dynamics, reinforcing the need for public policies that value and protect these memories and identities.

Lastly, in the territory of the sacred, the spirituality and religiosity of the residents of Alto da Serra emerge as central elements in building collective identity and community resilience. Moradora A's testimony reveals how faith and hope play a crucial role in moments of crisis:

> *[sic] Moradora A: "[...] I participated from the first to the last body being removed there. So, I had friends who, we could see, I couldn't take away their hope. You understand? I already knew because the firefighter had told me, 'There's no use because they aren't alive.' But she, she held on to that hope, that faith, you understand? So I, in the same way, tried to encourage her,*

> *but you know how it is, right? Keeping that hope even knowing that it wasn't there. [...]" (Field Notes, June 17, 2023, emphasis added).*

Moradora A emphasizes the importance of faith and hope as mechanisms of resilience and emotional support during the tragedy. Spirituality provides a refuge and source of strength for residents, allowing them to face pain and loss with a sense of purpose and community. This is also evident in Morador I's words regarding the St. Anthony Church (Figures 8 and 9), which stands as a landmark in the landscape of Alto da Serra and serves as a gathering place, reinforcing the territoriality of the neighborhood through shared practices and connections.

> *[sic] Resident I: St. Anthony Parish is the heart of our neighborhood. It's where we gather, celebrate, and find comfort, especially after the tragedy.* ***Faith gives us the strength to carry on and reminds us that we are not alone*** *(Field Notebook, June 17, 2023, our emphasis).*

This reflection by Resident I emphasizes the significance of sacred spaces as points of reference and emotional support for the community. The parish is not merely a place of worship but also a center for social and emotional support. Raffestin (1995) describes the sacred territory as a space imbued with religious and cultural meaning, offering a sense of continuity and security to the residents.

Figure 9: View of Alto da Serra from the churchyard of St. Antônio Parish today. In the background, Morro da Oficina. Photo: Glauci Coelho, June 17, 2023.

The analysis of the sacred territory in Alto da Serra should be based on the discussions by Tsing (2019) and Krenak (2019) regarding community resilience and adaptability in the face of adversity. Spirituality, along with memory and ancestry, provides a support structure that allows marginalized communities to resist external pressures and maintain internal cohesion, representing an essential dimension of identity and community unity. Faith and hope offer critical emotional and spiritual support for residents, highlighting the importance of inclusive and sensitive approaches that recognize and value these dimensions in the formulation of public policies and the promotion of socio-environmental justice.

CONCLUSIONS

This investigation into the memories, existences, and affections in Alto da Serra, Petrópolis, after the 2022 floods, revealed the complexity of the socio-environmental and emotional dynamics affecting the residents. By employing the cartography of affections and the participatory methodology of the game “The City I Live In,” we mapped the interactions between inhabitants and their territory, highlighting the importance of collective memory and community identity in building resilience in urban spaces. The analysis of the everyday, transactional, referential, and sacred dimensions of the territory demonstrated how emotional and social relationships shape the landscape and residents' perceptions of their environment. The collected narratives show a strong attachment to the place despite adversities, underscoring the need for public policies that promote socio-environmental justice and community inclusion. Thus, the intersection between socio-environmental vulnerability and environmental injustice drives us to consider the urgency of approaches that value resident participation in decision-making and equitable resource distribution. This study emphasizes the importance of considering affective and symbolic dimensions in urban management, fostering more human and sensitive planning to meet the needs and aspirations of communities.

ABSTRACT

The urban unsustainability and their climate change impacts generate vulnerabilities and greater efforts to transform cities in the face of catastrophes due to droughts, floods, extreme temperatures, among others. Taking as a basis the data, terms and definitions recommended by the UN on SDGs and ESG, this article brings analyses and considerations of the relationships between urban form and climate change, considering these and the other SDGs as indicators of service presented by the voluntary ESG reports made available on the Compact Global platform (ONU). Global Compact reports (ONU) are considered highly reliable and highly rational to determine qualitatively and quantitatively the relationships between cities and climate change, as well as parameterized definitions understood and guides to be followed. There was a compilation of data from voluntary reports in which companies indicate compliance with the SDGs obtained on the Compact Global platform, which concentrates global reports on ESG. It considered two samples, one without selecting the area of activity and the other for adherence to real estate, given the formal market and financial link of ESG reports. It was observed that the indication of compliance with the SDG, Cities and Climate Change, has a participation of over 70%, which leads to relational observations of participation and trends in the other SDGs, both for companies in general and for those operating in real estate. From this scenario, the oceans and seas, poverty, water and terrestrial ecosystems stand out as having the worst conditions of service for both samples. These low service take-ups by companies, in terms of the formal market, bring to light the great effort that companies, societies and cities need to transform not only how they serve to improve their SDGs. This statistical analysis is very important to build a urban form more sustainable and adapt to climate changes.

Keywords: ESG-UN, SDGs, cities, climate change

INTRODUCTION

According to the 2030 Agenda, cities must address parameters in accordance with the 17 Sustainable Development Goals (SDGs) regarding sustainable development in the face of the climate changes foreseen by the United Nations Organization (UN) (2015). These parameters must consider

transformations in urban form over time according to region, historical, social and cultural context, and economic conditions (UN-Habitat, 2020a).

Second, Wong (2001), the urban form and the understanding of spatial organization influence a city's environment, quality, and sense of place with two significant principles: theoretical and practical implications. Urban morphology, technological changes, income, wealth, preferences, economic restructuring development processes, and public sector actions are the main factors shaping the urban form. These indicators reflect the contemporary urban reality of an area characterized as a city space and its capacity for sustainable development. About 80% of the two SDG indicators contain an urban component, and its morphological factors corresponding to about one-third of the indicators are measured locally (UN-Habitat, 2020b).

Considering that companies establish business strategies of institutions and companies with financial implications such as “responsible investment” based on the bases and principles of ESG (Environmental, Social and Governance), or Corporate Social Responsibility (CSR) performance, environmental, social and governance needs to be disseminated. These responsible investments of companies can be aligned with the 17 SDGs, thus improving the structure of the city and involving the urban form. Ting-Ting et al (2021) observed that there is no unified concept of ESG actions between institutions, organizations and companies, reducing credibility, authority and doubts of adesões. Most of the ESG assessment systems are defined by a team of specialists, generating subjectivity. In the context, ESG urgently requires a quantitative basis for information on social, corporate and practical responsibility.

Machado (2024) highlights that many actions of markets, governments, and other institutions are needed to absorb the impacts of climate change and adapt city areas against flooding and heat waves in valued areas. Environmental inequality mainly affects people who live in vulnerable areas, leading to increased mortality, reduced wages, and reduced productivity and learning, among other things, in addition to altering the conditions of city growth and development.

On the one hand, the global and ambitious SDGs have directives that guide companies and organizations to contribute with quantified and substantiated results without ESG. Furthermore, the parameters obtained from two SDGs, Cities and Climate Changes, have direct ESG correlations and are integrated into declarations and reports. It is essential to know that there are expected differences and interdependencies on environmental, social, and economic issues. The SDGs can even transform or evolve for scenario analysis, starting when the status of the formal real estate market is declared. ESG. In other words, observation adheres to the contemporaneity of what is produced as real estate and local assets transformed by being human, and the human parameters and sustainable development are auxiliary as cities do not confront climate changes.

This article aims to underscore the importance of understanding the relationships between the variables taken as two SDGs in the face of climate change. This understanding, whether it's based on consolidated functioning or science, is vital for the successful implementation of sustainable urban development and for the achievement of the SDGs and ESG on the UN platform.

Database and communications on ESG

In the global context, actions to address the global problems foreseen in the SDGs are related to implementing risk analyses, but the increasing pace of organizations may fail to manage ESG issues and generate impacts on reputation, customer loyalty, and financial performance (COSO; WBCSD, 2018).

In many cases, the media reports to civil society and the organization when there are incidents related to pollution, customer and employee safety, ethics and management oversight, denigrating the image of companies, instead of having the role of communicating actions to mitigate and adapt to climate change. Environmental issues can generate short-term impacts on business and reflect their anticipated effects on the long-term market, mainly on cash flows depending on the associated risks. COSO and WBCSD (2018) highlight some environmental disasters caused by companies in the infrastructure, cities and construction sectors that suffered ecological impacts:

• 2010: In the area of infrastructure and energy construction, BP's deep-water oil platform explodes, killing 11 workers, injuring 17, and creating an environmental disaster.

• 2011: In the area of urban infrastructure, Flooding in Thailand disrupted the automotive sector, technology networks, and supply chains.

• 2013: In the area of constructed buildings, the collapse of a building killed more than 1,100 workers in Rana, Bangladesh, a manufacturing hub used by more than 25 global brands.

• 2014: Drinking water in Flint, Michigan was found to have high lead content, generating high risks to the environment and ecosystems. • 2015: Air pollution in cities: Millions of Volkswagen cars were recalled after the company admitted to falsifying emissions tests.

• 2016: Samarco (Vale and BHP) dam collapse that killed 19 people and caused iron ore and mining waste to spill into rivers, tributaries and into the sea.

Considering such environmental disasters and ESG issues, new tolerance limits for activities to mitigate the environmental impacts of pollution in the face of climate change are required. Such potential environmental impacts, linked to extreme weather situations such as floods and droughts, can affect both urban forms due to the need for adaptations to urban infrastructure and real estate, as well as business activities and the entire construction production cycle.

In Brazil, the primary conditions for ESG analyses are reports and communications regarding services and company reports by the United Nations Global Compact. Searches for the term ESG did not result in any company publications, but only six news items about Brazilian companies on the international page – “Compact Global”. It is worth noting that the global page of the “United Nations Compact Global” (2023) includes 7,264 communications in progress, in addition to 40 recommended websites, 12 events, 83 news items, 19 participations, and a library with publications. It proves that the term ESG and its indicators still lack more accessible formal structures, such as public data at the national level, justifying the joint effort and consistent knowledge for sustainability.

METHOD

The methodological procedures to identify the correlation and adherence of the SDGs in ESG by companies and institutions consist of:

1- Selection of the database and communications on sustainability – ESG

2- Definition of parameters to analyse the correlation between ESG as a basis and the methodology under considerations and delimitations on the SDGs.

3- Methodological development and correlation analysis between SDGs and ESG

Due to their absence in the Brazilian platform, the data search for international publications within the UN platform, Compact Global, could have been improved. After tabulation as indexes, an analysis of the possible differences between the areas, including architecture and urbanism, under the scope of voluntary declarations and reports of the formal market is carried out. Thus, the term real estate has become adherent to the market condition and its investments, to which the term ESG is appropriate.

In this sense, the term real estate refers to a portion of land and any natural or artificial improvements defined where natural annexes are part of the land and include trees, water, valuable mineral deposits, and resources such as oil, and artificial improvements include buildings, roads, sidewalks, and fences. In relation to categories, real estate can be divided into residential and commercial, and industrial properties are considered a subdivision of commercial properties (SEGAL, 2024). Therefore, regarding the SDG's compliance with the companies' reports, we sought to compile the checklist presented in the reports with excerpts of the general activities.

Given the lack of reports and communications on the Brazilian Global Compact platform, 7,264 ESG communications and reports available on the international website of the United Nations Global Compact, i.e., “Compact Global” (2023), were selected. First, the consistency of the communications was checked, and the consistency of the data was observed, i.e., the data was assessed to determine whether the download links were effective and contained the file that could be opened. Since some links did not have an unavailable file or interrupted access, 27 units were selected without choosing a filter by area or activity link with real estate. In this sample, the compartmentalization of data from the reports that companies voluntarily publish was considered according to their indication of compliance among the 17 SDGs.

In a second selection, the ESG reports related to real estate were considered, consolidating a sample of 105 units. The construction and compartmentalization of data by companies were tabulated in an Excel spreadsheet, considering the score “zero” for no citation and “1” for citation of compliance with each reported SDG, thus presenting the sum of indications from the reports constituting the samples (Table 1). In this way, it is possible to identify qualitatively and quantitatively the strategic actions of real estate properties in general and other specific real estate services. It allows the projection of actions related to each SDG, presenting the general practice of the formal market and the macro analysis of companies in relation to ESG factors.

Table 1. Number of indications of SDG compliance by companies operating in general and in real estate and the percentages of reports for each sample

ODS		GERAL COMUNICATION	% ESG GERAL	REPORT REAL ESTATE	% ESG REAL ESTATE

RESULTS AND DISCUSSIONS

Assess the proportion of compliance with the SDGs by ESG reports and communications using the radar chart format. This format allows, through a matrix, to compare the aggregated values of several data series and highlight adherences and possible conditions of fragility and/or potential. Figure 1 shows the general results of the SDGs declared in the reports. The highest adherence was for the SDGs: Gender with 89%, Economy with 89%, and Climate Change with 81%. It shows that reports based on the very definition of the terms that carry the acronym ESG, where Governance by Economy and the basis for financing and investments, Social by the main relationship is Gender and therefore Environmental by Climate Change, thus raising the question of whether these statements of greater compliance if carried out by companies in their practices, are sufficient to meet sustainability.

In compliance with approximately sixty percent of the declarations made by companies, there is Inequality, together with Consumption and production (18 or 0.67), Education and Energy (16 or 0.59), Cities and Infrastructure (17 or 0.63) and Global partnership (16 or 0.59), referring in the same way as the terms with the most significant focus, which are social, in this order, including Inequality and education, in which many of the reports indicate training and inclusion actions. The items of energy and infrastructure are reading as the drivers and bases for the means of production, and which correspond to the environment and whose resources impact business economic conditions and therefore the global partnership, the conditions of commodities, exports, and imports, transfer and bases of innovations, among other relations of international relations that economically and

financially articulate companies and markets. The SDGs suggested are Society (48%), Health (44%), Water (41%), Poverty (37%), Terrestrial Ecosystems (33%), which suggests that these are objectives that must meet. However, it can seem that these are companies in the formal market and supported by procedures that comply with licenses regarding impacts on terrestrial ecosystems, as well as the use, Consumption, and emissions of liquid effluents and part of the services that require health conditions for both employees and the surrounding area, it must consider that these are current practices and are underway by many of the companies and therefore few point to practices that go beyond operating conditions to more consistent goals for sustainability as common development objectives. ● The two worst SDG compliances for the sample of companies, in general, appear as compliance indications in 7 of the 27 reports, corresponding to 26% of this sample, which are Hunger and Oceans and seas, for which the objectives taken as externalities to the main actions and activities with a focus on sustainable financial responsibility are indicated.

To verify the behaviour of companies in the face of the opportunity for voluntary ESG reporting and provide analyses that demonstrate the adherence of the variables, an indicator of the reality and practice of companies in the construction and real estate sector, a quantitative and qualitative methodology based on the construction of a sample of data on SDG compliance in voluntary ESG reporting. For example, previously described and which were only available on the international platform, “Compact Global,” and with a search selection of reports in which companies classify themselves as operating in real estate.

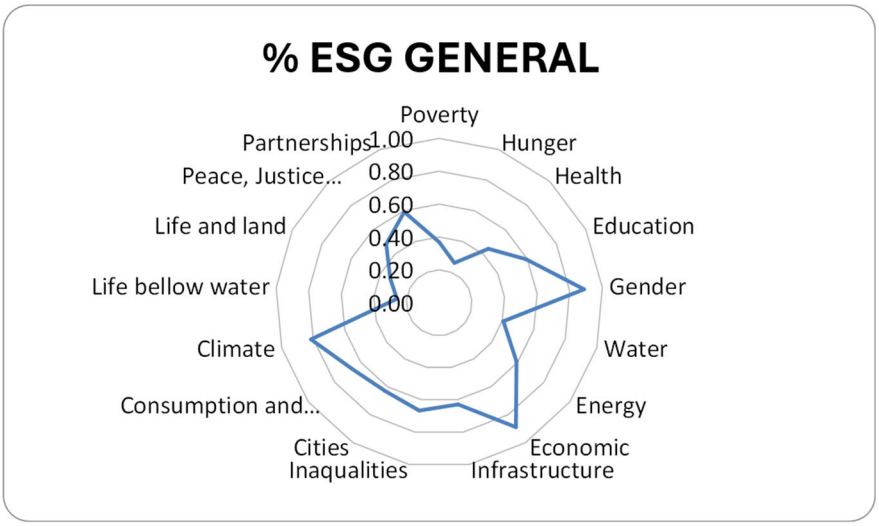

Figure 1. Diagram of quantitative adherence to the SDGs of companies operating in the general market. credit: authors.

These notes use radar diagrams plotted in Figure 2, which allows the comparison of aggregated values from several data series. This highlights adhesions and possible conditions of fragility and potential, highlighting individual maximum service points.

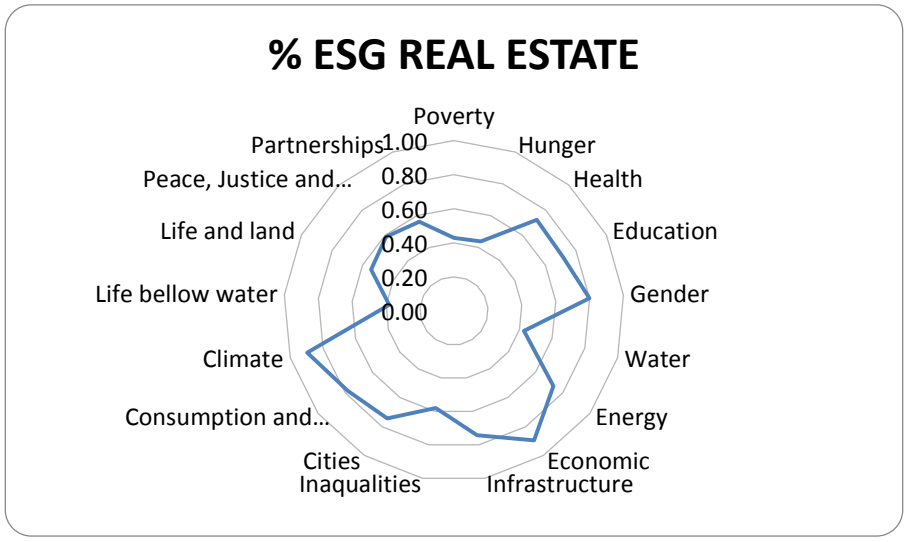

Figure 2. Diagram of adherence to the SDGs of companies operating in real estate. credit: authors

The economy and climate change are cited in the range of 90% to 80%, with both 94 indications of the 105 reports, that is 0.90. Compared to companies in general, the Gender SDG loses a mathematical representation, which is not substantial, from 0.89 to 0.80 for real estate. The main adhesions also show a noticeable reduction from 0.90 to 0.89 for the Economy and Climate Change SDGs from 0.90 to 0.81. Therefore, it can be said that there is no major strategic change in the main action for the SDG as a "flagship." The SDGs are in the range of 80% to 60%: gender (0.80), Consumption and production (0.78), Infrastructure and Cities (0.74), energy (0.73), Health (0.72), and Education (0.71).

Regarding the comparative performances of the real estate sector and in general, the Gender SDG follows the previous higher range. The real estate sector's services exceed 10% in the sense of better services for Consumption and Production, education and Energy (16 or 0.59), and Cities + Infrastructure (17 or 0.63). Global partnership services are equivalent, but the real estate sector is 10% behind in the Inequality item. From 60 to 40%, we have Society (0.59), Terrestrial Ecosystems (0.54), Water and Hunger (0.43), and Poverty (0.44).

Therefore, real estate surpasses general-purpose companies by around 10% for Society and Poverty. It is equal in the water category and superior to general-purpose companies for hunger and terrestrial ecosystems by 20% and 30% for education and health. The worst indicators for companies that declare themselves ESG adherents and indicate the SDGs are represented by oceans and seas 38%. For companies operating in real estate, this drops to 26% of the attention for general-purpose companies.

Figure 3 illustrates the comparative analyses indicated below. With the emergence of ESG, a new guideline that aims to integrate construction products into the links of the chain, it is crucial to stay updated. This guideline is very favorable, as it addresses certain variables related to the governance and economic-financial conditions of the company that are not specified in green certifications.

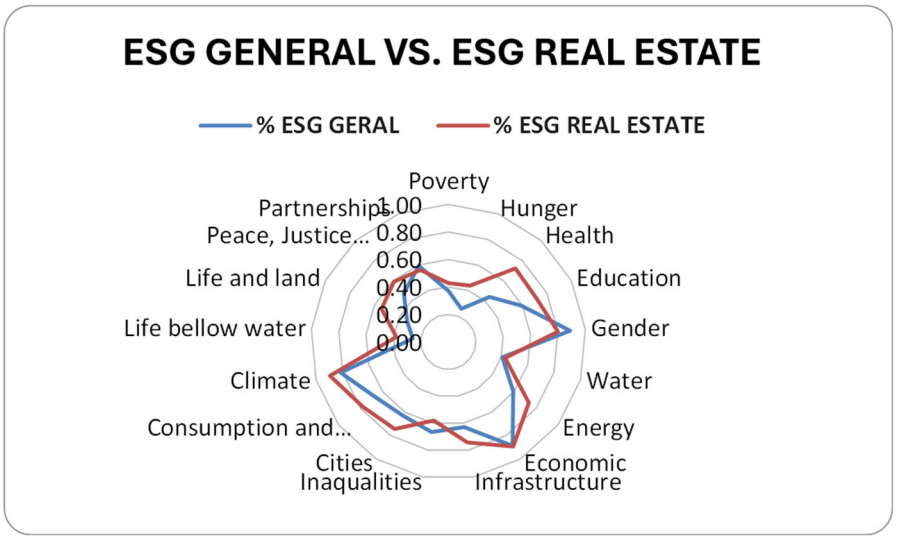

Figure 3. Comparison between diagram of adherence to the SDGs of companies operating in general and real estate. credit: authors

The integration of certification seals for construction and real estate projects into ESG reports, including the governance, social and environmental aspects regarding the business and financial aspects, is a service within the complexity of corporate actions. This complexity underscores the need for a comprehensive understanding of sustainability, as these actions are not always transparent with the environment and the actions of society.

Thus, the interpretation was about the values of the environmental footprint by-products and arguments about how global climate change is characterized. With the need to reduce greenhouse gas emissions, energy consumption, and the depletion of non-renewable resources, sustainability became the quality of performance of an intricate process and the way of acting used to obtain each production.

The desirable integration of ESG and building certifications and the understanding of the relationships between the variables of each of the actions lead to a new and broader look at what the life cycle and life cycle cost of products may be, more holistic but not diffuse, to provide the opportunity to offer conditions to link ESG and SDG data and reported items to specific actions of buildings and real estate properties and how they make up the territory and the urban forms of construction and occupation.

From this condition, this analysis of service trends can be brought; in the case of this article, it is to gather SDG services under ESG reports, thus having at its core the search for construction of alignments within the complexity that is sustainability, a way of adhering to variables that are requirements for sustainability, but that are not standardized and are not under the same metric, methodology applied in this study and gathered in Table 2.

The ESG guideline, a significant development, is designed to integrate construction products into the chain's links. This is crucial because it addresses certain variables related to the company's governance and economic-financial conditions.

Integrating certification seals for construction and real estate projects into ESG reports is a significant step. This comprehensive approach, which includes the governance, social, and environmental

aspects alongside the business and financial aspects, provides a clear view of corporate actions and their impact on the environment and society.

Thus, the interpretation that was had about the values of the environmental footprint being characterized by-products and arguments about global climate change, the need to reduce greenhouse gas emissions, energy consumption, and the depletion of non-renewable resources, sustainability became the quality of performance of an intricate process and the way of acting that is used to obtain each production.

The desirable integration of ESG and building certifications and the understanding of the relationships between the variables of each of the actions to lead a new and broader look at what the life cycle and life cycle cost of products may be, more holistic, but not diffuse, to bring the opportunity to offer conditions to link data and reported items of ESG and SDGs to specific actions of buildings and real estate properties and how these make up the territory and the urban forms of construction and occupation. From this condition, an analysis of service trends can be made. In this article, the aim is to group the SDGs under the ESG reports together. Thus, the core objective is to seek alignments within the complexity of sustainability, a way of adhering to variables that are requirements for sustainability but are not standardized and are not under the same metric, the methodology applied in this study and gathered in Table 2.

Economic	8	94	89.52%
Climate	13	94	89.52%

In this Table of trends, the real estate sector, perhaps due to its specificity, has the highest level of service in seven SDGs, between 100 and 82%, compared to only 3 items for the services in general. In the medium level of service, there are items that should bring up the profiles related mainly to the locations of service that are far from the basic vulnerabilities and precariousness and not those of consolidated urban centres.

Notably, the themes with the most significant global amplitudes and impacts are under the worst trends, with Oceans and Seas standing out. Poverty, water, and terrestrial ecosystems were the two

segments used in these data analyses. The topics of hunger and health have also been added for companies operating in general.

As a critical analysis of the context and the analyses presented up to this point, it is still worth considering and absorbing the limitations that even robust studies in sample compositions incur that can lead us to improvements. Still, it is considering that any tangible requirement, such as environmental resources, is not monitored by a standardized methodology and quantifications or even within a common scientific and statistical formulation and that there is no one for the monitored part, social, economic, political and go governance-related a structured and common way.

The trend diagram is a demonstration of evidencing the situation of materiality. Still, it starts from this inconsistency of possible relationships and for Don L Stevens Jr. and Anthony R Olsen (2004):

> "Environmental studies invariably involve populations distributed in space. Traditionally, such studies have focused on relatively small, well-delimited systems. However, some of the environmental issues we face today, such as global warming, long-range transport of air pollutants, or habitat alteration, need to be localized. Understanding and quantifying the extent of symptoms of widespread concern requires large-scale study efforts, which in turn require environmental sampling techniques and methodologies that are designed to address regional, continental, and global environmental problems."

The proposal, designed to address the dispersion and disconnection of variables as indicated by Don L Stevens Jr. & Anthony R Olsen (2004), is a significant step towards formalizing the contribution of sustainable works, including certified ones, to global sustainability and development. By seeking the relationships presented by the basic definitions of the SDGs and relating them to common practices in the real estate market, this proposal has the potential to inspire a greater advancement towards sustainability.

This analysis is grounded and characterizes that sustainable real estate products enable advancement in ESG strategies in a significant gain when compared to the insertion of services to real estate properties that elevate this service as being of great relevance to the condition of the sustainable quality of the product and without this condition, the formalization and indication of sustainability and its communication are faced with fragility and consistency and as proclaimed by Stevens Jr; Olsen (2004), which is fallible to the public's belief, resuming the condition that all parties should assess carbon emissions for proper integration of the bases.

Even if the analysis is structured to provide considerations on cities and climate change based on a data section on real estate from ESG reports, there is still a specific section parallel to the conditions of each country when it is taken as a reference. When companies in developed and underdeveloped countries find themselves, specificity is not achieved due to the lack of data offered on the Brazilian platform, UN Global Compact.

The situation of the base data generalization does not bring the asymmetries of historical contexts that intertwined in inequalities in infrastructure supply and socio-economic conditions by developing or precarious countries and regions. These factors affect the capacity to live in specific places.

These are structuring factors for selecting land use that impact other urban morphological variables in the long term (WONG, 2001). This consideration highlights the assumption of generalized indicators, but adherence to Stevens Jr. and Olsen (2004) is currently different on a large scale. However, it is necessary to consider the result of companies that SDGs already prepared and that the potential for transformation of cities is resumed, as they are inelastic variables that have a long-term impact on urban morphology.

Another point that stands out from this analysis is the results of the 2022 Brazilian CENSUS (IBGE, 2022), which shows that São Paulo has less than 6% inadequate sanitation, and Rondônia has more than 60%. This variable represents the unsustainability that influences the indicators of compliance with the SDGs.

CONCLUSIONS

The fragility, strength, and vigor of sustainability indicators tend to be unique and specific actions for a company, but this must go beyond the fact of belonging to and depend on an entire sector and its size. It is necessary to define its business strategy and objectives, which stakeholders are the primary ones in solving fragility and maintaining and even improving its potential so that its services to the global variables that have been demanded by environmental, social, and governance issues in a world that requires imperative values are expanding.

When it comes to ESG assessment, the role of professionals is paramount. Despite the lack of progress, there are scientific bases and references, such as the COSO and WBCSD guide (2018), that underscore the importance of professionals in sharing risk management results. Their contribution is crucial for a comprehensive understanding of the internal and external business context.

Therefore, our approach to sustainability should be one of optimism and action. By fostering a positive mindset, we can be more open to innovative actions and integrations that drive positive change.

Based on a tripod Environment, Social, and Governance, the requirement to address the complexities of actions and results and impacts with dependencies and related megatrends such as the SDGs, it becomes relevant for companies to look for ways that can identify the specific characteristics of natural, human, and social capital or other capital that the company can identify as a chain that demonstrates and predicts that a specific impact factor results in changes in the natural environment and a capital (or other capital) and consequently changes impact different interested parties, elucidating a path of dependence and interdependence as this study sought to follow and present. The universe of real estate developments will constitute a significant and fundamental sample space for ESG methodologies, in addition to the certifications that have been applied for some time, to be implemented under the risk of losing markets or reputations and, mainly, because we can foresee that the demands on them will increasingly constitute universes of pressure by the various agents that make up the chain of external and internal clients and will be characterized by factors of internal organization of cities and these as influencers of the form and structuring of urban morphology.

Comparative study on morphological indicators based on evaluating urban ventilation efficiency

Jiaying Li[1], Wowo Ding[2]

ABSTRACT

Indicators that characterize form and performance play a crucial role in urban morphology. Traditional indicators of morphological characteristics include the density of urban blocks, floor area ratio, average height, and average openness; some indicators express the space of urban streets or squares, such as aspect ratio, sky openness, and so on. Given the need to study the performance of the urban physical environment, researchers have explored the indicators that can express the performance of the urban physical environment, including the indicators that express the urban space (H/W, SVF) and some new density indicators, such as λp and porosity (Po), and theoretically confirmed the validity of these indicators. However, prior studies have also found that the same indicators have different correlation in different studies. This is due to different study have different study case with different morphological features at different scales. In urban climate studies, study areas are always divided by different sized grids. It is necessary to analyze these metrics in-depth and explore the mechanism of correlation between these metrics and urban ventilation performance as well as the working conditions of use. In this study, two typical areas in Nanjing, China, were selected as study cases: a complex commercial area sa non-homogenerous area and a single residential area as homogenerous. Then, the study areas are divided by four sized grids (with 200m, 100m, 50m, and 25m). Based on this, the effectiveness of four indicators, namely H/W, SVF, λp, and Po, in assessing the efficiency of urban ventilation and the utilization conditions were investigated. We found that 100m is the best sized grid to study the correlation ventilation and urban morphological; SVF and λp have better correlation in both cases; and homogenerous area has better correlation between ventilation and urban forms than non-homogenerous.

Keywords: urban morphology, environment performance, indicator, ventilation efficiency

INTRODUCTION

Characterising urban forms has always played a crucial role in urban morphology. With the development of digital platforms and analytical methods such as GIS, the demand for urban design has become more refined, and quantitative research on urban morphology has been emerging. Different scholars have proposed different indicators to express different urban form characteristics. For example, coverage ratio, floor area ratio and average height are put forward to describe the building density in study area. Height and width ratio and spatial openness can be used to express the

openness of urban streets and squares. These indicators can be used to research the process of urban form formation, the correlation with other non-physical performances, as well as the basis for urban form policy and urban design control.

Simultaneously, atmospheric scholars have recognized the pivotal role of urban morphology in affecting physical performance (i.e., solar, ventilation, and thermal performance). They've also proposed a series of urban form indicators to study this relationship, linking urban form to function in physical performance. At the earliest, Oke (1981, 1988) found that sky view factor (SVF) can reflect the urban heat island and height-to-width ratios (HWR) can relate with flow regimes of street canyons[1]. The roughness length formula proposed by Lettau used the ratio of area “seen” by the wind in the approach toward one characteristic individual obstacle to the lot area [2]. Plan area density (λp) is also a common indicator linking ventilation [3].Adolphe (2001) invokes the porous media theory and proposes indicators including Mineralisation (M), Rugosity (Hm), Porosity (Po) to correlate various physical performances in urban spaces[4]. Among all physical performance aspects, sunlight exposure is recognized as having the most distinct correlation with urban morphological characteristics, while wind and thermal conditions are deemed to be more complex. Wind and thermal environments are often considered inseparable, but the focus of this study is specifically on the performance of ventilation.

Interestingly, the urban form indicators proposed by atmospheric scholars are often similar sense to those proposed by urban morphologists in a mathematical computational. If these indicators can effectively correlate urban wentilation performance in real cities, they can be used to control and optimise urban ventilation. In fact, some of these indicators have already been used to control urban performance. However, the correlation of these indicators with ventilation in real cities is not the same as the theoretical correlation. Oke (1988) found that HWR can characterize the flow patterns of symmetrical canyons[1]. Li, You, Peng, and Ding (2024) found that more than 60 per cent of the spaces in real urban settlements have airflow patterns that cannot be correlated with their HWRs, even though the spaces studied are regular street canyons comprised of equal height and length buildings[5]. Moreover, research subjects with different morphological characteristics can also lead to varying degrees of association between the same indicators and ventilation performance. For instance, Yang, Qian, & Lau (2013) analyzed the correlation between the Sky View Factor (SVF) and the mean velocity ratio (WVR) in high-rise residential areas of Shanghai, yielding an R-squared (R^2) value of 0.62[6]. In contrast, Li, You and Ding (2022), who concentrated on urban forms in the city center, found a significantly lower R^2 value of 0.277 for the same correlation between SVF and WVR[7]. In addition, different study units and sizes in different studies also affects the correlation between morphological characteristics and ventilation performance[8]. One of the most common methods is to divide the urban area into research units using grids of different sizes. Side lengths of 25m, 50m, 100m, 200m are common grid sizes.

In summary, prior studies have also found that these indicators are not exact in expressing the physical properties of the city, especially in assessing the ventilation effectiveness of the town, and their accuracy varies depending on the environmental conditions and the morphological characteristics of the assessed opposite direction. For this reason, we try to explore that the correlation between different urban morphological indicators and ventilation performance in different cases with different morphological features under different sized grids. This study can be divided as five steps: Firstly, we

select study cases with different morphological features; Secoundly, study areas are divided by different sized grids; and ventilation data is getten on CFD simulation; Next, urban morphological indicators and ventilation indicators are caculated; Finally, correlation between ventilation and urban form are studied; Finally, we analyze the limilations of different morphological indicators and Impact of different study areas on correlation.

METHOD

Study case

In order to discuss the validity of different morphological indicators related to urban ventilation performance under different textures in real urban, it is necessary to find representative research areas with different morphological characteristics. Wowo Ding's team classified Chinese urban texture into homogeneous and non-homogeneous texture. Homogeneous texture generally refers to the texture composed of uniformly arranged buildings with similar volume, form and height, which is mainly distributed in urban residential neighbourhoods. Non-homogeneous texture is irregularly arranged by buildings with different volume, form, and height, which is mainly distributed in the city commercial center, cultural and sports building area, traffic hubs, as well as the scenic areas and so on. Therefore, we took two typical districts in Nanjing as study areas. Hexi residential area is a typical homogeneous texture, and Xinjiekou commercial centre area is a typical non-homogeneous texture (Figure 1).

Calculation Method of morphological indicators

Plan area density (λ p)

Plan area ratio (λ p) is the area ratio of all building footprints to the study area (Figure 2), which can show the building density. It can be calculated using Eq. (1):

$$\lambda p = \frac{\sum S_{_build}}{S_{_space} + \sum S_{_build}} \quad (1)$$

where $S_{_build}$ is the the footprint of any building; the $S_{_space}$ is total area of all spaces. From a morphological perspective, an increase in λp reflects a higher concentration of buildings. When λp is zero, it indicates that there are no buildings in the study area. Conversely, when λp equals one, it suggests that the area is fully occupied by buildings. Within the range of 0 to 1, the study area exhibits a coexistence of built structures and open spaces. From a ventilation perspective, a λp value of one implies that the area is entirely filled with buildings, precluding any airflow. As λp increases, the potential for ventilation decreases, establishing a negative correlation between λp and the quality of air circulation.

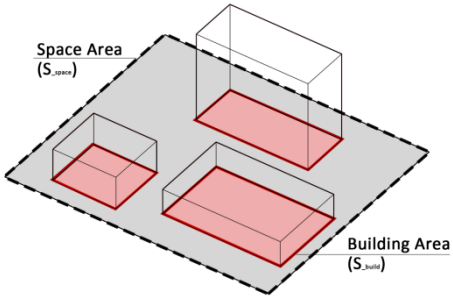

Figure 2. Caculation of λp

Porosity (Po)

Porosity (Po), which is the ratio of the volume of voids to the total volume within a study area, is used to describe the distribution of holes or gaps within a material or structure (Figure 3). The formula for calculating porosity is as follows:

$$\mathrm{Po} = \frac{Vol_{_space}}{Vol_{_space} + \sum Vol_{_build}} \tag{2}$$

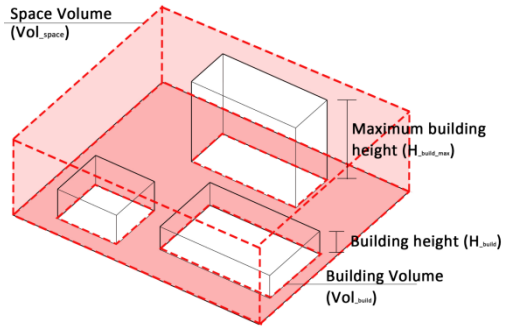

Figure3. Caculation of Po

Where $Vol_{_space}$ represents the total volume of space, while $Vol_{_build}$ is the volume of any building within the study area. $Vol_{_space}$ can be understood as the ratio of the maximum height of the tallest building within the study area ($H_{_build_max}$) to the total area of space within the study area, as follows:

$$\mathrm{Vol}_{\mathrm{space}} = H_{_build_max} \tag{3}$$

From a morphological perspective, the larger the proportion of space, the higher the Porosity (Po). It is noteworthy that when the study area contains no buildings and is completely open space, there is

no height, so the total volume of the study area is zero. Mathematically, Po cannot be calculated in this case. However, by definition, when the section contains no buildings and is entirely open space, Po equals 1. When the buildings fill the entire section with uniform height, Po equals 0. From a ventilation perspective, the higher the Po, the better the ventilation within the study area.

Sky view factor (SVF)

The sky view factor (SVF) refers to the ratio between the visible sky and the sky hemisphere at a given point (Figure 4). Two calculation methods were used to obtain the SVF in study area, which are the multipoint method and the simplified single point method. Li (2021) found that the correlation between SVF and ventilation is better by the multipoint method. Therefore, this study chose the multipoint method ro caculate SVF, noted as $SVF_{_ave.}$ $SVF_{_ave}$ is the mean value of all $SVF_{_single}$ in study area. $SVF_{_ave}$ and $SVF_{_single}$ can be calculated using Eqs. (4)-(5):

$$SVF_{ave} = \frac{\sum SVF_single}{n} \tag{4}$$

$$SVF_single = \frac{S_sky}{S_sphere} \tag{5}$$

where *n* represents the number of measurement points arranged within the study area. $S_{_sky}$ refers to the area of the sky projected onto the view sphere from the measurement point, and $S_{_sphere}$ denotes the surface area of the view sphere corresponding to the measurement point. From a morphological perspective, $SVF_{_ave}$ has similar morphological meanings to the Space Openness Index (SOI). It can characterize the openness of space in terms of form. The greater the SVF, the more open the space is. When SVF has no value, it means that the buildings fill the entire study area; when SVF is equal to 1, it indicates the absence of any buildings arround the study area when 0 < SVF < 1, it signifies the presence of at least one building within the study area or its vicinity. From a ventilation perspective, the higher the SVF, the better ventilation performance.

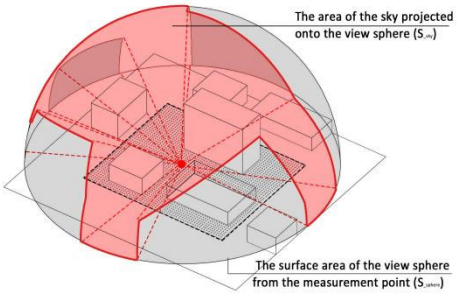

Figure 4. Caculation of SVF

Aspect Ratio (HWR_2_ave)

Oke (1988) used HWR of a ideal canyon perpendicular to the wind direction to correlate to ventilation[1]. But in real urban area, Li (2022) found that the HWR in one direction can not reflect the complex morphological features of the surroundings [5]. Therefore, we try employing the average of

HWRs in two orientations (aligned with and across the wind direction) to represent the characteristics of urban morphology (Figure 5), noted as $HWR_{_2_ave}$. It can be calculated using Eq. (6)-(8):

$$\mathrm{HWR}_{_2_\mathrm{ave}} = \frac{1}{\mathrm{n}} * \sum \frac{HWR_{_vertical} + HWR_{_parallel}}{2} \tag{6}$$

$$HWR_{_vertical} = \frac{\sum H_{_vertical}}{W_{_vertical} * 2} \tag{7}$$

$$HWR_{_parallel} = \frac{\sum H_{_parallel}}{W_{_parallel} * 2} \tag{8}$$

Where $HWR_{_vertical}$ is the aspect ratio of the building interface perpendicular to the wind direction, and $HWR_{_parallel}$ is the aspect ratio of the building interface parallel to the wind direction. $H_{_vertical}$ and $H_{_parallel}$ are the building heights perpendicular and parallel to the wind direction of the building interface, respectively. $W_{_vertical}$ and $W_{_parallel}$ are the widths between the building interfaces perpendicular and parallel to the wind direction, respectively. From a morphological perspective, $HWR_{_2_ave}$ can characterise the degree of enclosure of a space; the larger the $HWR_{_2_ave}$, the more enclosed the space is within the study area. similarly to the SVF_{ave}, where buildings stain the entire study area, there is no value for $HWR_{_2_ave}$.The value of $HWR_{_2_ave}$ depends on the degree of building enclosure in both directions of the test point, and is related to the cut location of the points contained in the average value of the points included in the cut location. Theoretically, the larger the $HWR_{_2_ave}$, the worse the ventilation.

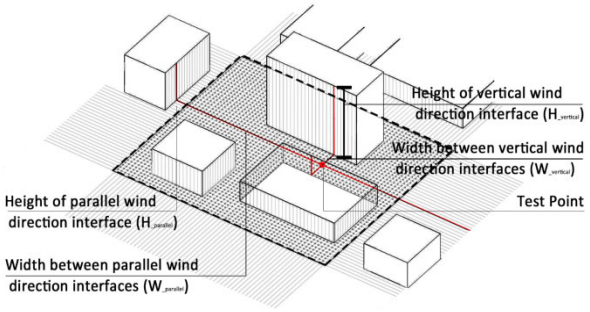

Figure 5. Caculation of $HWR_{_2_ave}$

CFD numerical simulation and Ventilation performance indicator

To predict the wind environment in the study area, Computational Fluid Dynamics (CFD) simulation was performed to simulate the wind field at pedestrian height (h=2m) in the area with south (S) wind direction. Reference wind speed is 2.8 m/s.

We chose the widely used mean velocity ratio (WVR) to evaluate the ventilation efficiency. The WVR is the average value of all velocity ratios the pedestrian heght (2m) of the space. The higher the value of the WVR in the area, the better efficient the ventilation of the area.

$$WVR = \frac{1}{n} \times \sum_{0}^{i=n} \frac{V_{ped_i}}{V_{\infty}}$$

Where Vped_i is the value of wind speed at pedestrian height and n is all the value points in the study area.

RESULTS

Study units by grids with different sizes

The study areas of Hexi and Xinjiekou are divisied by different sized grids. The division results can be categorized into three types by the situations of buildings in the study units: vacant units with no buildings (NBC), units with only partial buildings (PBC), and units completely filled with buildings (FBC). As the grid size continues to decrease, proportion of NBC and FBC increase, while the proportion of PBC decreases in Hexi and Xingjiekou.

Due to units with FBC are completely occupied by buildings, there are no ventilation data available, and thus these units do not participate in the correlation study. The presence of FBC is more prevalent in Xinjiekou, which may be attributed to the commercial building with larger footprints. In the Xinjiekou, FBC accounts for 1% in the 50m grid and 5% in the 25m grid. In Hexi, only two FBCs are included in the 25m grid (accounting for 0.125%)(Figure 6).

There are a larger number of NBC in Hexi than in xinjiekou.It is due to the strict adherence to sunlight spacing in residential design, leading to the inclusion of larger open spaces in the Hexi case. In addition, the presence of a significant amount of vacant land on the riverside in Hexi. In the 100m grid of hexi, NBC accounts for 5%; in the 50m grid of hexi, it accounts for 15%; and in the 25m grid, it accounts for 33%. In Xinjiekou case, the NBC account for 4% in the 50m grid and 20% in the 25m grid(Figure 6).

It is noted that units with FBC have no any ventilation data, and units with NBC have same values of λp and Po, separately. The four indicators can not reflect the surrounding morphological features due to their calculation method. Therefore, when the proportion of FBC and NBC is large, it may affect the correlation between the four morphological indicators and ventilation. However, the calculation methods of SVF and $HWR_{_2_ave}$ can reflect the surrounding morphological features. The units with NBC do not reflect the values of SVF and $HWR_{_2_ave.}$ Since FBC+NBC closed to 30% in a 25m*25m grid in both two study areas would have an impact on the correlation of λp and Po with ventilation, 25m*25m grid are not examined in the four indicators(Figure 6).

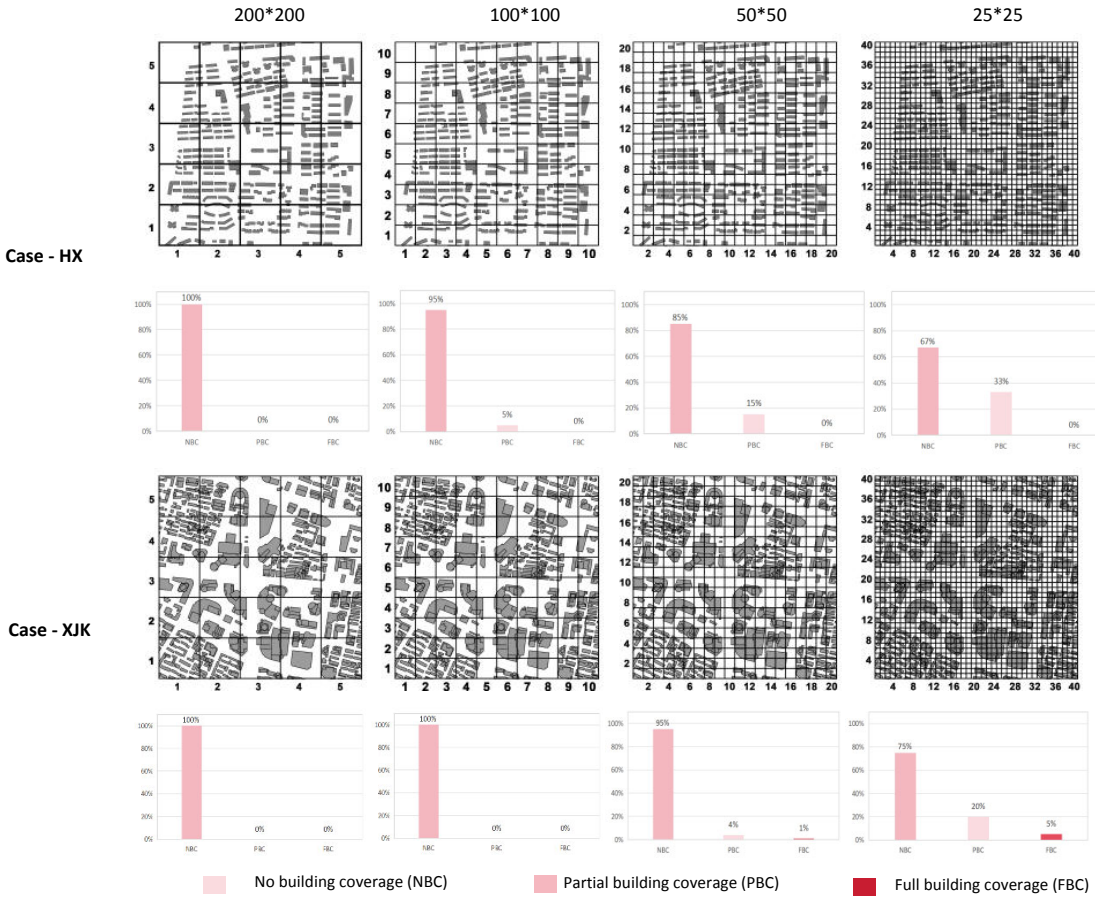

Figure 6. The study areas' dividision results

Results of morphological indicators

Whether it's Hexi or Xinjiekou, it can be observed that the larger the unit size, the smaller the threshold values for the four morphological indicators. This could be due to the fact that the larger the unit, the larger the range of buildings and spaces it contains, and the data obtained for each morphological indicator tends to be closer to the average. Therefore, a smaller grids might be able to capture finer morphological characteristics.

It can be seen that several indicators essentially conform to morphological significance (Figure 7). In Hexi, the northwest corner is the most open, hence these units have the smallest λp, the largest Po, the largest SVF_ave, and the smallest $_{HWR_2_ave}$; next are other units that include spaces such as squares, where λp are relatively small, Po are relatively large, SVF$_{_ave}$ is relatively large, and HWR$_{_2_ave}$ is relatively small; finally, there are other areas with denser buildings, where λp are relatively large, Po is relatively small, SVF is relatively small, and HWR$_{_2_ave}$ is relatively large. In Xinjiekou, the intersections, squares, and main roads are relatively spacious, so this area has a relatively small λp, a relatively large Po, a relatively large SVF$_{_ave}$, and a relatively small HWR$_{_2_ave}$; whereas in the old residential areas at the four corners, the buildings are denser, resulting in a relatively large λp, a relatively small Po, a relatively small SVF, and a relatively large HWR$_{_2_ave}$.

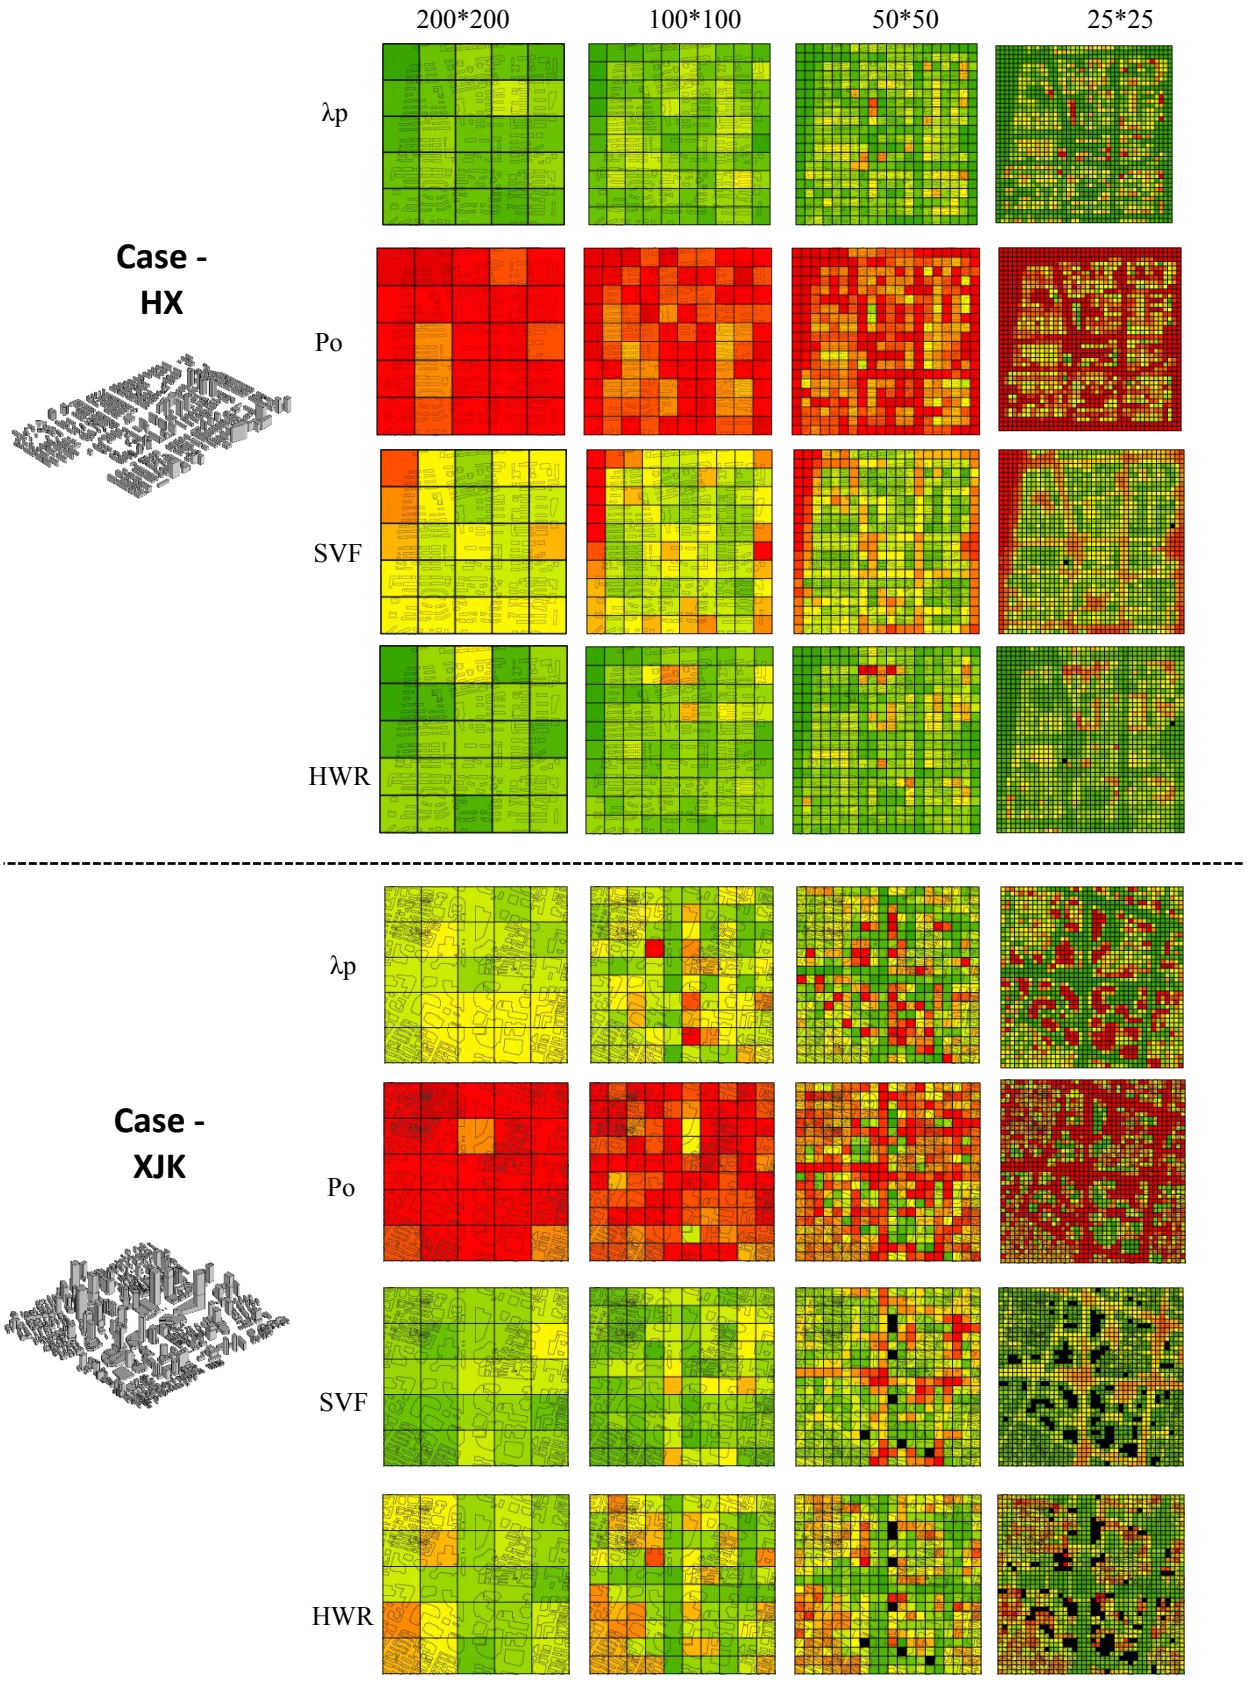

Figure 7. The morphological indicators results

Ventilation performance in the study area

Through the Computational Fluid Dynamics (CFD) simulation, we obtained the wind speed contour maps for Hexi and Xinjiekou (Figure 8). It can be observed that in Hexi, the wind speed is significantly higher in the open space areas and along the main roads that are parallel to the wind direction, and relatively lower within the residential areas. In Xinjiekou, the maximum wind speed is also concentrated on the roads that are parallel or nearly parallel to the wind direction, while the minimum wind speed is focused in the grids of the old residential areas at the four corners.

After dividing the two study areas by different sized grids, every units' WVR are caculated as Figure 8. It was found that in Hexi, the highest WVRs are located in the northwest corner and its vicinity, and are relatively smaller within the residential areas; in Xinjiekou, the highest WVRs are at the roads or intersections parallel to the wind direction, while the lowest WVRs are concentrated in the units of the old residential areas at the four corners. The results of the WVR are similar to those of the morphological indicators, where the lager the grid size, the more the WVR values are averaged out, resulting in smaller threshold values. Overall, the WVRs of study units generally conform to the ventilation conditions.

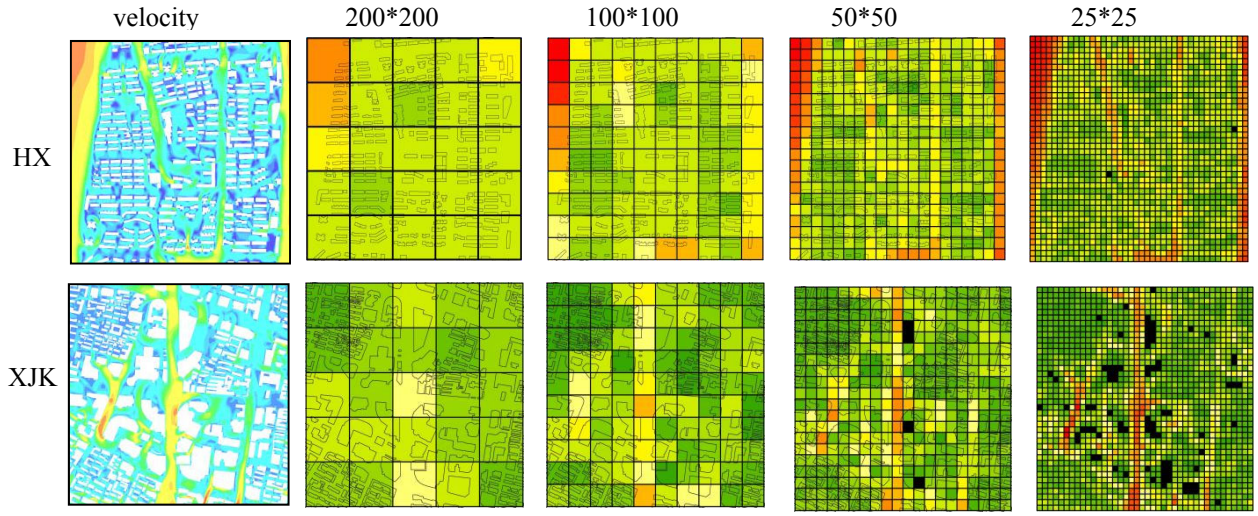

Figure 8. The ventilation indicators results

ANALYSIS

Correlation between morphological indicators and ventilation performance for study units with different sized

In four grids of Case A, as λp and HWR increase, the ventilation performance becomes worse; as Po and SVF increase, the ventilation performance becomes better; In Case B, all four indicators show the same trend as Case A in grids of 100m, 50m, and 25m. But in grids of 200m, four indicators did not correlate with ventilation performance (Figure 9).

Of these, λp and po had the best correlations at grids with side length of 100m and 50m in both cases; they have relatively poor corelations at grids with side length of 200m and 25m. SVF and HWR have better correlation in grids of 100m, 50m, and 25m. Four indicators have better correlation in grids with 100m and 50m. But grids with 100m are less computationally intensive. Therefore, it is better to use a grid with 100m.

With grids of 100m, it can be seen that the correlations of four indicators are better in Case A than in case B. Moreover, in Case A,.SVF shows a strong correlation, followed by λp, Po and HWR show weaker correlations; while in Case B, SVF, HWR and λp all show weak correlation, Po is almost irrelevant. So, we can see Po and HWR have relatively weaker correlation. this may be due to the limitation of these two indicators' caculated methods.

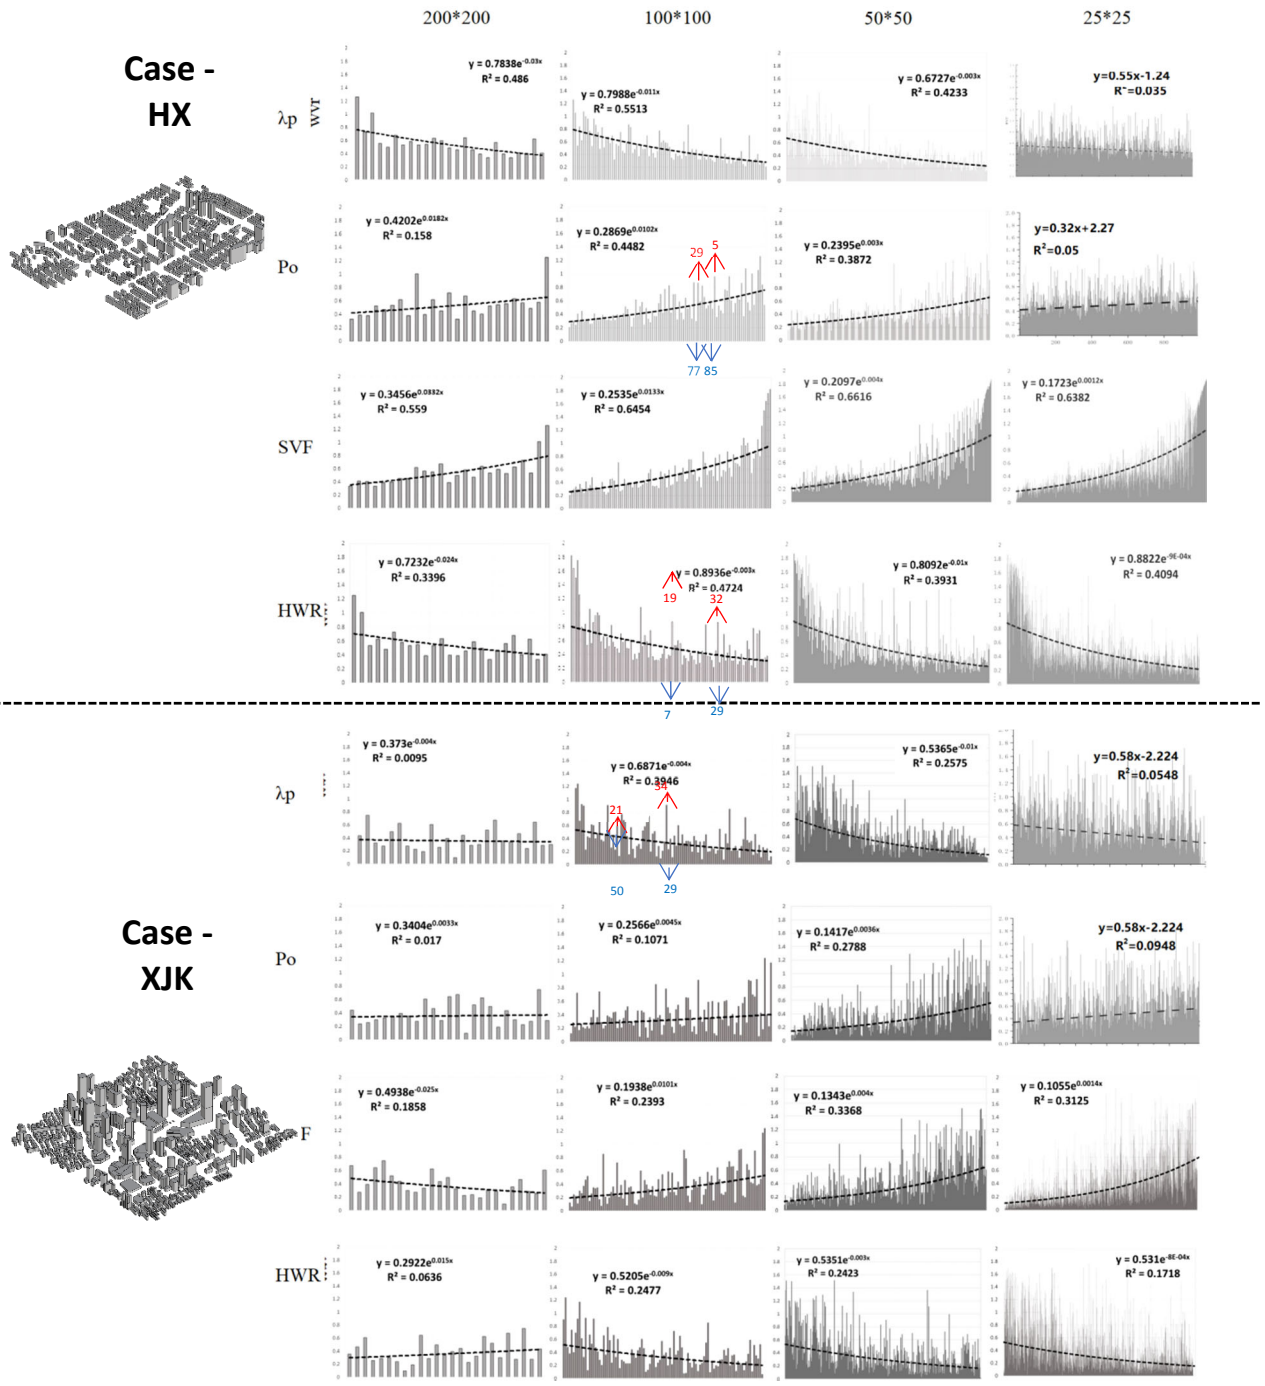

Figure 9. The correlation between urban forms and ventilation performance in two cases under four sized grids.

Impact of cacaulation method of indicators on correlation

Limitation of Po

The calculation of Po emphasizes the difference between the total volume of the study unit and the total volume of buildings within it. This can lead to situations where the total volume of several small and low buildings is the same or similar to that of fewer large and tall buildings. For example, H-S19 and H-S77 have similar Po values, but H-S29 has a higher WVR while H-S77 has a lower WVR. This is due to the fact that, although both H-S29 and H-S77 contain a taller building, H-S29 has another building with a larger volume, while H-S77 has more buildings but with smaller volumes. The sum of the volumes in the latter is similar to the sum of the volumes in the former, hence the similarity in Po. However, the space and buildings in H-S29 are more concentrated, while those in H-S77 are more dispersed. As a result, H-S29 experiences less obstruction to airflow, leading to a higher WVR(Figure 10).

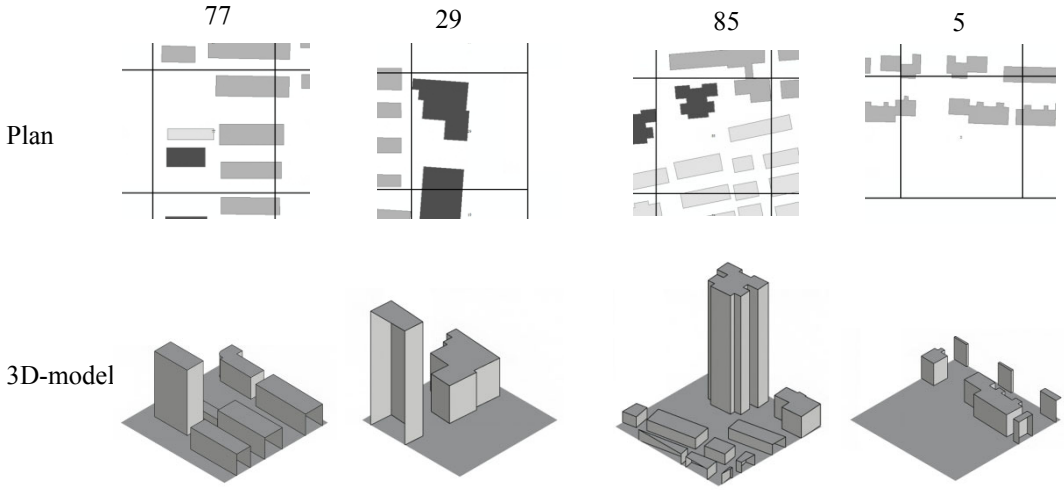

Figure 10. The limiration of Po

Limitation of HWR$_{2_ave}$

The HWR_2_ave can not identify the direction of space. Additionally, the HWR_2_ave value is affected by the data from two specific directions. For instance, H-S 7 and H-S 19 have similar HWR_2_ave values. H-S 19 has a completely open space running north-south on its east side, while C7 has a completely open road running east-west. Both of these open areas are similar in width, leading to a similar HWR for this part of the space. The presence of high-rise buildings in H-S 19 increases its HWR_2_ave value. Although the buildings facing north-south in H-S 7 are shorter, the density is higher, which results in a similar HWR_2_ave for both H-S 19 and H-S 7. However, the direction of the spaces and the degree of enclosure by surrounding structures are completely different for the two areas. The space on the right side of H-S 19 is parallel to the wind direction, which significantly increases its WVRcompared to H-S 7(Figure 11).

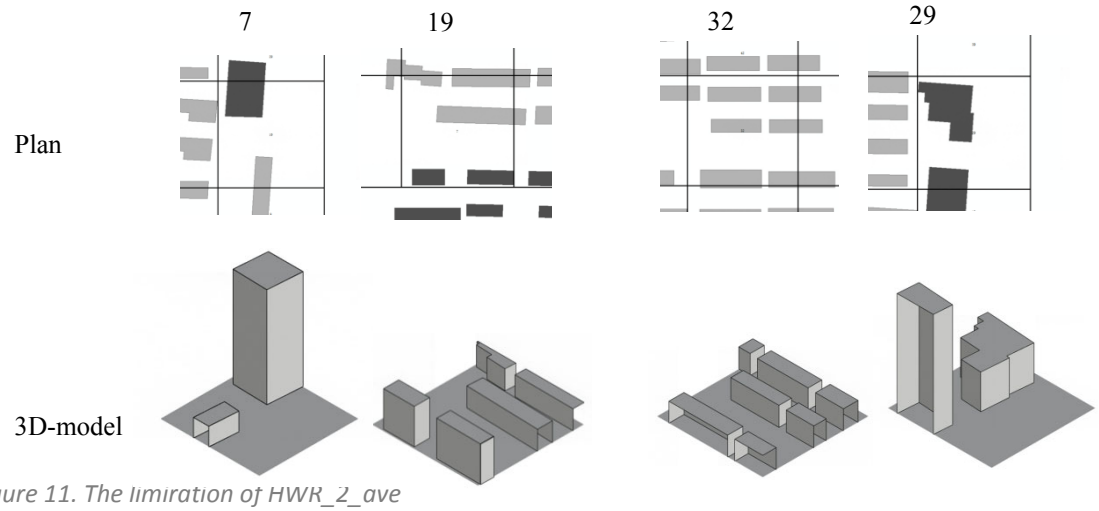

Figure 11. The limitation of HWR_2_ave

Impact of complex morphological features on correlation

Section 3.4 indicates that all indicators show better correlation in Hexi than in Xinjiekou, suggesting that the more complex urban form in Xinjiekou affects the ventilation performance of the space. Therefore, it is necessary to further explore the impact of more complex urban forms on ventilation performance. We select the 100*100m λp in Xinjiekou as a case.

Compared to Hexi, the differences in building footprint and building height in Xinjiekou are larger, both of which can affect the correlation between morphological indicators and ventilation performance. For example, there is a significant difference in the building footprint and the number of buildings within X-S34 and X-S93, yet they have similar λ p values. Althogh X-S34 have only two buildings, but the two buildings' footprints are large. So, the λ p of X-S34 is similar with X-S93 that have several buildings with larger footprings. And wvr of X-S34 is large. This interferes with the correlation between λ p and ventilation performance. Additionally, the location of high-rise buildings can also affect ventilation performance. For instance, X-S21 and X-S50 have similar λ p, but X-S21 have larger wvr. This is because in X-S21, the higher building faces the wind direction, leading to the airflow concentrating near the ground and enhances the WVR of X-S21 (Figure 12).

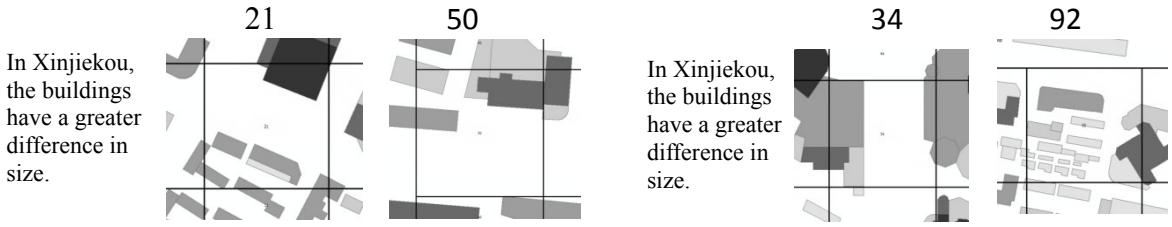

Figure 12. The imapact of complex morphological features on correlation.

CONCLUSIONS

This study uses the Hexi residential area and Xinjiekou commercial centre district in Nanjing as study cases. The two study case are divided by two sized grids (100m*100m and 200m*200m). Based on the

two grid sizes, four morphological indicators (λp, Po, SVF, HWR_2_ave) and ventilation performance indicators (WVR) are calculated, respectively. The study also provides a detailed comparison of the impact of different sized grids, morphological indicators, and cases with morphological characteristics on ventilation performance. The conclusions are as follows:

Among these indicators, λp and SVF have a better correlation with ventilation performance in both morphological characteristics, followed by Po and HWR_2_ave. Po are unable to distinguish between a study unit containing multiple buildings with modest height and a study unit with a few buildings with large height. HWR_2_ave cannot identify the direction of space within the grid. And the HWR_2_ave value is affected by the data from two specific directions.

Among the two grid sizes, 100m*100m and 50m*50m are better choice because theses grids shows better correlation in most morpohpgical indicators in both case studies. But grids with 100m have less computation. Therefore, it is better to use a grid with 100m.

In the homogeneous texture, the correlation of the four indicators with ventilation is better. This is because in the non-homogeneous texture, there are differences in building height variations and building footprint area, which affect ventilation performance. However, these four indicators cannot recognize these morphological features.

From the research results, it can be seen that the correlation of the four indicators is limited in both two cases, especially in Xinjiekou. This is mainly influenced by the limitations of the indicator algorithms and the diverse characteristics of urban form. Therefore, future research is needed to further study morphological characteristics and to supplement morphological feature indicators.

Does being poor in Juiz de Fora imply less access to public leisure spaces?

ABSTRACT

Leisure public spaces are essential components that promote recreation and diversity in urban environments, providing numerous social benefits to cities. Furthermore, these spaces positively influence the environmental quality of urban areas and the physical and mental health of their residents. However, the distribution and accessibility of these spaces do not always serve the entire population, revealing significant barriers to enjoying leisure in the public domain. The objective of this paper is to analyze access to public squares in Juiz de Fora (MG) based on urban configuration, considering different income and racial groups. The methodology employed includes an analysis of urban configuration through the Theory of Space Syntax, utilizing the Step Depth measure, spatial analysis with QGIS geoprocessing software, and correlation analysis of spatial and socioeconomic data. The results indicate that the distribution and accessibility of the city's squares are not equitable for the entire population, regardless of income or racial background, with particularly adverse conditions for lower-income groups. The configurational analysis of the squares revealed that most are situated in areas of higher integration, which exacerbates the lack of access and negatively affects populations in less integrated areas, regardless of whether they have low or high average incomes. This study concludes that the level of access identified in this research remains insufficient to ensure public leisure and high quality of urban life for the entire population.

Keywords: access, space syntax, income, race, leisure

INTRODUCTION

Leisure refers to time spent away from work, providing opportunities for relaxation and recreation. Open public spaces designed for leisure are essential components of urban environments, positively impacting human health both directly and indirectly. They promote social interaction and enhance environmental quality (Campos and Castro, 2017; Loboda and Angelis, 2005; Oliveira and Mascaró, 2007). Despite these benefits, such spaces are often limited or unevenly distributed within cities.

Leisure activities and consumption patterns among the middle class significantly drive urban transformations (Serpa, 2018). As a result, leisure spaces are often compromised and distributed unequally, primarily affecting the most disadvantaged populations. Considering the significance of

public leisure spaces as essential components for the well-being of communities, it is equally important to understand how access to these spaces can be evaluated and improved.

In the mid-20th century, structuralist trends that utilized computational tools gained significant prominence in recognizing and analyzing the existing conditions of urban space (Hillier, B., Leaman, A., & Stansall, P., 1976; Hillier & Hanson, 1997). The advent of computing technology, coupled with advances in mathematical knowledge, facilitated the discovery of underlying structures in urban design (Hillier, B., Leaman, A., & Stansall, P., 1976). Among the pioneering researchers in this field was Hillier, who sought to understand the relational dynamics between space and society using computational tools (Hillier & Hanson, 1997).

The urban form and its spatial relationships serve as the foundation for the Theory of the Social Logic of Space, or simply, the Theory of Space Syntax. This theory emphasizes the geometry of settlements, adopting a morphological perspective that highlights the significance of a city's shape as a crucial axis of investigation. It has made substantial contributions by interpreting how the configuration of the urban network affects accessibility and mobility. Through its methodology, the theory offers a means to evaluate, among other variables, the ease or difficulty of navigating urban roads. Bafna (2003) asserts that society utilizes space as a vital resource for self-organization, resulting in the configuration of inhabited spaces. The urban fabric can favor certain areas over others, whether in terms of access or urban mobility, thereby influencing route choices and either encouraging or discouraging the use of specific pathways (Medeiros, 2006; Hillier et al., 1993).

The justification for selecting Juiz de Fora lies in its status as the fourth most populous city in Minas Gerais. It has undergone urban development and real estate speculation similar to that of larger urban centers. The city's strategic geographic location—situated between BR-040 and BR-267 and in proximity to major urban centers such as São Paulo, Belo Horizonte, and Rio de Janeiro—along with its extensive array of services, shops, healthcare institutions, and esteemed educational facilities, has attracted significant migratory movements. This influx has contributed to the horizontal expansion of the city’s urbanized area. Intense urban sprawl has resulted in precarious housing clusters, which, coupled with a lack of planning, exacerbate socioeconomic issues and lead to population segregation (Chaves, 2011). As a consequence, access to urban and community public facilities remains limited.

This paper aims to analyze access to public leisure spaces for different income and racial groups in Juiz de Fora, based on its urban configuration. The hypothesis tested is that areas inhabited by a middle-to-high-income white population have a greater supply of, and consequently easier access to, public squares. The methods employed are grounded in urban configuration analyses through the Theory of Space Syntax. The Step Depth measure was selected to assess the configurational access to public leisure spaces using QGIS software, in addition to conducting a correlation analysis between spatial and socioeconomic data. This article is structured as follows: it begins with a review of the existing literature on public leisure spaces and space syntax. Next, it describes the research methodology employed in this study. The findings are then presented and discussed in detail. Finally, the concluding section summarizes the key insights and suggests areas for future research.

Public leisure spaces

The physical dimension of a city consists of both built and open spaces. Open spaces encompass all areas not covered by buildings, referring to any space open to the sky (Guzzo, Carneiro, and Júnior,

2006). These spaces include avenues, streets, squares, parks, backyards, and both public and private gardens, among others. Such elements are essential to daily life, as they contribute to the landscape and urban form, as well as to the history and collective memory of the city (Queiroga, 2011).

Open spaces play a crucial role in urban life, as many activities take place in streets, avenues, squares, parks, and similar areas. These spaces serve an integrated function that encompasses leisure, aesthetics, and ecological considerations (Cavalheiro and Del Picchia, 1992). Collectively, they influence the dynamics of cities and human behavior. Numerous benefits are associated with the creation and maintenance of open urban spaces, ranging from the enhancement of microclimates to their importance for social and cultural practices.

The concept of leisure can be viewed as a privilege that allows individuals to enjoy their time and the city, while also playing a crucial role in fostering relationships among citizens (Rolnik, 2000). Leisure serves both personal and social functions and aligns with the public dimension of society. Open spaces designed for leisure and recreation include public squares, urban parks, botanical gardens, green areas, and any open space that offers opportunities for relaxation, distraction, and enjoyment.

Public squares are urban open spaces designed for active leisure, contemplation, and social interaction. These areas often incorporate vegetation and typically feature urban furniture and recreational equipment (Guzzo, Carneiro, and Júnior, 2006; Brasil, 2020). The existence of these spaces provides numerous benefits to the quality of urban life. They enhance the habitability of the urban environment by facilitating social practices, outdoor gatherings, and expressions of community life, which promote human development and foster relationships among individuals (Oliveira and Mascaró, 2007).

Furthermore, they promote both direct and indirect contributions to the physical and mental health of individuals, primarily in areas characterized by predominant vegetation. The health benefits manifest directly, as the natural environment causes a sense of well-being, reducing stress and contributing to the ability to concentrate and maintain attention (Gressler and Günther, 2013). Additionally, there are indirect benefits, as the improvement of environmental quality—attributable to the presence of vegetation—makes the surroundings more enjoyable and encourages physical activity (Campos and Castro, 2017).

Despite their numerous advantages, public open spaces are often limited or unevenly distributed in urban areas. In Brazilian cities, there is a greater focus on the design and maintenance of public spaces intended for circulation, such as streets and avenues, often at the expense of those designated for leisure (Hijoka et al., 2007). Furthermore, local management through urban planning tends to privilege certain sectors of cities, frequently influenced by pressure from opinion makers or groups within the real estate market.

Space syntax and access

In the early 1970s, Bill Hillier and his colleagues at the Bartlett School of Graduate Studies in London developed a theory known as Space Syntax. The main goal of this theory is to understand the relationship between space and society by examining how spatial patterns carry social information. The theory gained systematization and ambition in Hillier and Hanson through the publication “The

Social Logic of Space" in 1984. Space Syntax employs a spatial-morphological approach, utilizing a set of analytical, descriptive, and quantitative tools to analyze the spatial configuration of urban and built environments. Since its inception, the theory has expanded into a comprehensive framework with a wide range of applications.

One of the main starting points of space syntax is that human society uses space as an essential resource to organize, and by doing that, the inhabited space starts to be configured (Bafna, 2003). According to Medeiros (2006), configuration could be understood as an articulation form or arrangement of structures in a system. It is the relation of a variety of spaces in an urban system and can be associated with morphology because it contemplates senses of position and pattern.

The application of analysis techniques of space syntax to comprehend the morphological logic of urban networks, especially related to urban growth, provided the discovery of the relationship between movement and configuration (Hillier *et al*., 1993). According to the authors, the configuration of the urban network is the main generator of patterns of movement, capable of shaping different social transactions. The spatial elements through which people move, such as avenues, streets, alleys, squares, and so on are linked together to form a global pattern. The influence generated by the urban network in the movement pattern, termed "natural movement," affects potential flow distribution even before land use and occupation are established (Hillier *et al*., 1993).

> In agreement with Hillier *et al*. (1993), natural movement could be defined as:
>
> Natural movement in a grid is the proportion of urban pedestrian movement determined by the grid configuration itself. Natural movement, although not always quantitatively the largest component of movement in urban spaces, is so much the most pervasive type of movement in urban areas that without it, most spaces will be empty for most of the time. It is also the most consistent, so much so that it is difficult to avoid the inference that natural movement is the raison d'être of the urban grid itself (Hillier *et. al*, 1993, p. 32).

For instance, it is possible to observe in Figure 1 (a) that the main street will be used, regardless of the chosen route, as it is a necessary path. On the other hand, Figure 1 (b) shows that flow concentration will be distributed beyond the main street, among the other horizontal roads.

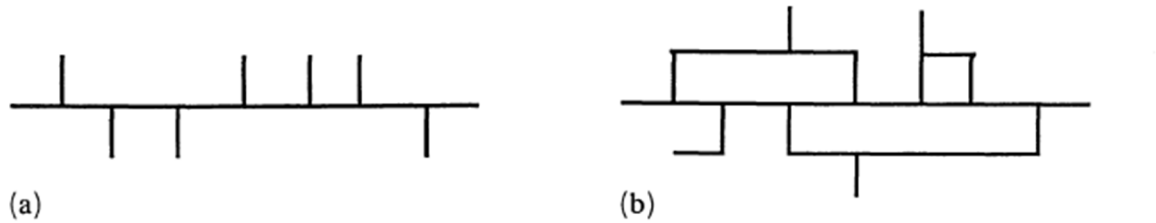

Figure 1: Hypothetical urban networks suggesting different movement patterns. Source: Hillier et al. (1993, p. 29) .

Each configurational pattern corresponds to distinct movement patterns. By concentrating or restricting flow and establishing a hierarchy within an urban system, the configuration prioritizes certain spaces over others in terms of urban mobility. This influences route decisions and either encourages or discourages the use of specific pathways (Hillier et al., 1993; Medeiros, 2006).

Movement attractors, such as commercial areas, function as movement multipliers; however, configuration can also impact movement in ways that are independent of these attractors, indicating that people's flow is not solely determined by land use.

Access is another key aspect, alongside movement, in urban environments influenced by spatial configurations. In this paper, access refers to the ease with which different parts of a spatial layout can be reached from a given point. It also contains an attribute of urban space, balancing the attractiveness of a location with the challenges of access, thereby representing "urban opportunities" for individuals based on their location (Silveira, 2004; Serpa, 2007). In other words, urban opportunities are the possibilities for accessing various locations where individuals can enjoy goods and services, serving as a measure of social inclusion (Castro et al., 2016).

In Space Syntax, access is analyzed through various synthetic measures, including integration, connectivity, choice, depth, control, and step depth, among others. Integration measures how easily a space can be reached from all other spaces within the layout. High integration values indicate spaces that are centrally located and easily accessible, often serving as focal points for movement and activity (Hillier, Yang, & Turner, 2012). On the other hand, connectivity measures the number of directly connected spaces associated with a given space. Higher connectivity typically indicates better access (Klarqvist, 1993).

Choice, also known as "betweenness," quantifies the frequency with which a space serves as a route between other spaces. High choice values indicate that these spaces are likely to be significant for facilitating movement (Hillier, Yang, & Turner, 2012). Depth measures the number of steps or transitions required to reach a specific space from a designated starting point, with lower depth values signifying greater accessibility (Klarqvist, 1993). Control assesses the extent to which a space controls access in relation to its immediate surroundings, taking into account the number of alternative connections available nearby (Klarqvist, 1993). Finally, step depth analyzes the relationship of a specific point within the system to the entirety of the network, following the shortest path from the selected line to all other lines within the system (Turner, 2004). The step depth technique enhances our understanding of the complexity of an urban grid from a human scale perspective.

Space syntax, like any other theoretical framework, has its limitations. It does not fully account for the role of space in the production and reproduction of society, overlooks informational and communicative exchanges, and neglects crucial metrics such as building sizes (Ratti, 2004). Furthermore, factors such as topography, road width, visual fields, and the diverse ways in which people appropriate urban space are not effectively captured by its analyses. Nevertheless, it is essential to recognize these limitations while also appreciating what distinguishes space syntax: its relational scope. The theory aligns with design intuition and opens up new possibilities for exploration (Hillier and Hanson, 1997). Although it does not fully explain urban reality, it significantly enhances our perception of the city.

METHOD

The methodology prioritizes the examination of the urban area of Juiz de Fora, with a specific focus on public squares and urban configuration, while correlating these elements with socioeconomic data derived from the IBGE demographic census sectors. It is important to note that the city features a

variety of public open spaces; however, this study exclusively includes public squares designated for leisure and recreation. Space Syntax was utilized as the primary methodological tool for configurational analyses. The study is limited to the routes within the urban perimeter.

The physical accessibility of the city's squares was calculated using the step depth measure. This technique enabled the analysis of the segments that provided immediate access to the public squares and their relationship to the entire urban system. The measure can be calculated using metric, angular, and topological radii. For this study, only the metric radius was considered, as comfortable walking distances indicated by various authors and urban indicators, are expressed in meters.

DepthmapX software version 0.50 was utilized to process the measurements, as this calculation can only be performed using this software. The values were subsequently imported into QGIS software version 3.16.10 to make the necessary adjustments for mapping. The results of the step depth measurements can be interpreted according to the following parameters:

Table 1. Parameters for interpreting the syntactic results of Step Depth. Source: Adapted from Turner (2004).

Measure		Chromatic Scale
Step Depth	Warm colors indicate the smallest distance from the analyzed segments. Cold colors indicate a greater distance from the analyzed segments. Therefore, the greater the number of lines in warm colors, the shorter the distance to the studied point, favoring accessibility. Axes in cold colors indicate greater distance, corresponding to more difficulty in access.	

The socioeconomic data associated with spatial information focused on population distribution by race or color and average nominal income. Census data were collected from the online database of the Brazilian Institute of Geography and Statistics (IBGE). The objective was to translate social information to a spatial level by creating thematic maps and integrating census data with distribution and spatial syntax analyses. The variables utilized in this study included the average nominal monthly income of individuals aged ten years or older (both with and without income) and the resident population categorized

RESULTS AND DISCUSSIONS

In this study, a total of 80 squares were selected as the sample for analysis, considered as public leisure spaces. The selection of this sample size was based on the Master Plan of Juiz de Fora and the Cadastral Map, and are all located in the urban area. The distribution of the squares is concentrated in Juiz de Fora’s downtown and its surroundings mostly, showing a lack of public leisure spaces in further

neighbourhoods. The configurational access of the squares is best in the central area, justified by the number of spaces and the proximity of one and other.

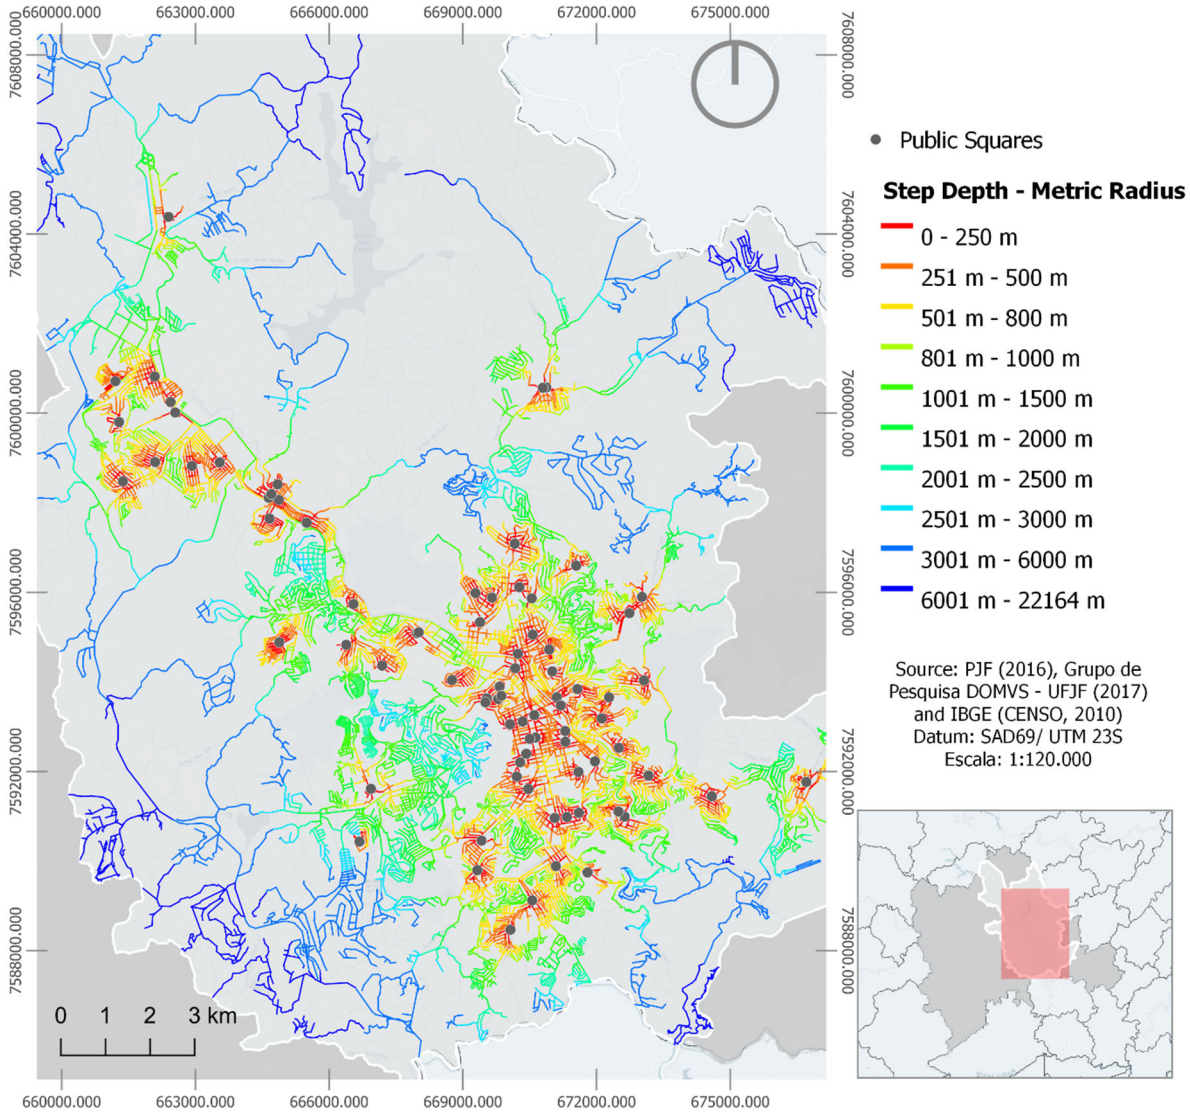

Figure 2: Step Depth measure in metric radius

The step depth measure showed that the squares in the downtown area are either in a radius of 250 metres or 500 metres which means between 3 and 6 minutes walking. If we look at the regions far from the centre we can see, especially in the west and northeast of the city, greater distances to access a public leisure space, indicated by colder tons, making them dependent on public leisure spaces in the closest surroundings. Those regions are also the ones with one of the highest altitudes, which adds another obstacle for the access.

The correlation between the Step Depth data and the income factor showed a moderate negative correlation due to the decrease of income as the step depth increases. When observing the concentration of the points further to the left of the graph, it is clear that almost all income ranges are correlated to some extent with greater proximity to the squares. However, when following the direction of the graphs' trend line, it is possible to say that the census sectors with the greatest

distances to the squares tend to be those with the lowest income. In this way, it can be said that the lower the income, the greater the distance to the squares.

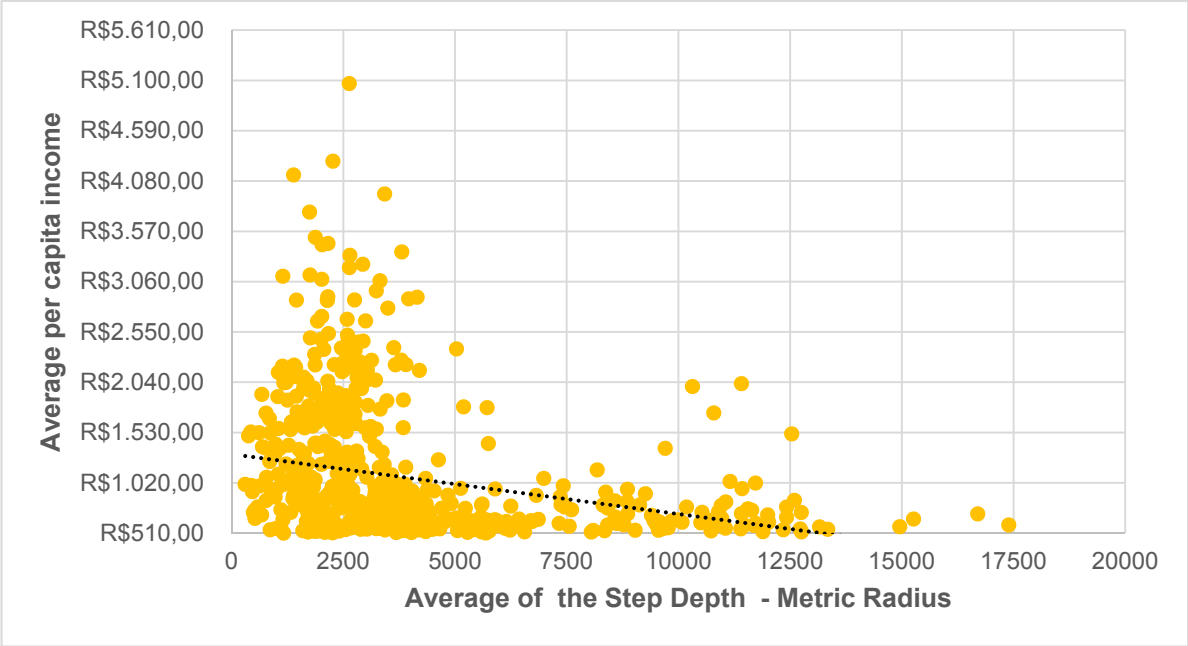

Figure 3: Average per capita income x Step Depth relationship in metric radius

Focusing on the racial composition of Juiz de Fora, 56.96% of the population identifies as white people, while 42.25% identify as black and brown people, according to Fundação João Pinheiro. The white population is mainly concentrated in the central area of the city, extending into adjacent portions, especially towards the west. In contrast, the black and brown populations are primarily located in the eastern part of the city, particularly on the right side of the Paraibuna River, as well as in the southern and north-western urban areas. The watercourse notably serves as a territorial boundary, demarcating the residential areas of different racial groups and highlighting the segregation by race. This pattern of settlement dates back to the beginning of the city's occupation, where the initial urban layout was established on the river's right side.

The comparison between step depth and the resident population by color or race (Figure 4) reveals that mostly white people have access to public leisure spaces, as illustrated in the map overlay. However, this overlay alone does not provide conclusive evidence that black and brown individuals have reduced access to these spaces. Further investigation is needed to obtain a more comprehensive understanding of access disparities. Regardless of color or income, the limited number of public squares in Juiz de Fora affects the entire population. Nonetheless, it is safe to say that low-income residents face greater challenges in accessing these spaces, due to mobility factors. On the other hand, high-income individuals benefit from better urban amenities and have greater access to private leisure facilities. They are also able to reach locations that are more distant without relying on public transportation, expanding even further the disparity in access to public leisure spaces.

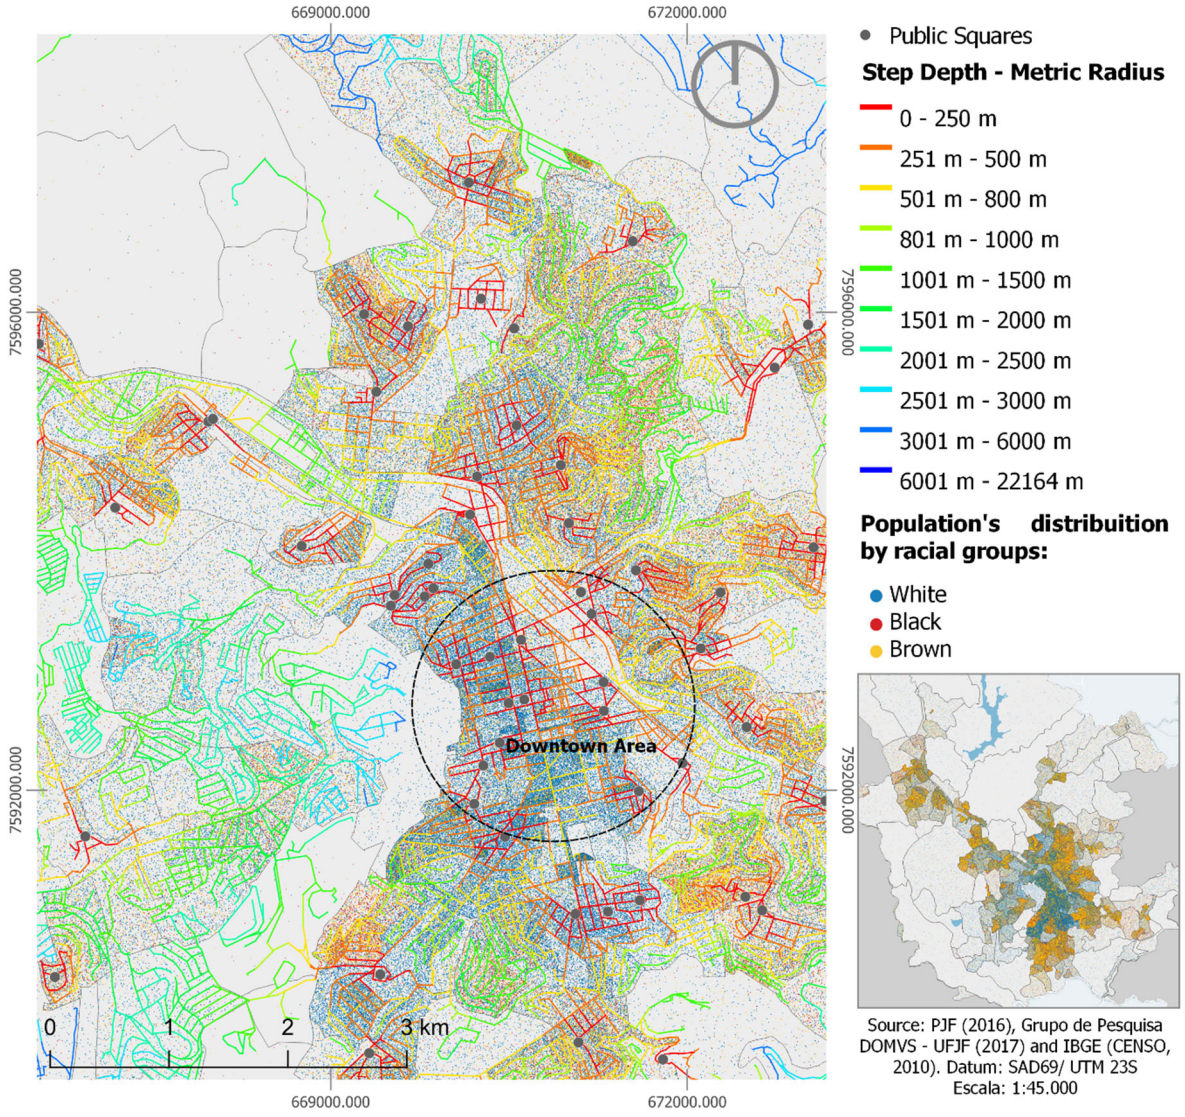

Figure 4 : Step Depth measure in metric radius overlapped with resident population by color or race

The city's topography is another factor that can be added to the socioeconomic and configurational access considerations. Although topography is not directly incorporated into syntactic analysis, it is indirectly captured, as areas with steep relief presented configurational patterns that differ from flatter locations, leading to different syntactic outcomes as well. Places with more difficulty to access public leisure spaces (according to the scale range on figure 2), matched most of the time with steep topography places. In this manner, people who live in regions with more rugged terrain suffer a significant impact on access to public leisure spaces, affecting how easily residents can reach these areas, and also how often they choose to go to those places. Steep slopes and elevated terrains can make it physically demanding for people to access public spaces. This is particularly problematic for individuals with mobility issues, such as the elderly, and those with young children. Additionally, topography can affect the efficiency and availability of public transportation. Steep roads can lead to longer travel times and reduced service frequency. Not to mention that, residents in areas with

difficult topography may face social and economic disadvantages due to limited access to leisure public spaces. This can contribute to social exclusion and reduced quality of life. Communities in hilly areas might have fewer opportunities for recreational activities or social engagement compared to those in more accessible locations.

CONCLUSIONS

Leisure is essential for a high quality of life, and the availability of public spaces for everyone, regardless of race or income, is crucial for fostering social connections. Although public leisure spaces are not always prioritized by governments, they play a vital role in society. These spaces can enhance both physical and mental well-being by promoting physical activity and providing a calming environment that alleviates stress. Furthermore, they offer significant environmental benefits, including improved air quality and the creation of wildlife habitats, while also raising awareness about conservation efforts.

This study examined the accessibility of public leisure spaces based on configuration patterns and sought to determine whether neighborhoods with middle-to-high income white residents have greater access to these spaces. The application of Space Syntax Theory revealed a correlation between configurational patterns and socioeconomic data, particularly income.

According to the syntactic analysis, low-income populations encounter significant challenges in accessing public squares. This issue is further emphasized by the map overlay that compares the distribution of the population by race with the step depth results. White residents generally have greater access to leisure spaces, indicating a disparity in access to public amenities based on race and income level. Nevertheless, it is clear that the number of public squares impacts the entire city.

Access is a continuum and is contingent upon political and economic decisions. The level of access observed in this study is a result of prior decisions and serves as a mechanism that can exacerbate spatial and social inequalities. The findings of this study reveal certain correlations; however, further research is necessary to broaden the scope of the issue and incorporate additional social factors.

Acknowledgements

We want to extend our deepest gratitude to CAPES and the Laboratório de Planejamento e Projeto at UFES for their invaluable support in providing the essential resources and facilities that were instrumental in the successful completion of the master's thesis from which this work originates.

ABSTRACT

The accelerating trend of global urbanization presents considerable environmental and social challenges, making a shift toward more sustainable and resilient urban habitats imperative. In this context, it is essential to explore the extent to which urban spaces can serve as supportive environments, capable of enhancing the psychophysical well-being and resilience of their inhabitants. A promising transdisciplinary approach in this regard is the concept of restoration, which is linked to the potential of environments to alleviate mental fatigue and foster cognitive clarity and overall mental well-being. However, despite its relevance and broad application in environmental psychology, no studies have systematically examined its connection to urban morphology and morphometry. This paper addresses this research gap by: i. undertaking a web-based survey across three UK cities (i.e., Glasgow, London, Winchester) of different sizes and socio-economic profiles through a methodology specifically designed to assess the stress restoration potential of different urban environments; ii. using a comprehensive set of morphometric indicators to achieve a rich morphological description of the three cities under examination; and iii. investigating the relationship between survey outputs and the set of morphometric indicators through correlation analysis. Findings across the three cities combined suggest that more ordered and Euclidean urban layouts with buildings and plots aligned with their respective streets, simple building shapes, and rectilinear streets, tend to be associated with more stress restoration. Correlations at the city level generally align with this finding but also show locally specific trends. The contribution of this paper is two-fold. It provides one of the first studies of the relationship between aspects of urban form and the psychological response of pedestrians to the urban environment. Second, findings can inform the development of new tools that assess walkability from a more people-centered perspective.

Keywords: Urban MorphoMetrics, walkability, sustainability, people-centered design, environmental psychology

INTRODUCTION

The world is rapidly urbanizing, with official reports projecting that 68% of the global population will reside in cities by 2050 (UN-DESA, 2019). This trend can be seen as positive, as urbanization often leads to improved living standards due to the concentration of economic activities and the provision of cheaper and better public services, including more efficient transport systems (Overseas Development Institute, 2008). However, large-scale urbanization also presents significant challenges, such as heightened socio-economic inequalities (UN-Habitat, 2008; Zhao, 2013) and environmental degradation (Wilson & Chakraborty, 2013), particularly in developing countries. Addressing these challenges requires pursuing more sustainable development forms and retrofitting existing urban areas to ensure safer, more livable, and equitable cities while minimizing urbanization's environmental impact on both local and global scales. Achieving these goals demands contributions from various disciplines, including environmental science, civil engineering, economics, transportation planning, and disaster management, among others. Urban design and environmental psychology also play crucial roles as the structure and perception of places influence a wide array of aspects, including livability and resource consumption patterns. Although there are well-supported theories in both fields regarding which types of urban environments are preferable and what features are conducive to more well-being, the literature on the intersection between morphological and psychological aspects remains underdeveloped.

A promising, yet largely unexplored, bridging concept is represented by the idea of restoration. According to the Attention Restoration Theory (ART) (R. Kaplan & Kaplan, 1989; S. Kaplan, 1995), the interaction between a person and a place can produce cognitive regeneration effects based on four key factors: i. fascination (the environment's 'ability' to attract involuntary attention); ii. extent (the perceived spatial extent); iii. being away (the sensation of being in a different place from usual); iv. compatibility (the compatibility between personal mental maps and the place being experienced/observed). The combination of these factors can result in different levels of restorative potential attributed to a specific place. Typically, such values are the highest in 'designed' green spaces (parks, gardens) and built environments of high historical-cultural value (Fornara & Troffa, 2009; Staats et al., 2016). Furthermore, restoration effects are typically linked to the perception of environmental preference and subjectively perceived well-being, suggesting that high restorative potential generally corresponds to a positive subjective experience (Pasanen et al., 2018). Moreover, some scholars (Gillis & Gatersleben, 2015) highlighted connections between the physical characteristics of a space and its associated restorative qualities. Key elements include materials such as wood and water, the presence of natural light, and views of the sky. The availability of fractal architectural forms has also been shown to enhance restorative qualities, as these patterns mimic the complexity found in nature. Additionally, biomimicry, the imitation of natural environments, plays a role in fostering a restorative experience (Gillis & Gatersleben, 2015). Another important factor is the ability of a space to provide both prospect and refuge (Appleton, 1975) – offering a sense of control over the surroundings without being easily seen. While these studies provide qualitative insights into what kind of urban environments tend to be associated with more restorative potential, systematic and numerical descriptions of the morphological structure of these environments are largely missing. The analysis presented in this paper is therefore one of the first attempts to systematically study the relationship between a comprehensive set of 74 morphometric indicators (primary characters) derived from Urban MorphoMetrics (UMM), an established approach to measure urban form

characteristics and identify morphological regions in cities (Fleischmann et al., 2022), and stress restoration responses, obtained through a survey focusing on three UK cities (Glasgow, London and Winchester).

METHOD

The methodology presented in this paper relies on the UMM approach for identifying distinctive morphological regions or urban types (UTs) from where to extract survey images in the case studies under examination and for obtaining a comprehensive set of morphometric indicators to study in relation to the survey outputs.

Urban MorphoMetrics (UMM)

UMM is a quantitative approach to measure the morphological structure of human settlements at the level of the main components of urban form, that is the building, the plot and the street segment (i.e., the line connecting two sequential intersections in the street network) (Fleischmann et al., 2022). Since plots are ontologically ambiguous (Kropf, 2018), UMM automatically generates plot proxies called morphological cells (or simply cells) from building footprints and streets through a Voronoi-based partitioning of space. The workflow consists of two main steps: i. computation of a comprehensive set of morphometric characters for each cell; ii. clustering such characters to identify distinctive UTs.

UMM operates using minimal information, specifically georeferenced polygons representing building footprints (with heights attached) and georeferenced lines representing street segments. The urban form is described based on 74 primary characters, which account for six key morphological properties (dimension, shape, spatial distribution, intensity, connectivity, and diversity) of buildings, plots (cells) and streets, across three scales (small, medium, and large) (Fleischmann et al., 2022). Four measures are then calculated for each primary character, resulting in a total of 296 contextual characters:

- Interquartile mean: the average of the values between the first and third quartiles of the distribution.
- Interquartile range: the range of values within the central 50% of the distribution.
- Inter-decile Theil index: a measure of local diversity.
- Simpson diversity index: a measure of the heterogeneity of values.

The contextual characters are computed up to the three topological steps from each cell and reflect the local tendency of the primary characters. Agglomerative hierarchical clustering (AHC) with a KNN = 3 spatial constraint is then applied to these contextual characters to identify UTs. As described by Venerandi et al. (2021), this clustering technique is preferred because it tends to output UTs with fewer misclassified cells. The silhouette score, a heuristic technique to assess the quality of the clustering (Rousseeuw, 1987), is used to identify the optimal number of UTs in each case study.

Psychological survey of the urban environment

The psychological dimensions of the urban environment were assessed using the exp-EIA© (Experiential Environmental Impact Assessment) method (Piga et al., 2023). This method was designed to address the crucial need for collecting data that capture collective experiences within urban spaces.

The final aim is to promote collaborative urban design processes through an evidence-based approach. The exp-EIA© method, grounded in environmental psychology and design sciences, enables the measurement of urban experiences across three main dimensions: emotional, cognitive and community/identity. By integrating these dimensions, it provides a comprehensive understanding of how urban environments impact human experiences. It also offers the capability to spatialize data in real-time and collect it through photographic stimuli (panoramas) and digital means (AR and VR), as well as through direct interaction with the environment. To the purpose of this research a digital platform employing spherical panoramas as stimuli was utilized as main tool. The following variables have been investigated:

- Sociodemographic variables: age, gender, residence, level of education, perceived national identity.

- Level of familiarity with the cities.

- Emotional dimension: measured through an affective slider referring to two orthogonal axes (pleasure and arousal), derived from the circumplex model of emotions (Russell & Lanius, 1984).

- Cognitive dimension: environmental preference was measured through four items addressing four main factors (coherence, legibility, complexity, and mystery), according to the Preference Matrix model (S. Kaplan, 1987).

- Restorative effects: according to the Attention Restoration Theory (ART) (R. Kaplan & Kaplan, 1989; S. Kaplan, 1995), the perceived restorative potential of every place was measured addressing four variables (extent, being away, fascination, compatibility).

In this paper, only data related to restorative effects (point 5) were analysed.

Selection of panoramic street views for the survey

UMM was separately applied to the case studies under examination to obtain UTs. The number of panoramic street views for each case study and UTs was decided based on their size, geographic position, and general socio-economic information in order to capture a relevant cross-section of the country where the case studies are located. The choice of how many panoramic street views to include in the survey accounted for the fact that each street view must be evaluated multiple times to hold statistical relevance, survey length, and modality (whether online or offline or a mix of both). The next step requires extracting centroids from each street segment of the case studies under examination, randomly selecting a number of these centroids in each UT based on the rationale illustrated above and downloading the panoramic street views for the centroids' coordinates from online services, such as Google Street View, Mapillary and KartaView. The selected panoramic street views were visually checked to ensure there are no distortions, flares, or other visual issues. If any issues were present, a different street view from the same street segment was selected as replacement. The selected panoramic street views were then uploaded to the survey platform.

Data aggregation and correlation analysis

UMM's 74 primary characters were computed for all the cells in the case studies under examination. However, to analyze the relationship between these characters and the survey outputs, the analysis was restricted to the areas around the panoramic street views, and the characters within these areas,

originally computed for single cells, were aggregated using the median value (a measure of central tendency). To achieve this, only the cells within a 200-metre radius of the selected survey points were retained for the analysis. To account for skewed distributions in the data of both survey outputs and the 74 primary characters, the Spearman correlation was implemented to analyze the relationship between the two. Spearman correlation evaluates a monotonic relationship based on ranks rather than continuous values, making it more robust in the face of skewed distributions. This correlation test produces two results: a coefficient (r_s), which ranges from -1 (indicating a perfect negative relationship) to 1 (indicating a perfect positive relationship), and a p-value, which indicates the statistical significance of the test.

APPLICATION

The morphometric taxonomies of Glasgow, London and Winchester

The analysis presented in this paper focuses on three UK cities: Glasgow, London, and Winchester, which differ in size (city, metropolis, town), geographic location (Scotland and England), and socio-economic profiles (relatively deprived, mixed and well-off). Building footprints (with heights) and street segments for these three cities are obtained from Ordnance Survey's MasterMap Building Height Attribute[57] and the OS Open Roads[58]. Following the UMM approach presented in the Methodology section, 74 primary characters are computed in each city from this data. Contextual characters were then computed and AHC was applied to explore possible clustering solutions. Silhouette scores were used to guide the selection of the optimal number of UTs for each case study, resulting in 14 UTs for Glasgow (Figure 1), 15 for London (Figure 2), and 10 for Winchester (Figure 3). General overviews of these cities, along with brief accounts of the correspondence between main historical-morphological phases and UTs, are presented next.

Glasgow

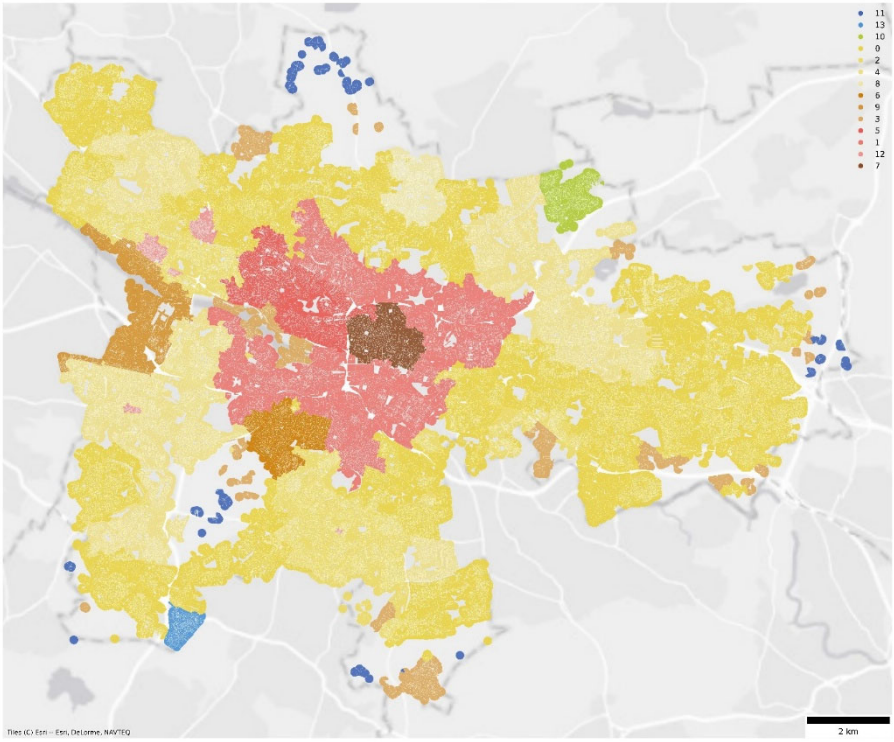

Figure 1. Morphometric taxonomy of Glasgow. The more similar the colors, the more similar the urban form of the UTs. Source: the authors, Esri, DeLorme, NAVTEQ.

Glasgow's historic core developed around the cathedral and High Street in the 12th century but shifted overtime. This shift, driven by economic growth—first through trade and later by various industries, occurred from the 18th to the late 19th century. The city expanded first westward (UT5), then to the southeast and north. The Merchant City (UT7), established during the 18th-century commercial boom, is characterized by its rigid orthogonal grid and now-repurposed warehouses. Glasgow's industrial surge in the 19th century dramatically expanded the city's population, reaching over 1 million residents by the 1930s. Residential areas from this period are marked by tenements, which maintained a consistent typology across the city but varied in character depending on the social classes they housed. Sandstone villas (UT6) were prominent in wealthier areas, and this typology persisted with more modest forms in later developments (UT2 and 4). Lush green spaces and significant architectural landmarks were also established during this time. By the early 20th century, overcrowding in tenements, coupled with the impact of two World Wars, led to a rapid decline in Glasgow’s housing stock. This decline spurred comprehensive redevelopment in large portions of the inner city, with modernist principles implemented in peripheral estates (UT0, 4, and partly UT2) and inner-city estates. The city's population decreased to 630,000, and many industrial and transport infrastructure areas, including the River Clyde, were repurposed for smaller-scale industry and depots (UT9 and 3). Redevelopment efforts in the 1950s and '60s, such as the controversial M8 motorway and the more recent M74, disrupted urban cohesion but also encouraged private development towards the city's fiscal boundaries (mostly UT2, with variations like UT6 and UT13). Today, Glasgow continues to focus on retaining its traditional areas and creating new ones based on placemaking principles, prioritizing safe, efficient transport alternatives and more walkable environments.

London

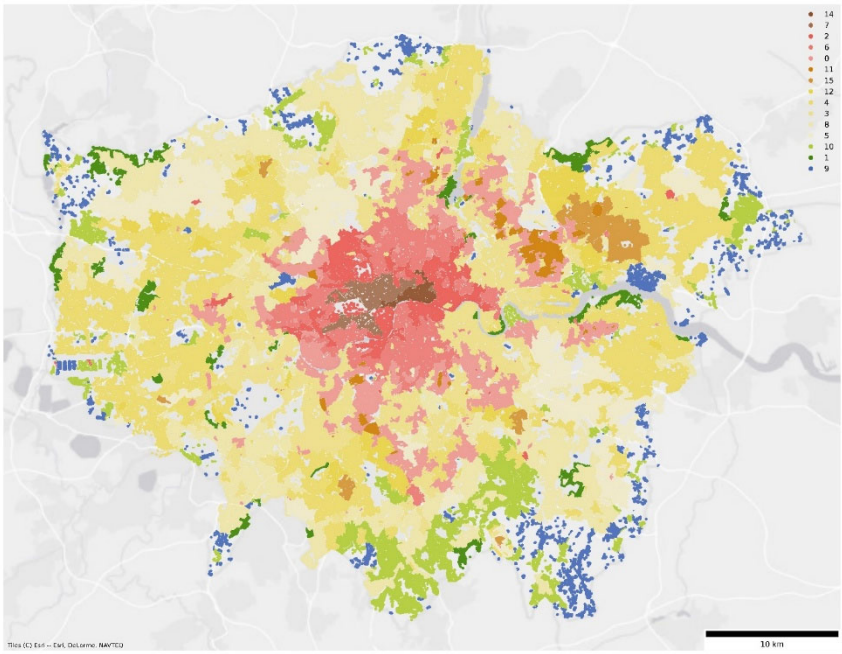

Figure 2. Morphometric taxonomy of London. The more similar the colors, the more similar the urban form of the UTs. Source: the authors, Esri, DeLorme, NAVTEQ.

Following the establishment of Londinium – now commonly referred to as the Square Mile – on the River Thames by the Romans in 47AD, the city has experienced remarkable levels of growth which have led to it becoming one of just two Alpha ++ cities globally along with New York.[59] These two places are the most integrated with the global economy across the world. London's growth was limited through the medieval, Tudor and Stuart Era's, which involved some expansion beyond the Roman city walls, the construction of the Tower of London, and the establishment of Westminster as a seat of government. Driven by the industrial revolution, between the start of the Georgian period and the end of the Victorian, the population of London increased over ten-fold from 630,000 to 6.5 million and the physical growth of the city followed suit. In the form of dense streets and terraces the city extended to Alexandra Palace to the north and Tooting Common to the south. There is a loose but perceptible relationship between the taxonomy presented in this paper (Figure 2) and growth periods within London. The Square Mile (UT14) is picked out clearly by the analysis, but there is little distinction between development within the Georgian and Victorian periods of expansion, which are defined within UT2 and UT6, indicating that the form of development in these periods was quite similar, even if there may have existed architectural deviations. Notably, the Georgian expansion of the Square Mile immediately west, through the vehicle of the great estates, is highlighted clearly by the analysis (UT7). The great estates represent a collection of large areas within central London that have been owned and managed by aristocratic families for centuries. Development within the great estates is unique and characterized by formal street patterns, terraces of townhouses or mansion blocks, and the incorporation of communal greens with strong boundary treatments. Over the 20th century, population growth and the growth of the city became decoupled, and the land area of the city increased significantly despite a fractional increase in its population. This resulted from efforts in

[59] *https://gawc.lboro.ac.uk/gawc-worlds/the-world-according-to-gawc/world-cities-2022/*

the inter- and post-war periods to improve housing conditions for the poor by demolishing dense inner-city neighbourhoods in need of modernization and rehousing their residents in lower density suburbs (UT 5, 8, 3, 4, 12). Supplementing the Victorian suburban development that came before it, this period of construction led to the position we are in today whereby most of the land within the M25, the city's ring road, has been urbanized.

Winchester

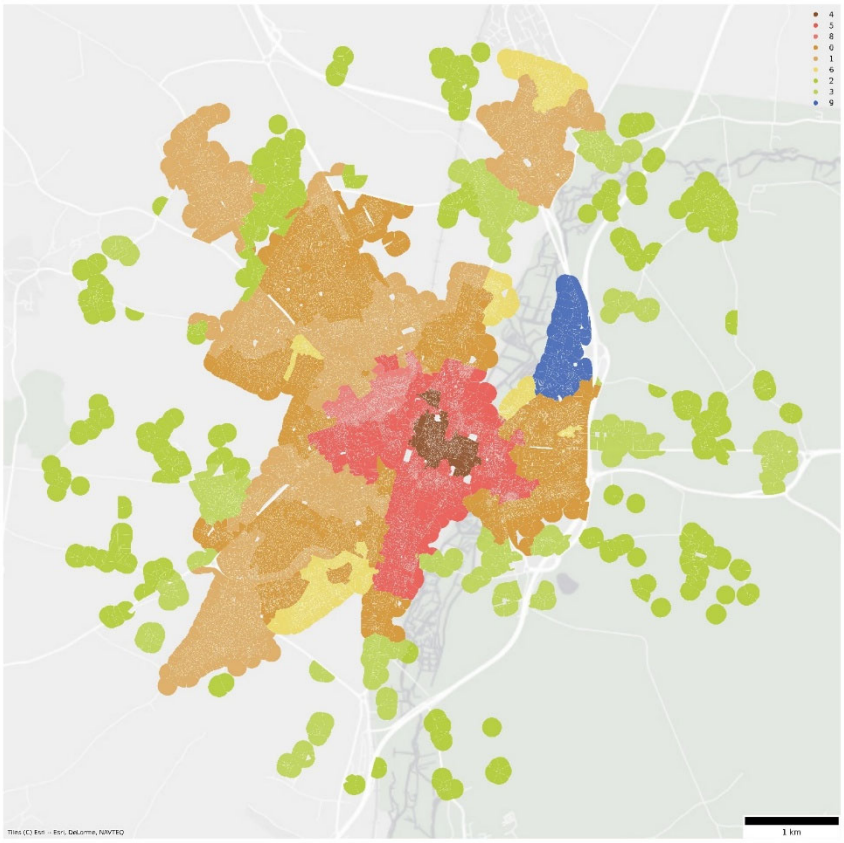

Figure 3. Morphometric taxonomy of Winchester. The more similar the colors, the more similar the urban form of the UTs. Source: the authors, Esri, DeLorme, NAVTEQ.

Winchester represents one of the most established settlements in the UK, with origins in the iron age before it was established as the Roman town of Venta Belgarum. The historic core of the city (UT4) follows the street grid that was imposed by the Romans after diverting the River Itchen. Outside of the historic core of the city, two phases are highlighted clearly by the morphometric taxonomy (Figure 3), first with UT2 and UT8 and later with UT0, UT1, and UT6. All the streets within UT2 and UT8 had been formed before the end of the Victorian period. The remaining development occurred after the Second World War in a period where car ownership became the norm, allowing less dense development forms which were designed to cater for vehicles. There exists a unique character area (UT9) to the north-east of the city which is highlighted in blue in Figure 3. This industrial centre emerged in the second half of the 20th century when it became possible to move goods in enormous quantities by road. It is strategically located adjacent to the M3, and its form is heavily influenced by its function, which is of a vastly different nature to other more residential development forms throughout Winchester.

Selection of survey points in Glasgow, London and Winchester

As described in the Methodology the number panoramic street view for each case study and UT were decided based on their size, geographic position, and socioeconomic status. The total numbers of survey points included 70 points for Glasgow, 105 for London and 27 for Winchester. To select the locations of the survey points in each city, the following steps were performed: firstly, each street's centroid was assigned to the UT of the closest cell; secondly, to determine how many points should be selected in each UT, the total number of survey points was divided by the total number of UTs in each city (resulting in 5 points per UT in Glasgow, 8 in London, and 4 in Winchester); thirdly, street segments centroids were randomly selected in each UT. Panoramic street views were gathered using the geographic coordinates of the selected street centroids and uploaded to the survey platform. Samples of these panoramic street views for Glasgow, London, and Winchester are provided in Figure 4. After selecting the survey points, 200-metre buffers were created around each point, and the values of the primary characters were aggregated by calculating their medians.

Figure 4. Samples of raw panoramic street views for Glasgow (Charles St, G21 2QA, top), London (Marne Rd, RM9 4BU, middle), and Winchester (Jewry St, SO23 8SA, bottom). Source: Google Street View.

Survey outcomes

182 people responded to the survey who evaluated 201 scenes from the three cities under examination. This resulted in 2,206 evaluations, with an average of about 11 evaluations per scene. The gender distribution of the respondents was evenly split, with 48.3% identifying as male and 48.3% as female, while 3.4% as non-binary. The average age of the respondents was 44.6 years. Regarding educational background, 3.3% of the respondents declared a lower secondary education level, 19.8% an upper secondary education level, 29.1% held a bachelor's degree, 35.2% had a master's degree,

and 12.6% had post-master's education. Most of the respondents were from the United Kingdom (68.7%), with the remaining 31.3% coming from other nationalities, including 4.9% from India and Italy. The average self-reported knowledge of the cities was 3.35 for London, 2.42 for Winchester, and 2.23 for Glasgow.

The results on regenerative potential divided by city show a moderate variability in average values, with slightly higher scores for Glasgow (m = 2.78), followed by London (m = 2.68) and Winchester (m = 2.58). However, there is a wide value variability within the three cities. In London, the highest score is achieved by survey point 102 (m = 4.11, the highest value among all evaluated images and the only one to exceed 4) (Figure 5, middle left). Six other points showed relatively high scores greater than 3.5. On the opposite end of the ranking, four points scored equal to or less than 1.8, with point 112 scoring 1.68 (Figure 5, middle right). In Glasgow, three points show an average restorative potential of 3.5 or higher, with survey point 62 showing the greatest value (m = 3.72) (Figure 5, top left). On the opposite end, only survey point 51 scores below 1.8 (m = 1.75) (Figure 5, top right), while two other points have scores equal to or lower than 2. Finally, Winchester generally shows lower scores compared to the other two cities. Survey point No. 2 has the highest score (m = 3.5) (Figure 5, bottom left) and three other points exceed the value of 3. On the opposite side, the lowest score in Winchester (and across the set of cities under examination) is recorded at survey point 27 (m = 1.55) (Figure 5, bottom right), while two other points do not exceed the threshold of 2.

Analyzing the relationship between survey outcomes and urban form

Spearman's correlation was applied to all pairwise combinations of primary characters and the stress restoration metric, both across the three cities combined (Table 1) and for each city individually (Table 2). In general, only a few (8 on 74) correlations were statistically valid (p-value <= 0.05) and correlations were weak (r = 0.14) to moderate (r = -0.6). These results were, to some extent, expected, as single morphometric indicators alone can hardly describe complex phenomena like those considered in this study.

Table 1. Spearman's correlations between primary characters and stress restoration across the three cities combined. Only statistically significant correlations are shown (p-value <= 0.05).

Primary character	Corr.	p-value
Proportion of 3-way intersections	-0.2189	0.001796
Street misalignment of a building footprint	-0.1912	0.006564
Shape regularity of a building footprint	0.1590	0.024163
Street misalignment of a cell	-0.1535	0.029562
Linearity of a street segment	0.1446	0.040493

The results of the analysis across the three cities suggest that greater stress restoration is associated with smaller proportions of 3-way intersections (r = -0.21), smaller angles between the axes of buildings and nearby streets (r = -0.19), as well as between cells and nearby streets (r = -0.15), buildings with simpler shapes (few or no recesses or protruding elements) (r = 0.16), and more rectilinear streets (r = 0.14). In summary, stress restoration tends to be linked to more regular urban fabrics, likely characterized by greater proportions of 4 (or more)-way intersections, buildings and plots aligned with their respective streets, compact/simple building shapes, and rectilinear streets.

Table 2. Spearman's correlations between primary characters and stress restoration in Glasgow, London and Winchester. Only statistically significant correlations are shown (p-value <= 0.05).

City	Primary character	Corr.	p-value
Glasgow	*Coverage area ratio of a cell*	0.2805	0.018682
	Corner irregularity of a building footprint	0.2575	0.031395
London	*Squareness of a building footprint*	-0.2166	0.026496
	Street misalignment of a building footprint	-0.2061	0.034886
	Volumetric complexity of a building	-0.2060	0.03496
Winchester	*Proportion of 3-way intersections*	-0.5955	0.001331

The patterns observed across the three cities combined only partially hold when analyzing relationships for each city individually. More specifically, like in the former, stress restoration tends to be associated with more regular urban fabrics, typified by smaller proportions of 3-way intersections, in Winchester, smaller angles between the axes of buildings and nearby streets and less volumetric complexity, in London. However, different patterns also emerge. In London, more elongated buildings, which are likely the result of densification processes related to the burgage cycle (Conzen, 1960), are associated with higher levels of stress recovery, suggesting a connection with denser and more historic city parts. Similarly, in Glasgow, density, measured in terms of plot coverage, and buildings with more irregular corners are associated with higher levels of stress recovery.

DISCUSSION, LIMITATIONS AND FUTURE WORK

The preliminary results presented in this study align with several insights from the literature on environmental cognition (S. Kaplan, 1987), suggesting that higher environmental preference and restoration scores stem from a perceived balance between understanding (ease of reading and mapping a space) and exploration (formal variability of the buildings). In terms of regular layouts, the "Gestalt laws" (Wertheimer, 1938) indicate that the perceptual system naturally tends to recognise regular and closed shapes in space. Similarly, other scholars (Yusli et al., 2021) emphasised the importance of perceived compatibility between individual cognitive schemas and the environment as a key factor in experiencing well-being within it, particularly due to its relationship with perceived safety (Stragà et al., 2023). Given the previously mentioned correlation between environmental preference and perceived restorative qualities, it is also possible to hypothesise that the high scores obtained from high-density environments and buildings with irregular footprints may be linked to the historical value of a place, which is a key factor in environmental preference (Stamps & Nasar, 1997). Additionally, Stamps (1999) has noted that the complexity of a building's facade is a significant predictor of preference, particularly in relation to its implied historical value. The analysis presented in this paper provides insights into the correlations between stress restoration and individual metrics of urban form. However, urban environments are multifaceted entities composed of multiple, interconnected features rather than single, isolated ones. Future work may thus consider summarising the metrics of urban form, for example, through clustering techniques, to obtain categories of urban fabrics that describe the morphometric complexity of different urban environments in a more comprehensive manner and test the correlation between stress restoration and these categories.

Further limitations concern the survey methodology. Weather conditions can influence responses. For example, it is possible that cloudy street views score less due to overcast conditions. Similarly, street views with greenery may receive higher scores because humans tend to find restoration in natural elements. A further limitation concerns the fact that the survey was not carried out in the real world. Respondents did not directly experience the streets they evaluated, which may have affected the scores they assigned. Similarly, the place where they took the survey (e.g., their own living room, office, coffee shop) and on what device (e.g., phone, laptop, PC) may have impacted the scores. The correlations found in this study do not imply causation, meaning that changing the configuration of streets according to the findings of this study may not improve stress restoration. More robust techniques of data analysis should be implemented to account for the cofounding factors mentioned above and investigate causal links. Although the analysis in this paper focuses on a cross-section of representative British cities, the findings are not universally applicable but may still inform broader discussions. Psychological surveys, morphometric assessments and correlation analysis should be carried out in other geographic contexts to extend the generalisability of the findings.

CONCLUSIONS

Both urban morphology and environmental psychology can contribute to achieving more sustainable forms of urban development. However, while both disciplines investigate and identify the features of the urban environment which tend to be better for pedestrians and residents, systematic approaches which harmonize both disciplines seem to be lacking. In this paper, we propose a methodology to reach this aim by: i. conducting a survey in Winchester, London, and Glasgow, using a method to evaluate the stress restoration potential of different urban settings; ii. employing a range of

morphometric indicators to provide a detailed morphological analysis of the cities studied; and iii. using correlation analysis to examine the relationship between the survey results and the morphometric indicators. The outputs of this analysis across the three cities combined show that more geometrically regular spaces, characterized by buildings with regular footprints, rectilinear streets, building footprints and plots aligned with their respective streets, are associated with more stress restoration potential. The patterns observed across all three cities apply only partially when examining the relationships within each city separately. The main differences are that higher density in Glasgow and more irregular building shapes in both Glasgow and London are associated with higher levels of stress restoration. Previous findings in environmental psychology seem to corroborate these preliminary results. The ease of reading a space (and perceiving it as more aligned with personal mental schemas), along with the formal variability of buildings, was found to be associated with better restoration scores. Furthermore, humans' perceptual system tends to more easily recognize regular and closed shapes in space. While this study has several limitations, primarily related to the lack of control variables (e.g., socioeconomic information on survey respondents, weather conditions in panoramic views), it paves the way for further research at the intersection of quantitative analysis in urban morphology and environmental psychology, potentially shedding more light on what forms of urban development better align with positive psychological responses of city dwellers.

ABSTRACT

Climate change is currently discussed as one of the greatest challenges for humanity. Its effects on the configuration of cities are evident, as they arouse the need for interventions to adapt them. However, the cities are very heterogeneous, so that depending on the morphology of the occupation, availability of free areas, topography, density and built typology, associated with the specific climatic issues of each location, indicate the need of different strategies. In this sense, the main objective of this study is to indicate possible urban intervention guidelines for adaptation on different urban fabrics at Metropolitan Area of São Paulo, concerning Urban Heat Island (UHI), based on the urbanistic studies that our research group has been developing in areas which suffer with extreme phenomena such as Paraisopolis, Lapa, Franco da Rocha, among others; combined with the Local Climate Zones System. The methodology adopted relates concepts and methods of climate sciences with morphology and urban design. The work steps include: literature review; production and analysis of maps and georeferenced aerial photos from official databases on watersheds, flood areas, land use and occupation, transport systems, surface temperatures, vegetation, topography, social vulnerability; classification of the studied areas according to the Local Climate Zones - LCZ; consultation of sustainable urban systems manuals; data analysis and development of guidelines based on urban design and nature-based solutions criteria and focused on the surfaces temperature. The findings of this research indicate that interventions for climate change cities adaptation may include the increase of vegetation cover, the implementation of Sustainable Drainage Systems and Green-Blue Infrastructure for the different typologies of urban fabrics, respecting their morphological specificities and climatic conditions, which can guide future public policies. Conclusions suggest that the urbanization model of Brazilian cities aggravates the effects of climate change demanding urgent revision.

Keywords: local climate zones (LCZ); urban heat island (UHI); surface temperature

INTRODUCTION

Climate change stands as one of the most pressing challenges of our time, impacting various aspects of human life and the environment, where the configuration and resilience of cities are put to the test. Over the past decade, the frequency and intensity of extreme events such as Urban Heat Island (UHI), floods, landslides, and potable water shortages, have intensified. Architecture and urbanism play crucial roles in this urgent and necessary process of city adaptation. However, despite the imminent risks, the agenda of mitigation and resilience of cities in the face of climate change has struggled to be implemented through public policies and urban intervention projects (Alvim, 2019). For this reason, it is necessary to develop studies that strengthen this agenda to technically and politically empower society to face these challenges. In this sense, this article discusses the urban-environmental patterns and their potential for transformation in the face of addressing the warning that the urbanization model of Brazilian cities exacerbates the effects of global climate change.

One of the major modifications caused by the urban environment is the drastic replacement of vegetation and permeable soils with buildings and impermeable surfaces, both in urban areas and in areas surrounding cities, which exert enormous influence on local, regional, and global climate. The removal of vegetation cover decreases soil infiltration and evapotranspiration rates. This factor, combined with impermeabilization, air, water, and soil pollution, alters the microclimatic and hydric conditions in cities, exacerbating urban socio-environmental problems (Stewart and Oke, 2012; Ferreira, 2019), and lead to varying energy balances, contributing to the formation of Urban Heat Island (Amorim, 2021).

Surface Urban Heat Islands, or inverse oasis, occur when urban surface temperatures are higher than those of their surroundings and are a significant concern for urban planning because it can have severe repercussions across all aspects of human life (Stewart and Oke, 2012). The morphology of urban fabrics influences temperatures because the construction materials in cities are often dark and, therefore, absorb and store more solar energy. For instance, the temperature of dark and dry surfaces in cities can reach up to 88°C during the day, while surfaces with vegetation and moist soil under the same conditions can reach only 18°C (Gartland, 2010).

The effect commonly leads to various implications, including alterations in the local microclimate, thermal discomfort, effects on public health, and changes in hydrological behavior, such as water mass displacement (Marengo, 2020; Almeida et al., 2021). Especially in cities with hot weather, the extra warmth can increase discomfort and potentially raise the threat of heat stress and mortality, and heighten the cost of air conditioning and the demand for energy (Stewart and Oke, 2012). It exposes vulnerable populations to extreme weather events, disrupts disease patterns, and endangers food security, access to clean water, and breathable air. Moreover, rising temperatures exacerbate drought conditions in typically arid regions, creating a fertile environment for forest fires and heatwaves (Marengo, 2018).

Urban centers are hotspots for major disasters but, on the other hand, also offer opportunities for action through the implementation of green buildings, the provision of potable water and renewable energy, the supply of sustainable transport systems capable of connecting urban and rural areas, and the potential to contribute to the organization of a more inclusive and just society (IPCC, 2022). Anelli (2020) suggests that evaluating the relation between climate change and cities requires two paths.

The first one is understanding urbanization as a strong agent that promotes climate warming and the second is understanding the effects of climate change on cities marked by social inequality of their settlements. Ferreira (2012) and Amorim et al., (2021) emphasize the need for specific approaches based on urban morphology and local climatic conditions.

The territorial mosaic of cities, characterized by diverse city fabrics patterns and their features (such as the morphology of occupation, availability of open spaces, and typology of surfaces), requires a nuanced understanding of how different areas respond to climate change. For this reason, the hypothesis discussed in this paper is that considering the extreme events that directly impact urban areas, adaptation strategies must consider urban pattern diversity to effectively mitigate and manage climate risks.

In the Metropolitan Area of São Paulo (MASP), there has been an increase in the frequency and intensity of extreme events over the last decade. Unfortunately, it is ill-prepared for extreme events, and the impacts are worse in peripheral areas where they affect socially vulnerable groups living in exposed areas (Marengo, 2020). This trend is closely related to the area's urbanization pattern, which includes a mobility model heavily reliant on automotive vehicles for daily commutes (Anelli, 2020). Additionally, the prevalence of reflective surfaces interferes with the natural rainfall regime and contributes to the formation of Urban Heat Islands (UHIs) (ibidem). For this reason, it is important to highlight that the heterogeneous physical and social characteristics of the MASP, along with the geomorphological layout of the area, directly contribute to these impacts (Jacobi et al., 2013).

Implementing Nature-based Solutions (NBS) at different scales and strategies emerges as a promising methodological path in helping cities manage stormwater, reduce heat, and improve air quality (Lima et al., 2023). NBS encompasses strategies inspired, supported, or copied from nature, aiming to address environmental, social, and economic challenges while simultaneously promoting human well-being and biodiversity benefits. These solutions are tailored to the specific characteristics of each location and involve actions used to sustainably protect, restore, and manage natural or modified ecosystems. By harnessing existing natural features, systems, and materials through systemic interventions, NBS minimizes the impact of human actions on the landscape and fosters resilient environments, and can be widely applied in cities (European Commission, 2021).

In this context, this research aims to identify, characterize, and classify distinct urban morphological and climatic patterns in both consolidated and expanding areas within MASP, focused on land use and occupation changes and Heat Island phenomena, and to provide urban planning and design guidelines for intervention, tailoring specific solutions to each type of urban fabric regarding the use of Nature Based Solutions. While each case responds differently to these factors, they all share vulnerability to extreme climate events. The paper is organized into five main sections: Materials and Methodologies, Results, Final Discussion and Recommendations, Conclusion and Acknowledgements. Additionally, it concludes with a list of references supporting the research.

METHOD

Seeking solutions to adapt the cities to climate changes, this study analyzes three specific situations in MASP. Specifically, the study examines a garden neighborhood (Vila Ipojuca), a densely populated favela (Paraisópolis) in São Paulo, and an urbanized zone of single-family homes (Villa Verde) in Franco

da Rocha. The three chosen regions are vertically aligned in a metropolitan scale territorial section that cuts through areas with different thermal and morphological characteristics, but which suffer from the effects of extreme events such as floods and heat islands (figure 1).

Figure 1: Location of the studied areas. Source: Imagem Google Earth, 2024 (modified).

The research process encompasses steps including: a comprehensive literature review that explores topics related to climate change, urban adaptation, resilience, vulnerability, and the formation of urban heat islands, relating occupancy patterns to urban fabric characteristics. Next, field visits are conducted to the study areas, providing firsthand insights and data collection opportunities regarding morphological and ecological aspects and surface temperature in the microscale, by using pictures captured in August 2024 by a thermal camera, FLIR E5 Pro model. For urban fabric patterns characterization, it investigated street layouts, block sizes, setbacks, vegetation cover, topography, land use and building typologies heights, and surface material on three specific cases using field visits collected data and geo-reference official data. Additionally, for macroscale analysis, georeferenced maps were produced using official databases, including surface temperatures images from June 20th 2023 using Landsat 8 data, by Nasa Satellite data by Landsat 8 Operational Land Imager/Thermal Infrared Sensor (OLI/TIRS), provided by the United States Geological Survey and generated from thermal infrared bands (USGS, 2024).

Furthermore, micro-scale climate classification relies on the Local Climate Zone System (LCZ): As stated by Oke (1987), the urban climate system is formed between the Urban Boundary Layer (UBL) - mesoscale, and the Urban Canopy Layer (UCL) - microscale, that follows the height and roofs of buildings and trees. Between UBL and UCL it is the Surface Layer, or local scale of urban climate, and it is where the phenomenon of Surface Urban Heat Islands takes place and is influenced by what occurs above in the UBL and below in the UCL (figure 2). This idea was used to define the LCZ theory.

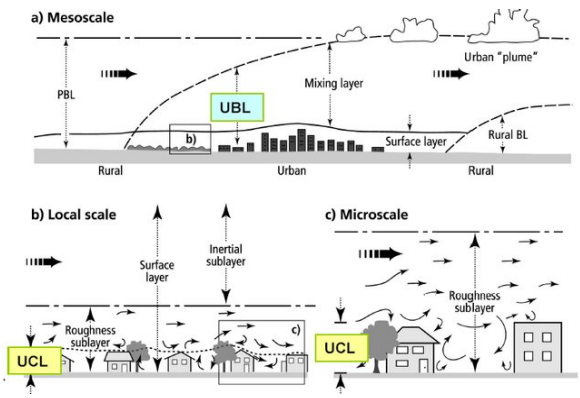

Figure 2: Key spatial scales in the urban atmosphere (adapted from Oke 1987). Source: Grimmond et al. (2016).

The LCZ (Local Climate Zones) theory posits that urban climate results from modifications due to urbanization and its impact on local atmospheric conditions. To assess urban occupancy models and their role in forming urban heat islands (UHI), the theory considers urban morphology, land use, activities, surface structure, and climatic data. The method categorizes the urban landscape into 17 types based on urban morphology and temperature data, establishing a direct link between urbanization and thermal impacts. This framework aids in documenting and comparing field sites and temperature data, benefiting UHI researchers, city planners, landscape ecologists, and global climate change studies. Qualitative and quantitative analyses explore urban-environmental patterns, with a specific focus on identifying heat islands within the study areas. Finally, the study examines the possibilities of application of NBS within established urban environments focusing on the construction of sustainable cities.

RESULTS AND DISCUSSIONS

The Metropolitan Area of São Paulo

The Metropolitan Area of São Paulo (MASP), located in the state of São Paulo, Brazil, is the largest metropolitan region in the country, housing approximately 20.7 million inhabitants. It ranks among the ten most populous metropolitan areas globally. Encompassing 39 municipalities, this area is undergoing rapid urbanization. São Paulo faces daily challenges such as high air pollutant concentrations, floods, cold waves, and heat islands. These issues are exacerbated by a large population with significant socioeconomic and environmental vulnerability. Notably, the relationship between air temperature and mortality in the municipality, according to McMichael *et al.*, (2008) reveals that, a 1°C increase in average temperature corresponds to a 3.46% rise in overall mortality and a 3.26% increase in cardiovascular and respiratory mortality (Barros and Lombardo, 2022).

Regarding the analysis of urban heat islands and surface temperatures using Landsat 8 images from the MASP, on a macro scale, the entire Metropolitan Area functions as an urban heat island (figure 03). It reveals that elevated surface temperatures are predominantly concentrated in urban regions, particularly those with high population density, such as São Paulo county. These elevated temperatures are primarily found in areas with impermeable surfaces. At the periphery of these urban zones, a noticeable decrease in temperature is observed, especially in rural and vegetated areas, which typically exhibit lower temperatures due to their green cover. That happens because in the urban area, vegetation has been replaced by impermeable surfaces that retain more heat, such as asphalt and other heat-absorbing materials.

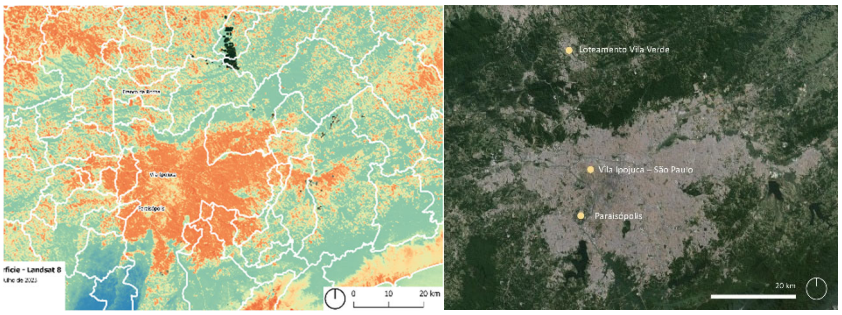

Figure 03. Surface temperature map of Metropolitan Area of São Paulo. Source: developed by the authors based on the United States Geological Survey (USGS) Landsat 8 data (2024).

This finding aligns with established knowledge that green and permeable areas tend to have cooler surface temperatures and that the difference between maximum and minimum temperatures observed in São Paulo during the daytime in the dry season was 10°C according to Lombardo (1985), 10.4°C according to Flores *et al*. (2016), and 12.8°C according to Ferreira (2019), which have been increasing due to the climate changes effects. Furthermore, this study has identified isolated pockets of higher surface temperatures dispersed throughout the city. Therefore, the analysis of surface temperatures in the area reveals significant temperature variations among different urban fabrics in São Paulo when conducted at a micro scale.

As stated by Marengo (2020), the prospect of recurring extreme events in the Metropolitan Area of São Paulo, such as prolonged droughts alternating with floods, necessitates a comprehensive planning approach regarding alterations in land use. It is important to mention the three cases of study. Moreover, it is likely that the urban heat island phenomenon will be intensified by deforestation, urban patterns and air pollution within the MASP, influencing the patterns of rainfall. Model experiments indicate that urbanizing areas originally covered by natural vegetation may lead to temperature increases of approximately 3.5 °C or more. The models predict fewer cold nights and more hot days, which can influence convective rainfall, intensifying its frequency and magnitude.

Paraisópolis Settlement, São Paulo - SP

Paraisópolis is located in the Southwest Zone of São Paulo. The area is located approximately 15 km from the city center, and it's known as one of the largest informal and unplanned settlements of the city, being characterized by dense urbanization and a lack of green spaces. It consists of a consolidated informal occupation that was originally projected to be an upper-class neighborhood with regular and orthogonal lots. However, around the 1950s, the uninhabited land began to be occupied, becoming an irregular dense occupation.

Paraisópolis is characterized by social vulnerability in the form of overlapping self-build houses, the use of materials that increase the warming and the topography formed by curves and slopes, which are integrated into the current occupation that allows access to the settlement. The blocks are rectangular and dense, most of them reaching up to 200 m x 100 m. There are very small or non-existent sidewalks, making it difficult to identify the limits of the street. The outline of the lots and the setbacks are almost non-existent, most of the buildings occupy the sidewalk or the street. The houses are built in materials like brick, concrete and fiber cement tiles, with two to six stores. The height of the buildings points out that there is a lack of space to build new homes, making verticalization the best alternative for residents. The closeness of the constructions due to the lack of space also

contribute to the heat island effect, making clear the association of land occupation, concentration of vulnerable areas and the formation of heat islands (Lima *et al*., 2023).

Land use in Paraisópolis is mostly residential and commercial, characterized by mixed-use buildings, with the ground floor being used for commerce or services and the upper floors for residences. The area suffers from flooding on rainy days with a high volume of precipitation, invading the homes built on Antonico stream banks. Observing the Landsat 8 it is possible to notice how surface temperatures manifest inside the perimeter study area of Paraisópolis. The map presents a high temperature surface, which can be related to the high impermeable and dense area, with lots of irregular occupations and no available green surfaces. The important fact to highlight about this case is that in the surrounding neighborhood, Morumbi, which presents a difference when it comes to density and green cover areas, the surface temperature is lower.

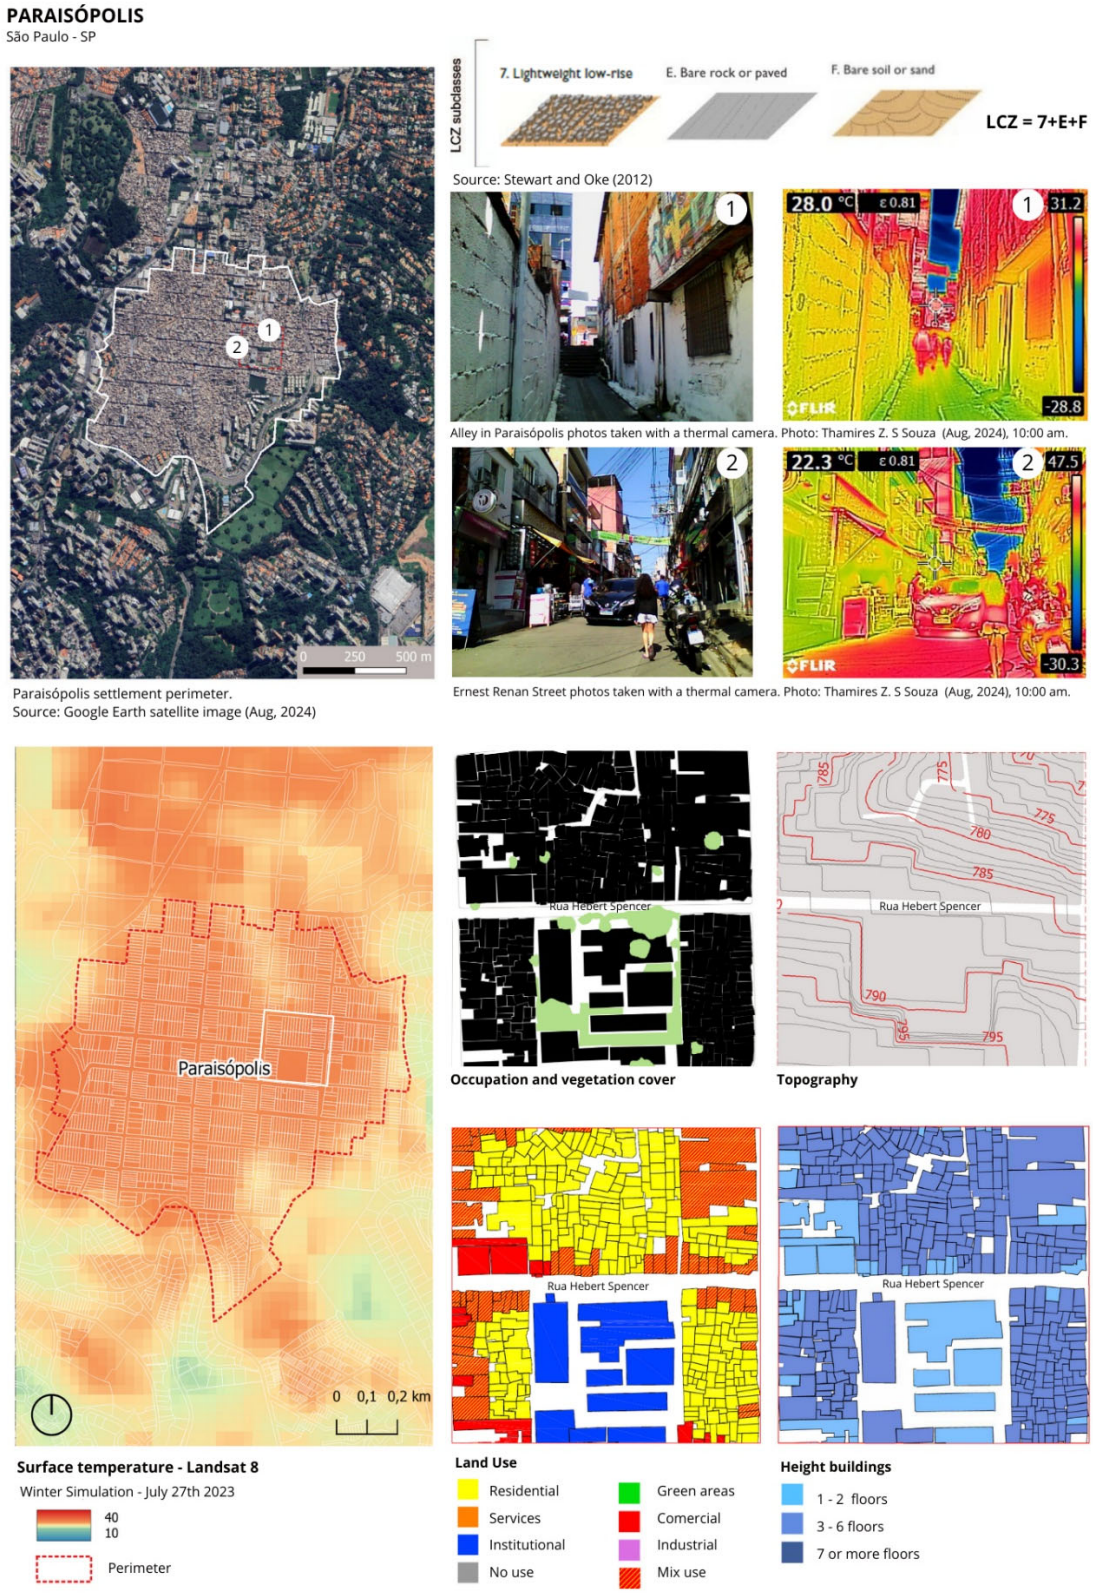

Figure 04. Characterization and analysis sheet for Paraisópolis. Source: developed by the authors based on the United States Geological Survey (USGS) Landsat 8 data (2024), GeoSampa (2024) and data collected by the authors.

Paraisópolis can be defined as a lightweight low-rise area (LCZ 7), it is described as a dense mix of single-story buildings, few or no trees, land cover mostly hard-packed and lightweight construction materials. Observing the thermal camera analysis, it is possible to notice that in the alley (1) where there is a channeled stream and drainage system, the surface temperature tends to be milder, presenting shadows, while on the Ernest Renan Street (2), a very dense commercial street, the temperature is much higher, especially on the street pavement. The lack of shade and low wind speeds further contribute to the formation of heat islands, posing risks to public health and mortality. Therefore, considering the type of coating and paving is crucial in addressing these matters.

To change this scenario in Paraisópolis it is necessary to focus on the expansion of areas with vegetation and trees as a way of reducing the intensity of heat island, improving the thermal comfort and health conditions of the inhabitants, as well as avoiding the risk of flooding caused by extreme rainfall, which can be developed in the form of green-blue infrastructure or other NBS. Some NBSs, such as green roofs and walls, flowerbeds and rain gardens, can be used in precarious settlements, but they present difficulties in the supply of free areas for their implementation, availability of financing for the project and construction, maintenance and forms of irrigation, which must be done with reused water and not with water from the treated water network.

Vila Ipojuca, São Paulo - SP

Vila Ipojuca is situated in the highest topographical region of the Lapa neighborhood, in the Western Zone of São Paulo. The area is approximately 10 km from the city center, positioned in an intermediate ring between the central area and the periphery. It comprises a well-established occupation area and an equally well-established surrounding area. Its occupation began in the 1920s, covering an area of hills and valley bottoms. The area's topography is rugged and organically integrated into the street layout, following the contour lines to provide gentle slopes. As a result, some blocks are very long, extending up to 1 km, and can only be crossed via pedestrian passages. The lot sizes vary, with most averaging around 300 m². The setbacks are not very wide, averaging 4 meters at the front and 1 meter on the sides. The rear setbacks are not consistent, with many occupied by outbuildings. Some side setbacks are non-existent (Figure 05).

Regarding the height of the buildings, the neighborhood of Vila Ipojuca is predominantly horizontal, with two-story buildings, and a few tall buildings. Land use is predominantly residential, although along the main roads, there are local services and commerce. Its generous green areas and tree-lined squares stand out, including São Crispim Square, which was threatened with deforestation but was preserved through civil society actions. However, there are streets without trees, such as a large part of Ricardo Medina Avenue. There is a stream that cuts the area, the Tiburtino Stream that has been identified under streets, alleys and squares. With the subsequent high impermeabilization of the soil, the speed of rainwater runoff increased, exacerbating flooding near the Lapa Market, where the stream is intercepted by the railway. At this point, floods are recurrent.

Observing the Landsat 8 image (figure 05), it is possible to notice that the lighter areas (which correspond to areas of lower surface heat) correlate to green areas and areas where the tallest buildings are concentrated (in the center of the image). According to the LCZ typology, it consists of a mix of zones 3, meaning dense mix of low-rise buildings (1-3 stories), few or no trees, mixed with type 4, that correspond to open arrangement of tall buildings to tens of stories, paved with stone, brick,

tile, and concrete construction materials. Concerning the thermal camera analysis, it is noted that in the region of Praça São Crispim (1), the shading from the trees significantly reduces the pavement temperature, while on Ricardo Medina Avenue (2) the street temperature is much higher due to the lack of shading.

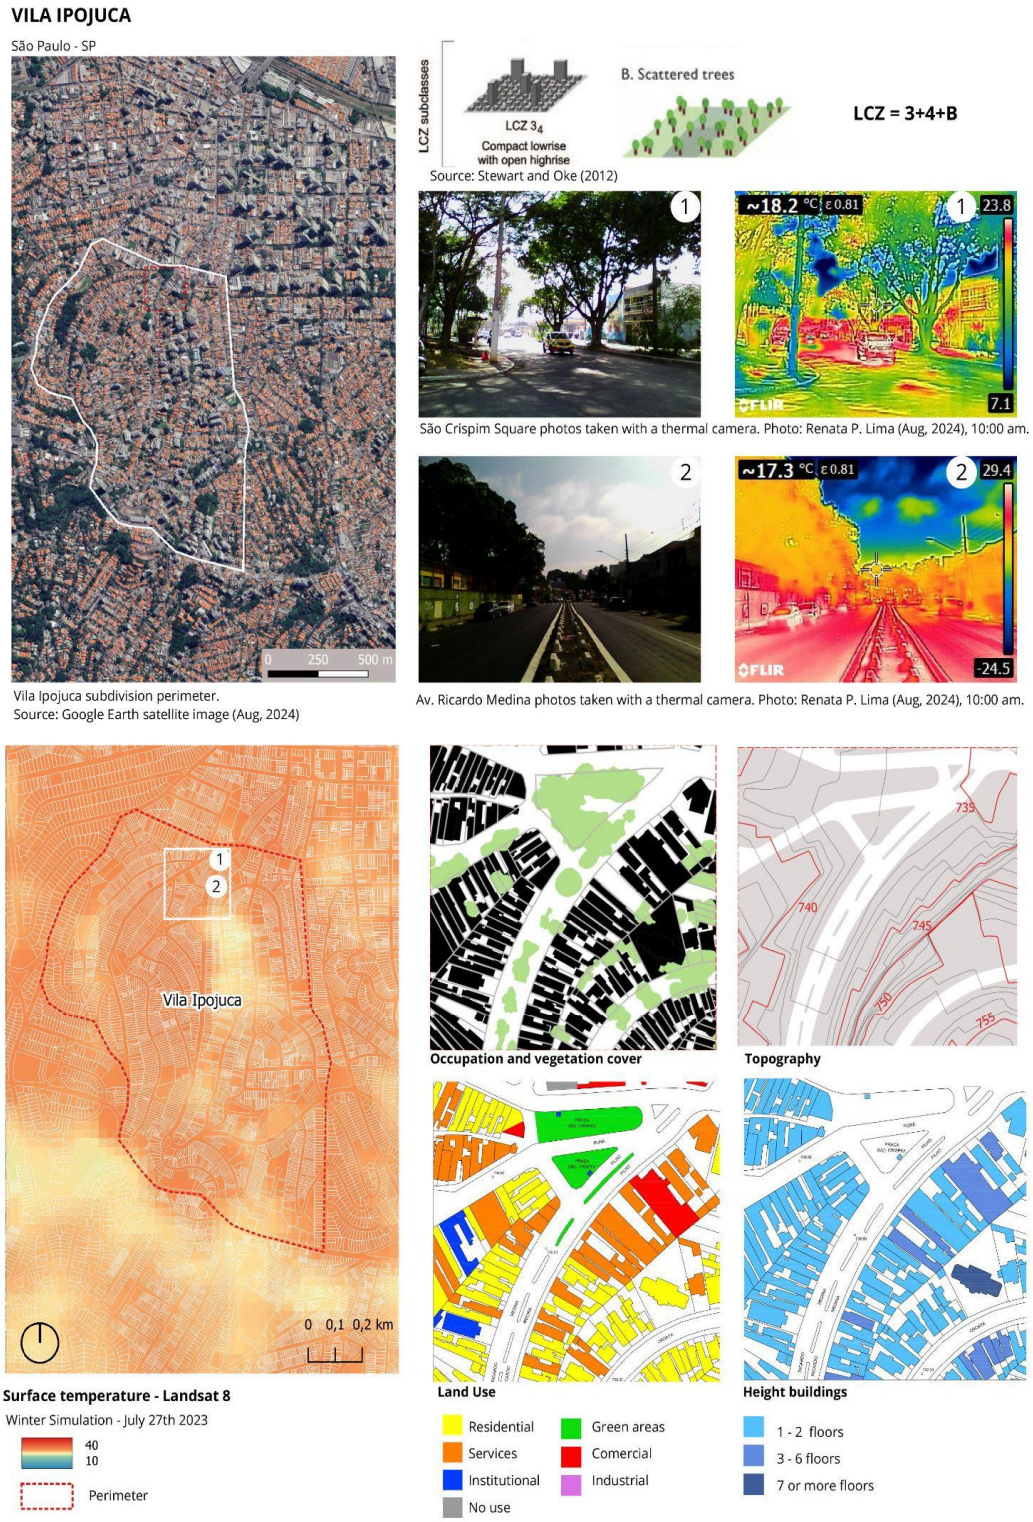

Figure 05. Characterization and analysis sheet for Vila Ipojuca. Source: developed by the authors based on the United States Geological Survey (USGS) Landsat 8 data (2024), GeoSampa (2024) and data collected by the authors.

In an effort to reduce heat in the area and mitigate the effects of urban heat islands in the area, which is predominantly paved and impermeable except for some green squares, replacing this pavement with cooler and permeable surfaces would be a viable solution. Additionally, a linear park could be established between São Crispim Square and Olavo de Peres Velasco Square, along the sanitary alley

where the river is channeled. This route could feature lakes, cisterns, rain gardens, and bioswales to collect clean water. Enhancing vegetation cover over the streets, green areas and lot through functional landscaping and protecting the existing ones would also be crucial. The use of bioclimatic architecture techniques in constructions could also bring very interesting results in this regard.

Villa Verde Neighborhood, City of Franco da Rocha - SP

Villa Verde is a Real Estate project located in Franco da Rocha municipality, situated 5,6 km away from its city center and about 43 km from São Paulo downtown. Villa Verde is characterized as a gated community surrounded by a still not urbanized area that preserves some vegetation. The access to the area is through a high-speed road (Presidente Tancredo de Almeida Neves Highway) that connects the city of Franco da Rocha to São Paulo and other centralities as Campinas and Jundiaí.

While the surroundings of the city center occupy a low-level region (725 meter from sea level) which is the cause of several drainage problems in the densest area of the city, Villa Verde is located in a high-level sector (approx. 100 meters higher) which makes this neighborhood less affected by flood events and, consequently, more costly in terms of land value. Moreover, while 62% of the city terrain is classified as strong hills (UFABC et al., 2021), Villa Verde presents a softer one direction inclined terrain. The topography also reflects on its social-economical standards: while Franco da Rocha is generally characterized by a prevalence of low-income settlements, Villa Verde neighborhood presents large and medium-high quality houses, which can often cost more than R$ 1 million.

Considering the urban pattern, Villa Verde presents similar features to the North American suburban neighborhoods: a monofunctional residential area, accessed exclusively by car, with coverage characterized most entirely by impermeable material in common areas, such as concrete on the sidewalks and asphalt on the inside roads. The few green areas in the neighborhood are in the form of lawns in front of the houses, with few trees. This gated community is occupied by 1 to 3 store houses, mostly made in reinforced concrete and concrete blocks, covered in metal or clay tiles.

Observing the Landsat 8 image (figure 06), it is possible to notice that the surrounding green areas correspond to a much lower surface heat in shades of dark and light green, while the inside of the neighborhood perimeter presents higher surface heat, represented by shades of red and orange, which match with paved and impermeable areas inside the gated community. Concerning the thermal camera analysis, it is noted that there is a strong difference in surface temperature of the impermeable pavement when compared to the green lawn in front of the houses, as well as to the shaded spots next to the few trees in the neighborhood. According to the LCZ typology, Villa Verde neighborhood consists of type 3 - Compact Low Rise, which is defined by a dense mix of low-rise buildings, few trees, most paved land cover and concrete as mainly construction material. In terms of land cover, it is possible to relate Villa Verde to type E - bare rock or paved, defined as a landscape of paved cover, with few or no trees. This type of cover is common in urban areas, increasing thermal inertia.

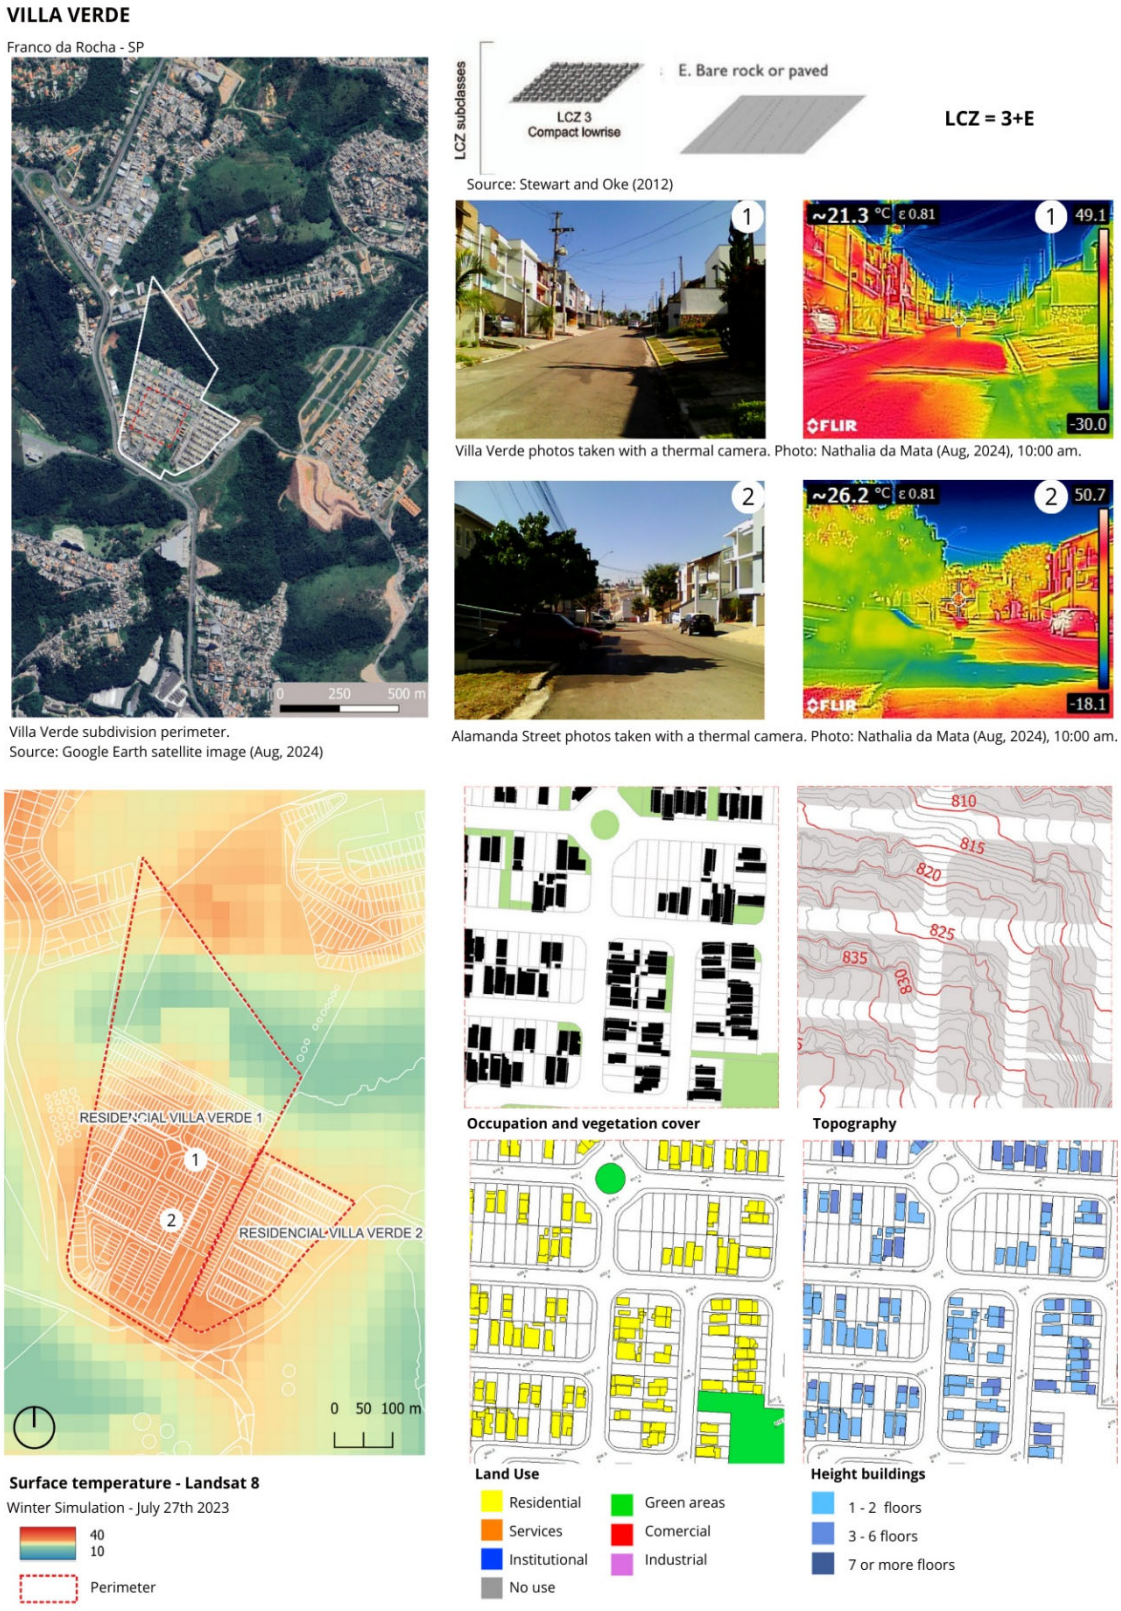

Figure 06. Characterization and analysis sheet for Villa Verde. Source: developed by the authors based on the United States Geological Survey (USGS) Landsat 8 data (2024), Inmap (2024) and data collected by the authors.

Aiming the reduction of the effects of urban heat islands analyzed, it could be recommended the increase of green cover on the common areas of Villa Verde, as well as increment in the number of larger vegetation such as trees to expand the shading in the neighborhood. The substitution of asphalt

by other covering materials is also recommended, due to its high thermal inertia, such as concrete and, in the best case, greenery.

The analysis of three MASP case studies shows that the morphological pattern of urban fabrics classified according to LCZ aligns with temperature differences observed in Landsat satellite images. It showed that heat tends to accumulate in regions with sparse vegetation and impermeable surface, indicating that urban development significantly alters local climate. These issues, along with the types of surfaces, are directly linked to architectural and urban planning decisions, revising the morphological pattern is a reliable means of mitigating UHI and should be urgently adopted as an urban planning central tool. So, the use of Local Climate Zones (LCZ) as a parameter could be beneficial for urban planning studies. But it is important to note that LCZ analysis needs to be supplemented with detailed investigation to recognize small squares and trees as it was done in this study with the thermal camera.

When comparing the three cases and the Landsat images simultaneously, it also becomes evident that not only the typology of the urban fabric and the surface materials matters in terms of urban climate and UHI configuration but also the positioning of the sample within the urban context. In Franco da Rocha, the Villa Verde subdivision lacks vegetation, resulting in higher surface temperatures compared to cooler surroundings. In Paraisópolis, densely packed areas exhibit higher temperatures, while more spaced-out areas like Morumbi are cooler. On average, these temperature differences amount to 3°C, but they can be even higher on extremely hot days. Interestingly, in Vila Ipojuca, the Landsat image does not show significant contrast between this neighborhood and its surroundings. This lack of contrast is likely due to the similar morphological typology of the surrounding areas. Building dense areas also seem hotter and spaced-out areas cooler if analyzing Landsat images. But with the thermal camera, it was noticed that alleys and spaces without light as it was found in Paraisópolis can bring humidity that reduces the temperature. However, in very warm situations, they tend to become stuffy and lack air circulation, which can greatly increase the discomfort of the inhabitants.

In the sense of providing tailoring specific solutions to each type of urban fabric, Nature-Based Solutions (NBS) offer a promising approach. In this way, vegetation acts as a microclimatic regulator, reducing solar radiation and modifying air temperature and humidity through shading. In large quantities, vegetation can also influence rainfall frequency and reduce air pollution through photosynthesis and respiration. Additionally, integrating water and greenery through Green and Blue Infrastructures (GBI) and Sustainable Drainage Systems (SuDS) enhances their benefits. Local and microscale strategies include rain gardens, planting small trees and palm trees. On individual lots and at the building scale green roofs, green facades, bio-swales, light cover materials, flower boxes and rain gardens reduce stormwater overflow, filter water and air, and contribute to local microclimates. Key actions include increasing tree planting and expanding and protecting green areas. Connecting parks, squares, linear parks, boulevards, gardens, and green roofs is also crucial for maximizing their cumulative effects. However, solutions for improving temperature conditions extend beyond increasing vegetation cover and drainage systems. It is recommended that climatic aspects be considered when specifying materials for pavements and coatings of public spaces decreasing the use of asphalt. Mitigation actions should also include controlling land use and improving the comfort

technology of buildings. exploring sustainable certifications for neighborhoods, and developing more assertive legislation regarding environmental and sustainable issues would be very beneficial.

CONCLUSIONS

This study endeavored to correlate the morphological patterns of three distinct areas in São Paulo with urban climate characteristics, utilizing the Local Climate Zones (LCZ) framework. The findings elucidate that anthropogenic activities markedly alter surface temperatures and impact the urban climate, engendering or exacerbating urban heat islands, as evidenced in the studied areas. This underscores the imperative to expedite adaptation processes. Methodologically, the study advocates for urban analyses to be interdisciplinary and multiscale, with a strong emphasis on incorporating surface temperature data in all urban studies. The LCZ framework offers invaluable insights into micro-scale characteristics, yet the unique features of each region necessitate bespoke analysis and design. This highlights the critical importance of urban planning and morphology studies and the necessity for developing bioclimatic micro-scale urban projects. Such projects should embrace a holistic approach, integrating heat island mitigation with green spaces, drainage, transportation, and other infrastructure systems. The incorporation of Nature-Based Solutions (NBS), such as augmenting vegetation cover, implementing Sustainable Drainage Systems, and developing Green-Blue Infrastructure, is essential. These solutions should be embedded into future public policies at MASP to bolster resilience and advance climate justice.

Navigating microclimatic challenges in urban morphology: integration of knowledge into practice in Brisbane, Australia

YiSong Liu[1], Mirko Guaralda[2]
[1] Queensland University of Technology, Brisbane, Australia, yisong.liu@hdr.qut.edu.au
[2] Queensland University of Technology, Brisbane, Australia, m.guaralda@qut.edu.au

ABSTRACT

Amidst its changing urban form, Brisbane, Australia, is grappling with complex microclimatic challenges. The city's increasing densification and growing population are contributing to a noticeable decline in thermal and wind comfort. Although there is significant scientific evidence on microclimatic effects, and both city and state governments have issued multiple guidelines and visions for addressing them, the challenges in this area continue to worsen. This points to an unaddressed concern: the effective integration of microclimatic design principles into contemporary urban development practices. Analysis and evaluation of existing urban planning and design paradigm through semi-structure reviews with built environment professional reveals a series of challenges: the ambiguous nature of current urban planning codes, a pervasive knowledge gap about microclimate implications, short-sighted political and economic considerations, and an absence of robust technical method during initial design phases. Future strategies should focus on continual professional development, increasing public awareness, and incorporating microclimate-sensitive practices into the city's urban planning and design frameworks.

Keywords: Microclimate-sensitive urban design; urban densification; thermal comfort.

INTRODUCTION

The recognition of urban sprawl's unsustainable nature has led to a growing shift towards higher-density urban development in contemporary cities (OECD, 2012). However, the compactness of such cities introduces significant environmental challenges, particularly concerning the urban climate. The dense concentration of buildings and infrastructure alters the microclimate, intensifying heat retention and reducing airflow, thereby exacerbating the urban heat island (UHI) effect (Oke et al., 2017). Consequently, there is an increasing emphasis on incorporating urban climate considerations into urban planning and design. This approach is viewed as vital for mitigating climate change impacts and enhancing the resilience and well-being of urban populations (Masson et al., 2020).

Despite the growing importance of this issue, the integration of urban climate knowledge into professional urban planning and design practices remains limited. Scholars have pointed there are limited examples of effectively translating urban climate insights into real planning and design

outcomes (Hebbert and Mackillop, 2013). Thus, the primary aim of this paper is to investigate the challenges of integrating urban climate considerations into planning and design practices in Brisbane, Australia. It is also important to recognise that urban morphology is shaped by various factors, including economic, political, and social dynamics. At the same time, professional planners and designers often have firsthand experience in navigating these influences. Therefore, this study primarily focuses on the experiences and insights of built environment professionals.

The study is structured in two parts: the first examines the evolution of Brisbane's urban morphology, providing essential context and its relationship with urban climate; the second offers a qualitative analysis of interviews, which uncovers the key barriers to effective implementation and presents recommendations for enhancing the incorporation of climate-responsive strategies into urban form.

BACKGROUND

Urban morphology plays a crucial role in shaping the microclimate within a city. The urban climate is influenced by various characteristics of the built environment, and numerous studies have explored a range of quantifiable urban morphological parameters and indices (Yang et al., 2023). At its core, this relationship is often defined by the three fundamental elements of urban form: streets, blocks, and buildings.

In vernacular cities, streets were often oriented to channel natural ventilation, enhancing airflow and cooling (Aynsley, 1999). However, in contemporary cities, tall buildings frequently create deep street canyons. While these canyons can reduce solar exposure and lower surface temperatures during the day, they also tend to trap heat and pollutants by hindering natural ventilation (Qaid & Ossen, 2015). Additionally, the compact blocks and reduced open spaces, a consequence of the larger functional areas of tall buildings, further obstruct wind flow, exacerbating heat retention and air quality issues (Sanaieian et al., 2014). Therefore, a well-considered urban design that balances building heights, street widths, and block configurations is essential for fostering a more favourable microclimate.

In Brisbane, the typologies of inner-city streets, blocks, and buildings have undergone significant transformation over the past two decades. Figure 1 presents a satellite imagery comparison of inner-city Brisbane. This transformation is part of a broader trend observed in many cities across the Anglosphere, where government initiatives promoting compact city development have led to increased densification within the central business district (CBD) and surrounding areas. These efforts reflect a growing political agenda aiming to reduce urban sprawl by concentrating development and enhancing the vibrancy of the city centre (Raynor et al., 2018).

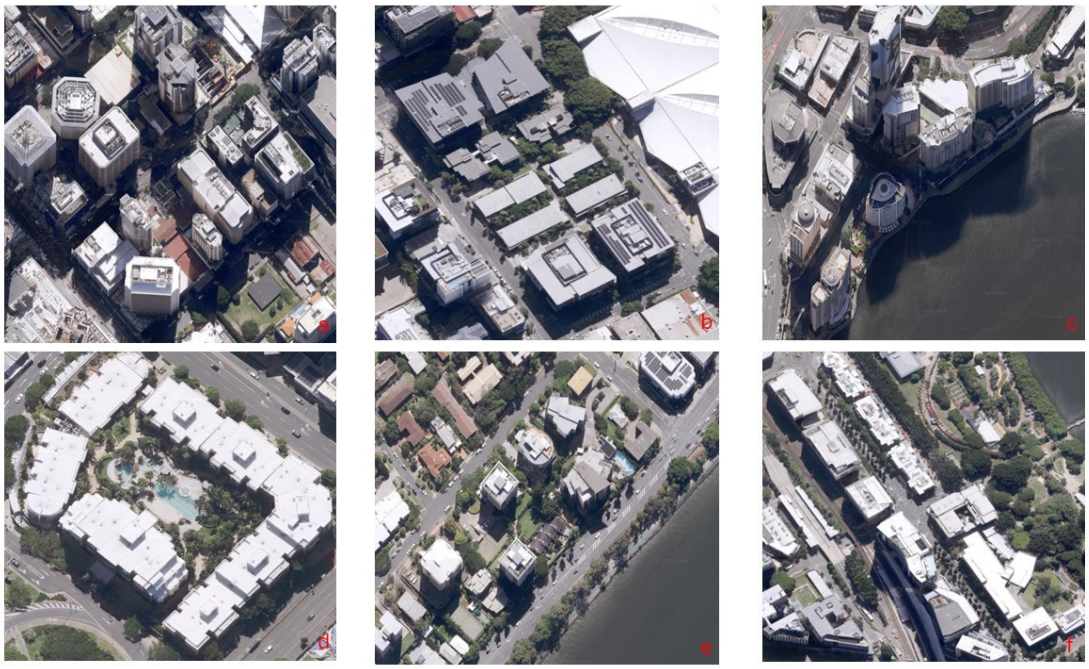
(Figure 1 Comparison of Brisbane's inner city land scape, Left. 2004, Right 2024)

Historical street and parcel layouts significantly influence urban form. Previous research by Siksna (1998) illustrates how city blocks affect the configuration of the parcels within them. In the context of Brisbane, the city was established both as an urban centre and as a fortress in a hostile environment. Unlike cities such as Adelaide or Canberra, where specific design strategies were implemented, Brisbane's inner-city parcels was primarily driven by surveyors, leading to the adoption of a grid pattern with minimal design consideration. The initial settlement pattern consisted of 200 x 90 m rectangular street blocks, arranged in a street mesh spacing of 221 x 111 m, with each block divided into twenty equal back-to-back plots (Sanders and Schroder, 2008). Over the course of two centuries, parcels were amalgamated to accommodate the demand for taller buildings with larger footprints. This trend indicates that the city blocks experienced subdivision from its inception, driven by landowners seeking the profits that such development opportunities offered (Figure 2).

(Figure 2. Building Footprint and Subdivision, Brisbane City Centre 1910, 1930,1960 and 2005, Sanders and Schroder, 2008).

The changing urban form of inner Brisbane is influenced not only by socio-economic and historical factors but also by regulatory frameworks. As argued by Gu (2014), form-based codes embedded within planning schemes are inherently morphological, extending beyond land use to control elements such as building height, setbacks, and site coverage. Since the early 2000s, Brisbane has undergone significant densification efforts, driven by changing planning codes. As a result, under various state-level statutory instruments, most new dwellings must be developed within existing

urban areas (Fig 3). To facilitate densification, amendments to the planning scheme have included reducing parcel sizes and removing building height restrictions (Gallagher et al., 2023).



(Figure. 3 Typical Block Typology, Inner Brisbane)

Developers typically work within existing property boundaries, which contributes to the development of local architectural characteristics (Stell & Tait, 2016). The extent to which this pattern persists varies according to factors such as planning codes and market demands. For example, the transition from low-rise office spaces and row shops to high-rise residential towers in the Brisbane CBD can be attributed to several factors. Firstly, the increasing urban population and growing demand for housing in proximity to employment centres have driven the need for more residential spaces within the city. Secondly, the economic benefits of high-rise residential projects, such as higher rental yields and property values, have attracted developers to shift their focus from office to residential developments. Thirdly, changes in lifestyle preferences, with more people seeking the convenience of living close to work, amenities, and public transport, have further fuelled the demand for residential towers. The transition is also supported by policy changes encouraging urban densification and the repurposing of land for mixed-use developments.

However, compact development has leads to more and more empirical evidence regarding the detrimental affects of urban heat island effects. Brisbane has experienced a steady increase in temperature in recent decades, with more frequent and longer heatwaves. Extreme urban heat island phenomenon has been detected in many infill development areas. (Deilami & Kamruzzaman, 2017). In addition, residents have been organising to oppose ongoing high-rise developments, arguing that these projects could exacerbate urban heat island effects and create potential wind comfort issues (Mongard, 2023).

Interview results

A series of qualitative semi-structured interviews were conducted between October 2023 and January 2024 with 19 professionals from five disciplines—urban planning, architecture, landscape architecture, urban design, and building engineering—based in Brisbane. The objective was to explore these professionals' experiences with the utilisation of urban climate knowledge in urban development projects (Liu et al., 2024)

The study on urban climate design implementation in Brisbane brings both relational and functional challenges faced by professionals in the built environment sector. Through in-depth interviews and thematic analysis, five primary areas of challenge emerged: awareness, policy and planning regulation, resources and capability, data and modelling, and future development (Table 1).

Table 1: Challenges and Recommendations from the Interviews

Challenges	Description	Recommendations
Awareness Disparity	Significant gap in understanding urban climate issues between professionals and clients, particularly between large developers and smaller projects.	Increase public and professional understanding of urban climate issues through education, outreach, and showcasing exemplar projects.
Weak Policy and Regulation	Existing frameworks are primarily advisory, lacking enforceability, which makes climate-responsive design negotiable rather than mandatory.	Develop more robust, enforceable policy frameworks that mandate the inclusion of urban climate considerations in all stages of planning and design.
Economic Viability Concerns	Short-term financial considerations often lead developers to resist incorporating climate-sensitive practices due to perceived cost increases.	Foster a culture in the market that prioritizes long-term sustainability alongside economic viability, encouraging developers to integrate climate-sensitive practices through monetary incentives
Resource Constraints	Restrictive project timelines and budget limitations make it difficult to align climate strategies with practical development realities.	Encourage more time and budget to planning and developers to ensure that climate-responsive strategies can be effectively implemented.
Limited Technical Capabilities	A lack of specialized knowledge and skills, particularly in CFD modelling and data analysis, hampers the effective implementation of climate strategies.	Enhance the technical skills of professionals through training and provide access to advanced tools and resources for better climate modelling.
Inadequate Data and Modelling	Insufficient access to accurate, site-specific data and the inadequacy of current modelling tools hinders detailed microclimate assessments.	Invest in the development of more sophisticated, publicly available, accurate, and user-friendly data and modelling tools that provide detailed, site-specific climate assessment

Relational challenges primarily concern the dynamics and interactions among various stakeholders involved in urban development. A significant issue highlighted is the dominance of political and economic factors that shape urban planning priorities. The study reveals that economic development agendas, often driven by market forces, overshadow sustainable and climate-resilient objectives. This market-led approach results in urban growth patterns that frequently neglect or inadequately address urban climate issues. Additionally, the study identifies a significant knowledge gap among stakeholders, with varying levels of awareness and understanding of urban microclimate issues. While professionals in the field are generally aware of these issues, there is a marked disparity in awareness among clients, particularly smaller developers, which hinders the broader adoption of climate-sensitive design practices.

Functional challenges relate to the technical aspects of implementing climate-responsive design strategies. The study highlights the limitations of existing policy frameworks, which, while

acknowledging the importance of climate-responsive design, are often advisory rather than mandatory. This lack of regulatory enforcement reduces the motivation among developers and planners to integrate microclimate considerations into their projects. Additionally, the technical complexity associated with urban microclimate modelling and simulation tools poses a barrier to their widespread use. These tools, although powerful, require specialized knowledge and skills, which are often lacking among urban planners and designers. The study also points to the challenges in data availability and accuracy, which are critical for effective microclimate assessment but are often inadequate, leading to reliance on less precise, rule-of-thumb strategies.

DISCUSSION AND CONCLUSION

Urban climate poses a complex challenge, requiring innovative design solutions across various spatial scales. The research identifies three key recommendations to improve the integration of urban climate knowledge into planning and design practices.

First, raising awareness of urban climate issues is crucial. Without recognition of these challenges, stakeholders, including politicians and the public, are unlikely to act proactively. The study highlights that responses often occur only after extreme events, such as floods or heatwaves. Demonstrating best practices through exemplar projects could be an effective way to increase awareness. Second, the research underscores the need for robust, flexible, and balanced regulations to guide market-driven planning. While the regulatory environment varies depending on economic, political, and cultural contexts, better communication of urban climate knowledge is universally necessary. Third, the study calls for more interactive approaches and accessible tools to engage stakeholders effectively. Practitioners need user-friendly modelling tools that provide clear, interpretable information for non-experts. GIS platforms and CFD modelling tools, such as EnviMet, are identified as valuable resources for detailed microclimate analysis.

The study also emphasizes that relational challenges, particularly political-economic factors, are more critical than technical issues in urban climate design. Future research should focus on how professionals navigate institutional barriers and power dynamics among stakeholders to achieve optimal design outcomes, offering insights into improving urban climate resilience.

In conclusion, this paper underscores the critical relationship between urban morphology and microclimate in Brisbane's planning and design practices. The research reveals that the city's evolving urban form, driven by densification, has significant implications for thermal comfort and natural ventilation. Addressing these microclimatic challenges requires a deeper integration of climate-responsive strategies within the existing urban morphology framework. Enhancing awareness, strengthening regulatory approaches, and advancing technical tools are essential to better align urban morphology with the need for sustainable and resilient microclimates.

Peripheral expansion of the Minha Casa, Minha Vida Program and their impacts on the fragmentation and functioning of landscapes, the case of the metropolis of Brasilia

Patrícia Silva Gomes[1], Octavio Araújo Vieira[2]
[1] Professor, Faculty of Architecture and Urbanism, University of Brasilia, Brazil, patriciasgomes@unb.br
[2] Architect and Urbanist, Faculty of Architecture and Urbanism, University of Brasilia, Brazil, octavioaaraujo1@gmail.com

ABSTRACT

The article aims to analyze the impacts on the fragmentation of the regional cerrado landscape and the loss of groundwater recharge resulting from the peripheral expansion of contiguous developments of the Minha Casa, Minha Vida Program (PMCMV) in Valparaíso de Goiás/GO, municipality belonging to the metropolitan area of Brasília. Were used satellite images taken from the Landsat 5 and 8, for these the atmospheric correction was made and the normalized difference for vegetation index (NDVI) was determined; this indicator makes it possible to compare changes in the types and densities of vegetation and land use between time periods, which allowed to contrast the urban form and vegetation before (July 02, 2009) and after (July 06, 2022) of the expansion of housing developments in the region. The result showed an increase of 39.63% in the urban fabric and from 27.19% to 35.68% in the impervious areas, which was particularly critical on the banks of the Santa Maria and Saia Velha Rivers. To analyze the consequences of the changes of form in functioning of the landscape, the Analytic Hierarchy Process (AHP) was used; thus, according to the literature and previous work by the authors, were processed in QGIS® the relative weight that each variable exerts on groundwater recharge, resulting in 50% for NDVI (as a proxy for land cover), 18% for paedology and 32% for geomorphology; and, at the level of each variable, scores from 0 to 4 were specified to determine the influence of every situation on recharge. The results showed the sensitivity of fragmentation to the loss of recharge and recommendations for the proper insertion of the housing developments on the metropolitan periphery, considering the importance and return of the PMCMV, as well as the need for measures to ensure water security through the preservation and connectivity of remnants vegetation.

Keywords: Landscape fragmentation, loss of groundwater recharge, Minha Casa Minha Vida Program, urban sprawl, metropolis of Brasília.

INTRODUCTION

The Minha Casa, Minha Vida (My House, My Life) Program is designing an important part of the urban fabric of Brazilian cities; launched in 2009, between 2009 and 2020 it produced 5,1 million units and, relaunched in 2023, the prospect is that these numbers will continue to increase.

In fact, alongside the first signs of the scale it would take on, there was already criticism in the literature about the urban, architectural, social and environmental impacts it would have. After all, a Program designed under the expectation of the market, which is in charge of selecting the land and building the units, meant choosing homogeneous and peripheral mega complexes, in order to gain land scale, without necessarily corresponding to the expectation of a better location in the city, in terms of community equipaments and mobility. It also meant little variation in building typologies that could meet the needs of different families; the adoption of standardized architectural solutions, without much adaptation to the climatic and landscape singularities of each site, and simplified, with the aesthetic impoverishment of the fabrics. As well as causing sociological impoverishment, with the segregation of the low-income population on the outskirts, sometimes in enclosed spaces, reproducing the paradigm of carceral cities, and without a sense of community, since it is common for residents to access the units where they can afford or where they have been granted by the government, without necessarily having emotional ties.

Furthermore, the implementation of huge contiguous complexes on the outskirts, usually through the physical extension of fabrics, has resulted in serious impacts on the connectivity of landscapes, through the reduction and fragmentation of habitats, and on water recharge; however, few studies have analyzed these cumulative effects on the sites that have received many complexes.

Likewise, the metropolis of Brasília was strongly impacted by the Program, receiving around 2664 developments (Brasil, 2024). In particular, the outskirts of Goiás, due to their large supply of cheap land, permissive municipal administrations when it comes to approving these developments and the great metropolitan demand for homes, have become the ideal location for attracting huge, contiguous and homogeneous Program developments. Furthermore, analysis of the impacts that this recent urban-metropolitan expansion has had on the reduction and fragmentation of habitats and on the water recharge patterns of the cerrado is still scarce.

The Cerrado is Brazil's second largest biome; it is the most biodiverse savannah in the world, with around 12,000 species, 5,000 of them endemic, and it is the place where the waters that feed the main basins of the South American subcontinent are stored and distributed. Despite this importance, it has been severely impacted; data from MapBiomas (2024) shows that the cerrado has already lost 50% of its vegetation cover and is losing its surface and underground water flow, mainly due to the advance of the agricultural frontier, but also due to urban expansion. However, there are few studies dedicated to understanding the role of urban expansion in the impacts on the cerrado. The report shows that deforestation in the Cerrado in 2022 represented 31.2% of the total deforested areas in Brazil (MapBiomas, 2024).

The aim of this study is to analyze the impacts on the fragmentation of the regional cerrado landscape and the loss of groundwater recharge resulting from the peripheral expansion of contiguous developments under the Minha Casa, Minha Vida (My House, My Life) Program in Valparaíso de Goiás/GO, municipality belonging to the metropolitan area of Brasília. The municipality has attracted 470 PMCMV developments with strong consequences for the sub-basins of the Saia Velha and Santa Maria streams, which cut through the city.

Thus, items 1 and 2 present the theoretical approach to the subject - the PMCMV in the fabric of the urban fabric; urban expansion and its effects on landscape connectivity and water recharge - while

items 3 and 4 present the method and empirical results, respectively. Finally, the conclusion consolidates the theoretical and empirical contributions of the research.

THE PMCMV IN THE WEAVING OF THE URBAN FABRIC

The Minha Casa Minha Vida (My House My Life) Program (PMCMV) was launched in 2009 by Federal Law nº 11.977, and extinguished in 2020 by Federal Law nº 14.118, which established the Green and Yellow House Program. However, with the return of the Lula government, the program was relaunched through Federal Law nº 14.620, so that over 11 uninterrupted years and one more re-launch, it has concentrated an action that results in important impacts on the urban fabric of Brazilian cities, something that needs to be brought into the debate as a way of improving housing policy.

Launched as a counter-cyclical measure in the face of the neoliberal crisis of 2008, the Program would represent an eclipse in the policy of the National Social Housing System, which had been set up since 2005, based on the idea of meeting the various municipal housing needs, based on bringing together the actors and instruments that would ensure well-located housing in the urban fabric. Thus, the executive bodies – national, state and municipal – would draw up the Social Interest Housing Plans as a way of sizing up the lines of action and budgets needed to solve the various local housing problems; be it in terms of upgrading the stock, through full land regularization, housing improvements, social rent, or increasing the stock, through the production of new units, while the financial bodies and funds would make the resources available in accordance with the Plans.

Contradictorily, the PMCMV is based on the promotion of new housing, in a *modus operandi* in which the construction companies are in charge of choosing the land and building the units, which are then passed on to the municipalities, to be distributed according to the municipal inscription in the housing deficit, in the case of Line 1 of the Program, or are sold directly with financing from CAIXA Bank, in the case of Lines 1.5, 2 and 3. The Program was launched with the manifest aim of alleviating the Brazilian housing deficit (FJP, 2023), concentrating its actions in the contexts where it is most significant – on the outskirts of cities, in the case of the population with an income up to tree minimum wages, and in the poorest states.

Thus, the Program is divided into four tracks – 1, for families in urban areas with a monthly income of up to R$ 1,800; 1.5 extinguished in the 2023 version; 2, for families with a monthly income of up to R$ 4,700 and 3 for families with a monthly income of up to R$ 8,000 – and the resources, budgetary (FAR, Public Offer, Entities and Rural) and onerous (FGTS), are distributed according to these. Thus, line 1 has a 90% subsidy, initially using resources from the General Budget of the Union (OGU), but currently from the FGTS, and a discount on financing with the use of the FGTS; lines 1.5 and 2 have a subsidy of up to R$55,000 and a discount on financing with the use of the FGTS; and line 3 does not have a down payment subsidy, but only financing with lower interest rates from the FGTS. The programmatic lines absorb the demands of the sectors, with the Residential Leasing Fund (*Fundo de Arrendamento Residencial – FAR*) modality serving the housing production contracted with companies; the Entities modality is intended for families organized in an associative manner, according to the Government's qualification and the Public Offering to serve municipalities with a population of up to 50 thousand inhabitants, according to the presentation of proposals by municipal governments or state

governments. It is worth remembering that this last modality is currently discontinued. Whereas subsidized financing serves higher-income families, mostly with FGTS resources (Brazil, 2020).

Based on this operational design, the Program has accumulated 6,075,704 contracted units and 5,162,407 completed units (table 1), and the significance of these numbers in cushioning the quantitative deficit should be considered, given that, in 2009, it was 5,703,003 units and, currently, it stands at 6,215,313 units (2022), as well as in the historical performance with the income line of up to 3 MW. Until then, this social group had not been effectively reached by a preventive housing policy for the production of new housing (Cardoso et al., 2017), but only with specific action, with the use of government resources – such as the Fundação Casa Popular (applying revenues from the Ministry of Labor) and the Residential Leasing Program (applying a mix of FGTS-OGU revenues) – or onerous resources from the FGTS – such as the popular programs of the BNH and the Housing Finance System of the Sarney and Collor governments (Popular Housing Program) (Gomes, 2018).

Financing (or FGTS)	215.749	150.127	3.108.378	363.349
Total	1.910.546	150.127	3.108.378	363.349

Nevertheless, the option for new housing has resulted in a series of urban, architectural, social and environmental impacts covered in important post-occupational research (Rolnik et al., 2015; Cardoso et al., 2017) and in the government's own self-criticism (Brasil, 2020). Thus, in urban terms, the Program has difficulty reconciling housing policy with urban policy, since the selection of land is the responsibility of construction companies, which has meant, as a rule, the choice of mega-projects on the outskirts of large cities and in projects outside the urban fabric, in small cities. Furthermore, many Programs were not accompanied by the qualitative and quantitative supply of equipment, green areas and mobility, promoting the paradigm of housing without a city, leading the government itself to recognize the failure and determine, based on Ordinance nº 660 of 2018, that the complexes could be equipped with equipment. Furthermore, as land prices were defined by supply and demand, the launch of the Program generated an initial increase in land values, further driven by the major events of the World Cup and the Olympics. However, with the economic crisis and the Covid-19 pandemic itself, there was, subsequently, a retraction in the real estate market and, with it, the tendency for land prices to stabilize. While the trend towards cost simplification meant, in architectural terms, the choice of homogeneous typologies, generally multi-family buildings of up to 4 floors, to dispense with elevators, with living room, kitchen, bathroom and two bedrooms, or single-family houses of 42,00 m² or semi-detached; without a greater typological variation, to meet the needs of each type of family. As a rule, there were no adaptations of bioclimatic comfort, which could adapt to the climatic needs of each part of the country, nor innovations, in the sense of introducing more environmentally sustainable materials and technologies for the rational use of resources.

This led the government itself to recognize the failure and require, through Ordinance nº 660 of 2018, that the size of each project be limited to a maximum of 300 homes in the case of developments

implemented under a condominium regime, and 500 units in cities with more than 500,000 inhabitants. However, there was no limit on contiguous developments, up to a limit of 2,000 units. Furthermore, the Ordinance indicated, but did not require, that projects promote typological variation; adapt environmental comfort measures that are more appropriate for each bioclimatic zone in the country, especially shading and cross ventilation in long-stay environments, with bedrooms and living rooms, and the choice of light-colored finishing materials for facades.

The condition of popular housing enclaves has led to these places being stigmatized in social terms as strongholds of violence, drug trafficking, marginalization, and lack of community ties. In addition to the paradox of families having to pay condominium fees, which are incompatible with the value of the monthly financing payments (Brasil, 2020).

The environmental consequences of the urban and architectural choices of these developments have mainly resulted in the extension of urban fabrics, the lack of landscaping and afforestation of collective spaces, and the little use of sustainable infrastructures. This was precisely incorporated into the measures to improve the policy by Ordinance nº 660 of 2018, which attempts to relegate developments located in urban expansion areas, established after April 10, 2012, to being subject to proof of the existence of a specific project that justifies such expansion, established by municipal law and with minimum planning requirements; as well as indicating that the developments adopt landscaping measures, with lighting, afforestation and collective leisure spaces; and environmental technologies, such as rational use of water, solar energy, among others.

However, the Ordinance does not provide more detailed indications about significant cumulative impacts on the reduction of habitats and water recharge, caused in regions that tended to receive many complexes, which may even reflect the lack of guidance derived from scientific research on the subject.

Ultimately, the adaptations of the Ordinance, although they have resulted in improvements to the new complexes, without, however, changing their *status quo*, signal the importance of improving public policy, especially based on the contributions of scientific research. However, the policy is still weak in addressing the causes of the problem, which is the induction of housing in better structured central areas and the use of the existing fabric itself, something less attractive to the market, the protagonist of the policy.

Isolating the case of the metropolis of Brasília, as an example, 21.36% of the developments were concentrated in the Federal District, none of them in the most central Administrative Region of the Pilot Plan, and 78.64% in the outskirts of Goiás (as shown in Table 2). Certainly, this condition can be extended to other Brazilian metropolises.

THE URGENCY OF AN URBAN MODEL THAT IS PARSIMONIOUS TO THE ECOLOGICAL FABRIC

The search for an urban model that is more parsimonious to the natural environment has historically been the subject of important reflections and proposals, such as the Boston Emerald Necklace (1878 and 1895), Broadacre City (1932) and the Copenhagen Finger Plan (1948), to name just a few examples. Perhaps Thoreau's authentic thinking was a pioneer in defending a transcendental relationship between man and nature.

The classic authors of environmental planning from the 1960s, such as Anne Spring, Michel Houhg, and especially McHarg, can be exemplified as seminal for the approximation of the themes, due to their contribution of the considered and combined reading of thematic overlayers, for the generation of a summary map of restrictions on site occupation.

However, there has traditionally been a tendency for these agendas to be segmented on the political agenda, with environmental issues being addressed only through sanitation and the protection of conservation units/water sources, within the comprehensive master plans of the 1970s, and the urban model, with only one chapter on the environmental issue, as can be seen in the Brundtland Report, where the topic is addressed in Chapter 9 of Part III (Costa, 2008).

More recently, criticism of the impacts brought about by modernist urban sprawl, producing dormitory suburbs around the world, has been addressed in theoretical and propositional reflections, based on models such as the compact city (Dantzig; Saaty, 1973) and Smart Growth (Duany; Speck, 2004). In these studies, the treatment of issues such as controlling the optimal size of each urban area, varying typologies to optimize density and diversity of uses, the presence of common spaces for local food production and the activation of community life, leads to them being touted as examples of so-called “sustainable cities”, although environmental reflection is not the core of these reflections. In the field of ecology, at the same time, important theoretical contributions were made with studies on modeling carrying capacity and ecological footprint, which have been included in the urban planning literature as methodological references for measuring natural and built carrying capacity.

Furthermore, on the political agenda, the worsening of the environmental crisis resulting from human activities has resulted in the approach to climate change as a harmful synthesis of imbalances in biogeochemical cycles, with the 61 IPCC Panels produced to date and the Climate Conventions/Agreements, such as the Paris Agreement in 2015, currently in force, being the main spheres of reflection and consultation.

It is considered that these studies advance in the direction of a deep ecology (Naess, 1984), understanding a dense network of causes and effects of natural cycles and humans as just one of the beings to be respected in the web of life, although the proposals do not yet change the status quo. At the same time, the UN's sustainable development goals (Agenda 2030) also currently represent a platform for the articulation of multiple actors and actions around the planetary environmental crisis, despite the ambiguities of their linkage and the search for social equity by the mainstream.

Data already show that between 2011-2020 the average temperature of the planet was 1.1ºC higher than in the period 1850-1900, that the global mean sea level rose by 0.20 m between 1901-2018; that hundreds of local species losses were caused by increases in the magnitude of heat extremes (high confidence) with mass mortality events recorded on land and in the ocean (very high confidence). Particularly for cities, they show that between 2010-2020 human mortality caused by floods, droughts and storms was 15 times higher in highly vulnerable regions, compared to regions of very low vulnerability (high confidence); in addition to causing greater damage to water and food security (high confidence) (IPPC, 2023). For the Cerrado, data show that the average temperature of the biome rose between 2.2°C and 4.0°C between 1961 and 2019, while precipitation fell by 15% in the same period (Hofmann et al., 2021).

One of the main consequences of urban expansion (due to changes in land use) for the natural environment is the loss and fragmentation of habitats and the reduction of water recharge.

To this end, it is believed that zoning is a key element in achieving an urban model that is more parsimonious to the natural environment, since it affects the entire municipal territory – urban, rural, natural – and is responsible for promoting the fair distribution of the different types of uses and occupation gradients throughout the territory. Thus, supply and demand balance methodologies for measuring natural and built support capacity and/or multicriteria analysis – combined and weighted – for generating a summary map of restrictions would be important instruments for this desired parsimony. Likewise, the importance of bottom-up reading and conservation of traditional and community actors and practices in zoning is defended.

The result would be the protection of environmental areas – conservation units, water sources, traditional management – for the provision of ecosystem services; conservation of family farming areas for supply close to the consumer market and control over mechanized farming areas to minimize impacts; creation of buffer zones between the urban and environmental areas; control over the urban perimeter for the compactness of the urban area; promotion of density and diversity of building typologies to minimize displacements and optimize occupation; promotion of environmental strategies from the lot, in terms of setbacks, templates, adoption of compensatory urban drainage measures.

Zoning would also be effective in promoting ecological coordination at the supra-municipal scale. Thus, the Ecological Economic Zoning (ZEEs), drawn up by the states as required by the Forest Code (Federal Law nº 12.651 of 2012), would be key to this, while the national ZEEs would promote coordination between biomes, crossing the ecological fabric between the different states. Even the Statute of the Metropolis (Federal Law nº 13.089 of 2015) advocates the need for supra-municipal zoning in the contexts of urban agglomerations and metropolitan regions. Ultimately, there is a

preservation zone, which provides ecosystem services, a transition/buffer zone, for the grading of natural and human uses, and a zone of concentration of anthropic activities. However, in practice, what we have in several Brazilian municipalities is a fragile zoning, proposed without a more restrictive reading of the natural environment, valuing the urban area more than the rural-environmental totality of the territory, without the effective bottom-up participation of traditional and community actors. This adds to the fragility of supra-municipal articulation of state ZEEs by river basin and of national ZEEs by biomes. Valparaíso, as we will see, is the sum of these deficiencies. Landscape ecology provides an important theoretical understanding of the structure, function and alteration of natural remnants with a view to constituting an ecological continuum that promotes biodiversity and various ecosystem services. Thus, according to Forman (2008), the structure constitutes the two-dimensional arrangement of the landscape through three elements – patches, corridors and matrices (Forman, 2008). Patches are the units of a landscape, which, according to Forman (2008), vary in terms of type, heterogeneity, size, shape and edge characteristics. The type refers to the prevailing land uses – urban, agricultural, environmental –; the heterogeneity to the density and distribution of these uses; the size – small, large –, in turn, to the environmental validity of the unit; the shape – circular, rectangular – to the area necessary for the survival of each animal; and the edge thickness to the limit necessary to ensure the integrity of the remnants and avoid the abrupt clash between natural/anthropic uses (Forman, 2008).

Corridors, according to the theory of island biogeography (MacArthur; Wilson, 1967), are connections between patterns of habitats dispersed in fragments, seeking to form a continuous network for the movement and genetic exchange between animals and plants. Thus, the passages existing in this continuum favor exchanges, while barriers inhibit them. Among the characteristics of corridors that interfere with their biological integrity are width – wide, narrow –; shape – straight, winding –; connectivity – continuous, discontinuous –; presence/absence of rivers, parkways, transmission lines; length – long, short –; connection or not by patches along the length and ends and, finally, the complexity of the use of the adjacent land. Stepping stones, on the other hand, are ways of creating small discontinuous connection points when there is no possibility of forming a continuous corridor (Forman, 2008).

The matrix is the surrounding area where the patches are embedded; constituting the most extensive and connected element and therefore playing a preponderant role in the functioning of the landscape (Forman, 2008).

While the function, or interaction between spatial elements, represents the flows of energy, materials and species between the ecosystems present (Forman, 2008).

While the alteration refers to changes in the structure and function of the ecological mosaic over time, articulating consolidated or transforming landscapes (Forman; Gordon, 1986). The authors thus classify five phases of land use change – perforation (when there is the creation of holes in the landscape), dissection (when there is a relative slicing of the landscape), fragmentation (when there is a break-up into pieces), shrinkage (when there is a reduction in size) and disappearance (when there is elimination).

The groundwater recharge process can be explained by an intrinsic interrelation between natural and anthropogenic factors (Gomes et al., 2022). Among the main anthropogenic characteristics are: i)

effectively impermeable surfaces – known as sealed – such as sidewalks, roads, parking lots, backyards, buildings, swimming pools, sports courts, etc., where infiltration is close to zero; ii) changes in soil cover, such as in the case of agricultural crops, pastures, orchards, gardens, exposed soil, compacted soil, reduction of native cover, especially trees, unpaved roads, etc. which, although they do not result in zero infiltration, alter the natural recharge pattern. The main natural characteristics that interfere with infiltration include: i) spatial variations in geomorphology, especially in terms of relative altitude and slope; ii) vertical percolation of water between surface layers, in the soil-vegetation relationship, and underground layers, towards underground aquifers. In geomorphological terms, regional highs are responsible for deep recharges and regional lows for discharges into surface water bodies (Silveira; Usunoff, 2009). In terms of percolation, the initial influence is vertical, due to the presence of vegetation (Gomes et al., 2022), and the subsequent influence is horizontal, due to the action of gravity and the materials that make up the soil (GOMES et al, 2022). Porosity (which is the relationship between pore volume and total volume), permeability (which is the soil's ability to allow water flow through its pores based on their size and connection) and soil thickness (holding capacity) all play a role in this process; the first two characteristics act initially and in combination, and the last one secondarily.

The main consequences of reduced infiltration are the reduction not only in the supply of underground aquifers, but also in the supply of springs during the dry season, in addition to increased surface runoff, which can contribute to increasing peak flow in the beds of watercourses, which can result in floods, inundations and flooding points; in addition to erosion and silting (GOMES et al, 2022).

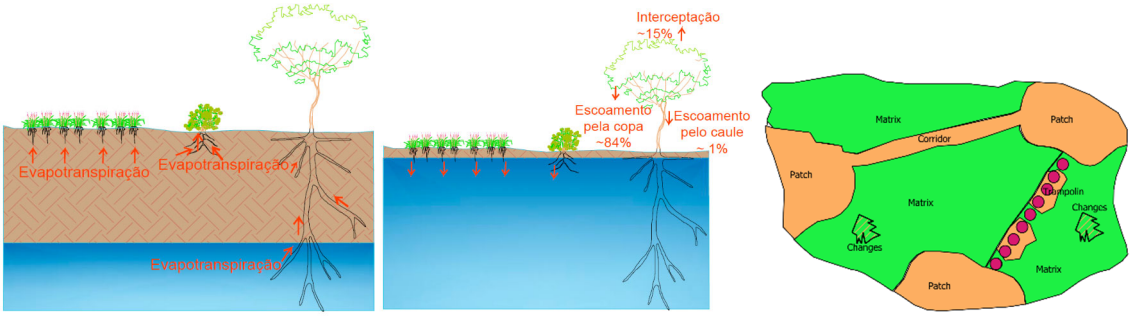

Figure 1. Interaction vegetation-soil in the groundwater recharge process. Source: GOMES et al., 2022.

Figure 2. Matrix-Patches- Corridors. Source: authors.

This knowledge was applied to the work of comparing satellite images before and after the expansion of the PMCMV sets in the region to understand the changes in the shape/size/edge characteristics of the vegetation. And in the analysis of the impairment of one of the most important functions of the ecological continuum, which is water recharge. Thus, a weight was assigned to each soil type according to its characteristics of allowing water recharge, as will be seen.

Studies have shown the impacts of reduced water recharge in the Cerrado. Among them, Salmona et al. (2023) performed statistical modeling of fluviometric and climate data from 81 Cerrado basins between 1985 and 2022, having identified that 88% of them already show a decrease in flow, mainly due to climate change and land use estimated to contribute 44% and 56% respectively to the impact.

Excerpting the data on the loss of vegetated area and river surface of the rivers in the municipality of Valparaíso de Goiás- GO, there is a loss of 33,46% of areas between 1985-2023 and a reduction in the maximum, average and minimum areas from 4-2-1 ha to 2-1-1 ha between 1985-2023.

METHOD

In order to analyze the impact of habitat loss and fragmentation due to urban sprawl in the municipality of Valparaíso de Goiás, the working method used satellite images taken from the Landsat 5 and 8, Instrument TM, spatial resolution 30 by 30 m, obtained from the NASA website https://earthexplorer.usgs.gov/ (2022), for orbit 221/point 71, for which the normalized difference for vegetation index (NDVI). This indicator makes it possible to compare changes in the types and densities of vegetation and land use between time periods, which allowed to contrast the urban form and vegetation before (July 02, 2009) and after (July 06, 2022) of the expansion of housing developments in the region. For this reason, we tried to use images taken from the same season (mid-drought) for greater data consistency.

The images were processed using the QGIS geoprocessing software, starting with atmospheric correction of the images, applying equation 1 for converting radiance to planetary reflectance at the top of the atmosphere, for the red (band 3 in Landsat 5 and band 4 in Landsat 8) and infrared (band 4 in Landsat 5 and band 5 in Landsat 8) bands, according to NASA (2022):

$1\rho' \lambda = ((Mp \times Qcal) + Ap)/ \theta SE.$ (Equation 1)

In which, $\rho' \lambda$ is the reflectance of the top of the atmosphere; Mp is the REFLECTANCE_MULT_BAND_X metadata parameter, where x is the band number; Qcal is the digital number value of each pixel; Ap is the REFLECTANCE_ADD_BAND_X metadata parameter, where x is the band number; θSE is the elevation angle of the sun. The NDVI was then calculated using equation 2:

$2NDVI = (NIR – RED) / (NIR + RED)$. (Equation 2)

Where NIR is the near infrared band and RED is the red band. To analyze the impact on water recharge, the method used the Analytic Hierarchy Process (AHP) to combine and weight the most influential anthropogenic and natural variables in the scenario before (2009) and after (2022) the launch of the PCMV in the municipality. Thus, according to the literature and previous work by the authors, were processed in QGIS® the relative weight that each variable exerts on groundwater recharge, resulting in 50% for NDVI (as a proxy for land cover), 18% for pedology and 32% for geomorphology and, at the level of each variable, scores from 0 to 4 were specified to determine the influence of every situation on recharge (table 4).

Table 4. Weight of variables used in AHP. Source: authors.

Ground Cover (50%)	Pedology (18%)	Geomorphology (32%)
High density Building (magenta) – 4	High density Building – 0	Medium dissection planes, cotas between 900 and 1100 m (good groundwater recharge) – 2
Low density Building (pink) – 3	Neossolo (low groundwater recharge: 10-7 e 10-8 m/s) – 3	Low dissection planes, cotas between 900 a 1100 m (good groundwater recharge) – 1
Lower density vegetation (dark blue) – 2,5	Aluviais (low groundwater recharge) – 3	
Medium density vegetation (light blue) – 2	Cambissolo (very low groundwater recharge: 10-7 e 10-8 m/s) – 4	
Hight density vegetation (green) – 1	Latossolo (good groundwater recharge: 10^{-4} m/s a 10^{-7} m/s) – 1	

THE PMCMV EXPERIENCE IN THE MUNICIPALITY OF VALPARAÍSO DE GOIÁS

Valparaiso de Goiás has been suffering the effects of its proximity to Brasília since the first years of the capital's inauguration in 1960. The municipality, which had 6,000 inhabitants in 1980, grew by 157.51% between 1980 and 1985, by 89.55% between 1987 and 1990, and by 43.58% between 1991 and 1996, reaching a population of 75,380 inhabitants. Before the PMCMV, in 2009, the population of the municipality was 123,444 people, jumping to the current 198.861 inhabitants (2022). The municipality, located approximately 33 km from Brasília, has approximately 42% of the population economically active working in Brasília. Furthermore, 4,109 make use of the public education system and 26,858 of the capital's hospitals and health centers (PMAD, 2018) (figure 3).

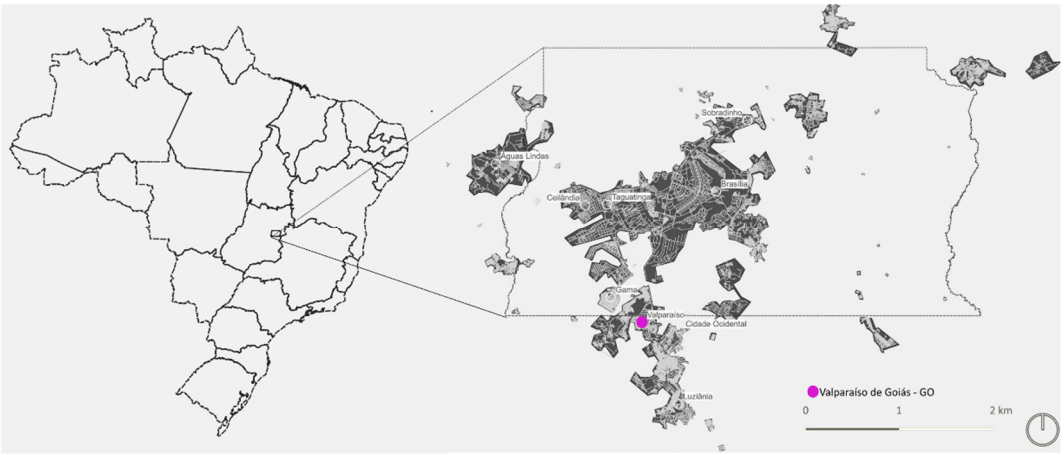

Figure 3. The location of the municipality. Source: authors.

The high metropolitan demand for housing, the existence of a large supply of cheap land for urban expansion and permissive municipal legislation, meant that the outskirts of the metropolis in Goiás received many PMCMV projects, it is worth noting that 470 are located in the municipality.

The NDVI data obtained for the municipality, before and after the attraction of these projects, show that the location had an increase of 39.63% in urban expansion in the 2009-2022 relationship; the impermeable areas increased from 27.19% in 2009 to 35.68% in 2022 (figures 4 and 5). This expansion occurred mainly in the Anhanguera, Ypringa, and Pacaembu sectors, in addition to a recent occupation around the only urban park in the municipality, by the new neighborhoods: Florais do Planalto, Rio

das Pedras, and Reserva Paraíso. There was also a significant increase in red spots near the northern edge of the municipality, which borders the Federal District, and also in relation to its extremes.

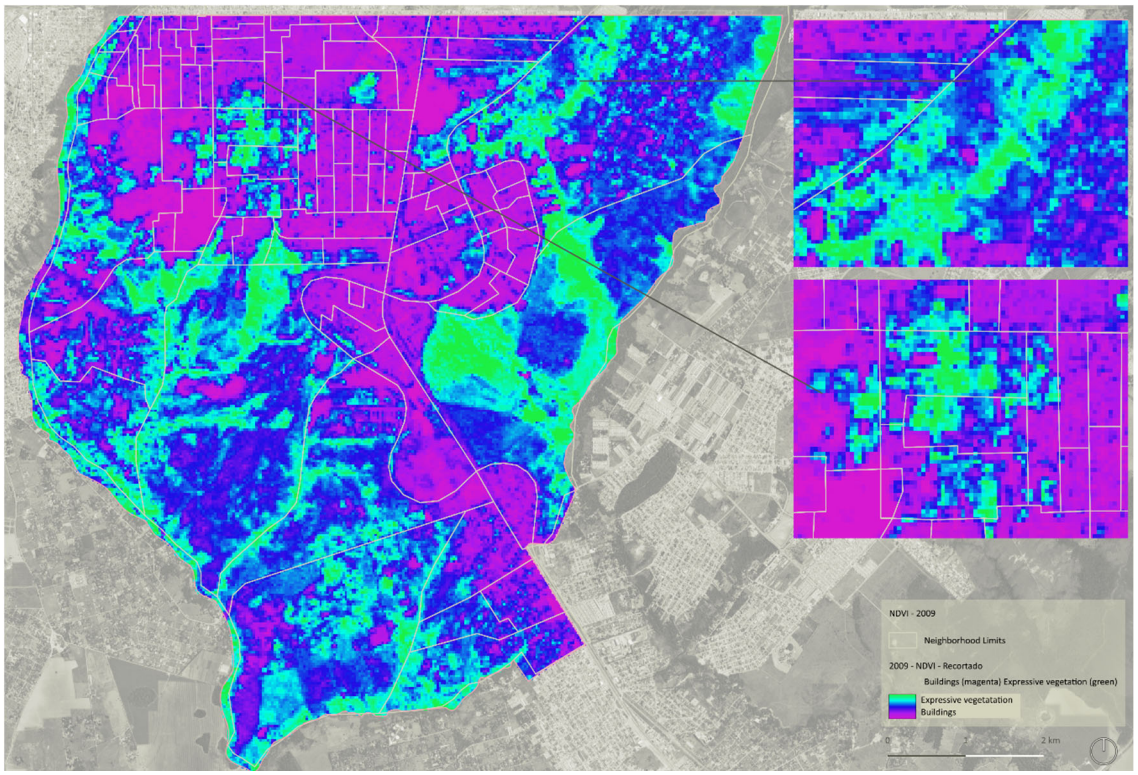

Figure 4. NDVI 2009. Source: authors.

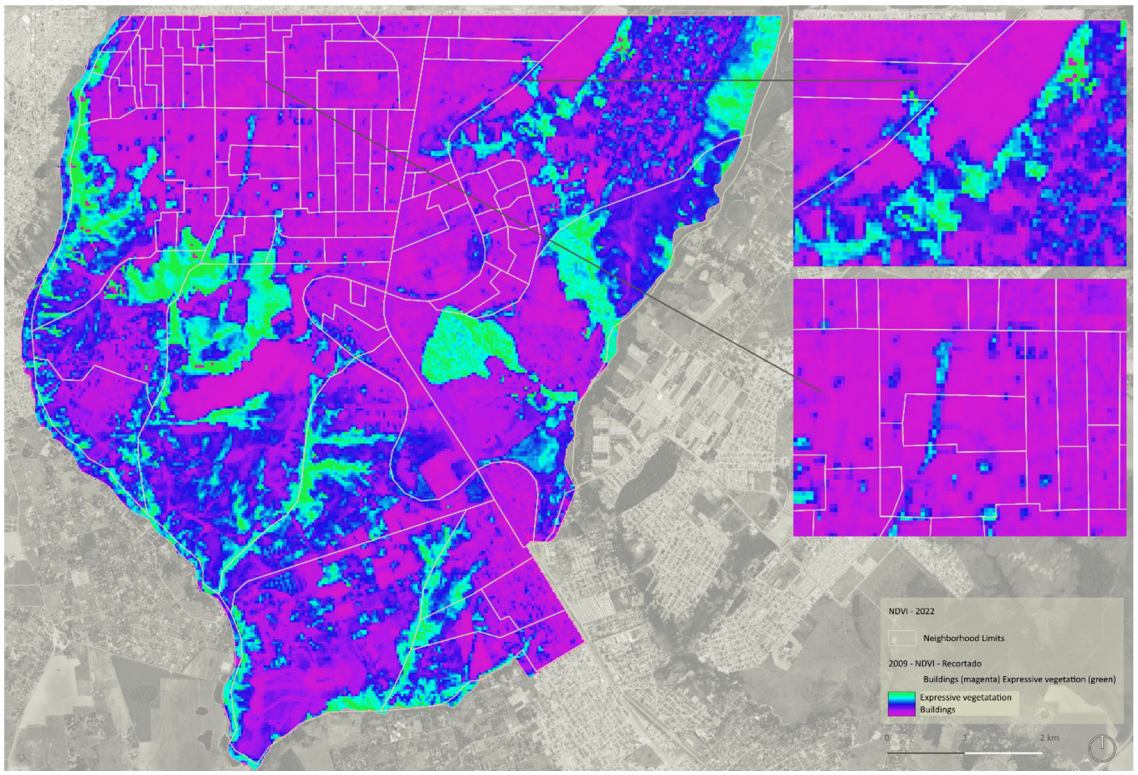

Figure 5. NDVI 2022. Source: authors.

It can be seen that zoning was the main factor responsible for this increase (figure 6), considering that most of the typologies responsible for urban expansion are residential in nature, mostly multi-family buildings and single-family condominiums. It is important to note that the Anhanguera and Ypiranga farms are located, respectively, in the Corumbá and São Bartolomeu basins, sensitive areas from the point of view of the water recharge potential of the cerrado. Superimposing zoning on this shape, we can see that it was responsible for this rapid expansion.

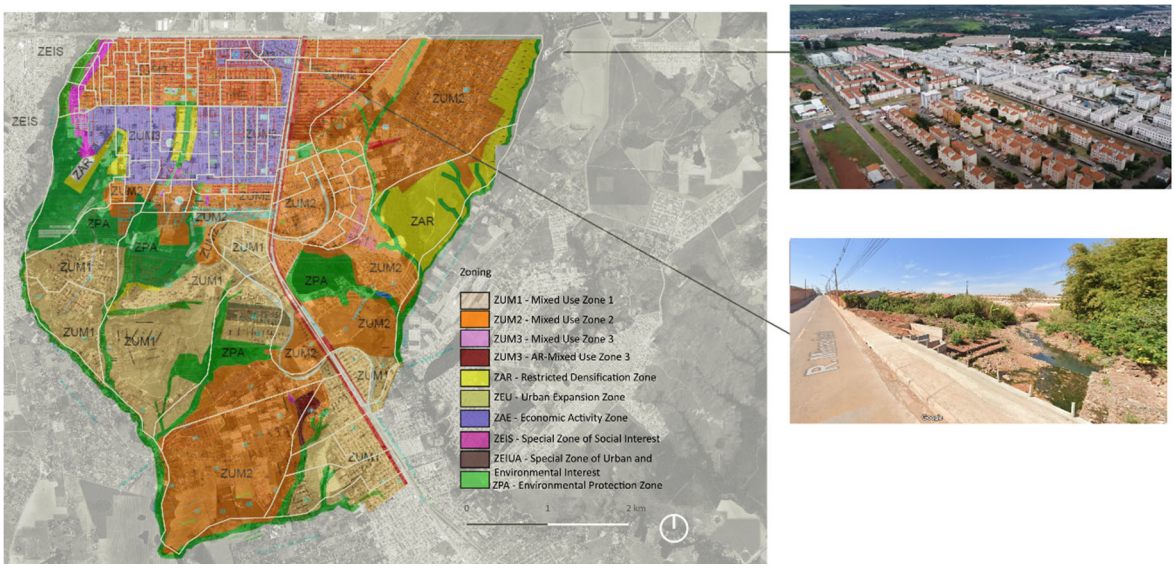

Figure 6. Zonning. Typologies (a) and river situation (b). Source: authors.

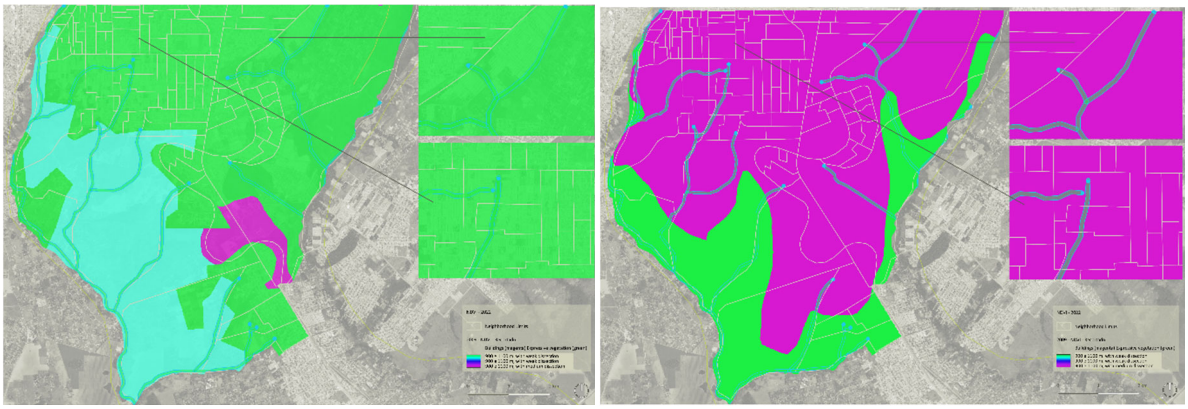
Below are the geomorphology and pedology maps that served as the basis for the AHP (figures 7 and 8).



Figures 7 and 8. Pedology and Geomorfology. Source: authors.

The results of these processes show the areas most critical to recharge in the 2022 scenario, compared to 2009; resulting in an increase of 35% in critical recharge risk areas (Figures 9 and 10). The map shows new critical areas precisely in the places that received the most ensembles (Anhanguera, Ypringa, and Pacaembu).

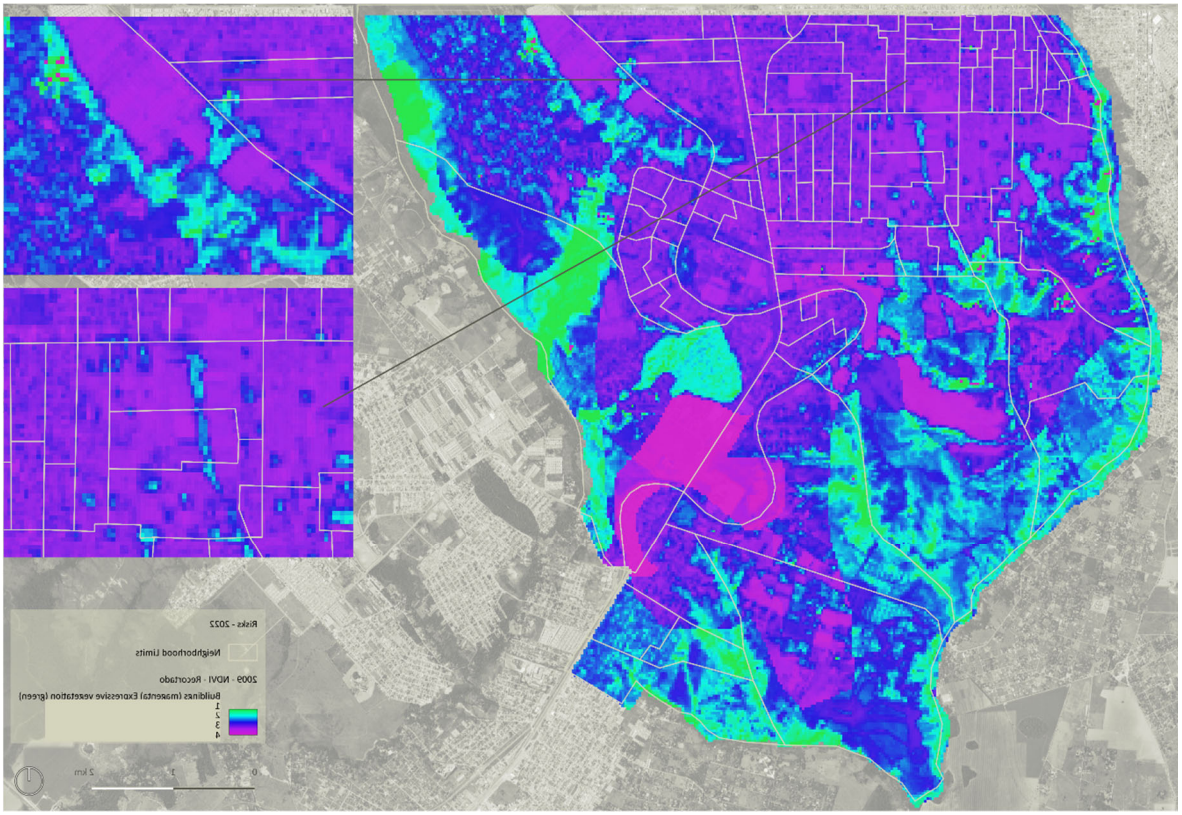

Figures 10. Risks for recharging. Source: authors.

CONCLUSIONS

The work showed the impact of urban sprawl on the reduction and fragmentation of vegetation and the reduction of groundwater recharge. The study's theoretical approach thus fills an important gap, given the scarcity of studies analyzing the impacts of urban sprawl on habitat fragmentation and groundwater recharge. As a result, the article's recommendations point to the urgent need to reconcile housing policy, the production of new housing, and urban policy, through strict zoning of the territory. The provision of risk analyses helps urban planning and public policy, by seeking to restrict the expansion of the urban fabric of Brazilian cities, a subject that is not only dear to the urban and social impacts it produces, but also the environmental impacts brought up in this work.

(Re)thinking green infrastructure: a morphological perspective

Jean-Bruno Morissette[1]
[1] School of Urban Planning, Faculty of Engineering, McGill University, Canada, jean-bruno.morissette@mail.mcgill.ca
[2] École d'architecture, Faculté d'aménagement, d'architecture, d'art et de design, Université Laval, Canada, jean-bruno.morissette@arc.ulaval.ca

ABSTRACT

Green infrastructure received significant attention over the past few decades. Literature on the topic emphasizes the relevance of natural environments for both human and non-human populations. Natural and semi-natural green spaces are also seen as highly beneficial for transforming urban landscapes in response to sustainability imperatives, either with the aim of improving the quality of the physical environment and people's lives, preserving biodiversity and natural processes, or adapting human settlements to the uncertainties of climate change. While research on green infrastructure is mainly based on environmental and ecological concerns, the relative absence of a morphological viewpoint on the topic is rather surprising. Against this backdrop, this paper aims to provide some answers to a simple but fundamental question in understanding and (re)designing built environments: how can green infrastructure be defined from an morphology perspective? The main objective of this paper is to illustrates what is meant by green infrastructure when examined on the basis of the conceptual framework and methodological tools specific to the study of urban form. The study draws from a typo-morphological analysis of parks and urban green spaces in Montreal (Quebec, Canada). The analysis focuses on their shapes and relationships towards geomorphological and anthropogenic systems at multiple scales. It also investigates their (trans)formation process. Findings underline that parks and urban green spaces generate a complex system of sites of varying shapes and relationships evolving over space and time at all scales of the built environment. They also reveal that their evolution is not always fully planned, but rather the result of territorial systems (trans)formation and the unstructured growth of urban fabrics. These insights contribute to the knowledge-building about green infrastructure morphologies and to debates regarding the quality of past, present, and future urban landscapes.

Keywords: green infrastructure, parks and green spaces, sites, morphology, definition.

INTRODUCTION

This paper is based on my research and teaching activities linked to my doctoral thesis on the topic of infrastructure landscapes, which specifically addresses the (trans)formation processes of green infrastructure. More specifically, it is grounded on the difficulty of capturing green infrastructure from a morphological viewpoint, and the relative absence of research tackling this cognitive gap.

Over the last few decades, green infrastructure has received significant attention, primarily aimed at meeting the imperatives of sustainability, and drawing on the many roles of natural and semi-natural features and areas to support the (trans)formation of built environments (Benedict and McMahon, 2006; Steiner, 2014; Bolleter and Ramalho, 2020). As an operative concept, green infrastructure is thus based on some definitions, including that of the European Commission (2013: 3), which is widely disseminated in the literature:*''a strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services''*. A review by Matsler et al (2021) suggests, however, that such a definition is not consensual. It is rather extended by disciplinary and geographical conceptualizations which translate green infrastructure, notably, as a green space planning concept, urban ecology concept or water/stormwater management concept.

However, the ecological perspective among definitions fuelling the literature on green infrastructure poses a cognitive and normative imbalance on a morphological level. In fact, literature is rather dominated by concepts, principles, methods and typologies related to the field of ecology, which orient the study of green infrastructure and drive many planning and design approaches (Bartesaghi Koc *et al.,* 2017; Monteiro *et al.*, 2020; Reed and Lister, 2020). Given the disinterest of urban morphologists in the study of parks, green spaces and natural environments (Whitehand, 2017; Whitehand, 2019), those fundamental to the study of and intervention on urban form are thus relatively absent within the literature and, thus, evacuated from the morphological perspective and debates on the topic of green infrastructure.

(Re)thinking green infrastructure: an imperative

Against this backdrop, this paper aims to provide some answers to a simple but fundamental question in understanding and (re)designing built environments: how can green infrastructure be defined from an urban morphology perspective? Its aim is to illustrate *what is meant* by green infrastructure when examined from the conceptual framework and methodological tools specific to the study of urban form. The study draws from a typo-morphological analysis of parks and green spaces in Montreal (Quebec, Canada). Three operative questions are thus put forward regarding their morphologies: 1) what are their shapes?; 2) what are their relationships with urban and territorial systems?; 3) how do these shapes and relationships originate?

This paper is divided into three parts. The first part presents Montreal as a case study and describes the methods. The second part presents the main research findings. Building on these results, the following discussion rethinks green infrastructure from a morphological perspective and puts forward a (re)definition. Finally, the conclusion describes the main limitations of the study and suggests avenues for future research on the topic.

MONTREAL AS CASE STUDY

Industrial, commercial, intellectual, and cultural hub, Montreal is located in the province of Quebec, Canada. It is Quebec's metropolis and the country's second most populous city, with 1,762,949 inhabitants. The Greater Montreal Area, comprising 82 municipalities, is the second largest after Toronto's in terms of population (4,104,074 inhabitants), accounting for 11% of the national population and 48% of the provincial one (Statistics Canada, 2021).

Montreal is located in the St. Lawrence lowlands, amidst an archipelago of over 300 islands and a complex hydrographic crossroads. This singular geography was one of the decisive factors in the city's foundation in 1642 on the Island of Montreal (Figure 1). It also contributed to its gradual development from a fortified village (and later a fortified town) supporting the missionary, social and commercial objectives of the French Regime into an industrial metropolis fostering the growth of the British Empire, the rise of the Canadian nation, and the ongoing development of Quebec (Marsan, 2016; Linteau, 2022).

Moreover, the administrative boundaries of Montreal now encompass nearly 70% of the Island of Montreal, as well as extending onto several neighbouring islands (Statistics Canada, 2021). This growth over almost 400 years was influenced by the inertia of the two colonial projects in both their physical and intangible structures (Marsan, 2016; Racine *et al.*, 2022). It is also a result of the progressive evolution of neighbouring towns and villages, and their gradual annexation to the City of Montreal from 1883 to 2002—first in response to bankruptcies, and lastly as part of the provincial government's plan to reorganize municipal administration in Quebec (Marsan, 2016; Beaudet, 2021).

Figure 2. A Panoramic View of Parc Lafontaine in the East End. Credit: Unknown photographer, circa 1910. Source: McCord Stewart Museum.

The interest in studying Montreal is manifold. Firstly, Montreal's parks and green spaces are highly diverse. Such diversity is mainly due to their piecemeal development as the city evolved. Examples include convent and ornamental gardens from the pre-industrial era, squares and urban parks from the 19th century (Figure 2), and neighborhood parks from the first part of the 20th century. This corpus also presents a variety of parks developed during the post-World War II expansion (neighbourhood parks, amenity parks, green networks, etc.) and several examples of infrastructure retrofiting for park purposes (canal, dam, dike, seaway, rail network, highway network, etc.).

Secondly, Montreal has been characterized by the growing synergy of numerous stakeholders in favour of the development and transformation of parks and green spaces since the end of the 20th century. This synergy is part of a shared vision for the sustainable development of the metropolitan territory, with the aim of increasing urban biodiversity and ecological connectivity, and ensuring the protection and enhancement of natural environments (CMM, 2013; Dupras *et al.*, 2015; Bissonnette *et al.*, 2018; Ville de Montréal, 2021). The development of nature parks initiated this approach in the 1970s. The development of green alleys followed, on a finer scale, in the 1990s. Jointly supported by the insights of landscape ecology and sustainability, green and blue grids, large ecological parks, biodiversity and ecological corridors, urban park redevelopment, sponge parks, green alleys, mini-forests and planted sidewalk buffers are among the solutions currently being planned and developed in the Greater Montreal area.

Thirdly, Montreal's park and green space network (Figure 3) is a complex historical object to define, given its continuous development since the 19th century and the variety of principles that have since guided its (trans)formation. It provides an excellent case for our morphological exploration.

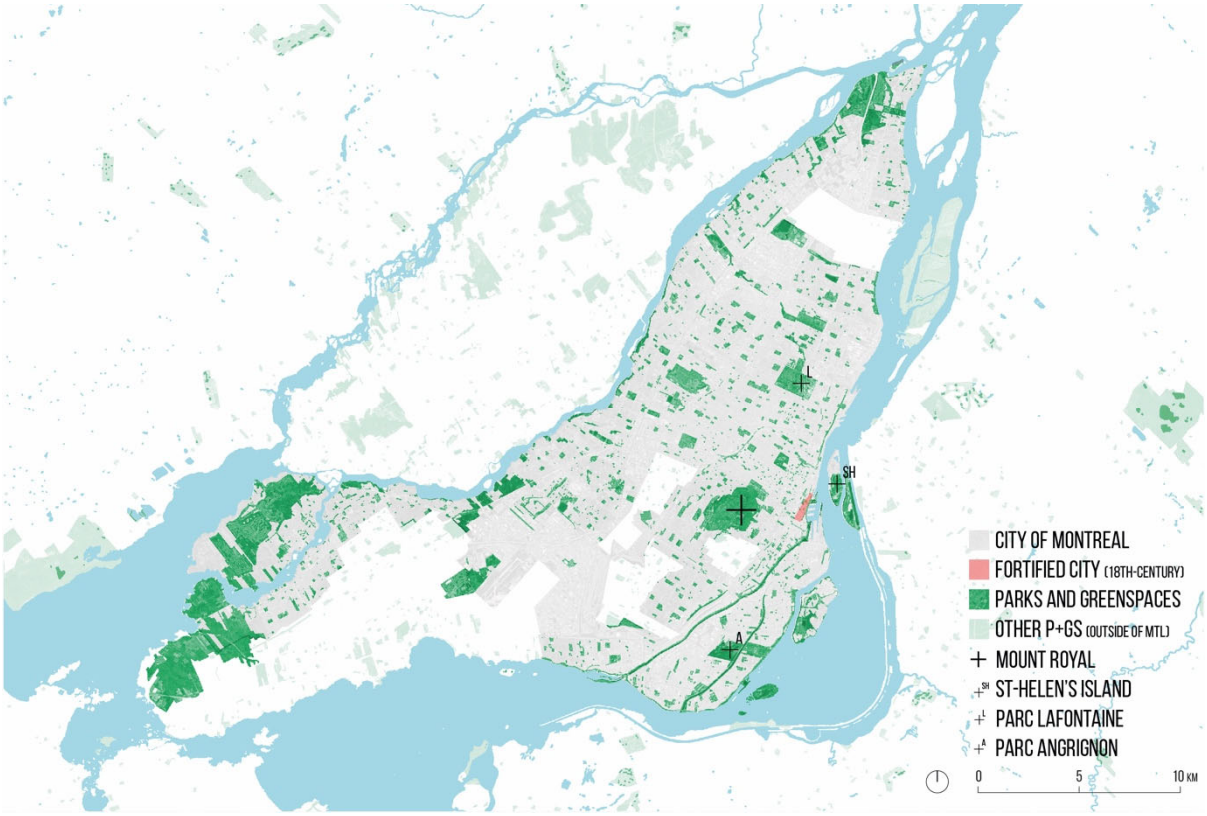

Figure 3. Parks and greenspaces in Montreal. Image by the author, 2024. Adapted from multiple sources.

METHODS

This study investigates the morphologies of Montreal's parks and green spaces from the viewpoint of their sites. This approach simplifies their physical reality, leaving aside their layout and uses, in order to facilitate our understanding of their formal and relational properties.

The study was developed in two parts. The first, a preparatory phase, included 1) gathering open geographic and historical data on Montreal's parks and green spaces, as well as data documenting Montreal's urban form (hydrography, topography, infrastructure networks, fabrics, etc.), 2) creating

a project file with these data (on QGIS, Lima 3.32), 3) validating their relevance and the need for additional data collection, and 4) screening the data, in particular that of parks and green spaces (eliminating invalid entries, grouping entries by sites, etc.). These steps were followed by 5) the initial analysis of quantitative and qualitative data for parks and green spaces, 6) the exploration of certain hypotheses (small and large sites, sites in relation to the hydrographic network and infrastructure networks) and, 7) the validation of the variables and methods to be used.

Table 1 summarizes data used in this study. The initial analysis of data on parks and green spaces reveals that there are nearly 1,700 in Montreal. These sites are mainly public spaces. Their total surface area covers almost 70 square kilometres, mostly administered by the Montreal Agglomeration (all the municipalities on the Island of Montreal) or the City of Montreal. They are also divided into

three functional types: parks, green spaces and roadway spaces (Figure 4). Hypotheses were explored in collaboration with 22 graduate students at Université Laval's School of Architecture in winter 2024 *(ARC-7032 : Morphologie et syntaxe des milieux bâtis)*.

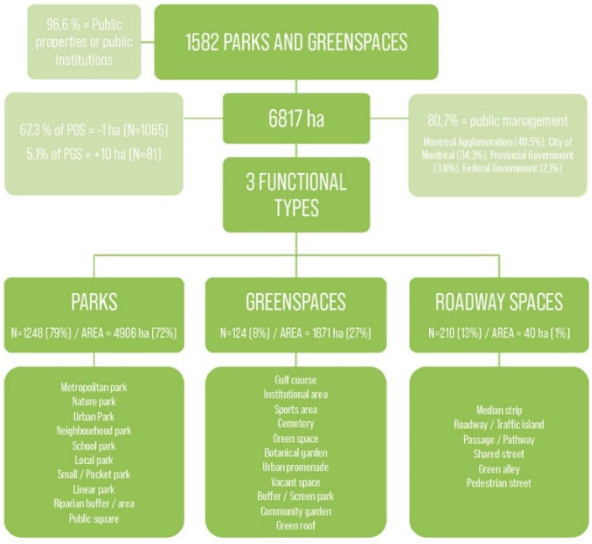

Figure 4. Initial observations on parks and green spaces in Montreal. Adapted from Ville de Montréal, 2020.

The second phase of the study covers the main analysis which was developed in three iterative steps (Figure 5). The first step consisted in analyzing the sites' shapes through manual classification (on Adobe Illustrator, for parks and green spaces of over 1 ha) and visual classification (on QGIS, for those of 1 ha or less). It focused on identifying their shapes (the common ones and their variations, the exceptional ones) and defining typologies. These typologies were then cross-referenced with data on the size and functional type of each site, with the aim of extending their understanding.

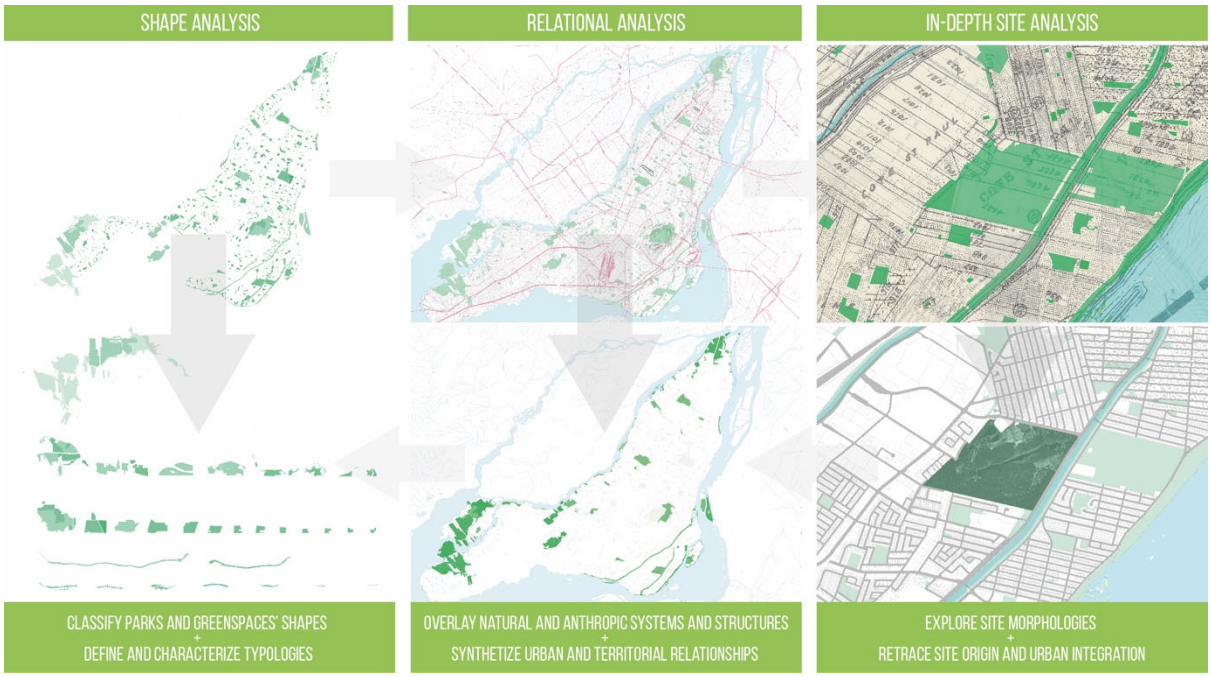

Figure 5. Exploring parks and green spaces morphologies. Types of analysis and overall methodological process. Image by the author, 2024.

During the second step, a relational analysis of the sites was carried out to better understand their relationships with urban form's systems and elements. This analysis was based on the typo-morphological approach, which recognizes that urban forms have different levels of complexity depending on the scale of analysis and the type of components examined (Table 2). It was also inspired by the work of Paola Viganò on analyzing urban systems (see Secchi and Viganò, 2009; Viganò, 2013; Viganò, 2023). The approach consisted in cross-referencing, in QGIS, the map layer for parks and green spaces with those for territorial systems (hydrography, topography, agricultural fabric, networks), agglomerations (basic and specialized fabrics) and fabrics (roads, parcels, buildings). This led to a series of maps showing the relationships between the various systems. These relationships were then compiled, classified within levels of complexity, and finally synthesized.

Table 2. Levels of complexity of built environments. Translated from Racine et al., 2022.

Organisms	Systems of structures	Structures of elements	Elements
Buildings	Building systems	Building envelope Framework	Exterior walls Roofs Roof frames Beams and columns

Urban fabrics	Street pattern Lots / plot pattern Building pattern	Pertinent strip of a street	Streets Lots / plots Buildings
Agglomerations (villages, town, cities, metropolitan areas)	Infrastructures (roads, acqueduct, etc.) Neighbourhoods (tissus and amenities)	Public/collective domain	Tissus (basic and specialised) Parks and public spaces
Territories	Networks (highway, railway, transmission lines, maritime routes)	Aglomerations and pertinent areas Agricultural fabric Productive areas	Agglomerations Infrastructures Routes Farms

The final step further explored park and green space shapes and relationships by examining the origins and the integration of certain sites. Their evolution was analyzed by superimposing current geographical data and historical maps, as well as by examining historical and iconographic sources. Integration was also examined through fabric analysis and a photographic survey. The case of Angrignon Park is presented in this paper.

PARK AND GREEN SPACE MORPHOLOGIES

This section synthesizes our main findings, in order to better understand the morphologies of parks and green spaces, and to support, through discussion, the redefinition of green infrastructure.

On shapes

Analysis reveals two main categories: punctual and linear. Thus, punctual sites assume the appearance of a point of more or less size on a map, whereas linear sites are more like a line of varying length and thickness. Based on typical examples identified for these two categories of sites, Figure 6 illustrates their essential characteristics and main variations. We notice that sites, both punctual and linear, can be regular in shape (square, rectangle, triangle, strip, etc.) or irregular when the complexity of their boundaries affects their intelligibility. Furthermore, sites tend to be continuous or discontinuous. In other words, each site may correspond to a single space—which is the case for the majority of sites—or be divided into more than one space. The discontinuities mainly refer to a site's fragmentation by the street or road network. They can also denote the dispersal of a site divided by waterways, urban or agricultural fabrics. Such cases are uncommon and limited to large-scale sites (metropolitan parks or nature parks).

Otherwise, the analysis highlights an interesting variation corresponding to the agglomeration of several contiguous sites. Mount Royal is an example of a punctual agglomeration, combining, for example, Mount Royal Park, large cemeteries and the Université de Montréal grounds. As another example, in the southern part of the Island of Montréal, a series of parks (urban, neighbourhood, local, etc.) organizes a linear agglomeration along the St. Lawrence River and Lachine Rapids.

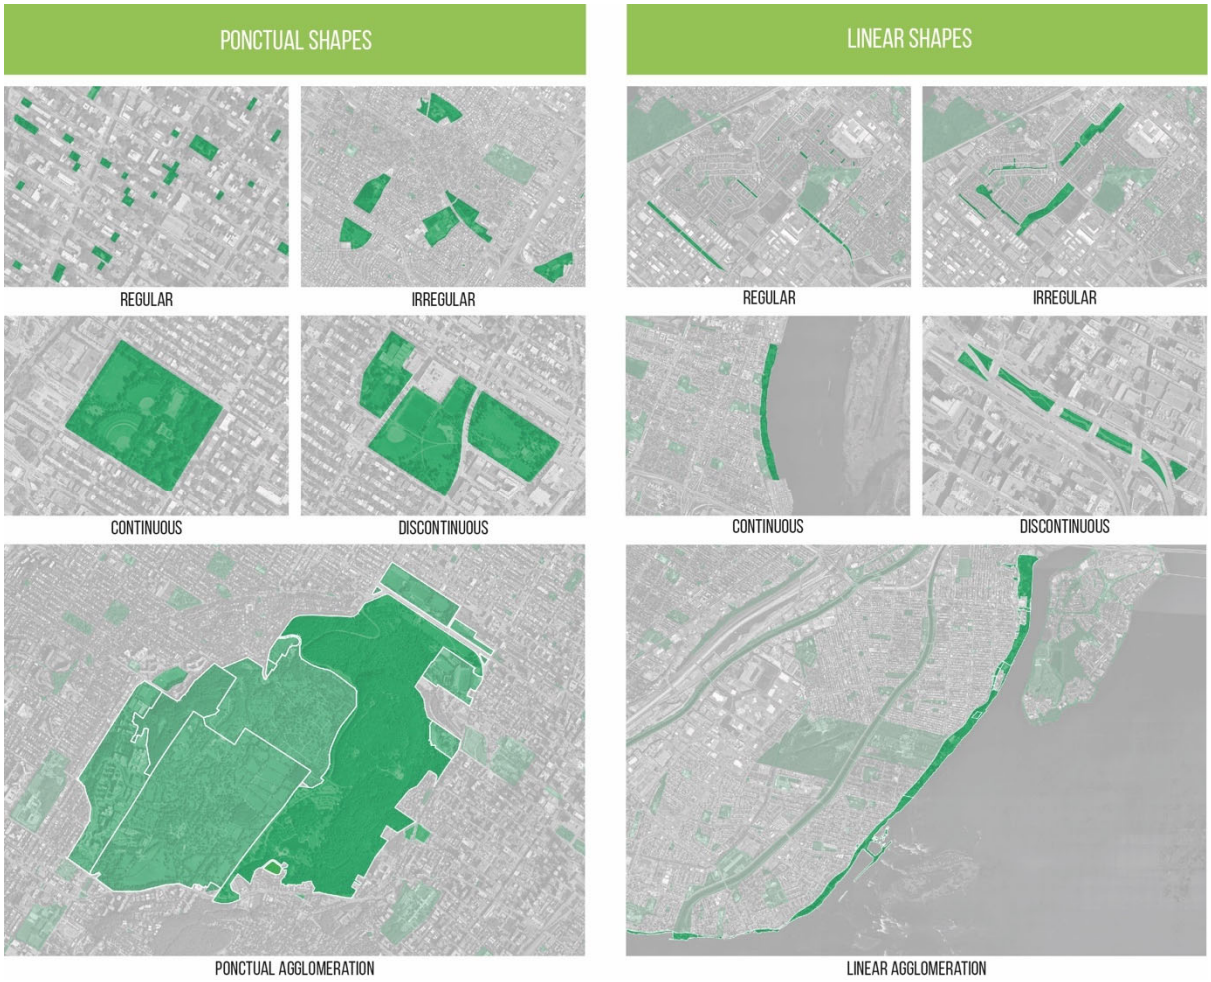

Figure 6. Basic typologies and sub-categories of park and green space shapes. Image by the author, 2024.

A closer look at the correlations between site shape, size and functional type reveals a number of interesting findings (Table 3). First, as functional types, parks and green spaces can be both punctual or linear, while roadway spaces are mostly linear. We also note that roadway spaces are the smallest, green spaces are generally less than 10 ha in size, and parks are distributed across all sizes. It's also interesting to note that certain functional sub-categories (e.g. neighbourhood parks and institutional spaces) are represented by both punctual and linear sites of widely varying sizes.

Table 3. Table illustrating correlations between park and green space shapes, sizes, and functional types.

Functional types	**Type of shapes**	**Less than 1 ha**	**1 - 9,99 ha**	**10 – 100 ha**	**More than 100 ha**
Parks (P)	Ponctual	NBHD park Local park School park Public square Small park	NBHD park Local park School park Public square Riparian area*	NBHD park Urban Park Nature park Metropolitan park* School park*	Metropolitan park
	Linear	Riparian area Linear park Public square* Local park * Small park*	Riparian area NBHD park Linear park Public square* Local park*	Riparian area NBHD park Urban Park Nature park	

	Other			Nature park	Metropolitan park
Greenspaces (GS)	Ponctual	Institutional area Sports area Green space Cemetery Vacant space Community garden Green roof	Institutional area Sports area Cemetery Vacant space	Golf course Institutional area* Sports area* Green space* Botanical garden	Golf course Cemetery
	Linear	Green space Buffer park Urban promenade Institutional area*	Institutional area Green space* Buffer park* Urban promenade*	Green space* Urban promenade*	Institutional area
Roadway Spaces (RS)	Ponctual	Traffic island	Traffic island*		
	Linear	Median strip Traffic island Passage / Pathway Shared street Pedestrian street Green alley	Median strip Shared street		

Note: All sub-categories of functional types shown in grey and marked with an (*) correspond to exceptions within a sub-category. Others in grey illustrate under-represented sub-categories in the sample (N<5).

On relationships

The relational analysis of parks and green spaces extends our understanding of their position in the complex arrangement of urban forms. Of course, parks are elements of the spatial structure of the collective public realm as table 2 illustrated. Nevertheless, the results reveal five key ideas that extend this scope (Figure 7). Firstly, parks and green spaces are building elements. There is only one green roof in our sample. However, given the importance attached to green roofs in green infrastructure and sustainability literature, this is sufficient to extrapolate. Secondly, parks and green spaces are elements of the urban fabric. They correspond to spaces within the street system and to smaller plots. They also refer to the pertinent area of the built system (open spaces), notably that of public buildings.

Thirdly, parks and green spaces constitute specialized fabrics. This character is determined by their size and/or the agglomeration of multiple sites. They tend to develop on the periphery, becoming places of destination and impacting fabric growth. They refer above all to large parks, often those linked to the main territorial systems (waterways, wetlands or forests, agricultural fabric).

Fourthly, parks and green spaces are thresholds between systems. This idea is closely related to linear sites/agglomerations positioned between fabrics or between fabrics and a territorial or urban systems. These sites are particularly common on the perimeter of the Island (riparian area or waterfront park), juxtaposing infrastructure networks, or highlighting the mismatch between a particular fabric and the road or street system.

Finally, parks and green spaces become transformative agents of territorial systems. In this way, sites play a part in retrofiting infrastructure networks, or enclosing natural systems or remnants of the agricultural fabric. The former generally play a part in re-articulating fabrics. The latter, in defining specialized urban fabrics, are more likely to act as barriers to development. This phenomenon follows in the footsteps of urban park development since the 19th century.

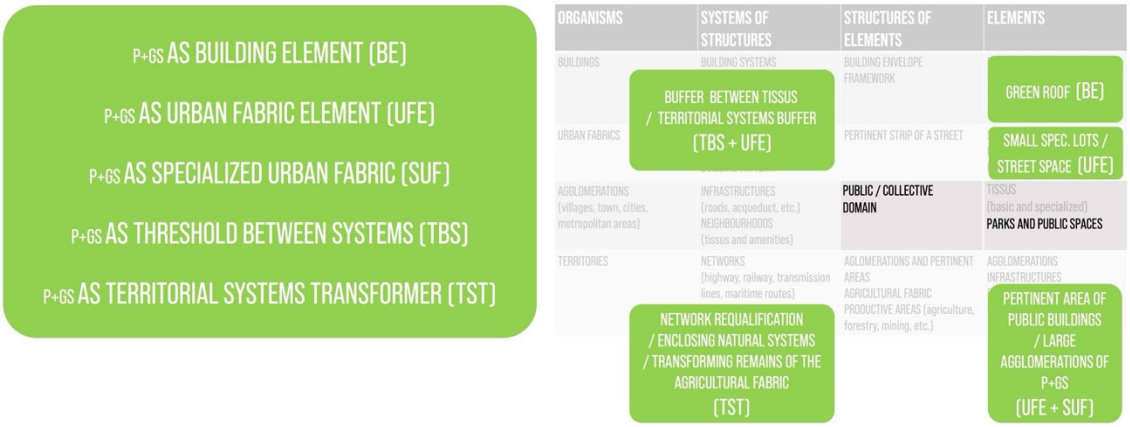

Figure 7. Five key ideas on park and green space positions within built environments. Image by the author, 2024. Adapted from Racine et al., 2022.

On origins and integration: Lessons from Park Angrignon

Angrignon Park is located in the southwestern part of Montreal. This urban park constitutes a specialized urban fabric of almost 100 hectares. It belongs to punctual sites and has a mostly regular and continuous configuration.

Figure 8 shows the key stages in the evolution of Angrignon Park. We notice that the site is a remnant of the agricultural fabric which was gradually transformed, over more than a century, by the impact of infrastructure networks and changes in land tenure.

Indeed, this process was initiated by the construction of the Aqueduct Canal in 1866, which resulted in the fragmentation of the agricultural fabric. Rendered inaccessible by this division, the back part of the lands was left uncultivated and, over several decades, became the dense woodland characterizing the site today. The construction of the railroad in the 1920s confined a part of this woodland, which was only recently reintegrated into the park.

Moreover, this process was heavily influenced by the reorganization of Montreal's administrative boundaries during the annexations of neighbouring villages and towns in the first part of the 20th century. The site thus became its western periphery. Until the 1950s, the City of Montreal leased the lands for park purposes and gradually acquired them.

Since then, the site's municipal jurisdiction has guided its main transformations. This led to the planning and gradual formalization of Angrignon Park - with its central lake, paths, parkway and complement to the existing urban fabric. In the 1970s, the park became the site of the metro extension terminus. The parkway was extended into a connecting road to accommodate the increase in traffic. In the 1980s, public housing buildings—managed by the City of Montreal—were built on the site, as part of the complement to the existing urban fabric.

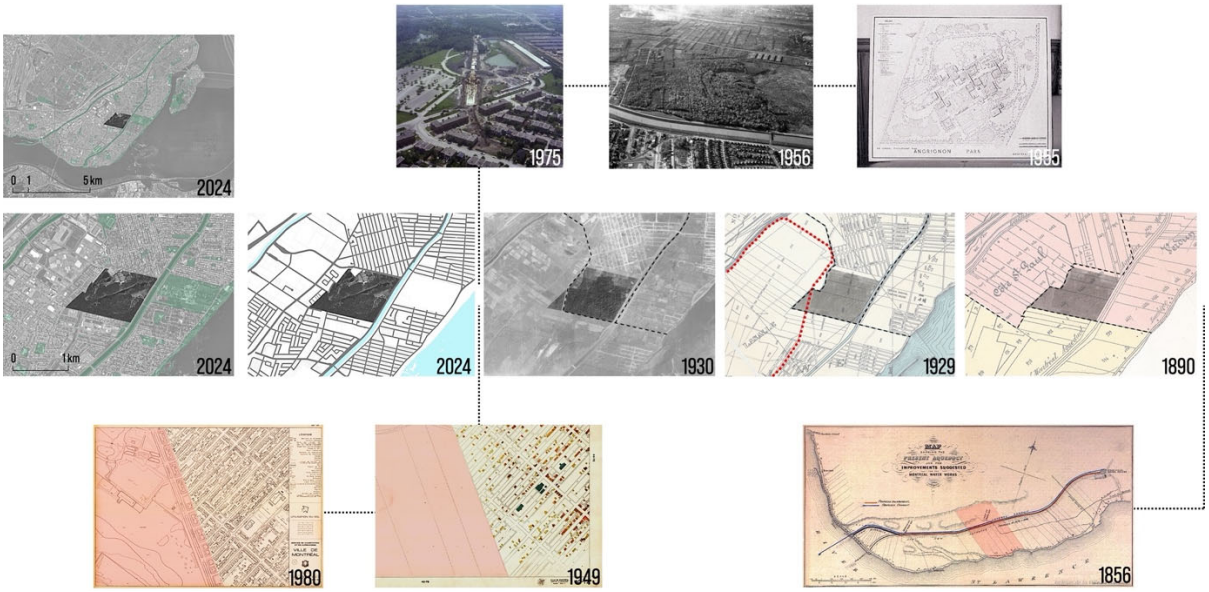

Figure 8. Angrignon Park evolution process. Image by the author, 2024. Adapted from multiple sources.

Thanks to this chronology, we can understand the roots of Angrignon Park's unbalanced relationship with its surrounding urban fabrics. Their interfaces are the main evidence (Figure 9). Indeed, the northern interface is the most coherent. It demonstrates the desire to integrate the site and the adjacent fabric from the planning phase onwards, thus accentuating the permeability between one and the other, and defining a built front which structures the collective public realm.

Rather, the interface defined by the Aqueduct Canal is a clear rupture between the two systems, and also amplifies the fragmentation of the urban fabric at a larger scale. The canal's barrier effect has even intensified over time, as other infrastructure networks have subsequently been built alongside (major road, power transmission lines).

The western and northern interfaces, meanwhile, are evidence of the enduring nature of administrative, cadastral, and infrastructural boundaries. Such permanences accentuate the separation of the park from the fabric that later developed within the neighbouring municipality. The park's entrances (those formal, informal and in the process of being formalized) are illustrative of the difficult integration of these systems, which rather turn their backs on each other. Important though they are, these entrances do little to alleviate the malaise.

Figure 9. Angrignon Park integration. Park interfaces, entrances, and permeability. Image from author, 2024.

DISCUSSION

Our findings offer a fresh look at parks and green spaces. Their transposition provides a better understanding of *what is meant* by green infrastructure, and helps (re)define their meaning beyond interpretations based on an ecological stance.

Therefore, it is crucial to recognize that parks and green spaces constitute the base layer on which green infrastructure elements are structured within urban settings. Thus, it is on and from this base layer that biodiversity can be increased, habitats and ecosystems preserved, cohabitation between human and non-human populations supported, and environmental benefits spread beyond individual sites.

Results show that sites are numerous, do not constitute a continuous network, are characterized by different forms and different relationships with and within urban and territorial systems. We note that they can be grouped into two more encompassing categories (punctual sites and linear sites), which synthesize the basic shape of several sites whose dimensions and functions are nevertheless very different.

This first set of observations resonates with the insights of landscape ecology and mainstream green infrastructure research. It is here, however, that our observations support another morphological perspective. In fact, the study of morphology in the field of landscape ecology is primarily concerned with the division between “green” systems and those relating to urban form. The urban morphology

perspective, on the other hand, is more interested in the relationships between the various systems, stressing the importance of their integration.

As such, our results reveal a number of tensions. The difficulty of extending formal categories and their correlations first highlights the exceptional nature of many sites and, by extension, their context-specific integration. The case of Angrignon Park is instrumental here, which poses integration issues that are common to many large parks. It exemplifies the historical depth of spatial structures which define a site's shape and relationships. It also demonstrates two opposing trends: 1) the benefits of jointly planning and designing the layout of a site and its adjoining fabric, and 2) the morphological consequences of laying out two systems independently, as two land-uses ignoring one another.

Urban integration of parks and green spaces is a genuine problem. Overemphasizing their ecological value will only amplify it. And since this issue is not being given much consideration in the literature on green infrastructure, it is necessary to bring it up for debate. Here, then, is a definition of green infrastructure based on our findings, and modelled on that of the European Commission (see introduction), from which to pursue our collective thinking on this matter: Green infrastructure is a relatively planned network of sites, including parks and green spaces, supporting natural, semi-natural, urban and collective spaces, and which should be designed and managed to deliver a wide integration of urban form systems.

CONCLUSIONS

The objective of this paper was to better understand green infrastructure from a morphological viewpoint. The study of the Montreal case proved highly informative. It raised a number of observations about the morphologies of their sites, shed light on the integration issues that characterize them and, ultimately, enabled us to reformulate their definition.

However, there are a number of limitations to our study. To begin with, the study does not cover all green infrastructure sites. We examined parks and green spaces, and based our definition on their findings. Therefore, our study does not take into account private sites contributing to green infrastructure (forest estate, farmland, specialized plots, front lawn, etc.). Examining them would further refine our findings and orientations. Secondly, the morphological perspective advocated in this study is primarily structural. The functional perspective has not been addressed. This omission does, however, raise a fundamental question: When researching green infrastructure, what should urban morphologists study from a functional perspective: the human, the non-human, both? Such limitations pave the way for very promising new research.

Otherwise, and since research on green infrastructure (or on parks and green spaces) is fairly poor in urban morphology, it is imperative to build up new knowledge on the topic. Integration issues must be tackled head-on. Other theoretical, conceptual or methodological principles specific to the field should be tested, and case studies compared and contrasted. As a result, urban morphology lessons can be brought to the forefront of debates and solutions on green infrastructure and, more broadly, on the accompanying processes of urban landscape (trans)formation.

ABSTRACT

Exploring sustainable urban form has been a crucial aspect in advancing sustainable urban development, particularly in the context of climate change and limited resources worldwide. Low-energy-oriented urban design strategies for new district development and existing district renewal are paid more and more attention among both researchers and designers. Commonly discussed urban form elements often revolve around building morphology, layout, and characteristics such as building height, floor area ratio, building density, orientation and so on. However, when considering energy performance at the neighbourhood block scale, urban design elements also encompass non-building spaces such as streets and open spaces, which are essential considerations in urban design for their impact on energy consumption. To furtherly discuss the relationship between urban form, urban design strategies and building energy, the study introduce several new indicators to describe the outer space form of urban neighbourhood blocks. Using Shanghai, China as a case study, typical urban block form types are chosen and extracted for comparation experiment. The energy consumption simulations are conducted by Ladybug Tools with the EnergyPlus engine. Based on the simulation results, an investigation and correlation analysis are conducted to examine the relationship between urban form elements, particularly urban design features such as effective streetwall length, effective street space and street space density, and neighbourhood building energy consumption. The results provide valuable insights for sustainable urban district design and renovation, aiming for low-energy performance, and stimulate further attention to the impact of urban block design elements on urban sustainability.

Keywords: urban form, neighbourhood building energy consumption, urban design.

INTRODUCTION

According to UN Habitat (UN Habitat, 2012), urban areas account for 75% of global primary energy consumption and are, therefore, the primary contributors to carbon emissions driving climate change. A significant portion of urban energy demand arises from the heating and cooling needs of buildings. In response to the challenges posed by rapid urbanization and the pursuit of sustainable urban development, researchers have increasingly focused on strategies to reduce energy consumption in

urban buildings. In recent years, with the gradual deepening and expansion of research on the relationship between urban form and building energy consumption, the main object of study has begun to shift from the macro scale of cities and urban districts to the meso and micro scale of blocks, and from merely focusing on the energy consumption of buildings themselves to paying attention to the influence of the surrounding environment on them. Many studies have highlighted the influence of the urban environment, particularly at the neighborhood scale, on building energy performance.

Ratti et al. (Ratti et al., 2005) identified four key factors affecting energy performance: user behavior, energy system efficiency, architectural design, and urban form. Subsequent research has established a clear correlation between urban form and building energy consumption. For example, Delmastro et al. (Delmastro et al.,2015) found that variations in urban form could lead to an 11% difference in heating energy consumption, with the difference increasing to 16% when solar gain is considered. Similarly, Silva et al. (Silva et al.,2017), using the city of Porto in Portugal as a case study, demonstrated that urban form could explain 78% of the variance in energy use, including heating, cooling, and mobility. These studies commonly examine urban form indicators such as density, street aspect ratio, and sky view factor.

However, a common issue in existing studies on the impact of urban morphology on building energy consumption is the lack of definitive conclusions regarding the morphological factors that influence energy consumption and the extent of their impact. This uncertainty stems from various reasons. On one hand, cities, as complex systems, are influenced by numerous factors; on the other hand, findings in existing research are often constrained by climatic characteristics, scale, and other contextual factors. Broadly speaking, there are two common research approaches: the first involves conducting simulation experiments under given morphological conditions to measure corresponding energy performance and then analyzing the relationships and the degree of influence; the second approach entails correlating actual energy consumption data with morphological indicators to identify significant factors and their impact.

Regardless of the approach, the research is closely related to the description of urban form. As summarized by Quan (Quan and Li, 2021), the methods used in existing studies can be broadly classified into four categories: density measures, geometric measures, land use and land cover measures, and typologies. These classifications are based on the identification and categorization of morphological factors found in previous studies. However, when attempting to synthesize findings on energy consumption changes for each specific factor, it becomes clear that most studies do not allow for direct comparison of results under a single morphological factor.

Therefore, a classification based on the sources of the studies is presented here. By reviewing recent research on urban morphology and energy consumption, the morphological indicators and their corresponding energy impacts are summarized below (Table 1), focusing primarily on studies at the block scale that employ energy consumption simulation as the primary research method.

Table 1. Some morphological indicators and their corresponding energy impacts.

Researchers	Year	Location	Indicators	Influence

Liu *et al*.	2023	Jianhu,China	Building density (BD), open space ratio(OSR), shape coefficient (SC), average perimeter-area(PAR)	+BD, +OSR, +SC, +PAR
Zhang and Gao	2021	Nanjing, China	Floor area ratio (FAR), surface area ratio (SAR), sky view factor (SVF)	-FAR,-SAR,+SVF
Ahmadian *et al*.	2021	London, UK	Plan depth (PD), number of storeys (NS), building density (BD)	-PD,-NS,+BD
Lima *et al*.	2019	Maceio, Brazil	Building shape factor (BSF), building height (BH), building density (BD), building orientation (BO)	-BSF, +BH, -BD, BO
Javanroodi *et al*.	2018	Tehran, Iran	Building density (BD), height to width ratio (H/W)	-BD, +H/W
Quan *et al*.	2016	Shanghai, China	Building density (BD), building height (BH), floor area ratio (FAR)	-BH,+BD,+FAR

Common morphological indicators include Floor Area Ratio (FAR), Building Density (BD), and Building Coverage Ratio (BCR). These indicators mainly describe the relationship between buildings and the surrounding space, representing a building- or solid-dominated perspective. Another set of indicators focuses on describing the "void" aspects of morphology, such as Open Space Ratio (OCR), obstruction angle, and the Sky View Factor (SVF).

It is worth noting that although many studies focus on the impact of urban morphology on energy consumption at the neighborhood scale, the indicators used to describe urban morphology often tend to focus more on building form, lacking relevant indicators from an urban design perspective. For example, when describing urban morphology using only density and floor area ratio (FAR), vastly different situations can arise due to variations in building form and layout. These differences not only affect the morphology of the buildings themselves but also have implications for the form of public spaces influenced by building morphology. Using the open space ratio as a sole indicator may fail to comprehensively represent the real urban morphology, while also lacking consideration from the perspective of pedestrian use within urban design.

Current morphological indicators often overlook the form of public spaces, despite their critical importance in practical urban design. Given this context, it becomes particularly important to address how public space morphology indicators influence building energy consumption, especially when the design goal is to create more sustainable urban forms. Achieving this goal requires not only low-energy solutions but also the creation of public spaces that are more conducive to human activity.

This study selects several indicators that describe public space morphology from different perspectives within the broader context of urban morphology. By combining these indicators with building form types and analyzing energy consumption under simulated urban morphologies, the study aims to identify correlations between these indicators and building energy consumption. Furthermore, it seeks to highlight the impact of common urban design strategies related to urban morphology on energy performance, thereby offering some guidance for designing more sustainable and livable urban forms in the future.

METHOD

To investigate the relationship between energy performance of different form prototypes and urban design indicators, this study follows a three-stage process (Figure1): parametric modeling, energy consumption simulation, and correlation analysis. The focus is on simulating the energy consumption

of a designed set of comparative experimental forms. By comparing simulation results with urban form types and urban design indicators, the study aims to elucidate the relationship between urban forms, building energy performance, and the characteristics of urban public spaces.

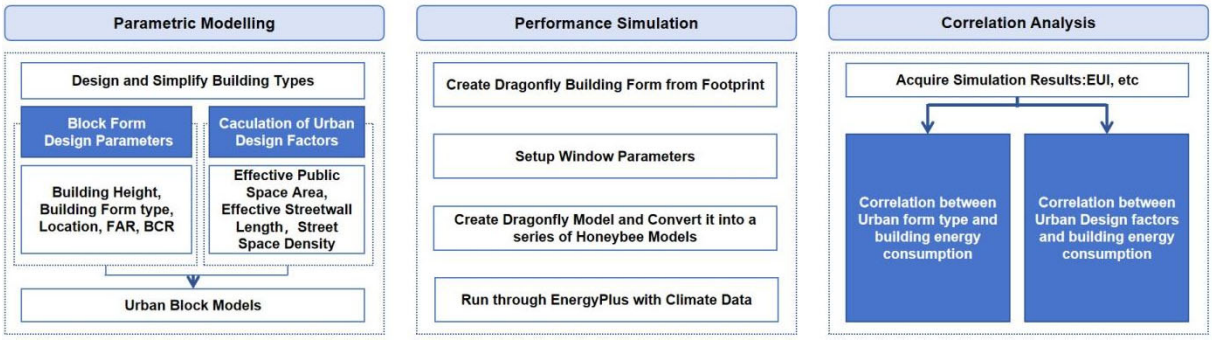

Figure 1. Three-stage research process. diagram credit: author.

The first stage focuses primarily on establishing a reasonable and effective parametric model. This phase consists of two main steps. First, a standard residential unit needs to be selected to facilitate morphological combinations and calculations. Then, by extracting and abstracting the real residential block morphology, a 3D morphological model is built, while controlling key variables and determining other block morphology indicators. Following this, the urban design-related indicators and their corresponding values are calculated and recorded based on these models, laying the groundwork for the subsequent building energy simulation.

To explore the questions mentiond, an experiment is designed with these six urban block form types using the same residential unit (Figure 2) so that it may conviently make sure that they share the same total building area. These are different urban form with the same FAR. The table below (Table 2) shows the basic form situation and block design parameters. The six hypothetical block types are selected and generated based on the real residential neighbourhood in Shanghai. The size of each block is defined as 120m * 120m, which is usually seen as small and middle scale block.

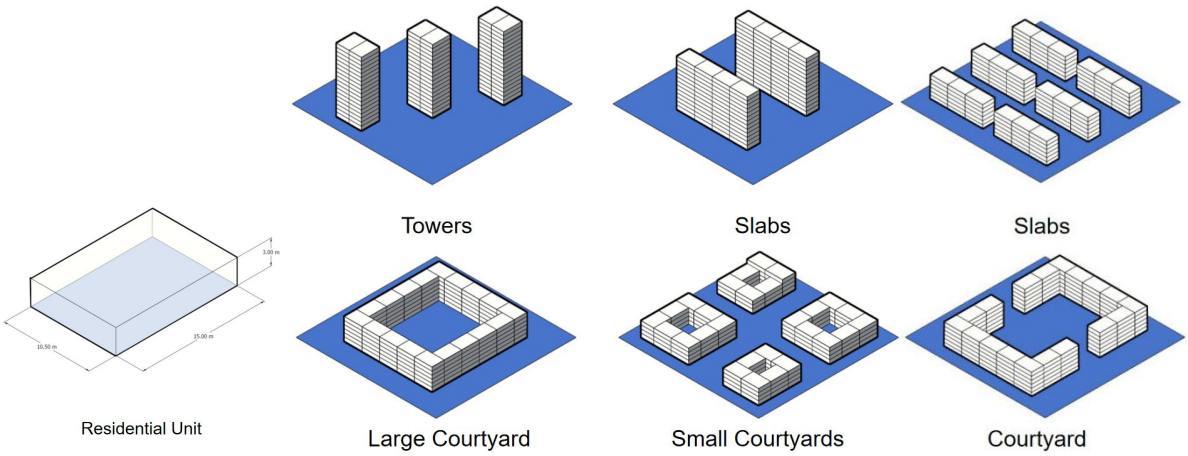

Figure 2. Residential unit and six urban block form types. diagram credit: author.

As research on urban building energy consumption advances, the use of computer models to simulate building energy performance under specific conditions has become a leading quantitative method.

Various energy simulation tools and software have significantly contributed to researchers' ability to understand and optimize urban design from a city performance perspective. One example is CityBES, a web-based open tool that facilitates city-scale building energy planning (Chen, 2017). However, for smaller-scale block energy simulations, the applicability of city-scale platforms and software diminishes. Consequently, building energy simulations frequently rely on the EnergyPlus engine, developed by the U.S. Department of Energy. EnergyPlus offers comprehensive simulations of a building's thermal performance, humidity levels, airflow, and lighting, accounting for factors such as thermal conduction, air infiltration, solar radiation, lighting, and HVAC systems. To enhance practicality and ease of use, platforms like OpenStudio, DesignBuilder, and Ladybug Tools have integrated the EnergyPlus engine into their interfaces.

In the second stage, this study uses the parametric design plugins Dragonfly, Ladybug, and Honeybee within the Ladybug Tools suite, based on the EnergyPlus simulation engine, to simulate building energy consumption. This simulation provides data on EUI and annual heating and cooling loads (Figure 3).

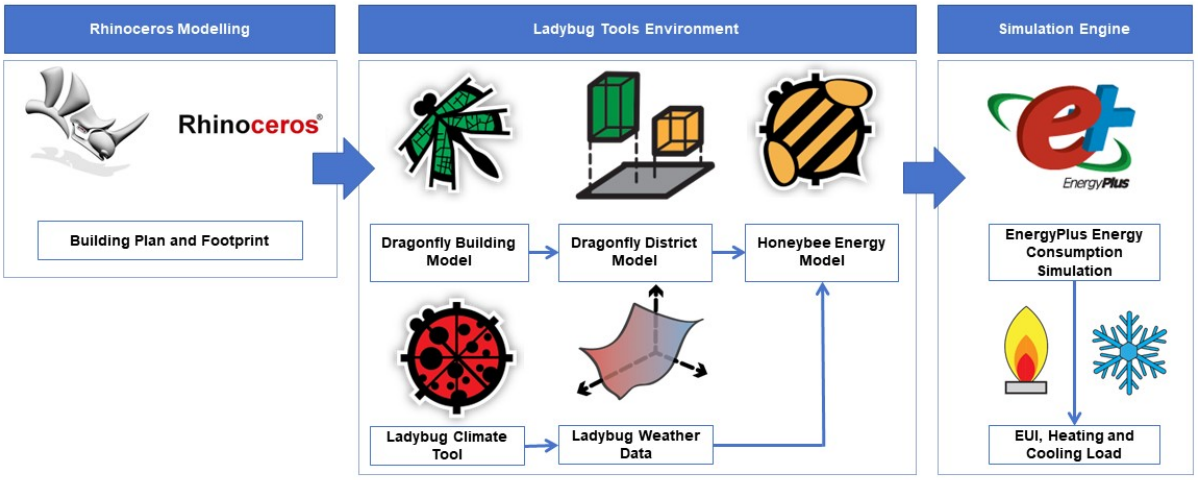

Figure 3. Performance simulation method and process. diagram credit: author.

This simulation provides data on EUI and annual heating and cooling loads. The selection of simulation software prioritizes the reliability of results, process consistency, and parametric manipulation of forms. The simulation workflow involves using the Grasshopper parametric design platform within Rhino to select and recognize pre-set building site plans, set building volumes by floor height and number of floors, and configure daylighting parameters by window-to-wall ratio. The Dragonfly model is then created and converted into a series of Honeybee models for energy simulation, with a window-to-wall ratio limit of 0.35 for residential buildings.

Environmental settings place all the blocks in the same urban context to exclude interference from other factors. For this study, focusing on heating and cooling loads and EUI, Shanghai is chosen as the experimental background city due to its typical hot summer and cold winter climate, classified in ASHARE standards as 3A (temperature: warm, moisture: humid; Köppen Classification: Humid Subtropical - Warm Summer). The EnergyPlus simulations, based on Shanghai's climate parameters, generate annual EUI and monthly heating and cooling load data.

Table 2. Block form design parameters of six experiment types.

No.	Block Form Type	Geometric Model	Site Area	Total Building Area	Building Footprint Area	Number of Floors
P-1	Point		14400㎡	17010㎡	945㎡	18
S-1	Slab		14400㎡	17010㎡	1260㎡	14,13
C-1	Courtyard		14400㎡	17010㎡	2835㎡	6
C-2	Courtyard		14400㎡	17010㎡	4410㎡	4,5
S-2	Slab		14400㎡	17010㎡	2835㎡	6
C-3	Courtyard		14400㎡	17010㎡	2835㎡	6

Furtherly, more proposed form indcators which could show street and open sapce differences concerning on pedestrians are introduced in. As urban designers care more about urban spaces formed by buildings and the quality of urban public spaces, the new indicators represent these concerns.

Firstly, the effective streetwall length plays a crucial role. Streetwall buildings help define the shape of the street, creating a cohesive spatial experience while bringing ground-floor activities closer to urban pedestrians. This indicator highlights the contrast between object-in-space blocks, such as tower and slab types, and streetwall blocks, including courtyard-based designs.

Secondly, the effective street space area which refers to the street spaces that could provide usage possibility to all pedestrians. It depends on the streetwall space formed by buildings. As shown in the table (Table 3), the towers type is hardly capable of creating effective street space area as it lacks the supporting of streetwall.

Thirdly,the new indicator Street Space Density need to be further explained. street space density is defined as the percentage of non-urban space occupied by buildings in relation to the total site area (Figure 4). It mainly shows the urban space situation formed by buildings, as the higher street density represents more compact and pedestrain-friendly block.

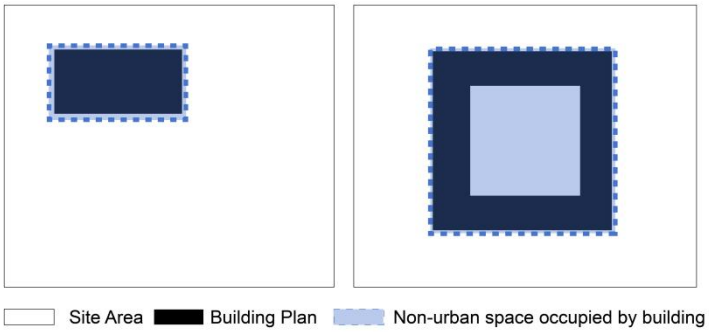

Figure 4. Diagram of definition of street space density . diagram credit: author.

In table 3 it also shows the commonly use indicator Open Space Area for reference. It represents the typical choice for former research.However, from the view of urban design, the indicator open space area is not capable of fully describing the real street and public space situation of a blcok. For instance, the courtyard types have less open space area but share more effective street space and higher street space density. This situation indicates that more indicators about outer urban space are quite necessary.

The calculation methods of urban design factors for block forms are as follows:

$$ESL = \sum EffectiveStreetwallBuildingSurfaceLength$$ (ESL: Effective Streetwall Length)

$$ESSA = \sum EffectiveStreetwallBuildingSurfaceLength * PedestrianSpaceWidth$$ (ESSA: Effective Street Sapace Area)

$$SSD = \frac{\sum Non\text{-}urban\ Space\ Occupied\ by\ Buildings\ Area}{Site\ Area}$$ (SSD: Street Space Density)

Table 3. Urban design factors of six experiment types .

No.	Block Form Type	Effective Street Space	Effective Streetwall Length	Open Space Area	Effective Street Space Area	Street Space Density
P-1	Point		-	13455㎡	-	-
S-1	Slab		120m	13140㎡	1200㎡	-
C-1	Courtyard		291m	11565㎡	8325㎡	42%
C-2	Courtyard		462m	9990㎡	8959.5㎡	37%
S-2	Slab		180m	11565㎡	2700㎡	-
C-3	Courtyard		291m	11565㎡	6045㎡	52%

RESULTS AND DISCUSSIONS

The simulation results of each form type are gathered and showed below(Table 4 and Figure5).The C-1 courtyard type perform the lowest EUI while the S-2 slab type shows the highest. The three courtyard types and one long slab type exhibit relatively equal and lower building energy performance. When considering the balance between cooling and heating loads, the C-2 courtyard type demonstrates the best balance.

Table 4. Simulation results of six block form types.

No.	Block Form Type	EUI	Cooling Load	Heating Load
P-1	Point	175.174 KW/㎡	58.175 KW/㎡	45.356 KW/㎡
S-1	Slab	171.992 KW/㎡	55.728 KW/㎡	43.960 KW/㎡
C-1	Courtyard	167.41 KW/㎡	52.310 KW/㎡	43.434 KW/㎡
C-2	Courtyard	170.308 KW/㎡	49.207 KW/㎡	49.343 KW/㎡
S-2	Slab	178.845 KW/㎡	53.171 KW/㎡	54.283 KW/㎡
C-3	Courtyard	171.858 KW/㎡	53.512 KW/㎡	46.462 KW/㎡

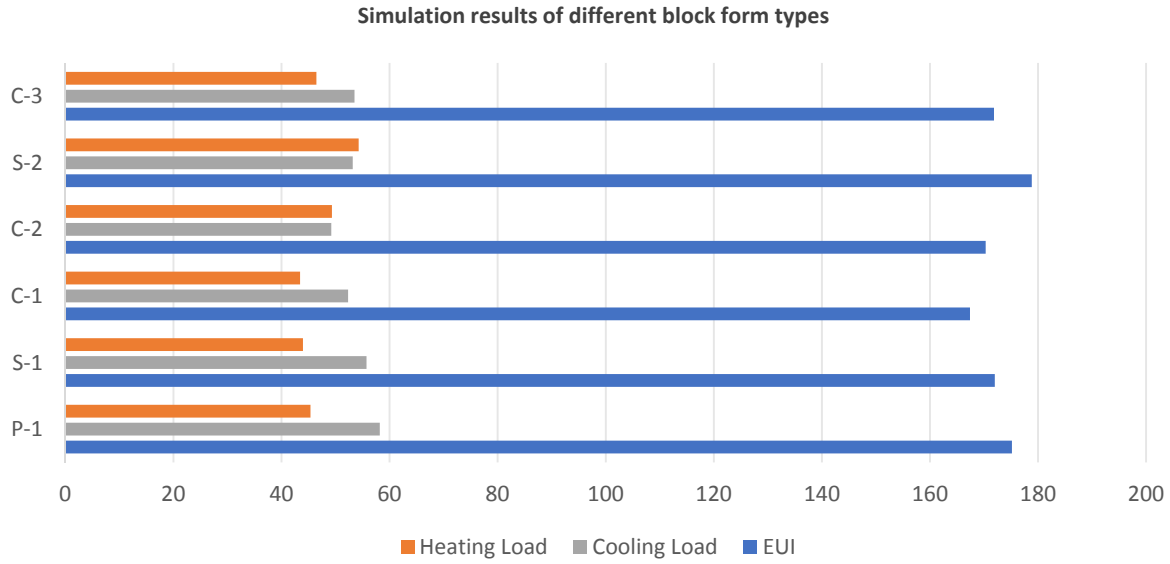

Figure 5. Simulation results of different block form types. Diagram credit: author.

Across all six morphological prototypes, the difference between the highest and lowest Energy Use Intensity (EUI) is approximately 6.8%, indicating that under the simulation conditions, the energy performance of the different types is generally similar.

he relatively small differences in the building energy simulation results may be due to all types being tested under idealized environmental conditions, excluding other influencing factors. Some of the variation in cooling and heating loads could be attributed to differences in building orientation among the various morphological types, particularly under Shanghai's climate conditions.

However, when the urban design morphology indicators mentioned earlier are factored in, it becomes apparent that the C-1 and C-3 block types not only maintain relatively low building energy consumption but also have higher ESL (Effective Streetwall Length), ESSA (Effective Street Space Area), and SSD (Street Space Density) values. This indicates that while achieving a sustainable level of building energy consumption, these types provide greater value for urban public spaces and pedestrians compared to the other types. This result suggests that, given the same Floor Area Ratio (FAR) requirements, it is possible to select urban block types that both meet low building energy consumption standards and offer better public space environments and walking experiences.

In contrast, the P-1, S-1, and S-2 types, which perform relatively poorly in terms of urban design morphology indicators, do not demonstrate particularly outstanding energy performance. When comparing the results, it is clear that the block types with better performance in urban design indicators hold a competitive edge. By ranking the data from best to worst (6-1) and summarizing the results, the table and the figure (Table 5, Figure 6) below reveal the more advantageous and balanced morphological types.

Table 5. Simulation results comparation rank with urban design indicators.

No.	EUI	Effective Streetwall Length	Effective Street Space Area	Street Space Density
P-1	2	1	1	1
S-1	3	2	2	1
C-1	6	4	5	5
C-2	5	6	6	4
S-2	1	3	3	1
C-3	4	4	4	6

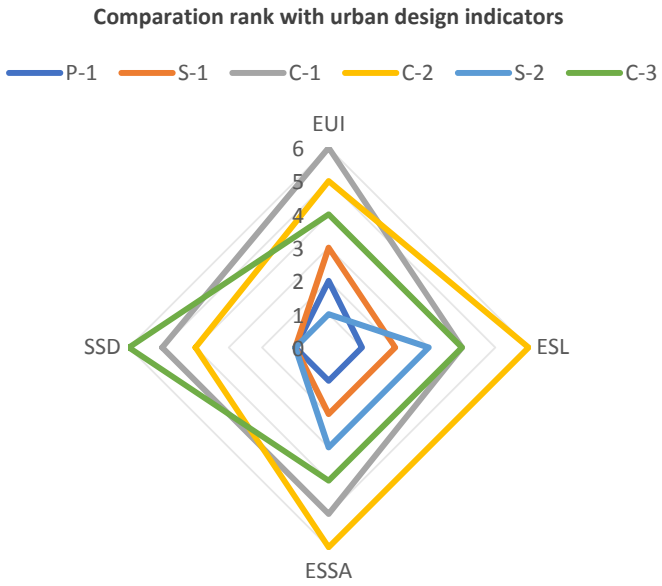

Figure 6. Comparation rank with urban design indicators. Diagram credit: author.

This study also have some limitations. First of all, the morphological characteristics in the experiment are limited, and although these types are designed based on the neighbourhood blocks in reality, some of the form details are simplified. Besides, the types have more possibilities when considering on a larger block scale and other programmes.

Secondly, urban design strategies need to be considered more during the first stage of experiment to emphasize the starting point, which is the importance of urban design view.

CONCLUSIONS

This paper introduces several morphological indicators from an urban design perspective when discussing the correlation between urban form elements and building energy consumption. Through energy simulation and comparative experiments under consistent conditions, it verifies the existence of morphological types that achieve a balanced performance in multiple aspects. The findings suggest that urban and architectural designers can, from the early stages of planning, focus on block morphology to create designs that not only meet sustainable building energy performance standards but also provide walkable and high-quality urban street spaces through effective urban form. Balance between energy efficiency and proper public urban spaces can be achieved through early-staged urban form design.

This research seeks to provide new insights into the relationship between urban form and building energy consumption, with a particular focus on the urban design perspective. It aims to encourage a reevaluation of design approaches when initiating new urban projects, emphasizing the importance of creating urban forms that are not only energy-efficient but also walkable and sustainable. The study aspires to contribute to the ongoing pursuit of urban environments that balance energy performance with broader sustainability goals.

In future research, more standardized and normalized indicators will be needed to describe and evaluate urban form, particularly the characteristics of public spaces. This will enhance the accuracy of early design guidelines and allow for a deeper exploration of how these indicators specifically influence changes in block energy performance. Additionally, future studies should address the issue of over-reliance on simplified prototypes when describing urban form in related research. This challenge could potentially be resolved through the development of a new system for morphological description.

ABSTRACT

In the early modern period, Tone River basin, the largest in Japan, developed an environmentally symbiotic watershed structure by integrating castle towns with the river landscape. This study explores what lessons can be drawn from this landscape-based urban morphology in early modern Japan, to promote a harmonious relationship between water environment and urban form in the face of climate change. The aim is to identify how the urban form responded to the river basin landscape in early modern Japan, Tone River basin as a case study. A morphological analysis of the river landscape and castle towns in the early modern period was conducted by using GIS (Geographic Information System). The results show that the 12 castle towns are arranged in a balanced manner on the plateaus and plains of the basin with three different landscape characteristics: upstream, midstream and downstream. These castle towns can be classified into four typologies in relation to the dynamics of river landscape: water flow utilisation type, water environment adaptation type, topography-defined type and flood defence type. Each urban typology had a distinct approach to adapting to the surrounding water landscape, and these differences were reflected in their urban forms. Analysis of the relationship between these urban typologies and the three regions - upstream, midstream, and downstream - reveals that they do not necessarily correspond directly to these three regions. Instead of a general model of urban form for each region, urban typologies were shaped by individual adaptations to the specific river landscape dynamics of each location. Forming such a harmonious relationship between urban form and the basin-wide river landscape is also being addressed in contemporary advanced flood control measures. These historical towns, with their integration of natural landscapes provide important lessons for contemporary urban and landscape design, particularly in the context of creating climate-adaptive cities.

Keywords: Landscape-based urban morphology, Japanese early modern castle town, Adaptive approach, River basin, River landscape.

INTRODUCTION

Background and purpose of this study

In early 17th-century Japan, castle towns were constructed simultaneously across the country, resulting in diverse urban forms tailored to the unique landscapes of different regions. The environmental symbiosis formed the foundation of the design of these towns, taking into account

factors such as topography, geology, and water systems. In Tone River basin, which flows through multiple prefectures including Tokyo, Saitama, Chiba, Gunma, Ibaraki, and Tochigi, making it the largest water basin in the country, approximately one-tenth of Japan's castle towns were concentrated. This development coincided with large-scale river improvement efforts, leading to the creation of urban forms in balance with the river landscape, effectively supporting flood control and water utilisation.

The question addressed in this study is what can be learned from the landscape-based urban morphology in early modern Japan to consider the harmonious relationship between river landscape and urban form in response to climate change. This study uses Tone River basin as a case study to identify the urban forms that responded to the river basin landscape in early modern Japan, and discusses its contemporary significance.

Extensive research on the morphology of cities and settlements in response to landscape dynamics, particularly those shaped by rivers and coastal forces, has provided valuable insights into how urban areas have adapted to water-related challenges. Studies on historical urban structures and landscape systems underscore the significance of landscape-based spatial planning, which emphasises fostering a symbiotic relationship between landscape dynamics and urban development to promote sustainability, ecological resilience, and effective water management (Nijhuis, 2022). Case studies of historical settlements in low-lying areas, such as the early settlements in Zeeland in the Netherlands, illustrate how communities have navigated these challenges through innovative spatial transformations, reflecting the water management and demands of their time (Rutte, 2023).

As for research on early modern castle towns in Japan, some have systematically analysed castle towns across Japan in terms of urban form and urban design (Yamori, 1970; Satoh, 2015), while others have discussed the flood control and water utilisation methods and landscape design methods of castle towns in relation to the surrounding rivers (Niitani, 1987; Yoshida and Niitani, 1998; Mizuta, 2012a; Mizuta, 2012b; Tanaka *et al.*, 2016).

However, there have been no studies that consider multiple castle towns connected to the same river as a network and systematically discuss urban form in relation to the river landscape of the entire basin.

Therefore, using Tone River basin as a case study, this study aims to categorise the urban form of early modern castle towns located in the basin, focusing on the surrounding river landscape, and to clarify their relationship with the landscape of the entire basin. The contemporary significance of this river basin environment established in early modern times is also examined, based on comparisons with an example of advanced flood control measures in the Netherlands and a discussion of the challenges caused by the changes in Tone River basin due to modernisation.

Overview of the case study (See Fig.1)

This study focuses on Tone River basin in Japan. During the Edo period (early 17th century to late 19th century), large-scale river improvements occurred alongside multiple urban developments, highlighting the diverse and interdependent relationships between river landscape and urban form.

The basin area is the largest in Japan at 16,840 km^2, with mountains, hills and volcanic areas accounting for about 49% of the total area, plateaus for about 27% and alluvial plains for about 24%. While most river basins in Japan are largely mountainous, Tone River basin is characterised by a large proportion of plateaus and plains, allowing many castle towns to be built in the basin of a single river.

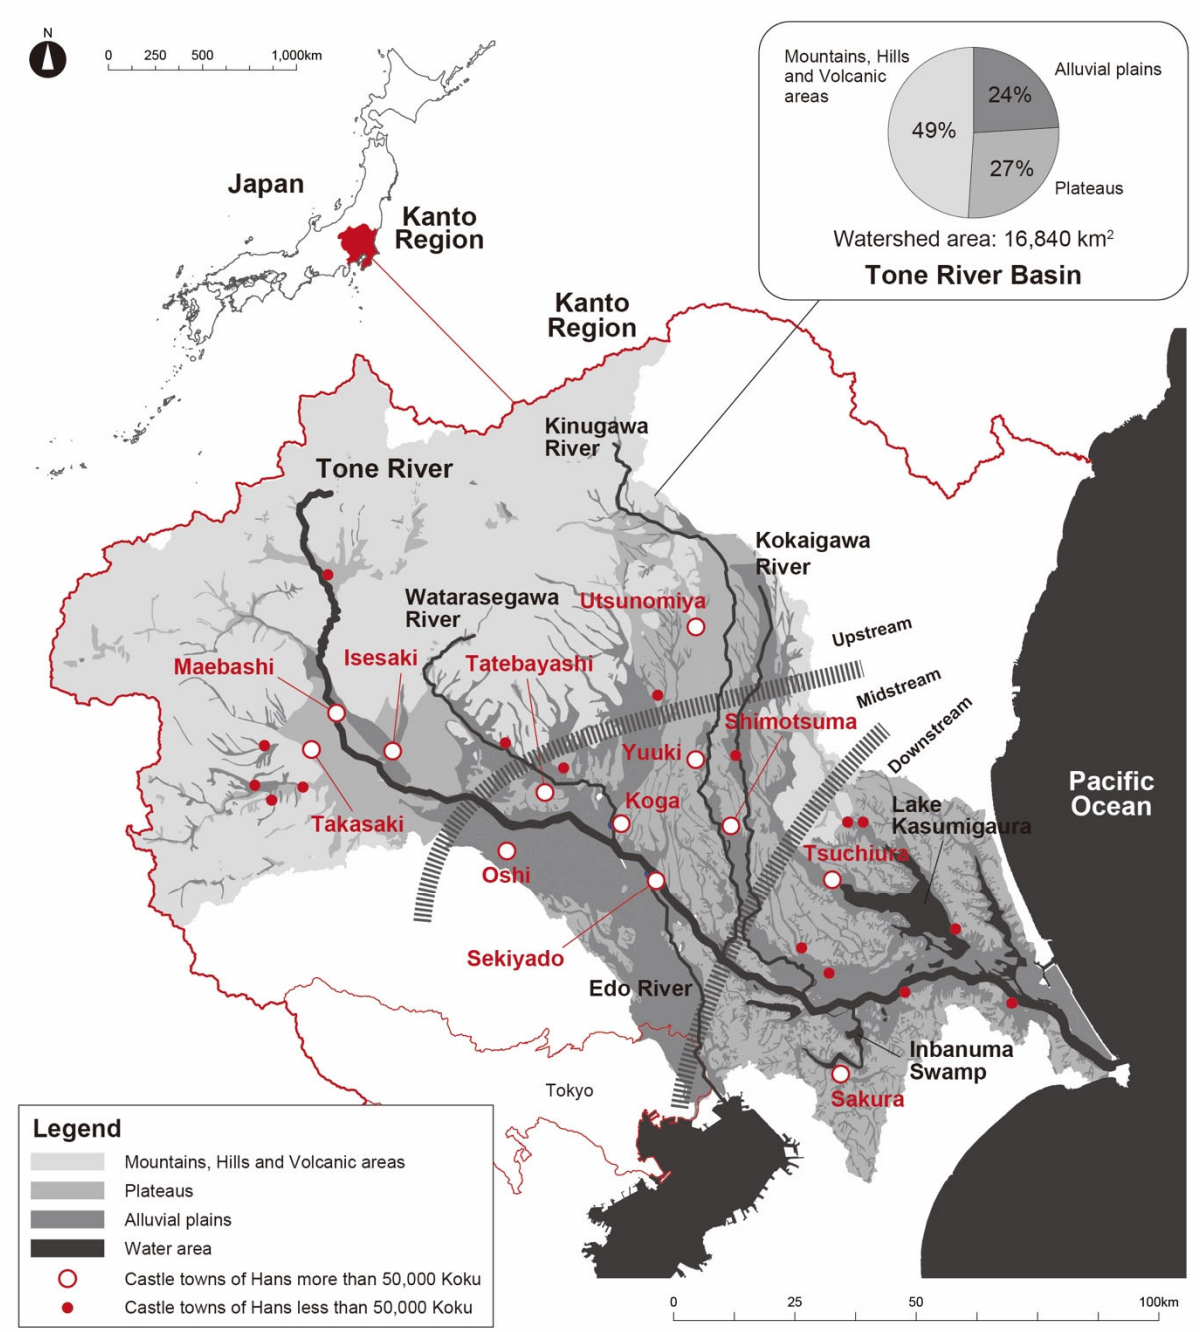

Figure 1. Basin environment of Tone River.

In Japan, the construction of early modern castle towns occurred nationwide in the early 17th century. In Tone River basin, this urban development was accompanied by a large-scale river improvement project known as Tone River Diversion (Tone Gawa Tohsen in Japanese). The primary objectives of Tone River Diversion were to secure agricultural irrigation water for new paddy fields, establish a shorter and more reliable shipping route to Edo (political and economic centre of the Edo period and

the predecessor of Tokyo), and protect Edo from flooding. Tone River Diversion indicates that the stream channel of Tone River was shifted to the east, and Tone River, which had been flowing in a north-south direction towards Edo, was replaced in its midstream by an east-west channel that drains into the Pacific Ocean. As a result, several rivers were connected and irrigation channels were developed, and especially in the midstream, rivers began to divide and merge in complex ways. In addition, water from Tone River began to flow into the low marshy areas downstream, where several large swamps were located and flooding due to backwaters became frequent.

After Tone River Diversion, Tone River consists of three rivers confluence to the main river from the north and one river distributing to the south, connecting to two large swamps downstream. The three rivers that confluence are Watarasegawa River, Kinugawa River and Kokaigawa River. Kinugawa and Kokaigawa Rivers were not originally included in Tone River basin, but were merged into Tone River in Tone River Diversion. The diverging river is Edo River. After Tone River Diversion, water from Tone River began to flow into this river. The two large swamps downstream are Lake Kasumigaura and Inbanuma Swamp. These were connected to Tone River by Tone River Diversion and backwaters flowed into them.

Around 30 early modern castle towns were built in Tone River basin at the same time as Tone River Diversion. There is no other place in Japan where so many early modern castle towns were built in the basin of a single river at the same time as large-scale river improvement, making it suitable for the purpose of this study to understand the diverse patterns of urban form in response to the river landscape.

In Tone River basin during the Edo period, Edo was located at the southern end and several feudal domains, called “Han” in Japanese and their castle towns were dispersed throughout the river basin. A total of 28 Hans survived from the early to the end of the Edo period and formed the basis for urban and regional development in modernisation. There were approximately 300 Hans in Japan at the end of the Edo period, indicating that about one-tenth of all Hans in the country were located in Tone River basin. The scale of Hans ranges from 10,000 to 170,000 Koku. “Koku” is a unit of land productivity in early modern Japan and indicates the scale of a territory. Eight Hans had more than 50,000 Koku at the end of the Edo period and four had more than 50,000 Koku during a certain period of time in the Edo period, making a total of 12 Hans, which can be positioned as large Hans with a central position in this area. Of the approximately 300 Hans in the country, only the top one-third were larger than 50,000 Koku. In this research, 50,000 Koku or more was considered to be large in scale. (Table 1)

Table 1. Scale of early modern castle towns in Tone River basin.

Scale	Name of Hans and their castle towns
Over 100,000 Koku	Maebashi(17), Sakura(11), Oshi(10)
50,000-100,000 Koku	Tsuchiura(9.5), Takasaki(8.2), Koga(8), Utsunomiya(7), Tatebayashi(6)
Less than 50,000 Koku	Sekiyado(4.8), Numata(3.5), Annaka(3), Mibu(3), Isesaki(2), Obata(2), Ishioka(2), Shimodate(2), Yuuki(1.8), Sano(1.6), Ashikaga(1.1), Shimotsuma(1), Nanokaichi(1), Yoshii(1), Omigawa(1), Takaoka(1), Asoh(1), Ushiku(1), Shizuku(Unknown), Ryugasaki(Unknown)

*Parentheses indicate the number of Koku (Unit: 10,000) at the end of the Edo period.
*Underbars indicate Hans that had 50,000-100,000 koku during a certain period of time during the Edo period, although the amount was below 50,000 koku at the end of the Edo period.

*For Shizuku and Ryugasaki, the number of Koku at the end of Edo period is unknown, but as no record can be verified that they had more than 50,000 Koku during the Edo period, it was taken to be less than 50,000 Koku.

Structure of this paper

The structure of this paper is organised into four chapters:

Chapter 1 (INTRODUCTION) presents the background and purpose of the study, providing an overview of Tone River basin's landscape composition. It also examines the river improvement efforts of Tone River, which occurred concurrently with urban development during the early modern period, offering a comprehensive picture of the basin's transformation following these improvements.

Chapter 2 (METHOD) outlines the methodology used in the study.

Chapter 3 (RESULTS AND DISCUSSIONS) details the results and discussions, organised into four sections. The first section identifies the castle towns within Tone River Basin, analysing their locational characteristics. The second section categorises the urban forms of the larger castle towns at the core of the basin in relation to the surrounding river landscape. The third section explores the relationship between the typology of these urban forms and the broader basin landscape. Finally, the fourth section highlights the contemporary significance of the river basin environment established in early modern times, based on comparisons with an example of advanced flood control measures in the Netherlands and a discussion of the challenges caused by the changes in Tone River basin due to modernisation.

Chapter 4 (CONCLUSIONS) concludes the paper, synthesising the findings from the previous chapters.

METHOD

In this study, a morphological analysis of the river landscape and castle towns in the early modern period was conducted using GIS. The following three maps were overlaid and analysed on Arc GIS Pro by Esri.

First is the "Original 1:20,000 rapid survey map of the First Military District (hereafter referred to as the rapid survey map)", which was produced by the Army's General Staff between 1880 and 1886. This map is used to display the river landscapes and the urban forms of the late 19th century on the GIS. The late 19th century in Japan was the end of the early modern period and the time of gradual urban development due to modernisation. The 1880s, when this map was produced, was a period shortly after the start of modernisation, and the environment of the river basin at the Edo period was not considered to have changed significantly. In this study, the basin environment shown in the rapid survey map is regarded as of the end of the early modern period. This map has been produced for most of Tone River basin, but some are missing. The urban forms of the castle towns located in the missing areas were identified using castle town drawings in the Edo period.

Second is the "Land Classification Map at 1:500,000", which was produced by the Economic Planning Agency in 1968. This map is used to display the topographic classification into three categories: mountains, hills and volcanic areas, plateaus and alluvial plains, to show the landscape structure on the GIS.

The third is the “Basic Map Information” published by the Geospatial Information Authority of Japan. In particular, the Digital Elevation Model (DEM) is used to analyse the cross-sectional configuration of the landscape with the 3D analyst tools in Arc GIS Pro.

RESULTS AND DISCUSSIONS

Layout configuration of early modern castle towns in Tone River basin

Figure 1 shows the location of the castle towns that served as bases for each of the 28 Hans. Five castle towns are located in mountainous areas, while the other 23 towns are located on plateaus and plains below 120m above sea level, out of the mountainous areas. Focusing on the castle towns of the 12 larger Hans, all of these are located on plateaus and plains, and are well balanced on the upstream, midstream and downstream of Tone River and midstream and downstream of Kinugawa River. Their locations can be divided into three based on landscape characteristics.

Upstream: Upstream of Tone River and midstream of Kinugawa River

This region is located at the foot of the mountains that are the source of Tone and Kinugawa Rivers, with water flowing down gently sloping open plateaus. Maebashi, Takasaki, Isesaki and Utsunomiya are located in this region.

Midstream: Midstream of Tone River and downstream of Kinugawa River

This region is located around an area where rivers were replaced and irrigation channels were built during Tone River Diversion, and where rivers converge from many directions, creating diversity in the landscape due to the complex diversions and mergers. The six towns of Oshi, Tatebayashi, Koga, Sekiyado, Shimotsuma and Yuuki are located in this region.

Downstream: Downstream of Tone River

It is a low marshy area where several large swamps are located, and where flood damage due to backwaters has increased as water from Tone River began to flow into the swamps as a result of Tone River Diversion. Two towns, Sakura and Tsuchiura, are located in this region.

The layout configuration of castle towns in Tone River basin is a balanced arrangement of 12 larger castle towns on the plateaus and plains of three different regions - upstream, midstream and downstream - with smaller castle towns scattered around them.

Four types of urban form in relation to the river landscape

The 12 core castle towns were categorised by focusing on the planar and cross-sectional relationship between the urban form and the river landscape. Focusing on four urban and regional elements - surrounding water landscape around the castle town, water moats in the castle town, the castle and the street of the castle town - the relationship between their layout, forms and water flows are analysed. Where necessary, the shape of the topography and river embankments were also included in the analysis. As a result, they could be classified into four types: water flow utilisation type, water environment adaptation type, topography-defined type and flood defence type.

Water flow utilisation type: Maebashi, Takasaki, Isesaki, Utsunomiya (see Fig. 2)

This type of town draws water from the surrounding area into the town by using water flows along a gentle topographical slope from the surrounding water landscape to the castle and the castle town.

Maebashi, Takasaki, Isesaki and Utsunomiya belong to this typology. The castle and the castle town are located on highlands, with the castle facing a river flowing through the lowlands. In many towns, the large part of the water moat is formed in a rectangular shape, which follows the street pattern of the castle town. In Takasaki, for example, the castle is located facing east of Karasugawa River, a tributary of Tone River, and the castle town is formed to enclose the northeast of the castle. The streets of the castle town are arranged in a north-south and east-west direction, and the water moat surrounding the castle and the castle town is formed in a rectangular shape to match the street pattern. Water for the water moat is drawn from Naganozeki irrigation canal from Haruna Shirakawa River, which confluences with Karasugawa River upstream from the castle town.

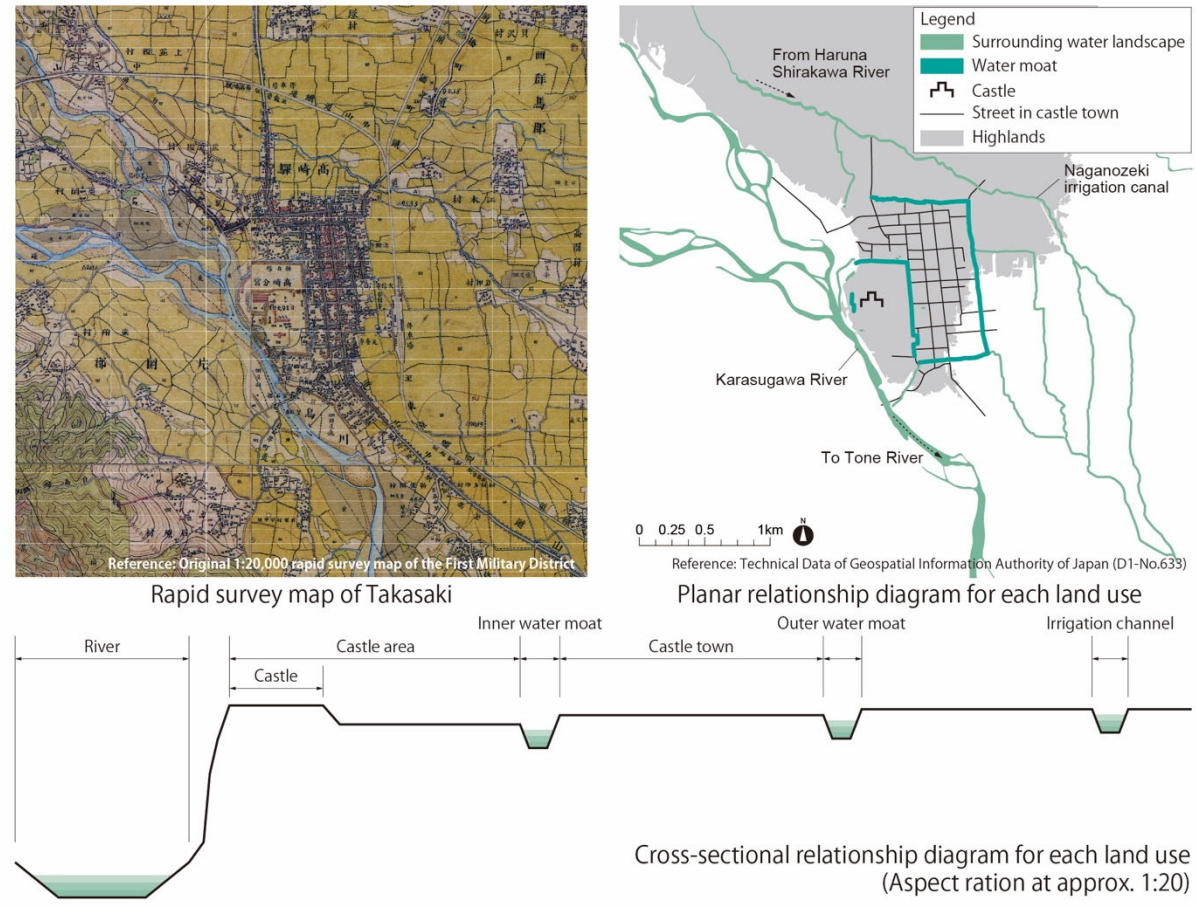

Figure 2. Urban form of Takasaki.

Water environment adaptation type: Tsuchiura, Koga, Oshi, Shimotsuma (see Fig. 3)

This type of town has an adaptable form that encompasses extensive water moats and flexibly receives water flowing in from surrounding water landscape. Tsuchiura, Koga, Oshi and Shimotsuma belong to this typology. What these towns have in common is that they are located in areas where water collects from several directions. In Tsuchiura and Koga, which are located at the confluence of rivers, both water flowing in from upstream and backwaters from downstream enter the castle town area. Oshi is located in the middle of an open lowland area of paddy fields, with drainage from the surrounding paddy fields flowing into the castle town. Shimotsuma is located at the tip of a tongue-shaped plateau, with adjacent wetlands forming a water moat and water flowing from the plateau. Koga, for example, has a castle located on the eastern side of Watarasegawa River, with extensive water moats surrounding the castle. Water moats have an organic form that is adapted to the

microtopography and allows flexibly to accommodate rising water levels. To the south of the water moat is the confluence of Watarasegawa and Tone Rivers, with hinterland wetlands integrated with the water moat. The castle town is formed on a slight elevation on the north-eastern side of the castle, reducing the risk of flooding in the living environment.

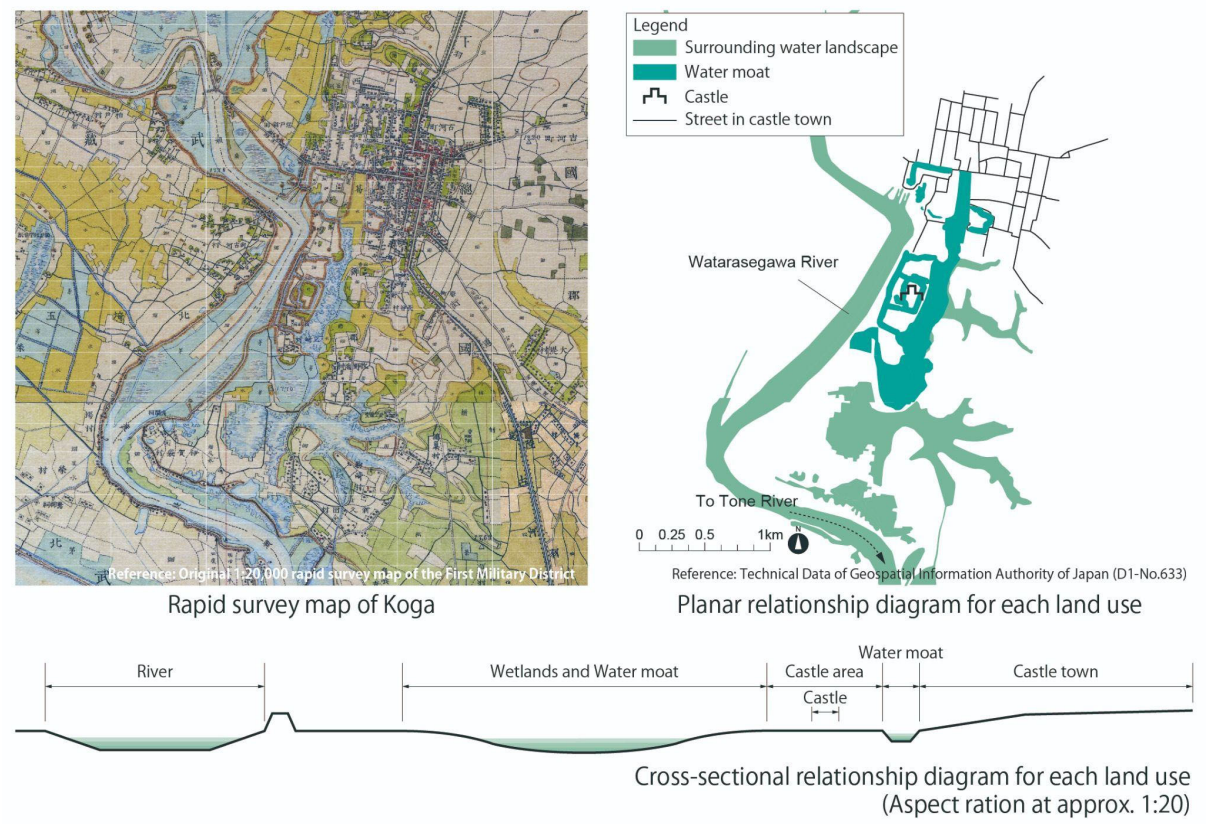

Figure 3. Urban form of Koga.

Topography-defined type: Yuuki, Tatebayashi, Sakura (see Fig. 4)

This type of town has urban areas compactly located on a plateau surrounded by water landscape, with the natural topography defining the urban form. Yuuki, Tatebayashi and Sakura belong to this typology. For example, Sakura has a castle and castle town on the plateau facing Inbanuma Swamp. After Tone River Diversion, the backwaters of Tone River began to enter Inbanuma Swamp, and various facilities located below the plateau were relocated and consolidated on the plateau. The castle is located at the tip of the plateau, while the main street, which forms the backbone of the castle town, is located on the ridge line, following the topographical shape. The water moat is located at the foot of the plateau and its shape follows the topography, taking in water from the surrounding water landscape.

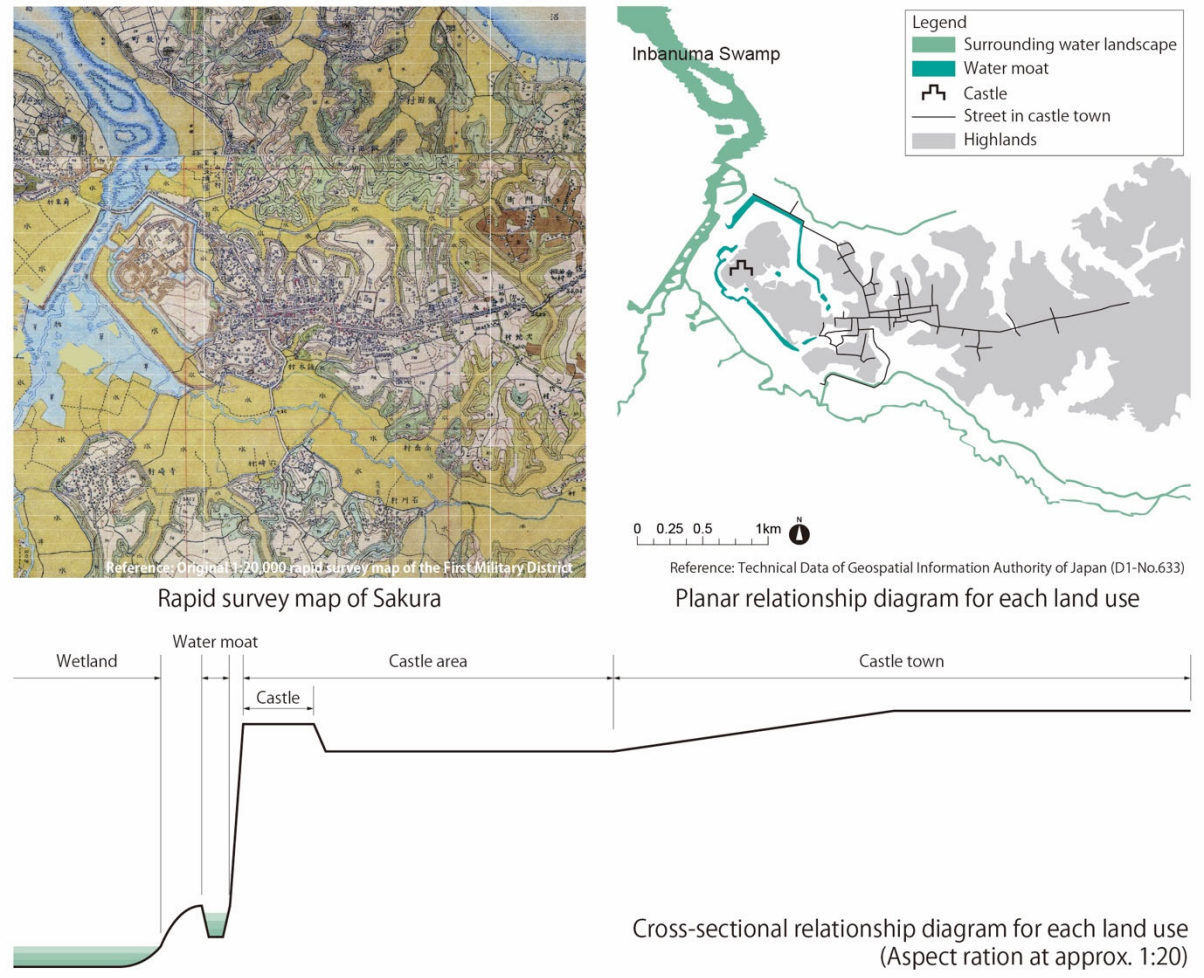

Figure 4. Urban form of Sakura.

Flood defence type: Sekiyado (see Fig. 5)

This type of town is integrated with embankments along the river and provides flood defence by enclosing the whole urban area with embankments. Only Sekiyado belongs to this typology. Sekiyado is located at the divergence of Edo and Tone Rivers and is surrounded on three sides to the north, east and west by river embankments. The castle is adjacent to the diversion point and is surrounded by a ring-shaped water moat. This water moat takes water from the river beyond the embankment and is also connected to the irrigation canal downstream. The main street of the castle town, located outside the water moat, is formed on a slight elevation and is continuous with the river embankment. On the extension of the main street, a jetty called “Bodashi” is located on Edo River. The Bodashi gently channel water from Tone River into Edo River, stabilising the navigation channel and protecting Edo, which is located at the bottom of Edo River from flood. As it is located at a key transport point, functions as a checkpoint are also integrated in the castle town.

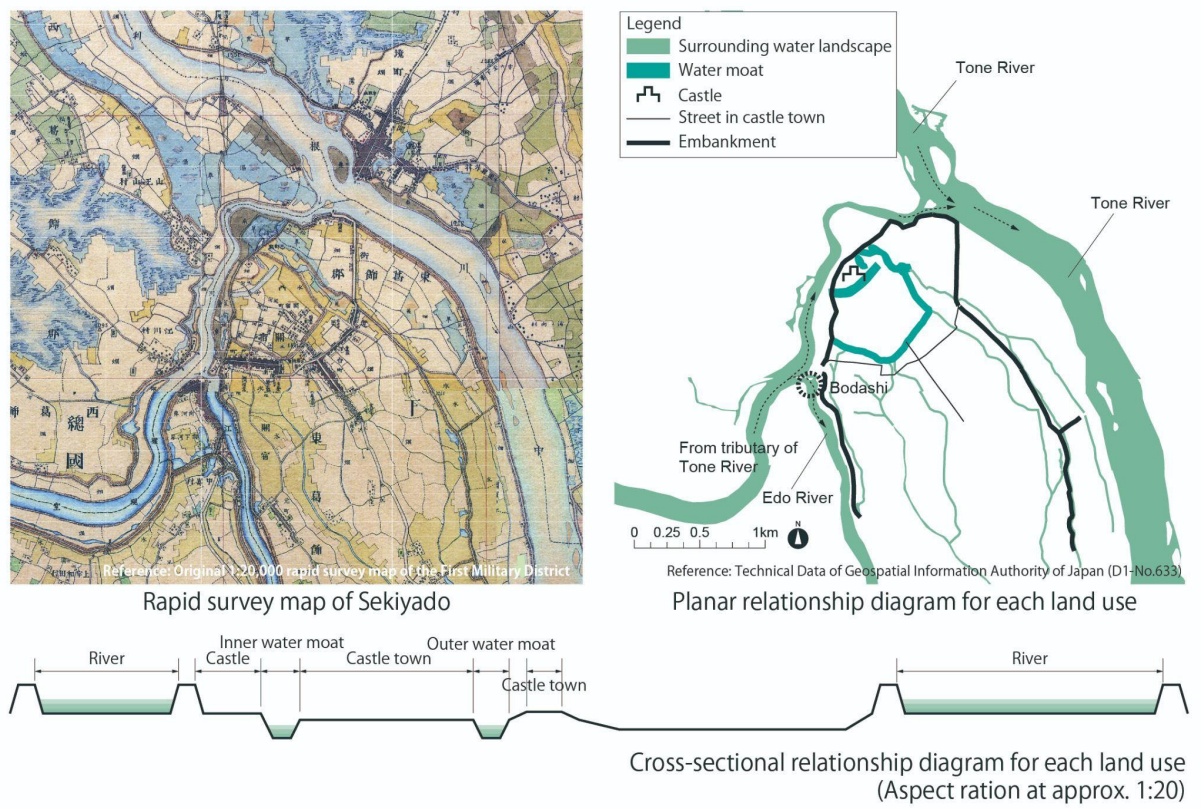

Figure 5. Urban form of Sekiyado.

In summary, it is possible to interpret each type as having a different approach to adapting to the surrounding water landscape. The water flow utilisation type is an approach that draws on relatively stable water flows into the urban area. The water environment adaptation type, on the other hand, is a more flexible approach that receives water flowing in from multiple directions. In contrast to these two types, the topography-defined type and flood defence type attempt to separate from, but partly relate to, the surrounding water landscape. The topography-defined type makes use of differences in elevation with water landscape as a method of separation, while the flood defence type creates a clear boundary with the water landscape by incorporating embankments into the urban area. These differences in the creation of relationships with the surrounding water landscape are reflected in the differences in urban form.

Relationship between the location and the urban typologies

In terms of the relationship between the location and the urban typologies, the following three features can be identified.

First, the four towns located on the upstream (Maebashi, Takasaki, Isesaki and Utsunomiya) all share the same principle of the water flow utilisation type. The wide plateaus and gentle slope of the topography in this region made it relatively easy to incorporate natural water flows into the urban areas. This made it possible to control the flow of water and form the water moat in line with the street pattern of the castle town. These towns also share the common feature of the castle being located on a plateau alongside the river. The river, and the difference in elevation, is thought to have been effective in protecting the castle from warfare. On the other hand, there are examples where

open views of the river and surrounding mountains from the castle were incorporated into the garden design. At Obata, which is also located on the upstream, the castle area was designed with a Chisen Kaiyu style garden (a style of Japanese garden with a path around a central pond and spring) called Rakusan-en, where the river and surrounding mountains were incorporated as a borrowing landscape. The layout of the castle adjacent to the river was probably designed as an integral part of the landscape experience as well as for defensive purposes in warfare.

Second, in the six towns located in the midstream (Oshi, Tatebayashi, Koga, Sekiyado, Shimotsuma and Yuuki), the surrounding river landscape is different in each town and the urban form is also diverse, with no unified typology. The diversity of the landscape in this region is influenced by the confluence of rivers from many directions and by river diversions. Various urban forms were constructed in response to the different landscape conditions in each town. The area is also at high risk of flooding, and three different approaches to flood prevention were adopted: internalising flood-adaptable water landscape within the town (Water environment adaptation type), consolidating the town on safe higher ground (Topography-defined type), and integrating river embankments for flood protection (Flood defence type).

Third, the two towns downstream of Tone River (Tsuchiura and Sakura) have in common that their towns are located facing large swamps, but they do not share the urban typologies. After Tone River Diversion, the swamps in the downstream region experienced more frequent flooding. The towns adjacent to these swamps were forced to respond to this change of river dynamics, but their approaches differ. In Tsuchiura, where the main factor of flooding was by the high-tide from the sea, the adaptive urban structure was strengthened (Water environment adaptation type). While in Sakura, which was directly impacted from the rainfall upstream, urban functions that were located around the swamp were relocated and consolidated in a town that was built on a plateau (Topography-defined type). These varying responses to changes in the landscape dynamics and water flow have resulted in the development of different urban forms.

The above shows that the division of areas into upstream, midstream and downstream and typologies of urban form does not accurately describe the relationship between river landscape and urban morphology or Tone River Basin. It is reasonable to assume the impact of the river landscape on urban morphology in the midstream and downstream regions is greater than that of the upstream with narrow and high velocity watercourse. Consequently, various urban forms have emerged in order to accommodate these dynamics in the castle town plan. The principle of spatial composition is the establishment of a living environment that is adaptable to water flow in relation to the topography of the context.

Reviving early modern water management for modern climate adaptation

In early modern castle towns, there was an inherent relationship between the built environment and the natural landscape. These castle towns were not only designed to respond individually to the river landscape but also functioned as comprehensive flood mitigation systems. Similar to the "Room for the River" project in the Netherlands (2006-2015), where 30 projects were integrated to work as a unified system - these towns collectively managed water flow and flood risks. They were interconnected, ensuring flood mitigation efforts were across the entire region rather than just within isolated areas.

However, as modernisation and industrialisation progressed, particularly after the Meiji era (1868-1912) and during the postwar economic boom, this integrated approach began to weaken. The space allocated for water management such as embankment in the upper stream was abandoned and the crucial connection between rivers and spatial development was replaced by strengthening the dikes and widening the river beds. As a result, increased discharge to low-lying areas intensified flood risks, highlighting the effectiveness of river watershed system wide water management practices (Okuma, 1991).

Revisiting these lost connections offers valuable insights for addressing flood risks and creating healthier, more sustainable urban environments. By integrating green infrastructure that aligns with natural landscape systems, we can develop adaptive typologies, especially in flood-prone areas. Grounding urban development in river dynamics, as seen in historical planning, can better inform modern climate resilience strategies and enhance the sustainability of urban landscapes.

CONCLUSIONS

This study reveals the urban form of early modern castle towns in balance with the landscape in Tone River basin in Japan. Each of the urban form typologies found in this study has a different approach to adapting to the river landscape. It can be said that the differences in urban forms are, in other words, differences in the approach to how the living environment is constructed in finding the balance with the river landscape.

A key finding of this study is that urban form typologies do not necessarily align with the regional divisions of upstream, midstream, and downstream, but are instead specific to the river dynamics of each site. It is more appropriate to interpret that urban typologies were established through individual adaptations to the river landscape dynamics interacting in the cross-regional relationship of the entire basin, instead of a general model of urban form for each region. The spatial composition was significantly shaped by water dynamics, geological conditions, and topography of the site, which made a sustainable relationship.

Forming such a harmonious relationship between urban form and the basin-wide river landscape is also being addressed in flood mitigation systems adapted to contemporary climate change. The principles derived from this study offer valuable insights for spatial design and basin-wide flood management planning.

In addition, the urban form of early modern castle towns in Tone River basin can be seen as a representation of the human effort to explore and establish a living environment that could co-exist with the river landscape. This attitude of working with landscape dynamics and striving to find a way of living with these dynamics provides important insights for contemporary urban and landscape design in the era of climate change.

The contribution of open circulation spaces to the socio-environmental quality of the city: infrastructure and connections in Campos dos Goytacazes/RJ

ABSTRACT

Among the important structures that make up urban form, the Open Space System is the result of the formation and production of urban spaces. These systems are related to subdivision norms and land use, geo-biophysical support, the society that lives in them and their economic and sociocultural demands, whilst also maintain links with built spaces. Within this system, open spaces for circulation, such as streets, sidewalks, and cycle paths, stand out, as they connect the other open spaces. Facing climate change, Open Space System plays an important role in urban areas, because in addition to being spaces for leisure and social interaction, they perform functions such as preservation and conservation and can improve the quality of the urban environment. For these spaces to work properly, it is necessary to ensure that everyone can access them, reinforcing the role of open circulation spaces. These can contribute to the quality of the environment by connecting other spaces and by incorporating features that contribute to the environment, such as urban trees and urban drainage systems. In this context, healthier, non-motorized, forms of travel, such as walking and cycling – known as active mobility - are also considered. This research, therefore, focuses on circulation spaces, aiming to analyse, in Campos dos Goytacazes/RJ, their capacity to connect other open spaces, understanding whether this structure contributes to equal access and healthier commutes. To this end, in addition to reviewing the literature on open spaces and active mobility, this research prepares and carries out critical cartography and field surveys. Even with its hot climate the city has potential for promoting active mobility as it is flat and has short commutes. What the research will show, however, is that open circulation spaces reproduce the following logic: narrow sidewalks, without standardization, without trees or other elements that mitigate temperatures and disconnection between elements, deprivileging active mobility.

Keywords: open circulation spaces, active mobility, urban socio-environmental quality

INTRODUCTION

The following paper is fruit of both the results of the author's PhD, that was about the Open Space System of Campos dos Goytacazes, a city in the state of Rio de Janeiro, Brazil, and subsequent studies that focused on an important category in the same system: open spaces of circulation. Studies that make use of surveys, mapping and debates about urban mobility to examine active mobility and the

structure of the city, or in other words, the street, and evaluate characteristics that can contribute to a better quality of commuting around the city.

As a component of urban form, the Open Space System evolves in conjunction with a city's growth and development, adapting to changes in functionality and characteristics. Urban form refers to the different spatial patterns and arrangements that cities can adopt. These forms are influenced and molded by diverse factors, such as physical, historical, cultural and technological aspects, and urban planning. They are made up of open and built, public and private, legal and illegal spaces. Urban form is a social product, but at the same time a prerequisite for social processes (Lefebvre, 2001). It encompasses the interrelationship between the physical structure and the processes of formation and transformation achieved by the various actions that shape the spatial configuration of a city. Urban form is susceptible to the influences of different factors that act upon the urban territory, whether physical or otherwise, and ultimately leave their mark on the shape of a city.

The physical aspect is composed of elements of relief, soil, water, and vegetation, which are superimposed upon the productive and occupational structures, representing the initial basis for the formation of any settlement. These structures have been built or modified by human action. In this context, living beings, especially human beings – who are particularly responsible for the processing of elements of the city (Macedo, 2012b) - group together, organize themselves and move around. In urban settlements, one of the main actions of the processing and modification of the landscape occurs through urban planning and the division of land use. These actions define the relationship between public and private spaces, built or non-built areas, generating morphological structures that make up the urban form, these very structures shaped by social and legislative standards (Aliprandi, 2017).

Within the set of morphological structures generated by land division it is the spaces free of buildings that stand out. Open Space has been defined by Miranda Magnoli, since the decade of 1970, as: “all of the space that is not occupied by a built volume (soil-space, water-space, light-space around buildings that people can access)”[60] (Magnoli, 2006b, p.179). An open space is one that is uncovered and may or may not include natural elements such as vegetation. It may be designated as public or private, and may be utilized by pedestrians, vehicles, or for the purposes of environmental conservation. Moreover, according to the same author, in the urban context, open spaces should always be understood in their relationship with built volumes, because: “[...] each one explains itself through the other, through its interdependence”[61] (Magnoli, 2006a, p. 152).

Open spaces form, according to Lima (1996), a pervasive fabric that permeates all the urban space. They are more susceptible to transformation over time, because within the urban context, as Macedo (1999) affirms, they are subordinated to forms of property and land division, they suffer the pressures of the formal and informal real estate market, and are transformed by urban infrastructure investment (Macedo, 1999; Tângari, 2013). Open spaces cannot be analyzed or proposed in isolation. It is necessary to recognize the inter-relations between them and, moreover, their relationship with biophysical aspects and with living beings, whether human or non-human, which consequently

60 The original: “O espaço livre é todo espaço não ocupado por um volume edificado (espaço-solo, espaço-água, espaço-luz ao redor das edificações a que as pessoas têm acesso)”.
61 The original: “[...] cada um se explica na medida do outro, na interdependência”.

enforces the idea of system (Bertalanffy, 1995 apud Uhlmann, 2002), forming in this way the Open Space System.

The Open Space System has important functions in the urban landscape. This includes the constitution of the image of the city, the exercise of leisure activities, and the implementation of the public sphere, which refers to all of public life, including debate and communicative action, which means that the general public sphere can be, in a strict sense, the political public sphere (QUEIROGA, 2014). This is due to the freedom that open spaces, especially public open spaces, can offer, providing access, use and appropriation for different groups of society. Furthermore, it can help improve the quality of the environment, because open spaces whether public or private, can provide the opportunity to produce food for domestic or commercial consumption, through the planting of vegetables, which can improve the air, the microclimate and the physical health of living beings, whilst also providing leisure and relaxation activities that can bring mental health benefits. With this said, facing the current climate change situation and the role that the Open Space System can have in this context, urban planning must recognize it as an important infrastructure of the city.

The Urban Open Space System include different categories of spaces that maintain this systemic interrelationship between them: spaces geared towards permanence (squares, parks, lakes, gardens, clubs etc.), areas geared towards circulation (sidewalks, streets and avenues, roundabouts, railways etc.), areas related to infrastructure (gas pipelines, water pipelines, electricity cables etc.), residual spaces (empty lots, expropriated land, slope stabilization etc.) and open spaces of environmental character (which are subject to environmental legislation and not authorized to be urbanized) (Aliprandi, 2017).

The open spaces of circulation are fundamental to connect the other open spaces of the Open Space System, whether public or private, and the built areas. It is by way of the street that we get to work, to school, to nurseries, hospitals, parks, squares, and to a number of different important spaces of our everyday lives. The street, in particular, is a fundamental element in the structure of a system and can be considered the most important public open space of the city (Macedo, 2012a; Macedo et al., 2015).

The street, including its sidewalks, is an important public open space, because beyond its role to provide a place for circulation and articulation between places and other types of other open spaces, whether public or private, it can accommodate other activities, as Jacobs affirms (1961, p. 29):

> Streets in cities serve many purposes besides carrying vehicles, and city sidewalks—the pedestrian parts of the streets—serve many purposes besides carrying pedestrians. These uses are bound up with circulation but are not identical with it and in their own right they are at least as basic as circulation to the proper workings of cities.

For the Open Space System to work and the aforementioned functions (constitution of the image of the city, the exercise of leisure activities, the implementation of the public sphere in general and the improvement of environmental quality) to perform well, it is necessary to guarantee that everyone has access to diverse elements, reinforcing the fundamental role of the open spaces of circulation. By connecting these other spaces, they can contribute to the quality of the environment.

Moreover, they can incorporate characteristics that contribute to the environment, such as urban trees, for example, and can serve as a platform for the development of healthier forms of commuting, by less motorized means, like walking and cycling, now known as active mobility.

Urban mobility can be understood as the ability to move around a territory (Vasconcellos, 2001). It involves the circulation of individual vehicles, collective transport, freight vehicles, bicycles, pedestrians and animals. All these types of circulation should work in a systematic way, or in other words, through a certain degree of interdependence on one another. Daily commuting involves different modes of transport, which should operate in an integrated way, but more active mobility represents the weakest type of circulation within this system.

In Brazil, since the 1980s, we have seen the prioritization of individual motorized transport in urban planning. This context has created more space for cars, broadening roads, allowing for faster speeds, and consequently, amid these transformations, sidewalks and cycle paths began to lose space, making the roads more dangerous, warding people off. Since the introduction of motorized vehicles in the city, roads have been broadened in detriment to the surroundings and to the existence of vegetation, making the sidewalks narrower and interspersed with different elements, like posts and signs (Macedo et al., 2018).

The possibility of circulating around the urban environment enables individuals to establish a relationship with their surroundings, and, therefore, experience the city. For this movement to happen in a healthy way, the urban environment must have an adequate infrastructure, guaranteeing security and comfort for those who move around it every day. According to Andrade and Lonke (2017, p.60): "The healthiest alternative is to promote active transport, which includes walking and using non-motorized transport – a bicycle, for example -, and linking it to public transport"[62]. It is important to emphasize that no mode of transport should be considered unsuitable or as an option to be abolished, but it is necessary to rethink the priorities of current planning, especially when facing climate change, an urgent reality to be addressed.

Considering this discussion, now we will direct our observation to the city being studied, Campos dos Goytacazes, in the north of the state of Rio de Janeiro. Situated 290km from the capital, it is the state's biggest municipality, extending 4,037.7km², with a population of 463,731, 90.30% of which live in the urban area (IBGE, 2010). It stands out in the region's economy due to the activities connected to the extraction of oil and gas from the Campos Basin.

During a long period, the economy of the region was based on sugar cane production, from the town's foundation in the XVII century until the industry's decline in the 1970s and 80s. The municipal resources have increased significantly due to the oil royalties received since the discovery of the oil in Campos Basin, in the 1970s.

As a result of the economic changes, the urban area began to spread over the countryside, causing a significant rural exodus and consequent problems with housing, service provision and urban infrastructure. Among these problems the shortcomings concerning urban mobility stand out,

62 The original: "A alternativa mais saudável é o incentivo do transporte ativo, que inclui caminhada e uso de transporte não motorizado - bicicleta, por exemplo -, somado ao transporte público."

exacerbated by the extensive way the expansion took place over the territory, comprising of vast plains which are irrigated by the Paraíba do Sul River, and the prioritization of the use of cars.

The city has a humid tropical climate, with high temperatures during most of the year, presenting a flat topography throughout its urban extension. The distance from one end of its urban area to another is no further than 15km, a characteristic that, considering that it is a plain, could contribute to active mobility in the city, but also represents a challenge for a city with a hotter climate, which is Campos' case. Previous studies have shown that the open spaces of circulation in Campos dos Goytacazes are lacking in physical characteristics and connectivity, but also present potential regarding use and appropriation and for the effectivity of urban connections, as we shall show.

Consequently, there has been an increase in interest in understanding if the city in question, considering the mentioned characteristics, presents the infrastructure that could contribute to this type of commuting. Questioning, moreover, if the current structures contribute to equal access to the different elements of the city's Open Space System. Thus, this research focuses on the spaces of circulation in the city of Campos e Goytacazes, evaluating its capacity to connect with other open spaces, understanding whether this structure contributes to the equal access to them and whether it contributes to healthier commuting.

The following section will present the steps taken and the potential avenues for discussion. It will also present the methodology and its stages, the results of the surveys conducted thus far, and some cartographies. Finally, the conclusions reached so far will be presented.

METHOD

There were three main stages to the methodology used in this study: revision of the literature about open spaces and active mobility, as presented in the previous section; a field survey and the elaboration of critical cartography.

Although the most important part of the street is that used exclusively for motorized vehicle traffic, the infrastructure geared towards active mobility involves the whole street, given the constant interrelationship between the roadway, pedestrians and cyclists, especially by way of street crossings. Despite this, the research focused on the sidewalks and their characteristics, because no other studies about them in the city of Campos were found. Furthermore, from the perspective of the sidewalks and observing their capacity to connect other elements of the structure and other modalities, it showed itself to be a sufficient tool of analysis for this moment of research.

The survey method includes six characteristics that are analyzed during the field visits (Soares e Aliprandi, 2024):

- Technical: aspects like the dimensions of the sidewalks are observed, if they fit into the minimal dimensions required by legislation and allow for the exercise of necessary activities, the existence and conditions of ramps and tactile signs, and the conditions of the preservation of these sidewalks.

- Use and benefits: aspects such as how commerce affects the use of sidewalks are observed, as are the ways in which the front of residential buildings or businesses interfere and whether street furniture, like bins and benches, exist and are efficiently available.

- Environment: here we analyze shadow, whether there are elements that provide shadow, such as trees, and whether they are sufficient to provide comfort to the user. In addition, we observe if there is rubbish in the street and whether it is correctly disposed of in bins and, also whether the noise pollution is at an acceptable level or not.

- Security: we analyze whether there is efficient public lighting, if the street crossings that are normally used are in the correct place, and whether signs are present in a satisfactory way.

- Circulation and mobility: we analyze the flow of pedestrians, whether it is possible to walk without interruptions or if there are obstacles that could be avoided on route, we also analyze the circulation of motorized vehicles, observing whether cars are within the ideal speed, and if the size of the street blocks is adequate.

- Interaction with other modalities: we analyze the interaction of the sidewalks with the cycle paths, if there are cycle paths or routes nearby. Concerning public transport, we analyze whether there are bus stops nearby and, regarding the general interaction between sidewalks, cycle path routes and public transport, we observe whether the three modalities interact well, whether there is the necessary structure for this.

From the forms elaborated in the field, which analyze the stretch of a sidewalk from one corner to another, the characteristics are inserted into maps through the geoprocessing program Arcgis, which permits a visual analysis of the distribution of the infrastructure and an overlaying of the information on the territory, allowing critical reflections about the results. In addition, the trees on the sidewalks are mapped in the same program, which made it possible to analyze their distribution and their influence on mobility. These new maps are read in parallel with the analyses already carried out in the doctoral thesis, confirming or complementing the notes made at that time.

RESULTS AND DISCUSSIONS

The municipality of Campos dos Goytacazes is in the northern region of the State of Rio de Janeiro, Brazil, with eight neighboring municipalities: São João da Barra, Carapebus, Cardoso Moreira, Conceição de Macabu, Quissamã, São Fidélis, São Francisco de Itabapoana and Macaé, as shown by Figure 1. The region has an area of 9.730.443km² and a population of 861,084 inhabitants (IBGE, 2010). The study presented here focuses on the area inside the urban perimeter, demonstrated in Figure 2.

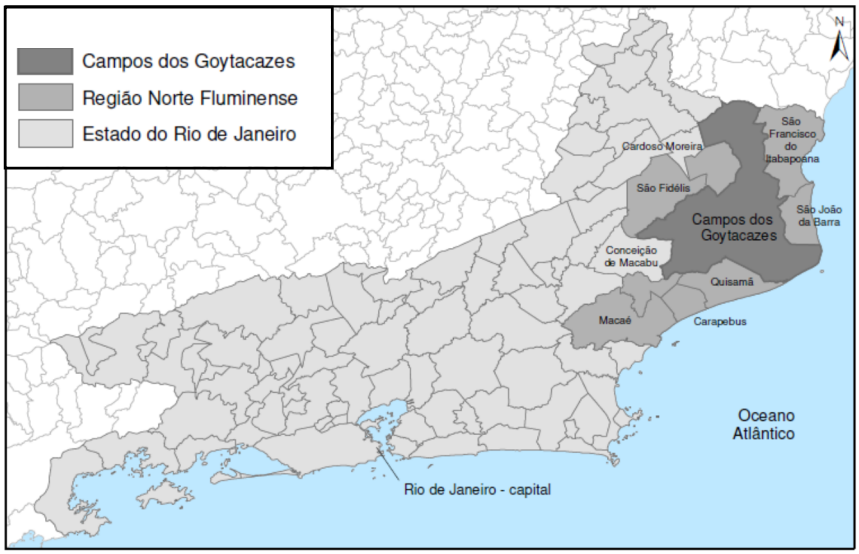

Figure 1: Location of the municipalities of the north of Rio de Janeiro and the state capital. Source: Aliprandi (2017), based on IBGE (2010) data.

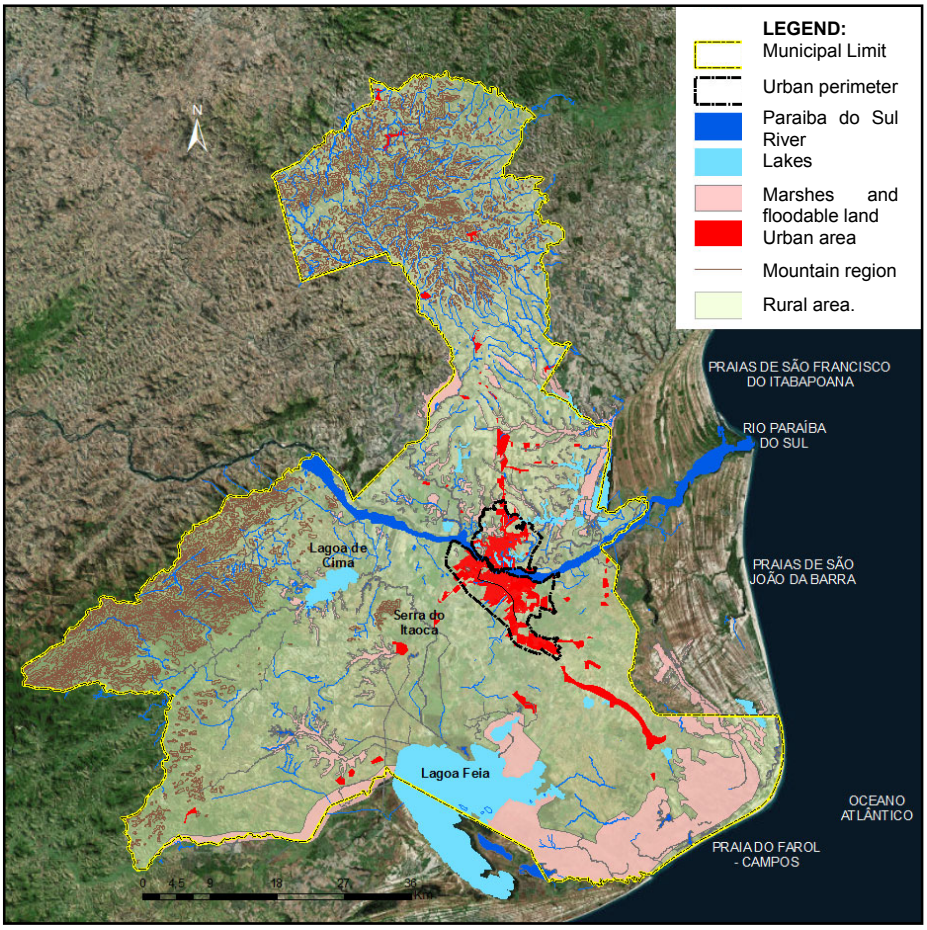

Figure 2: Campos dos Goytacazes Municipality and localisation of the urban area. Source: Aliprandi (2017), based on the IBGE (2010) and PDPCG (2008) maps and the field surveys.

In the author's thesis (Aliprandi, 2017), the Open Space System of the city was evaluated in terms of its qualitative characteristics: environmental, social and aesthetic. Environmental quality is related to

the maintenance of permeable areas that contribute to permeable areas, and to the creation of microclimates, primarily due to the existence of large vegetation. This vegetation increases shadow and the retention of particles of air pollution, whilst also promoting the existence of animal life. Moreover, in the case of urban circulation, it facilitates the movement of pedestrians and cyclists. Social quality is concerned with meeting the social demands of the population, which are heterogenous, consequently the Open Space System must adhere to the principles of access equality and of multifunctionality. This allows for a balanced and diversified distribution of the types of open spaces and functionality. Aesthetic quality is related to the image we create of the city.

To perform this evaluation, field observation was carried out, which was later supplemented with information from Google Earth and Google Street View, filling in Table 1, considering each urban sector defined in the doctorate research (Figure 3):

TYPE	SUBTYPE	Characterisation				Accessibility			Social Practice/ Activity	Landscape characteristics			
		Legislation	Dimension	Title situation	Management	Physical Access físico	Protocol	Visual Access		Conservation	Urban furniture	Paving	Vegetation - Trees
Environmental character	sustainable use												
Urban character	related to permanence												
	related to circulation												

Table 1: Model used in the evaluation of Urban Space System attributes

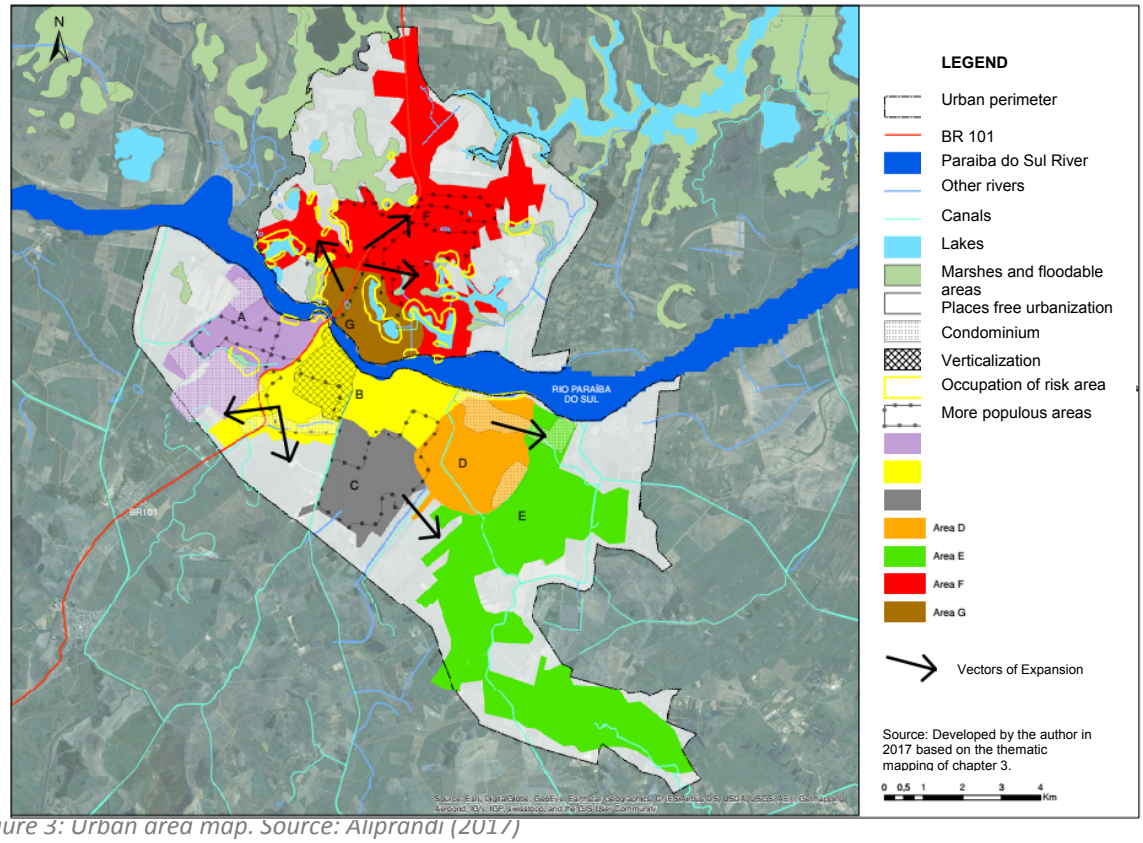

Figure 3: Urban area map. Source: Aliprandi (2017)

The sectors are the result of the overlaying of the mapping of characteristics like private open spaces, the presence and distribution of public open spaces and the distribution of population and income in the city's territory, including the form in which some urban problems are distributed in the city, such as urban fragmentation, spatial segregation, the treatment of water resources, to mention just a few. It is not within the scope of this paper to engage in a deep discussion about these problems and about the division of these areas, as they are a result of an analysis that goes beyond the issues presented here. It is worth highlighting, however, that carrying out area research contributes to the comparative analysis about the behavior of the problem analyzed all over the territory.

As our focus is open spaces of circulation, and considering Table 1, the most relevant issues for this analysis are found in the characteristics "Social practice/activity", identifying whether the streets allow for diverse uses, beyond circulation itself, "Paving", identifying the types of road surface, observing the permeability of the ground, and "Vegetation", with a focus on the existence of trees. About the latter, in current study that also being carried out guided by the author, the urban tree canopy in the city is being mapped, and the findings so far have confirmed the existing data. In addition, the mapping of sidewalks, presented in the methodology, analyses and complements the item "Vegetation", by identifying the areas with shadow, and the item "Urban furniture/buildings", that are elements that are considered in the categories "Uses and benefits", "Security", and "Circulation and Mobility", also explained in the methodology.

What was observed is that the open spaces of circulation in the city are somewhat impermeable, generally paved with tarmac, with a few examples of cobblestone streets, particularly in the limits of

the urban perimeter. The streets have few trees, presenting merely 10 to 30% of urban tree canopy, a situation which worsens in the more central area B, and its neighboring area A. Regarding social practices, with the exception of central areas B and G, it is possible to find different activities, like children playing in the streets or people sat on the sidewalk, a more prevalent phenomenon in the residential neighborhoods.

In relation to the most up-to-date mapping of the characteristics of the sidewalks, seeking to test the method and carry out an initial analysis considering the diverse urban areas of the city, points of analysis scattered around the territory were chosen, shown in Figure 4. The points chosen were crossroads, permitting the analysis of at least four streets in each place. Thirteen stretches were selected considering as criteria, apart from being crossroads, being spots with large facilities such as shopping centers and bus terminals, as they are areas of high pedestrian traffic.

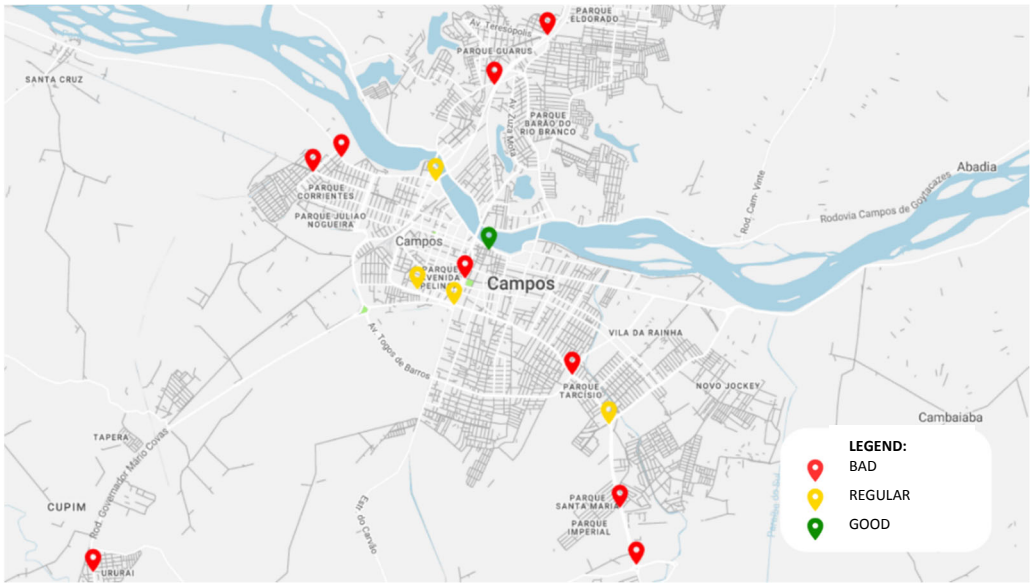

Figure 4: Points mapped in the first cycle of the study. Source: Layla Soares, IC grant student (2024).

The data is collected on site using the survey form and in the laboratory the data is used to fill in a attributes table from Arcgis. With the compilation of this data, the stretches observed receive evaluations as can be seen in Figure 4: red = bad, yellow = regular; and green = good. The result showed here is more general, to illustrate the method. It to present the map of each category and their subcategories goes beyond the scope of this paper, consequently we cannot analyze the issues separately, but we will highlight them below.

Through the survey it was possible to observe that the sidewalks face some common problems, such as the lack of accessibility, where tactile paving, access ramps, signs, satisfactory safety and preservation provisions are not identified, making walking more difficult. Furthermore, we identified high levels of noise pollution due to the significant number of motorized vehicles, a lack of urban furniture and shelter, including trees, exposing the pedestrians to sun and rain.

The spot marked in green on the Figure 4 is in the historical center of the city. It is a place where the roads are well maintained, well-lit and well shaded, but this is mainly due to the shops along the street and the fact that the streets are narrow, bringing the buildings closer together. The sidewalks, however, are very narrow and there are many obstacles, owing to the shops that line the sidewalk.

The occupation of the sidewalks by businesses is a common occurrence in the other spots studied, interrupting the flow of people. The dimensions and quality of the sidewalks, and of the crossings, considering both how they were engineered and how they are maintained, are the points that most interfere in the flow and use of the sidewalks. The situation is more precarious in places in more peripheral areas, where we find most of the red points on the map.

During the survey we perceived and witnessed various challenges to the simple act of walking in the city, from the bad maintenance or incorrect choice of workmanship, narrow or almost inexistant sidewalks, lack of adequate signaling for pedestrians, traffic lights with insufficient time to cross, to the numerous violations of traffic law, mainly disrespecting pedestrians. These observations are best presented in the article by Soares and Aliprandi (2024).

Concerning cycling in the city, there is not a detailed mapping in this study about the characteristics of the structure, like is being carried out about the sidewalks, but it is important to highlight that the city went through a number of reforms in its cycle path network in 2023 and 2024, expanding the possibilities of the circulation of this category, connecting points in the city that were previously excluded from the network, reducing problems of discontinuity that were faced by the cyclists. In the map shown in Figure 5 it is possible to observe the plan of this modification.

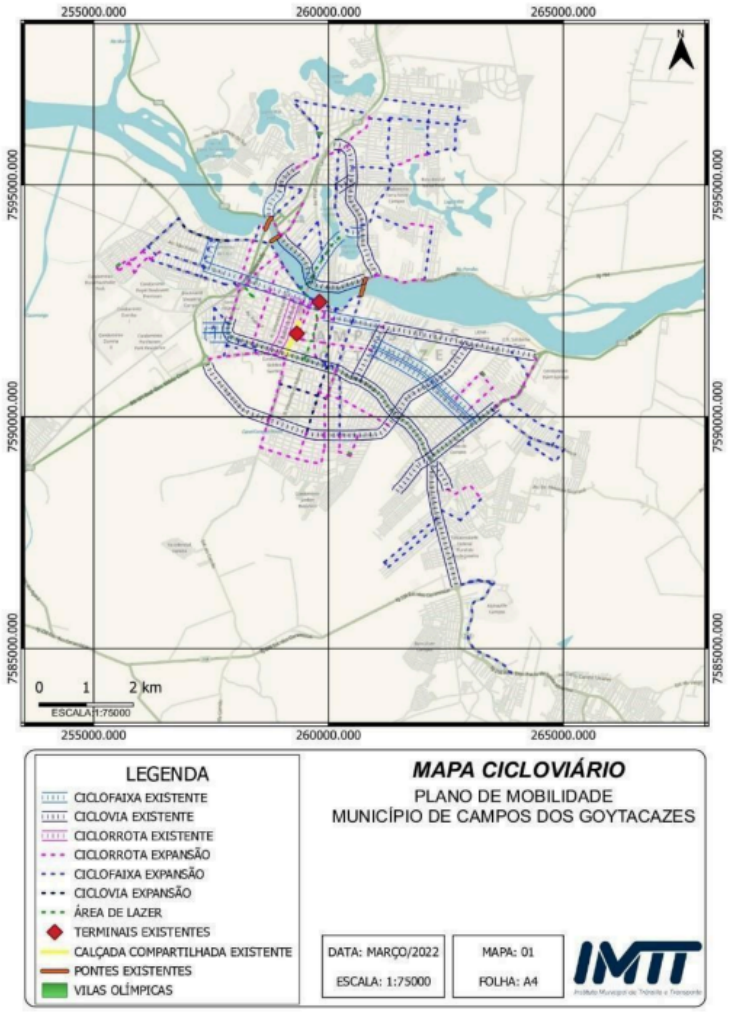

Figure 4: Cycle map of Campos dos Goytacazes proposed by the Mobility Plan. Source: Made available by the Municipal Institute of Traffic and Transport (IMTT) during a meeting (2022).

During some field trips to observe this infrastructure, people were seen walking and running on the cycle paths and lanes in many stretches, a lot of the time because of the surrounding precarious sidewalks, it doesn't existent urban facilities that support cyclists, like bike racks, and also other problems like unevenness in the sidewalks and narrow cycle lanes and dangerous intersections.

CONCLUSIONS

Considering the data shown, the infrastructure for active mobility in the city of Campos dos Goytacazes does not contribute fully to the promotion of this type of commuting, particularly the circulation of pedestrians. The findings indicate that the infrastructure is of a low quality and does not allow for a pleasant or safe pedestrian experience, hindering the access to the city's other open spaces, via this mode of circulation. Whilst in relation to the cycle path network, there is a significant improvement, broadening the possibilities of use and access to several spaces in the city, and therefore the safety of its users.

The integration between the modes was positively evaluated in terms of its potential, as it was identified that public transport routes and some kind of bicycle network could be easily accessed in

the spots analyzed. It is important to stress, however, that even so they lack support facilities, like bus stops and bike racks, other problems in the crossings were also identified, making the integration unsafe. Furthermore, the high impermeableness of the ground and the low number of trees in the open spaces of circulation in the city stood out, which can have a detrimental impact on environmental quality.

The data collected and analyzed thus far reinforces the importance of this study and the need to continue with the surveys, which can provide more precise information, so that future public interventions can be more efficient.

Acknowledgements

The financial support of the Research Support Foundation (Fundação de Amparo à Pesquisa - FAPERJ), through the creation of the research laboratory and the scientific initiation scholarship has been fundamental. Also, Campos dos Goytacazes City Council, through the More Science Program (Programa Mais Ciência), and the Federal Fluminense Institute (Instituto Federal Fluminense) for providing scientific initiation scholarships. The latter also for its support in carrying out the research.

ABSTRACT

The green city seeks to intertwine greenery, landscapes and agriculture into townscapes to create a sustainable urban form that will support high standard of living with nature, increased biodiversity and circular flow of resources. This paper conceptualizes and discusses visions, scales and elements of the agroecological urbanism and the green city through morphologically informed urban design. Urban designers analyse cities in three dimensions, whereas urban morphologists understand cities as a hierarchy of design elements: streets and their layout, plots and their aggregation in blocks, buildings, and land uses. The green city can be morphologically understood as a set of design elements such as windows farms, roof gardens, vertical farms, greenhouses, community allotments, backyard gardens, etc. that can be composed within the morphological hierarchy of cities. The urban agricultural systems and agritech (a shortening of agricultural technology) can utilize local wastes and employ underutilized space in urban areas for food provisioning to circulate resources. This includes e.g. vacant buildings, parking garages, basements, roofs, storage rooms, shipping containers, etc. Bringing urban morphology, landscape architecture and architecture, urban agriculture, landscape and industrial ecology together opens possibilities to better understand needs and challenges in developing productive green cities.

Keywords: green city, typomorphology, urban agriculture, food production, nutrient circularity

INTRODUCTION [Heading 1]

The future requires bold disruptive visions of future cities to achieve smart sustainability challenges. The green city prioritizes environmental design, greenery, landscapes, agriculture and townscapes that intertwine in a sustainable urban form that supports high standard of living in nature, biodiversity and circular flow of resources. The green city relates to buzzwords such as urban village, eco-village, eco-town, garden city (reviving a concept from the end of the 19th century), sustainable community, sustainable urban extension, etc. (Cowan, 2021). In parallel, smart sustainability emerges as a new transformative approach focusing on development of eco cities and sustainable neighbourhoods, digitisation of urban infrastructure, and collaborative experimentation with low-carbon and digital technologies (Evans & Karvonen, 2014; Evans et al., 2016; Cugurullo, 2021). This paper looks and discusses green architecture and eco city visions from self-sufficient hermit huts to social utopias,

working cities and productive landscapes (Howard, 1898; Le Corbusier, 1987 [1925]; Wright, 1935; Viljoen et al., 2005; Gorgolewski et al., 2011; Viljoen, A. & Bohn, 2014; Davis, 2020), informal urban agriculture (Hardman & Larkham, 2014), landscape architecture and urbanism (McHarg, 1992 [1969]; Turner, 1996; 1998; Waldheim, 2016), to emerging agricultural technologies (abbreviated as agritech) inspiring high-tech smart sustainability experiments (Farhangi et al., 2020), such as urban food labs or indoor, vertical or rooftop farms (Orsini et al., 2017; Martin & Molin, 2019; Martin et al., 2019; 2023; Martin & Orsini, 2023).

To discuss physical prerequisites and opportunities for agroecological urbanism and productive green cities, this paper converges perspectives from urban morphology, agriculture and food systems, and industrial ecology to conceptualize scales and elements for a handbook for morphologically informed urban design. Morphological analysis is defined by a hierarchy of three fundamental elements: streets and their layout, plots and their aggregation in blocks, buildings and land uses as building utilisation (Conzen, 1960; Moudon, 1997; Kropf, 2011; 2014; 2018). Urban designers focus on the experiential qualities of cities in in three dimensions (3D), liveable city and the human scale (Southworth, 2016). They combine imagery, diagrams, and maps to analyse and design cities (Talen, 2009). They develop typologies and they turn typologies into visions, design codes or Form-Based Codes (FBCs) with morphological methods (Duany & Talen, 2002; Carmona et al, 2006; Walters, 2007; Talen, 2013). Urban morphology informs urban design as hierarchy of design elements and sub-elements at various scales conventionally structured in urban design handbooks based on typologies. If urban morphology is about inference and interpretation of type, urban design is about invention of types and intervention using type in a systematic fashion (Marshall & Çalişkan, 2011). The agroecological urbanism of the green city can be morphologically understood as design elements at various scale such as rural and urban farms, community or private urban gardens, vertical farms and fields, windows farms, or roof gardens, etc. that can be integrated in the morphological hierarchy of the city. Many underutilized spaces in urban areas, particularly open spaces between buildings, that characterise the 20th century urbanism (Le Corbusier, 1987 [1925]) can be used for food provisioning and promotion of a circularity. This includes open green spaces, vacant buildings, parking garages, basements, storage rooms, shipping containers, and integrated in-store in commercial locations (Martin & Bustamante, 2021). This paper aims to inspire debates on implementing old and new urban agriculture technologies to produce high quality food and contribute to food security and nutrient circularity locally.

The city, nature and agriculture

The green city intersects cities and nature, integrating urban environments with natural ecosystems and agriculture needed to sustain cities. Figure 1 diagrammatises the relationships between cities, agriculture and nature highlighting aspects of investigation of the relationship where agriculture is cultivated nature typically understood as countryside and the city stands as opposite. The city is within the domain of urban morphology that looks at the formation of urban elements (streets/squares, plots and buildings) and their transformation over time, nature is conceived as landscape, ecology and biology. Landscape architecture, urban design and landscape urbanism have a unique location in this relationship to integrate vegetation and water (green and blue design elements) in cities as landscape ecology (McHarg, 1992 [1969]; Turner & Gardner 2015 [2001]). Landscape architecture is the art, science and technology of composing gardens for private or public use, and green spaces and outdoor environments as public realm with good social, aesthetic and ecological, incorporating landform,

vegetation and water elements with buildings, landmarks, built structures and paving (Turner, 2014). The term landscape ecology was introduced by the German biogeographer Carl Troll (1939) and combines the spatial approach of the geographer with the functional approach of the ecologist (Turner & Gardner, 2015, p.3, see McHarg, 1992 [1969]). It focuses on the spatial relationships among landscape elements, or ecosystems, the flows of energy, nutrients, plants and animals and the ecological dynamics of the landscape mosaic through time (Forman 1983).

Figure 1: Intersection of city and nature conceptualizing relationships between disciplines focused on the green city and urban agriculture

The food systems intersect agriculture and city starting with food production (on farms as cultivated nature or within natural ecosystems as hunting and gathering) through food distribution and trade (that includes global chains of warehouses, ports, transport and logistic infrastructure) to wholesale and retail food distribution (food markets at squares, big box supermarkets and grocers and supermarkets in buildings). Food preparation happens in kitchens and restaurants as sub-elements of buildings. The green city exist is many variations across the city, nature and agriculture fields. Some theoretical frameworks have roots in social utopianism, anarchism and even hermit communities, while others can be located in urban morphology and design, but incorporate biological and ecological narratives (from biomimicry, and biophilia, most radical assume generic engineering of proto cells to create living settlements), ecology and environmentalism (living in/living with nature), landscape architecture, etc. There is also permaculture that seeks to imitate natural ecosystem circularity for agriculture. To structure the literature of green cities and (utopian) visions that highlight agriculture, this paper starts with morphological dissection of scales and elements.

The morphology of the green city

Urban morphology studies the physical elements and structure of cities, the physiognomy and character of their buildings, streets or neighbourhoods. One of the important aspects is the resolution of analyses or the scale (Moudon, 1997). Figure 2 shows the theoretical framework for morphological resolution based on environmental perception of urban space and the public-private spaces morphological structure of cities from a private building and plot to a public street/square (Figure 2E). The environmental perception of urban space is shaped by anthropometrics in architecture (armreach) and personal and social distances in anthropology (Hall, 1959; 1966; Gehl, 1986 [1971]) (Figure 2A). The visual world is like a sphere around a person and is clear everywhere while the visual field is the area within the field of view of both eyes (Figure 2B). The field of view is clear in the centre (foveal vision) and vague in the periphery (defined by Gibson, 1986) and the visual acuity is within a

radius of 100-200 m. Visual perception is enhanced when supported by related auditory cues and vice versa. Sounds provide an important link to reality, are enriching and protective (Southworth, 1967; 2020). Sounds come from any directions. They are aural and turn the head around (Stojanovski & Axelsson, 2018; Axelsson, 2020). The operational environment defines the space where people move and work. It is a movement space and can extend up to 100 kilometres. The perceptual environment is the space where people are directly conscious and to which they give symbolic meaning (it can extend up to 1 kilometre). In the behavioural environment, people are not only aware but also perform behavioural response (Rapoport, 1977). Figure 2C show the nested structure of operational and perceptual hierarchy of environments, whereas Figure 2D shows the amoebic shapes that are created by the urban morphology and the physical and social factors that shape the inner behavioural environment, as well as the operational environment shaped by walking.

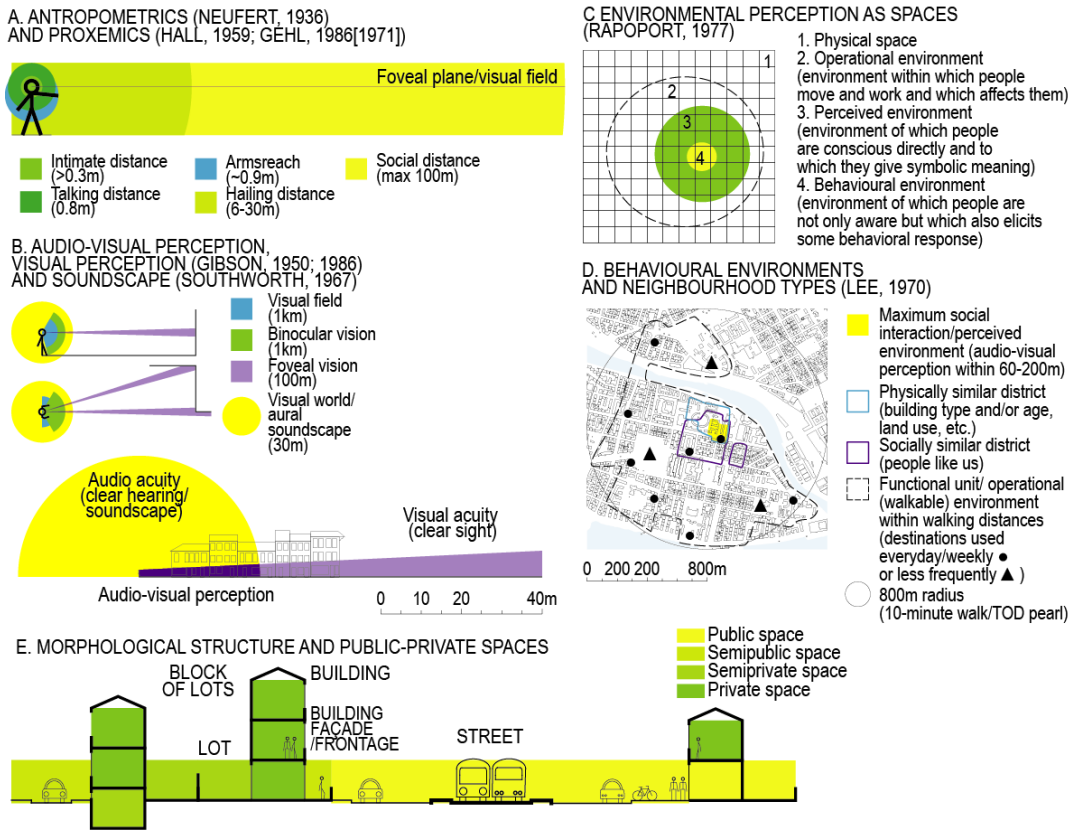

Figure 2: Theoretical framework for morphological structure of scales based on environmental perception

This paper furthermore explores the literature of green cities and (utopian) visions that highlight agriculture. It classifies concepts, projects, technologies, etc. by discipline, scale and agricultural technology level, by expert approaches and by regulations. To structure the literature review it uses a genealogical approach (Stojanovski & Samuels, 2023). Urban designers eclectically combine imagery, diagrams, and maps in urban design handbook urban design manuals (Bentley et al, 1985; 2024; Talen 2009) and for advocacy for design guidelines (Duany & Talen, 2002; Carmona, et al., 2006; Walters, 2007; Talen 2013) as urban design can be defined as the art of making and shaping cities by creating compositions of morphological elements in physical space (Taylor, 1999; Marshall 2016). Figure 3 shows a diagram of urban agriculture, mapping important events, models, references, actors, etc. in respect to morphological schools and approaches (see Stojanovski, 2022) highlighting disciplines such as economy/geography, architecture and landscape architecture that worked with agricultural

models. There is a dominance of architects who worked with green architecture, self-sufficient communities and urban agriculture who developed visions from entire cities such as Le Corbusier and Frank Lloyd Wright, to biospheres and neighbourhoods as CPUL (Continuous Productive Urban Landscapes) to green buildings, indoor farming, guerilla gardening and foodscaping of urban spaces (Hardman & Larkham, 2014; Elmlund & Haas, 2019).

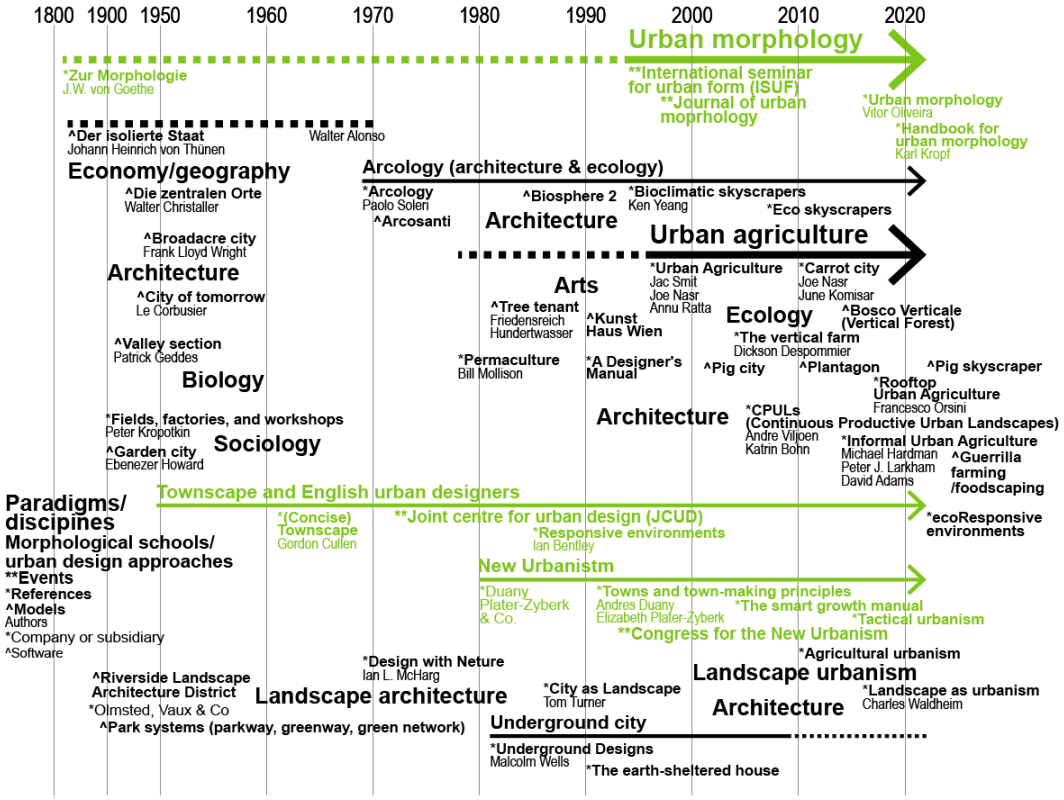

Figure 3: A genealogical diagram of urban agriculture, mapping important events, models, references, actors, etc. in respect to morphological schools and approaches (see Stojanovski, 2022, for the entire genealogical diagram of urban morphology)

Green city visions

There are various green city visions. Historically, the towns were a mix of city and agriculture located at transport foci surrounded by arable land and/or abundant fisheries. These historical towns/cities created a hierarchy of centres (smaller towns and villages) along transportation axes at a scale of an urban region. Johann Heinrich Von Thünen (1966 [1826]) proposed a theory of cities developing as concentric rings (Der isolirte Staat, or the Isolated City) based on transportation costs that was further developed in a theory of central places (Die zentralen Orte) by Walter Christaller's (1966, [1933]). With the industrialisation of agriculture and transport emerged models for self-sufficient communities and social utopia by thinkers as Henri de Saint-Simon, Charles Fourier and Robert Owen. A phalanstère (or phalanstery) was a type of building proposed by Charles Fourier in the early 19th century by Charles Fourier and designed for self-contained and self-sufficient community consisting of thousands people working together. Fourier combined the French word phalange (phalanx, an emblematic military unit) with the word monastère (monastery) to describe the social ethic of the utopian community. Peter Kropotkin created the most detailed model for social utopian community surveying food production in England in the 19th century. The community consisted of 200 families with five members, living on

1000 acres. 340 acres were to be used for growing the cereals like wheat, oats, barley, 400 acres used for all the green crops and fodder required to keep 30 or 40 cows for milk and butter and 300 heads of cattle for supply of meat. 20 acres were to be used for growing vegetables and fruits from which 2 acres under glass. Half an acre is attached to each house for hobbies and amusement, like poultry keeping, or any fancy culture, flowers, and in the end, there are remaining 140 acres for all sorts of purposes, like public gardens, squares, manufactures. Landscape architecture also emerged in the 19th century to address the need of green spaces in cities. Frederick Law Olmsted was pivotal in designing parks, parkways, greenways as green networks in cities that with green belts and wedges remain as a landscape planning and architecture typology for green spaces in cities (Turner, 1995; 2006). Ebenezer Howard (1898) summarised the industrialization dream of mixing city and countryside by proposing a polycentric city of tomorrow consists of railway suburbs that reside in the green tranquillity of the landscape and have a speedy connection to the diverse and exciting industrial, but polluted city. Le Corbusier's (1987 [1925]) city of tomorrow and Frank Lloyd Wright's (1935) Broadacre city created also visions of green and self-sufficient cities. Ebenezer Howard estimated roughly six times smaller agricultural area than Peter Kropotkin (6000-acre garden town assumes 5000 acres under agriculture to fulfil the needs for a city of 32000 people vs. 1000-acre community for 200 households or 1000 people), whereas Frank Lloyd Wright (1935) planned 1400 small farm units (8000 residents) on four square miles (2560 acres) in the Broadacre city. Paolo Soleri, a student of Frank Lloyd Wright planned the Arcosanti community of 5000 residents on a 4060-acre land preserve property, being one of the last agricultural utopias planned in that tradition.

A new revolution with urban agriculture, green architecture and landscape urbanism came with the environmental movement in the 1970s. Concepts such as permaculture (permanent + agriculture) by Bill Mollison, tree tenant by Friedensreich Hundertwasser, underground and earth-sheltered houses Malcolm Wells, etc. in the 1980s preceded a revolution in urban agriculture since the 1990s supported by development of new agritech (hydroponics, aeroponics, etc.). Some systems like aeroponics came out from trials to grow food on space stations in zero gravity (Stojanovski, 2023; Stojanovski & Adams, 2024). Furthermore, there is a new generation of entrepreneurs and enthusiasts as actors advocating for agroecological urbanism such as "artisan farmers", who are local businesses running farms that specialize in a specific crop (e.g. mushroom farms, salads, etc.) and supply local food with high quality and cost, typically to the local community and restaurants, "agrotechnologists" entrepreneurs developing new innovative agritech for global impact and markets, guerilla farmers or gardeners who grow food predominantly for recreation, and "agritects", typically architects who as professionals advocate for urban agriculture and green architecture, etc. This has created development of indoor and rooftop agritech, visions and experiments with vertical farming including pig skyscrapers (see Despommier, 2010; Gorgolewski et al., 2011). Food growing, farmer markets and food festivals also play important role in placemaking as guerilla gardening and city farming (Adams & Hardman, 2014; Hardman & Larkham, 2014; Hardman, et al, 2022).

Figure 4 classify the visions, concepts, models, projects, technologies, etc. by scale and agricultural technology level. Figure 5 shows them by expert approaches (professional farmers and agronomists vs. recreational agriculturists) and by regulations (formal permits for agricultural land uses or farming activities vs. informal placemaking acts such as guerilla farming/gardening). Most of the models and elements from landscape agriculture are summarised by Tom Turner (1995; 1996; 1998; 2006), whereas in architecture by Joe Nasr and June Komisar (as "carrot city" advocacy, see Gorgolewski et

al, 2011, Nasr & Potteiger, 2023, as depositories of urban agriculture concepts, models, projects, typologies, etc.). Additional resources are agritects such as Andre Viljoen and Katrin Bohn (2005; 2014), Janine de la Salle & Mark Holland (2010), Craig Verzone and Christina Woods (2021), and their books on productive landscapes, agricultural and food urbanism.

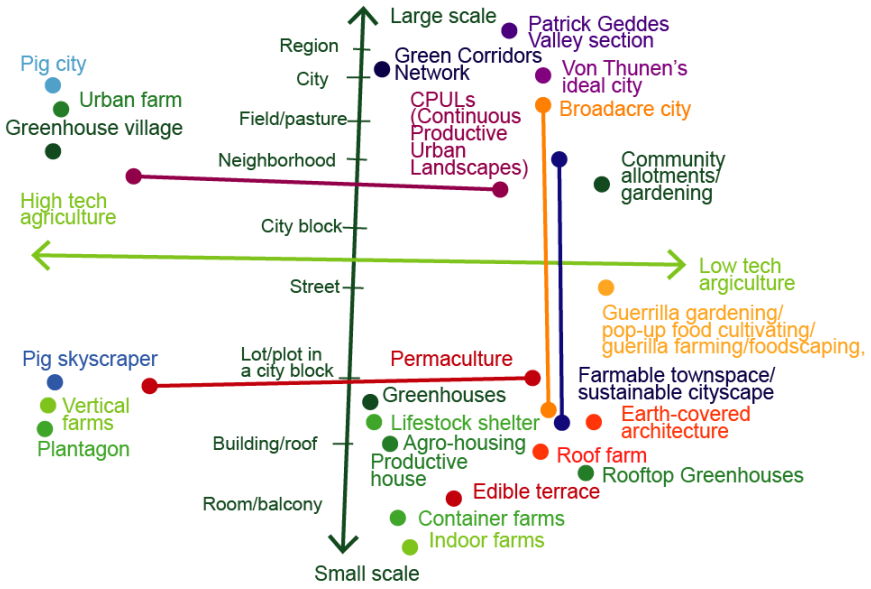

Figure 4: Urban agriculture and agroecological urbanisms by scale and agricultural technology level

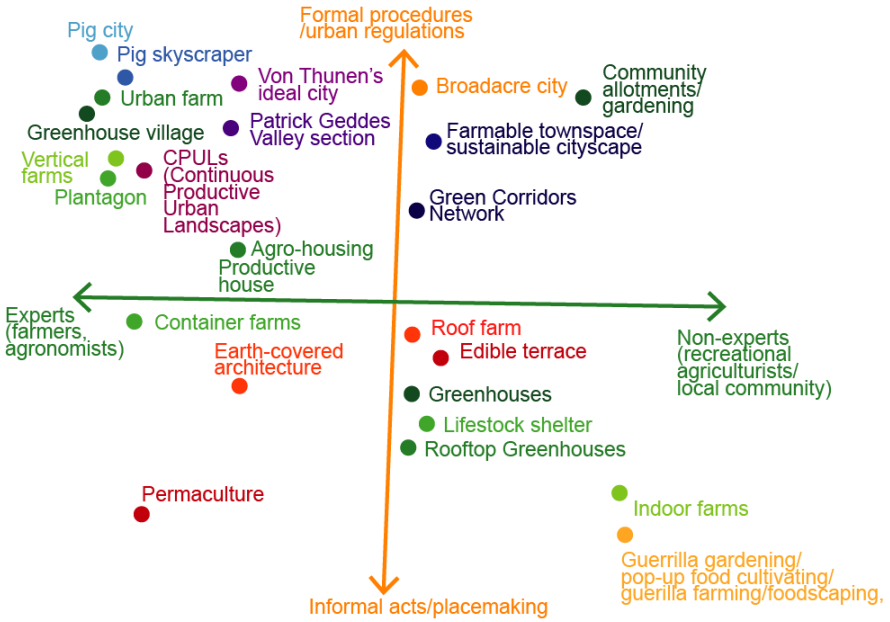

Figure 5: Urban agriculture and agroecological urbanisms by expertise and regulations

The figures above show visions, concepts, models, projects, technologies, etc. of urban agriculture and agroecological urbanisms at various scales with intention to map and classify morphology, scales and elements within a framework of perceptual morphology and inspire debate on integrating them in typologies of neighbourhoods, streets and buildings in various international contexts. The aim is to develop green city urban design handbooks considering local morphological context and perceptual constraints. Table 1 summarizes the visions for agroecological urbanisms, urban agriculture projects and agricultural technologies at morphological scales from a room to a city and it also juxtaposes

agricultural technologies and landscape elements in a respect to direct sun or shade, public and public spaces and accessibility.

Table 1: Morphological scales transposed with agricultural technologies and landscape elements

Morphological scales	Agricultural technologies and landscape elements	Insolation	Public space and accessibility
Room (windows, doors)	Pots, indoor farming systems (plant pods, indoor gardens), window farms	Partially in sun/shade	Private space (within an arm's reach)
Balcony/terrace (door, windshield)	Planting walls/hanging planters		
Building story	Composters	Shade	Private space (within an arm's reach)
Ground floor (entrances, doors)	Raised beds/containers/soft planters		Private space or public space (within a VIEWSHED)
Roof	Row of plants	Direct sun/ possibly shaded from buildings	Private, semi-private or semi-public (within an arm's reach)
BUILDING	Row of trees		
Building façades (windows, doors, balconies)	Arbor/pergola		Private space or public space (within a VIEWSHED)
PLOT/PARCEL	Greenhouses		Private or semi-public space (within an arm's reach and a VIEWSHED)
Backyards/open spaces	Livestock shelters/sheds		
Front yards/open spaces	Hydroponic/aquaponic systems		
City block front	Green façades		Public and semi-public spaces within a VIEWSHED/aural space of audio-visual perception (30-200m)
CITY BLOCKS	Parks, pocket parks, garden lots, community gardens, allotments	Direct sun	
Plot division			
STREET/STREETSCAPE	Strips of greenery/tree alleys		
Sidewalks	Street landscaping		
STREETS/ROUTES (as a neighbourhood pattern/hierarchy)	Boulevards		
	Parkways		
NEIGHBORHOODS/DISTRICTS (urban tissue)	Park belts		**Typically, public spaces in WALKABLE/ CICLYING RADIUS (15MIN CITY), 1.2km/5km**
	Green trails		
City (urban tissue)	Park system		
	Green belt		
	Greenway system		
Open space/agricultural land	Fields/pastures		Private spaces within VISUAL EXTEND (1km)
	Woodlands/rockcrops		
	Stables/stalls/corrals/pens/styes		
	Silos, barns, storages		
	Drainage systems and water treatment		
	Waste treatment and composting landfills		
	Irrigation/fertilization systems/fertigation		
	Pest management		
Region	Farms (urban, peri-urban and rural)		Private spaces within MOTORIZED ACCESS

Table 1 differentiate scales by colour. There is agritech that can be placed in a room or a balcony as sub-element of an apartment/house or building story. The roof and the open spaces on a plot (front and back yards) can use a range of technologies from pots and raised beds, greenhouses, livestock shelters/sheds, hydroponic/aquaponic/aeroponic systems as well as green walls. At a scale of city

block there are parks, pocket parks, garden lots, community gardens, allotments and the street space can include also agritech besides street landscaping. At a scale of neighbourhood and city there are parkways, park belts, green trails, park systems, green belts and wedges, greenway systems, etc. There are various elements of farms on agricultural land such as fields, pastures, woodlands, rock crops, stables, stalls, corrals, pens, styes, silos, barns, storages, drainage systems and water treatments, waste treatments and composting landfills, irrigation and fertilization systems (including fertigation tech) and pest management facilities and systems.

DISCUSSIONS AND CONCLUSION

This paper maps visions, concepts, models, projects, agricultural and urban technologies, etc. of urban agriculture and agroecological urbanisms arguing that green city can be morphologically understood as elements. This knowledge can be used to develop urban design handbooks and guidelines for green city considering local morphological context. The paper starts with a diagram of the interactions of the disciplines that tangle city, nature and agriculture and it defines scales of perceptual and cognitive morphology to analyse urban agriculture. It creates a tentative genealogy of the visions, concepts, models, projects, technologies, etc. and maps representative examples of visions, projects and elements firstly by scale and agricultural technology level, and secondly by agricultural expertise and by urban regulations. In the end, it presents a list of agricultural technologies and landscape elements in respect to the morphological elements at various scales, the need of insolation for the vegetation, considering the duality of public and private space in cities and accessibility. This paper sets a framework for writing an urban design handbook for green cities based on eclectic urban morphology.

There are various green city visions, some deriving from social utopianism, anarchism, environmental recluses and hermit communities, etc. Other come from wishes to integrate nature, living with nature, love of nature, biomimicry, and biophilia. There are many agritects' visions that seek to create green architecture and productive landscape, some can get radical forms as Malcolm Wells who promotes underground living (additional underground city scenario can be found in Stojanovski, 2007). There is another stream of green city concepts that seeks to integrate landscape in cities, starting from Frederick Law Olmsted, Le Corbusier and new proponents of landscape urbanism. Furthermore, there is a new generation of entrepreneurs and agricultural enthusiasts as such as "agrotechnologists" developing new innovative agritech, "artisan farmers" that innovate and animate local communities and business, as professionals and as recreational guerilla farmers and placemaking gardeners who plant and grow food predominantly for fun and relaxation. Food growing, farmer markets and food festivals also play important role for social cohesion and economic revival of many neighbourhoods and communities. The discussions in this paper we focus on agriculture, not as recreational activity, but as (circular) food systems that seek to eliminate wastes and produce high quality locally grown food that complements industrial production. Industrial production is crucial for grain and meats, but local production can supply high quality vegetables and fruits, as well as small scale animal husbandry. There is a great potential to integrate various agritech across the morphological elements at various scales and it needs coordination between the various disciplines. Architects and landscape architects can create visions and prototypes. Agronomists and industrial ecologists can create circular food systems. The urban agricultural systems can utilize local wastes and employ underutilized space in urban areas for food provisioning to circulate resources. This includes e.g. vacant buildings, parking garages, basements, roofs, storage rooms, shipping containers, and agritech integrated in-store in

commercial locations. Bringing together urban morphology with architecture, landscape agriculture, agronomy, landscape and industrial ecology in dissecting the morphology and elements of the green city can contribute to better possibilities for developing productive green cities and reaching the goals of the smart sustainability paradigm in development of eco cities and sustainable neighbourhoods.

ABSTRACT

The process of verticalization in urban areas triggers significant changes in urban morphology, directly influencing environmental comfort. This process, characterised by the construction of high-rise buildings, impacts the urban landscape and modifies the city's profile and spatial dynamics. These alterations in urban spaces in semi-arid climate regions, such as Sobral (located in the interior of Ceará), can intensify the formation of heat islands and create situations of significant thermal discomfort. In this context, the present work presents a case study of sections of the municipality of Sobral, where the transformations foreseen in the recently revised and approved Municipal Master Plan, if executed as such, may drastically affect the local urban microclimate. Sobral has a population of around 200,000 inhabitants and is characterised by urban sprawl. The urban morphology is predominantly horizontal across most of its territory. The city has a hot semi-arid tropical climate with an average temperature of 26 to 28 degrees Celsius, reaching high temperatures above 36 degrees in the last months of the year. High-rise buildings can create urban canyons, restricting air flow and contributing to heat islands. This, in turn, has implications for air quality and the well-being of the inhabitants. This work aims to show scenario studies through in loco studies using temperature measuring equipment in geographically close locations and to analyse how this revision of the Master Plan and zoning can impact the spatial configuration and microclimate of the city, affecting the comfort and health of the inhabitants. We hope that, with this work, more careful studies will be conducted before laws that disregard the quality of life of citizens are approved, as they are formulated solely to meet the needs of a real estate market concerned only with its own interests.

Keywords: verticalization; local microclimate; heat islands

INTRODUCTION

Located in the interior of Ceará, northeastern Brazil, Sobral is considered a medium-sized city due to its size of inhabitants as well as its intermediary role in the region. According to França (2007, p. 51-52):

[...] for the Brazilian Institute of Geography and Statistics – IBGE -, the average city is one with a population between 100,000 and 500,000 inhabitants. According to the United Nations - UN -,

medium-sized cities are those with agglomerations between 100,000 and 1,000,000 inhabitants [...] Andrade and Serra (2001) also work with this same definition of medium-sized city presented by IBGE. While Amorim Filho and Bueno e Abreu (1982) established a minimum size of 10 thousand in the municipality's headquarters [...].

However, according to Sposito (2010), when we refer to the city considering only its demographic character, we are considering “medium-sized” cities, that is, those that have between 50 thousand and 500 thousand inhabitants, but it cannot be conceptualised these cities as average only employing the demographic element. In other words, a “medium-sized” city is not the same thing as a “medium-sized city”, medium-sized cities are those that play intermediary roles in their urban networks, differentiating them from “medium-sized” cities, which are those that are defined exclusively in function of their demographic size

Sobral is a city characterised by its horizontal morphology, made up mostly of houses and low-rise buildings. The city has a semi-arid climate with an average temperature between 26 and 28 degrees Celsius, reaching high temperatures, above 36 degrees, in the last months of the year.

In 2018, with the amendment of the Land Use and Occupation Law, in the amendment of templates, this scenario began to change. The maximum height of certain areas went from 12 metres to 48 metres or 72 metres, causing a change that we will only be able to perceive the effects of in the long term.

Verticalization is a common phenomenon in growing cities, characterised by the construction of tall buildings that transform the urban landscape. In regions with a semi-arid climate, such as Sobral, in Ceará, this process can exacerbate environmental problems, including the formation of heat islands and increased thermal discomfort.

This study aims to analyse the consequences of verticalization on urban environmental comfort, focusing on microclimate changes resulting from the implementation of the revised Municipal Master Plan.

Considering cities as arenas of conflict over urban space, the appropriation of urban land and the establishment of private property have become central issues in this conflict. For some, land represents use value, while for others, it represents exchange value (Kowarick, 1983; Harvey, 2011; Maricato, 2015). This conflict is highly disproportionate: while some use land, or urban soil, for speculation, others are deprived of everything, being excluded from the constitutional right to build the city and often lacking access to leisure spaces, public services and infrastructure, adequate housing, among other things.

The problem of urbanization and verticalization in Sobral

The urban form is decisive for the biodiversity and ecological footprint of Sobral that we aim for. It is possible to identify a dichotomy in the spatial patterns resulting from the proposed models for the city (Andrade, 2014). One model is based on landscape architecture, interfacing landscape ecology and urban ecology, aiming for greener cities according to sustainable planning standards. Verticalization must respect a limit appropriate to the human scale, as already pointed out by Alexander et al. (2013). Its occurrence in certain areas without prior studies, as is happening in Sobral,

is concerning. In front of Sobral Shopping, where there is a Priority Occupation Zone (ZOP), the allowed construction height is 72 meters, and in the Priority Densification Zone (ZAP), constructions up to 48 meters high are permitted.

In 2022, in another article, was alerted that

> On the number of floors, Christopher Alexander puts it that "To have small scale, for human reasons and to keep costs low, buildings must have the lowest height possible." (Alexander, 2013: 474). The consequences of verticalizing the city are already known by the example of other larger cities that have suffered from this process previously, such as the increase in temperature, for example. Verticalization can create or accentuate heat islands. The increase in roughness lines and surface wind turbulance can also destructure the city's air circulation system. We have the climate change factor, which today already affects cities (Okretic et al., 2022)

This effect of heat islands is already something "natural" of the city's urbanization process, as we can see in the images below.

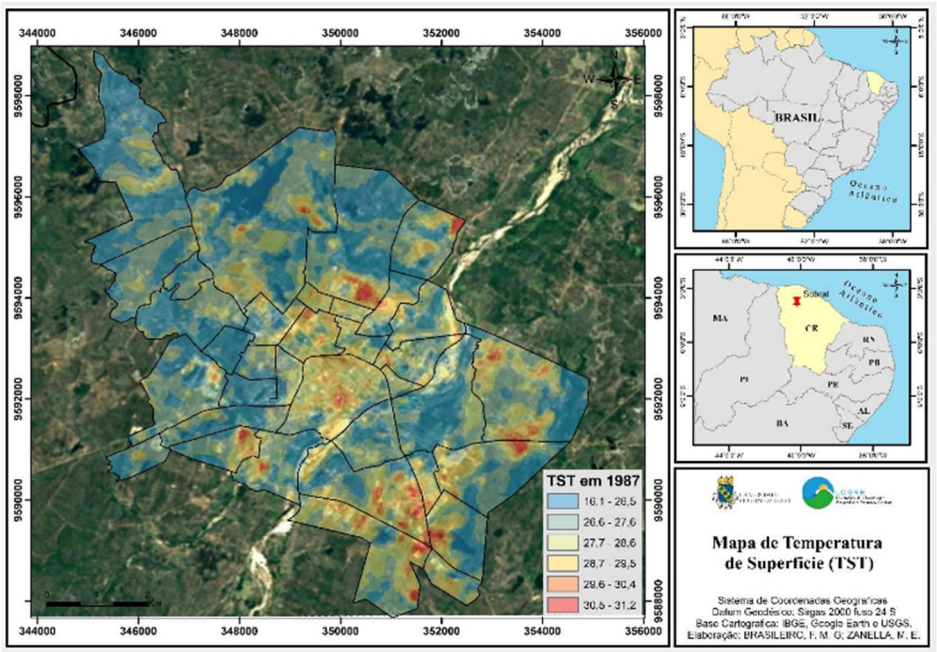

Figure 1. Surface Temperature (ST) of Sobral in 1987. Credit: Prepared by Brasileiro; Zanella (2020).

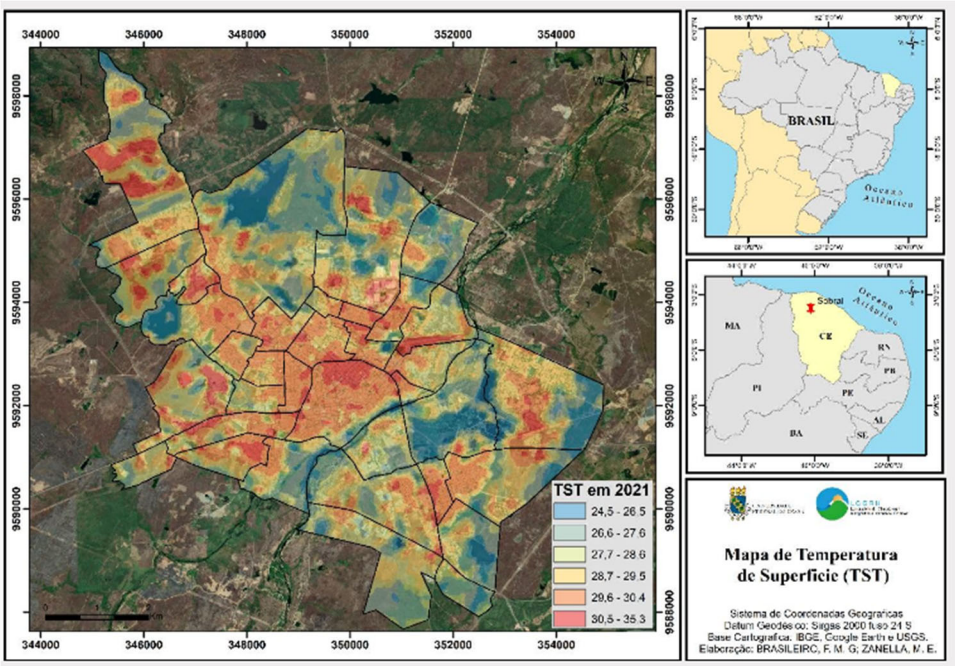

Figure 2. Surface Temperature (ST) of Sobral in 2020. Credit: Prepared by Brasileiro; Zanella (2020).

Heat islands – effects on the city

The formation of urban heat islands is a complex and multifactorial phenomenon, resulting from the interaction of several anthropogenic and natural processes. The intensification of urbanisation, described by the sealing of the soil, the reduction of vegetation cover and the concentration of materials with high thermal capacity, contributes significantly to the increase in temperatures in urban areas (Bias et al, 2023). These factors show that "albedo patterns", that is, the ability to reflect solar radiation, play a crucial role in the spatial distribution of temperatures in urban areas, with high temperatures in the centres and lower temperatures in suburbs and rural areas. Buildings also reduce average wind speeds, delaying the transfer of heat from surfaces to the air and intensifying the thermal sensation. According to Gartland (2010; p.10):

> [...] The combination of dark building materials and pavements with a canyon-like configuration absorbs and stores more solar energy. The temperature of these dark, dry surfaces can reach 88•C during the day, while vegetated surfaces and moist soil under the same conditions only reach 18•C. Anthropogenic, man-made heat, lower wind speeds and air pollution in urban areas also contribute to the formation of heat islands.

Sobral's spatial configuration, wind dynamics and soil sealing intensify the effects of heat islands in the city, compromising the population's quality of life, increasing urban vulnerability and the action of extreme events associated with the climate crisis. In addition to the greenhouse effect, heat islands have been reducing housing conditions in many urban areas, and considering that more than 75% of the world's population lives in these areas (United Nations, 2002), the impacts of heat islands have many consequences that , to mitigate them it is necessary to first understand their causes. Gartland (2010) lists the main urban characteristics that contribute to the formation of heat islands (Table 1).

Thus, these characteristics can be highlighted in five main causes for the formation of heat islands: reduced evaporation; greater heat storage; increases in radiation balance; reduced convection and

increased anthropogenic heat. In urban areas, the tendency to have lower wind speeds is greater than in rural areas, as buildings act as barriers against the wind, reducing wind speeds by up to 60% (Landsberg, 1981).

Due to the breadth of the area, it is true that with the advancement of geotechnologies and the use of resources such as remote sensing, it will be adopted as a way of identifying heat islands within the polygon referring to the urban perimeter of the headquarters district.

Characteristics that contribute to heat islands formation	
lack of vegetation	effect on energy balance
widespread use of impermeable surface	reduces evaporation
greater thermal diffusion of urban materials	increases the heat storage
low solar reflectance of urban materials	increases radiation balance
urban geometries that trap heat	increases radiation balance
urban geometries that reduce wind speed	reducess convection
increase in pollution levels	increases radiation balance
increased energy use	increases anthropogenic heat

Figure 3. Table with Urban and suburban characteristics important for the formation of heat islands and their effects on the energy balance on the Earth's surface. Credit: Gartland, 2010.

Thus, these characteristics can be highlighted in five main causes for the formation of heat islands: reduced evaporation; increased heat storage; increases in radiation balance; reduced convection; and increased anthropogenic heat. In urban areas, the tendency to have lower wind speeds is greater than in rural areas because buildings act as barriers against the wind, reducing wind speeds by up to 60% (Landsberg, 1981).

Due to the vast area, it is factual that with the advancement of geotechnologies and the use of resources such as remote sensing, it is adopted as a means of identifying heat islands within the polygon corresponding to the urban perimeter of the district seat.

The formation of urban heat islands is a complex and multifactorial phenomenon resulting from the interaction of various anthropogenic and natural processes. The intensification of urbanization, characterized by soil sealing, reduction of vegetation cover, and the concentration of materials with high thermal capacity, significantly contributes to the increase in temperatures in urban areas. Bias et al. (2003) highlight that albedo patterns, i.e., the ability to reflect solar radiation, play a crucial role in the spatial distribution of temperatures in urban areas, with higher temperatures in the centers and lower ones in the suburbs. The spatial configuration of Sobral, the dynamics of the winds, and soil sealing intensify the effects of heat islands in the city, compromising the quality of life of the population and increasing urban vulnerability to extreme events associated with climate change. Due to the vast area, it is factual that with the advancement of geotechnologies, the use of resources such as remote sensing is adopted as a means of identifying heat islands within the polygon corresponding to the urban perimeter of the district seat.

METHOD

To investigate the impacts of verticalization in Sobral, two zones were selected that will possibly be most affected by the release of the new templates, the ZOP (Priority Occupation Zone) and the ZAP (Preferential Density Zone). Thus, an approach was adopted to analyze the changes in land occupation laws from 2000, comparing with the drastic changes that have occurred in recent years, especially from 2018 to today, combining on-site temperature measurements with analyzes of future scenarios based on the guidelines of the Municipal Master Plan. Data collection was carried out with the aid of software to collect temperature data at different points in the city, representing areas with different construction densities. The data was analyzed to evaluate possible changes in the microclimate.

In the present analysis, the Landsat-9/TIRS satellite image was obtained for free through the Earth Explorer platform, provided by the United States Geological Survey (USGS, 2022), with a reference date of July 14, 2024. The data was processed using the open-source software QGIS 3.30. The extracted information corresponds to the thermal infrared channel (band 10) of the satellite, which has a spatial resolution of 30 meters and shows low cloud cover.

The processing of the thermal infrared band was conducted according to the procedures established by Coelho and Correa (2013) and Avdan and Jovanovska (2016). In this context, the TIRS band data were converted from spectral radiance to brightness temperature using the Semi-Automatic Classification plugin of QGIS 3.30.

Using the Raster Calculator tool of QGIS 3.30, the land surface temperature, corrected for emissivity, was calculated according to Equation 1. For the conversion of temperature from Kelvin to Celsius, the results were adjusted by subtracting the value of absolute zero, approximately −273.15°C.

Sobral yesterday, today and tomorrow – scenario analysis

The historical analysis reveals that Sobral had predominant horizontal urban growth, characterized by the expansion of peripheral neighbourhoods and the maintenance of a low population density. The city developed basic infrastructure to support its growth, but faced challenges related to rapid and disorderly urbanization.

- Os parâmetros definidos para a ZRO só poderão ser aplicados após elaboração de Plano de Recuperação de Áreas Degradadas (PRAD), incluindo Plano de Reassentamento de áreas de risco.

Figure 6. Table with current urban indices. Credit: Sobral City Hall (2023).

Currently, Sobral is a city of approximately 200,000 inhabitants, with an urban landscape in transformation. The introduction of tall buildings and the verticalization of central areas indicate a significant change in urban morphology. However, this transformation brings challenges such as the formation of heat islands and the impact on environmental comfort.

The projected future scenarios suggest that if the guidelines of the Municipal Master Plan are implemented without adaptations, Sobral may face significant environmental challenges. Verticalization may intensify the formation of heat islands, restrict air flow, and increase thermal

discomfort, affecting the quality of life of the inhabitants. In the following map, it is possible to see the zones that have suffered and will suffer medium- and long-term changes due to the approval of urban indices, which are the ZAP and the ZOP, as mentioned. We crossed these maps with the heat islands.

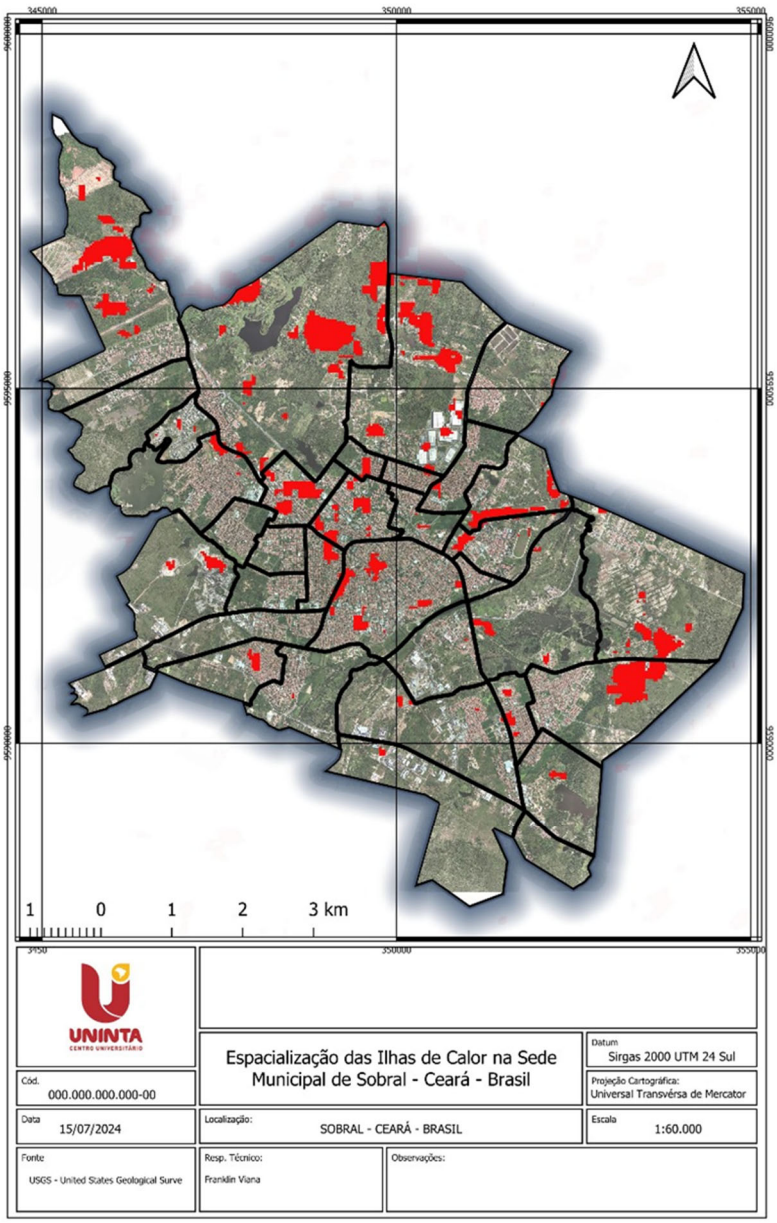

Figure 7. Map with the Heat islands Priority in Sobral. Credit: Own elaboration based on data from Sobral City Hall (2023).

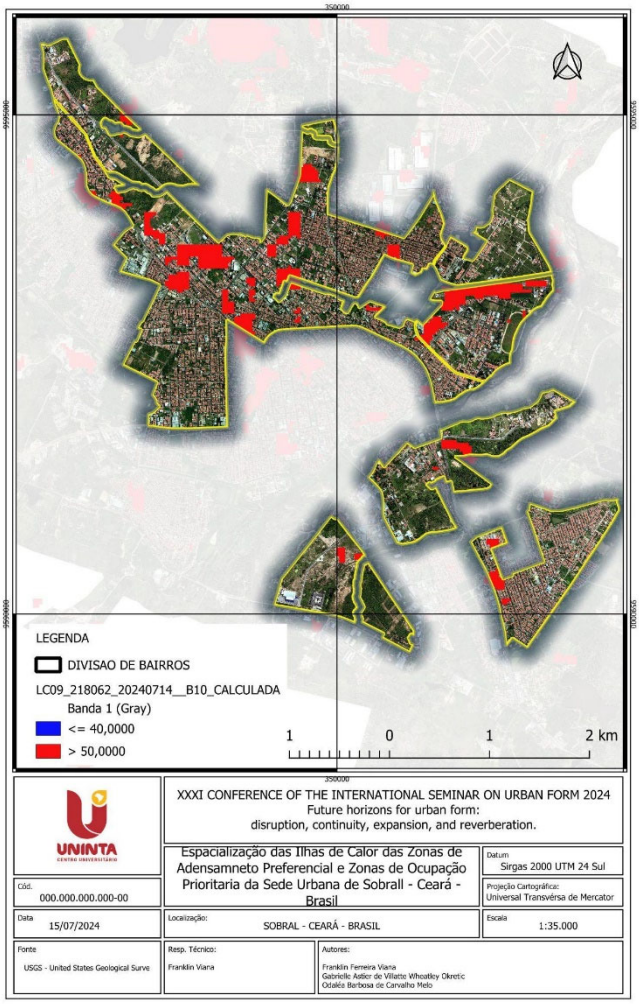

Figure 8. Map with the Heat islands located in Priority Occupation Zones (ZOP) and Priority Density Zones (ZAP). Credit. Own elaboration based on data from Sobral City Hall (2023).

RESULTS AND DISCUSSIONS

The results indicate that the construction of tall buildings in Sobral can create "urban canyons," which restrict air flow and contribute to the formation of heat islands. Temperature measurements revealed significant differences between areas with different building densities, with verticalized regions exhibiting higher temperatures. The analysis of scenarios outlined in the Municipal Master Plan suggests that if implemented without adaptations, the new guidelines may exacerbate thermal comfort issues in the city.

The discussion of the results emphasizes the importance of considering environmental impacts in urban policy formulation. While verticalization can be a solution for urban densification, it must be carefully planned to avoid deteriorating the quality of life for inhabitants. In Sobral, the revision of the Municipal Master Plan offers an opportunity to implement mitigation strategies, such as incorporating green areas and adopting construction materials that minimize heat absorption.

CONCLUSIONS

This study highlights the need for a balanced approach to urban verticalization, especially in semi-arid regions like Sobral. The construction of tall buildings can bring benefits in terms of densification and efficient use of urban space, but also poses significant challenges for environmental comfort. Urban policies that consider these factors are essential to ensure sustainability and quality of life in growing cities.

ABSTRACT

Over the past decades, unprecedented urban growth has brought about a convergence of challenges that pose significant risks to the environment and human well-being. This situation underscores the critical need for integrated urban development approaches that prioritize the preservation of natural resources and the promotion of resilient, equitable cities. In this context, several studies have highlighted the benefits of urban forests as a nature-based solution to climate change adaptation, biodiversity conservation, and the enhancement of human well-being. While much of the research has focused on green infrastructure within large protected areas, such as national and provincial parks, there has been limited exploration of how accelerated urban sprawl and changes in land use have affected tree populations in ordinary urban spaces. This research addresses this gap by (i) recognizing the need for a systemic approach in assessing open spaces and green areas, and (ii) acknowledging that the impact on urban trees is influenced by management decisions at various levels, from institutions and municipalities to individual landowners. Our study aimed to assess the distribution of trees across public and private open spaces in the city of Rio de Janeiro, Brazil, by developing a methodology that uses the normalized difference vegetation index (NDVI) and geo-processing techniques to map, categorize, and quantify tree clusters based on the type of open space they occur. The resulting database represents a pioneering effort to support comparative analyses and cross-references with existing urban infrastructure and socio-spatial indicators. Our findings reveal, for instance, that in high-density neighborhoods, private open spaces play a crucial role in preserving tree fragments, thereby contributing to the improvement of local social and environmental conditions. We hope this work will serve as a valuable resource for public agencies, scholars, urban planners, and other stakeholders interested in aligning sustainable urban planning policies with climate adaptation efforts in Brazil.

Keywords: Sustainable Urbanization; Urban Trees; NDVI, Urban Forestry; Rio de Janeiro

INTRODUCTION

Urbanization has emerged as one of the most transformative processes of the 21st century, reshaping landscapes, economies, and the lives of millions worldwide. As cities expand at unprecedented rates, they bring forth a range of complex challenges, including environmental degradation, loss of

biodiversity, and increased risks to human health and well-being (Davis, 2006; Brenner and Schmid, 2015). These challenges have made it imperative to adopt integrated urban development strategies that not only accommodate population growth but also prioritize environmental sustainability and resilience (UN-Habitat, 2022).

Among the various proposed strategies, nature-based solutions have gained significant attention for their potential to address urban environmental issues while simultaneously enhancing the quality of life for city dwellers (Raymond et al. 2017; Fastenrath et al. 2020; Longato et al. 2023). Urban forests, in particular, have been recognized for their critical role in climate change adaptation, biodiversity conservation, and the improvement of human well-being (Nowak and Dwyer, 2007; Baur et al. 2013; Nowak et al. 2016). Despite this recognition, much of the existing research has focused on trees within protected areas, such as national or state parks, leaving a gap in our understanding of how urban sprawl and changing land use patterns affect tree populations in more ordinary, everyday urban spaces.

This work aims to address this gap by first, recognizing the need for a systemic approach in assessing open spaces and green areas, and second, by acknowledging that the impact on urban trees is influenced by management decisions at various levels, from institutions and municipalities to individual landowners. Our findings not only provide a comprehensive overview of the current state of urban forestry in Rio de Janeiro but also uncover the complex relationship between green spaces and the concentration of wealth within the city. This contributes to the ongoing discourse on how socioeconomic disparities are spatially manifested and how they affect the quality of life for city dwellers, particularly in the most vulnerable communities.

Cade study

This study focuses on Rio de Janeiro as a case study. As Brazil's second-largest metropolis, following São Paulo, the city is home to approximately 6.212 million people. For administrative purposes, Rio is organized into five planning areas (APs), defined by the 1992 Decennial Master Plan, and further divided into 33 Administrative Regions (RAs). These regions bring together neighbourhoods grouped by their shared morphological and socio-environmental characteristics (Figure 1).

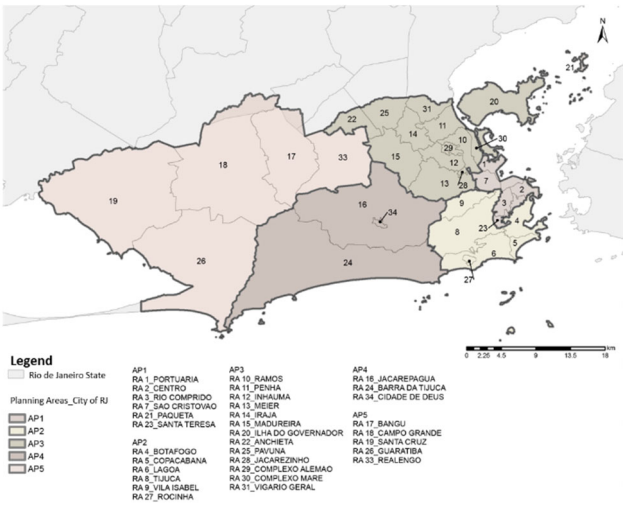

Figure 1. City of Rio de Janeiro and its administrative boundaries. Source: Data.Rio Portal, 2022.

To begin with, it seems important to outline some foundational concepts adopted in this work to support further discussions regarding the object of study:

Open areas, open spaces, and green areas

In the urban environment, open areas correspond to the set of undeveloped, unbuilt spaces within the urban fabric. This concept was initially established at the University of São Paulo by Miranda Magnoli (1982), and was adopted by several Brazilian researchers (Macedo et al. 2018). When analysed at the neighbourhood scale, open areas can differ from open spaces and green areas as follows: open spaces serve a social function and present practices as attributed to them, such as leisure, recreation, contemplation, parking, circulation, etc. They may serve for public uses – including parks, squares, plazas, and public gardens – or restricted to private use, such as clubs, governmental facilities, or residences. Green areas, on the other hand, are undeveloped areas with a significant presence of vegetation, but they do not have a specific social function. Their presence in the urban fabric represents an important environmental component, due to the maintenance and diversification of natural flora, in addition to contributing to higher rates of soil permeability, percolation, and climate balance.

A systemic approach for assessing open spaces and green areas

By recognizing open spaces and green areas as integral components of a dynamic and complex urban infrastructure system, we can achieve a more holistic understanding of how these spaces interact with one another and the broader urban environment. A systemic approach considers the spatial distribution, connectivity, and accessibility of these areas, alongside their ecological, social, and economic functions. This perspective is crucial for identifying interrelationships within the urban landscape, and uncovering patterns and dynamics that might be overlooked in more isolated analyses. In this context, concepts from landscape ecology are particularly valuable, as they highlight how patterns of occupation—such as patches, fragments, and corridors—can guide interventions aimed at landscape or environmental restoration in specific territorial segments (Forman, 1995]

METHOD

The mapping, categorization, and quantification of urban tree clusters were carried out using a combination of remote sensing techniques and spatial analysis tools, specifically employing the software ArcGIS/ESRI©. This process relied on a series of orthophotos of the city territory, generated from low-resolution satellite images (Sentinel-2 - ESA) and Landsat-8 - NASA/USGS), provided by the Pereira Passos Institute (IPP/PCRJ) in 2015. In total, 265 orthophotos were utilized to ensure comprehensive coverage of the city's entire area, distributed per Planning Area (AP) as follows: AP1 – 19 orthophotos, AP2 – 30 orthophotos, AP3 – 48 orthophotos, AP4 – 48 orthophotos, and AP5 – 107 orthophotos. To ensure accuracy and consistency in data collection and analysis, we established two key criteria in order to guide our approach, providing a structured framework for the methodology.

a) The urban forest fragments within protected areas were excluded from the inventory:

The City of Rio de Janeiro preserves significant fragments of the Atlantic Forest biome, along with associated ecosystems such as restingas and mangroves. To protect these areas, they are recognized as Conservation Units (UCs) , regulated by the National System of Nature Conservation Units (SNUC). The SNUC system sets out the criteria and regulations for the establishment and management of

conservation units. The UCs are divided into two main categories: (a) Full Protection Units; and (b) Sustainable Use Units. The primary purpose of Full Protection Units is to preserve nature, allowing only indirect use of natural resources. They are strictly reserved for environmental conservation, prohibiting any other uses, including urban, industrial, or agricultural activities. Sustainable Use Units focus on conserving nature by preserving biomes and living organisms while permitting economic and extractive activities. It is also worth noting that, by law, UCs take precedence over local land use and zoning regulations and are often reinforced by local environmental protection categories, such as Macro Zones , and Areas of Special Environmental Interest , thereby strengthening protection across all levels of government (Nunes et al. 2022).

For the purposes of this investigation, we excluded urban forest patches located within Full Protection Units from our analysis. This is because the inclusion of these areas could significantly skew the outcomes, as the focus of our work is to assess the distribution of urban trees in everyday spaces, where strict environmental protection rules do not apply. In the city of Rio de Janeiro, 24 areas are designated as Full Protection Units (Figure 2) and are divided into the following categories: Municipal Natural Park, Biological Reserve, Natural Monument, State Park, and National Park. These areas collectively cover approximately 25,740 hectares, representing about 21% of the city's total territory.

The mapping, categorization, and quantification of urban tree clusters were carried out using a combination of remote sensing techniques and spatial analysis tools, specifically employing the software ArcGIS/ESRI©. This process relied on a series of orthophotos of the city territory, generated from low-resolution satellite images (Sentinel-2 - ESA) and Landsat-8 - NASA/USGS), provided by the Pereira Passos Institute (IPP/PCRJ) in 2015. In total, 265 orthophotos were utilized to ensure comprehensive coverage of the city's entire area, distributed per Planning Area (AP) as follows: AP1 – 19 orthophotos, AP2 – 30 orthophotos, AP3 – 48 orthophotos, AP4 – 48 orthophotos, and AP5 – 107 orthophotos. To ensure accuracy and consistency in data collection and analysis, we established two key criteria in order to guide our approach, providing a structured framework for the methodology.

a) The urban forest fragments within protected areas were excluded from the inventory:

The City of Rio de Janeiro preserves significant fragments of the Atlantic Forest biome, along with associated ecosystems such as *restingas* and mangroves. To protect these areas, they are recognized as Conservation Units (UCs)[63], regulated by the National System of Nature Conservation Units (SNUC). The SNUC system sets out the criteria and regulations for the establishment and management of conservation units. The UCs are divided into two main categories: **(a) Full Protection Units; and (b) Sustainable Use Units**. The primary purpose of Full Protection Units is to preserve nature, allowing only indirect use of natural resources. They are strictly reserved for environmental conservation, prohibiting any other uses, including urban, industrial, or agricultural activities. Sustainable Use Units focus on conserving nature by preserving biomes and living organisms while permitting economic and extractive activities. It is also worth noting that, by law, UCs take precedence over local land use and zoning regulations and are often reinforced by local environmental protection categories, such as Macro Zones[64], and Areas of Special Environmental Interest[65], thereby strengthening protection across all levels of government (Nunes *et al.* 2022).

For the purposes of this investigation, we excluded urban forest patches located within Full Protection Units from our analysis. This is because the inclusion of these areas could significantly skew the

[63] Federal Law 9.985 of July 18, 2000.

64 Macro Zones are large-scale zoning designations that organize the city's territory into distinct areas based on specific land-use and environmental guidelines.

[65] Areas of Special Environmental Interest (*Áreas de Especial Interesse Ambiental or AEIA*) are designated zones that receive special protection due to their ecological, cultural, or environmental significance.

outcomes, as the focus of our work is to assess the distribution of urban trees in everyday spaces, where strict environmental protection rules do not apply. In the city of Rio de Janeiro, 24 areas are designated as Full Protection Units (**Figure 2**) and are divided into the following categories: Municipal Natural Park, Biological Reserve, Natural Monument, State Park, and National Park. These areas collectively cover approximately 25,740 hectares, representing about 21% of the city's total territory.

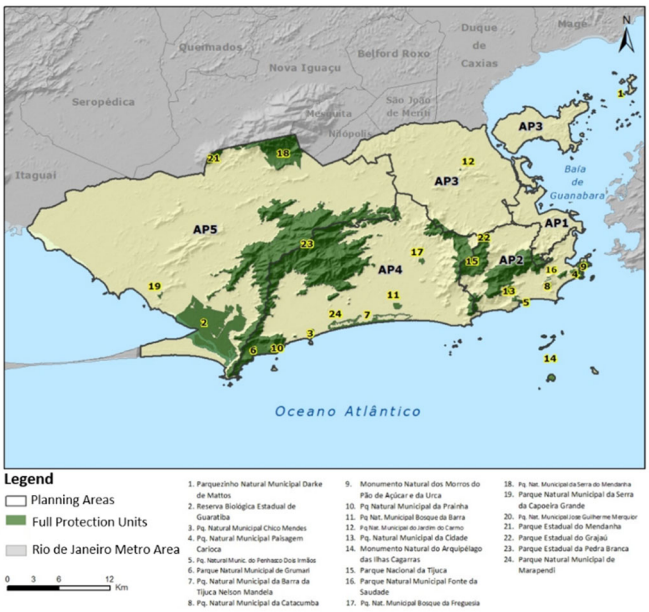

Figure 2. Full Protection Units in the city of Rio de Janeiro. Source: Data.Rio Portal, 2022.

b) Mapped tree clusters with an area smaller than 1sqm were excluded from the inventory:

Our primary objective was to focus our analysis on areas with a continuous and substantial tree canopy within the city's territory. By concentrating on these larger, interconnected green spaces, we aimed to capture and analyse tree patterns that have a meaningful impact on the urban landscape and contribute significantly to environmental quality. Smaller, isolated units, which would not have a substantial influence on the overall urban ecosystem, were intentionally excluded from the analysis to ensure that the results reflect the broader, more impactful trends. To achieve this goal, we established a criterion to exclude tree clusters smaller than 1sqm (*1m²*), thereby refining our focus on those clusters that shape significantly the urban environment.

Mapping

In the mapping process we applied the Normalized Difference Vegetation Index (NDVI) which is an indicator used in remote sensing to assess and monitor vegetation health and density, made possible due to the intensity of chlorophyll activity in tree and shrub species and their reflectance in satellite images. It is calculated by analysing the difference between the near-infrared (NIR) light, which vegetation strongly reflects, and the visible red light, which vegetation absorbs (Figure 3).

$$\mathrm{NDVI} = \frac{R_{\mathrm{NIR}} - R_{\mathrm{red}}}{R_{\mathrm{NIR}} + R_{\mathrm{red}}}$$

NDVI values range from -1 to +1, with higher values signifying healthy, dense vegetation, and lower values indicating sparse or stressed vegetation, barren land, or water bodies. The index has been extensively utilized in various studies to analyse vegetation cover and identify spatial patterns across

different landscapes (Franco and Rosa, 2004; Eduardo and Silva, 2013; Lima et al. 2013). These studies demonstrate the effectiveness of NDVI in distinguishing between diverse land cover types and assessing vegetation density. Table 1 provides a summary of the NDVI values corresponding to the primary elements identified in satellite images, highlighting the typical ranges associated with different land cover types.

Figure 3. Comparison of an orthophoto in RGB composition (red, green, and blue) and RED + NIR composition (red + infrared). Source: IPP, 2015.

Table 1. NDVI value for different mapped elements. Source: Korchagina et al. 2020.

Type of objects	**NDVI value**
High, dense vegetation (forest)	0.7 – 1.0
Sparse vegetation (shrubs, pastures)	0.2 – 0.5
Open soil	0.025 – 0.2
Clouds	0
Snow, ice, dust, rocks	-0.1 – 0.1
Water	-0.42 - -0.33
Artificial materials (concrete, asphalt)	-0.5

In this study, we applied a threshold value of 0.45 to differentiate between dense vegetation and sparse or non-existent cover. This threshold was determined after extensive testing and calibration against various spectral responses. The chosen value provided a satisfactory rate of accuracy, achieving 92.6% when compared to a manual digitizing process. This high level of accuracy demonstrates the effectiveness of the automated method in reliably identifying and categorizing vegetation density, while significantly reducing the time and effort required for manual mapping. Additionally, this threshold enabled us to consistently detect and analyse large surfaces of tree cover, ensuring that the results were both precise and replicable across different sections of the study area. To further enhance the accuracy of the mapping process, we carried out a final routine of manual verification and editing of polygons, what helped mitigate potential inconsistencies and ensured the integrity of the dynamic mapping process (Figure 4).

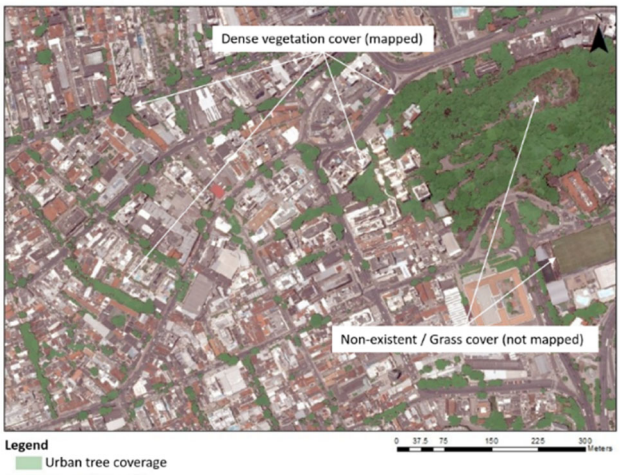

Figure 4: Results from the automated method of mapping dense vegetation cover.

Categorization

Based on previous work conducted by Tângari (2018; 2019), primarily focused on mapping and developing a typology of public and private open spaces in the city of Rio de Janeiro, we identified and proposed five (05) main categories to classify urban trees, taking into consideration where they are located (Figure 5). Table 2 summarizes the typology and presents a detailed description of each category.

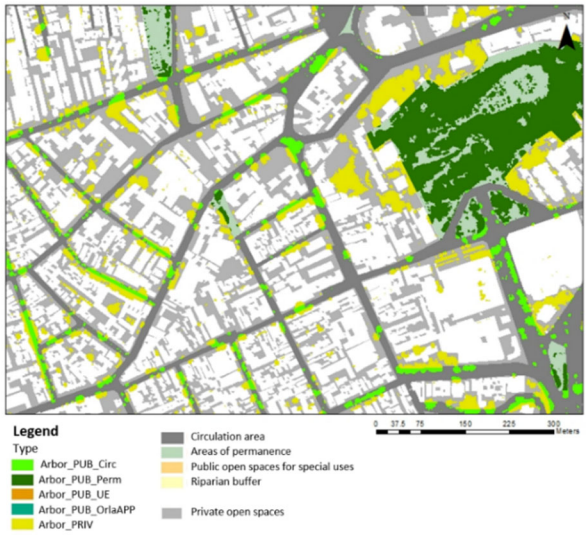

Figure 5: Map illustrating the distribution patterns of urban trees following the categorization process.

Table 2. Summary of the proposed categories of urban trees.

Category	Description
Trees located in public open spaces (circulation areas) (**Arbor_Pub_Circ**)	Trees located within public circulation areas such as streets, sidewalks, avenues, and pathways
Trees located in public open spaces (permanence areas) (**Arbor_Pub_Perm**)	Trees located within public areas of permanence such as parks, squares, plazas, and public gardens.

Trees located in public open spaces (special uses[66]) (**Arbor_Pub_Ue**)	Trees located within public areas for special uses as defined by the Brazilian Civil Code (CCB).
Trees located in marginal protection strips of water bodies (**Arbor_Pub_OrlaAPP**)	Trees located within riparian buffer areas along rivers, canals, lagoons, and beaches.
Trees located in private open spaces (**Arbor_Priv**)	Trees located within private urban lots.

RESULTS AND DISCUSSIONS

In this section, we present the findings of our research, highlighting the key outcomes derived from the data collected where we primarily focused on the spatial distribution and density of tree clusters. Figure 6 illustrates the distribution of tree clusters across the city, while Graphs 1 and 2 compare the extent of these clusters per hectare and the canopy density within each planning area. It is worth noting that the measurement of canopy density was specifically focused on private and public open spaces where vegetation can thrive and be managed, intentionally excluding water bodies, fully protected units, and built areas, in order to ensure an accurate assessment.

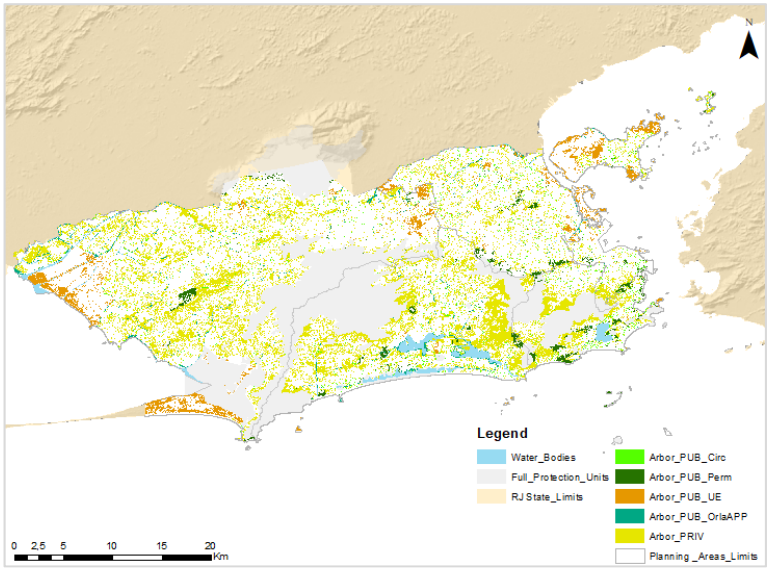

Figure 6: Map illustrating the distribution of tree clusters based on the typology of urban trees.

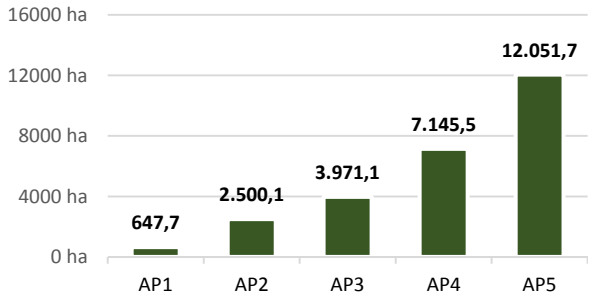
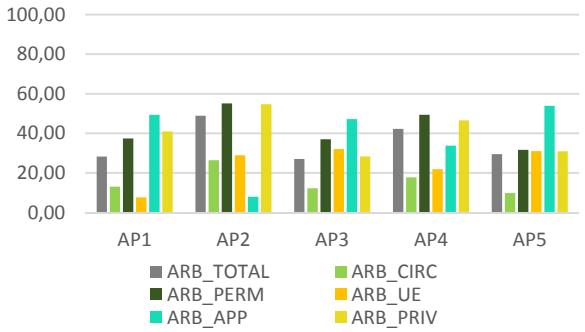
In absolute terms, the extent of tree clusters is naturally influenced by the size of each planning area, with larger areas tending to have extensive clusters. However, when we examine the density values, a different picture emerges—revealing significant disparities in tree coverage across the city, suggesting underlying factors beyond the land surface, further presented in this section. Furthermore, disaggregating the data into smaller areas (Administrative Regions - RAs) allows for a more granular and precise analysis of the distribution and correlation between open spaces and urban tree coverage. This approach, illustrated in Graph 3, enhanced our ability to identify localized patterns and relationships, that are overlooked in a broader scale of analysis, thereby providing deeper insights into the spatial dynamics of urban greenery.

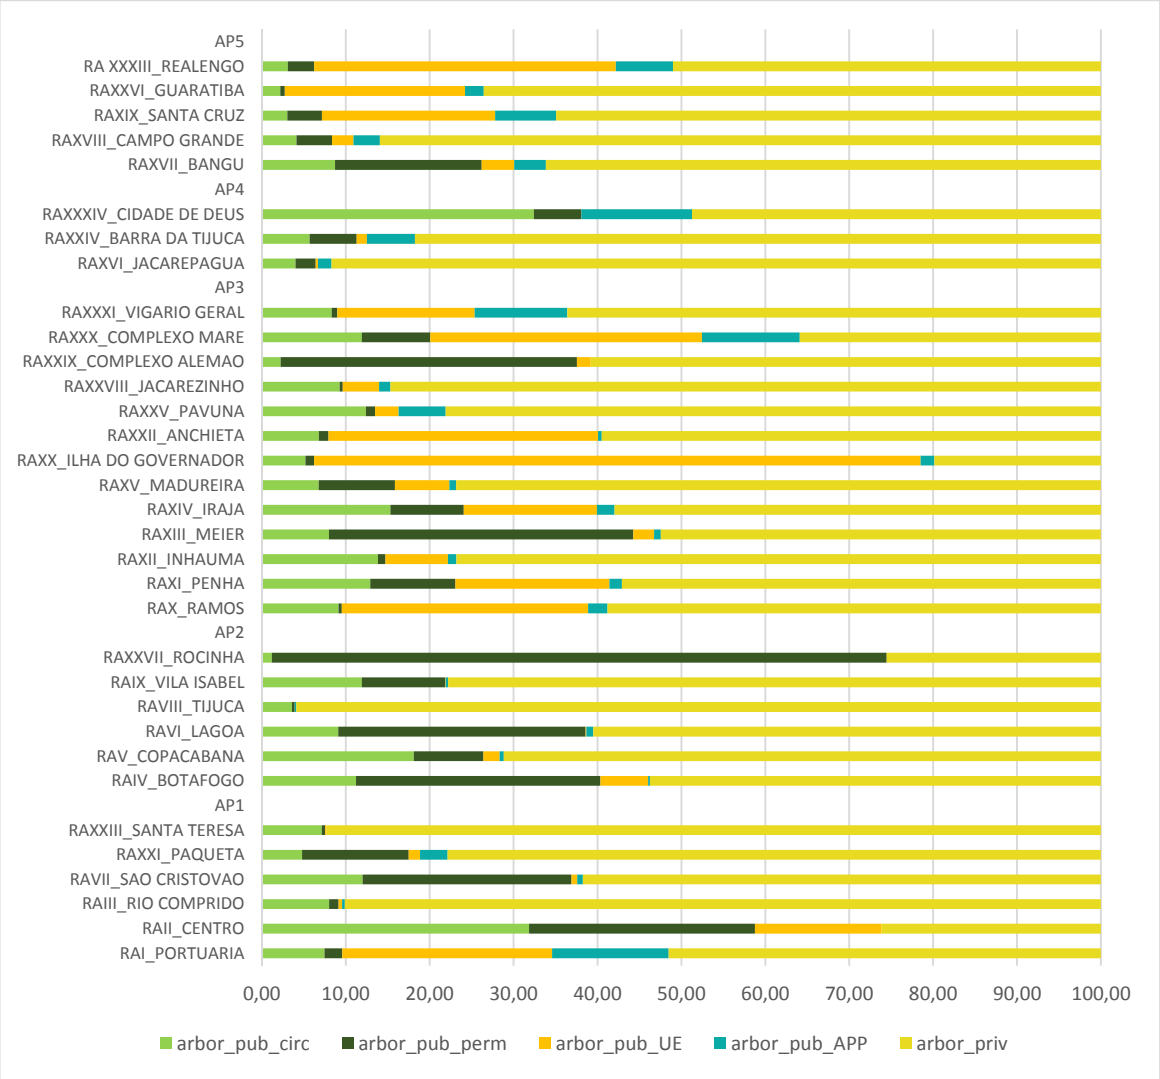
[66] These are areas designated for specific activities often used in the performance of state activities. Examples include military areas, railways, port, and airport lands, as well as spaces related to urban infrastructure such as water and sewage treatment plants.



Graph 1. Extent of tree clusters per planning area (hectare).



Graph 2. Canopy density per planning area (AP).



Graph 3. Canopy density per Administrative Area (RA)

Urban trees in densely populated and fragmented areas

In densely populated areas that are also significantly fragmented, the lack of trees is often a direct consequence of the spatial and structural limitations imposed by such environments (Heynen et al. 2006). Urban fragmentation, characterized by the proliferation of small, disconnected parcels of land that are developed with minimal open space, severely restricts the availability of greenery (Figure 7). This fragmentation not only diminishes the overall space for tree planting but also disrupts the ecological continuity necessary for sustaining cohesive clusters of urban trees.

Figure 7: Aerial image showing the fragmentation and the high built density of the urban fabric in Madureira, neighbourhood located in Planning Area 3. Source: SEL-RJ, 2016.

This combination of high building density and fragmented land use creates a challenging environment for the growth and maintenance of urban trees, leading to a significant deficit in green cover. In Rio de Janeiro, this problematic intersection is particularly evident in Planning Areas 3 and 5 (Figure 8), the most densely populated parts of the city, which, conversely, according to our mapping, show the lowest tree density in public spaces designated for circulation and permanence.

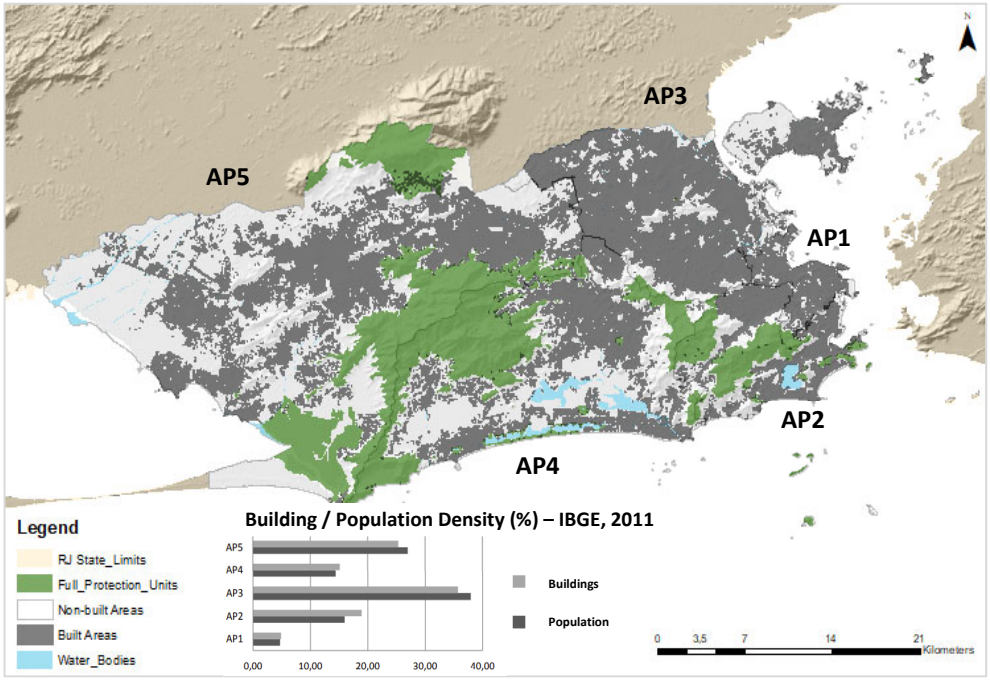


Figure 8: The figure ground map illustrates the relation between built and open spaces. It also summarizes the building / population density per planning area.

Urban inequalities and tree clustering patterns

Urban inequality extends beyond the unequal distribution of income to encompass the uneven access that different segments of the population have to essential services, such as healthcare and education facilities, public transportation systems, and likewise, public open spaces designed to support a diverse range of social activities. Despite their environmental, aesthetic, social, and economic benefits (Lynch, 1976; Cullen, 1961; Woolley, 2003; Stanley et al. 2012; Baptista et al. 2015), as explored in several studies, the open space infrastructure are often unevenly distributed across urban areas,

leaving marginalized communities underserved. In cities like Rio de Janeiro, socioeconomic disparities have historically concentrated wealth and resources in affluent areas, while a functionalist legacy in suburban and peripheral regions has delayed the development of these vital spaces (Mendonça, 2018). This imbalance plays a significant role in how these inequalities manifest spatially, affecting the quality of life for the most vulnerable urban populations.

In that sense, we highlight the existing spatial correlation between the income distribution pattern (Figure 9) and tree coverage across different areas of the city. Areas with higher income levels, such as planning areas 2 and 4, exhibit a more homogeneous distribution of trees compared to smaller and fragmented patches in less affluent regions in planning areas 3 and 5. Figure 10 illustrates these differences by emphasizing the tree-lined corridors located in the main streets (open spaces for circulation) of wealthier neighbourhoods. These corridors play a crucial role in connecting tree clusters across private and public spaces, enhancing ecological continuity, supporting biodiversity, and improving environmental quality. Conversely, in underserved neighbourhoods, the urban greenery is located in smaller tree patches, often confined to areas for special uses and private spaces.

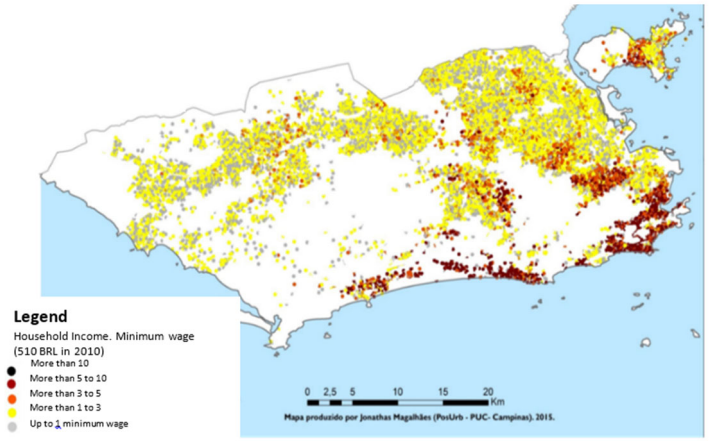

Figure 9: Income distribution pattern in the city of Rio de Janeiro. Source: Map elaborated by Jonathas Magalhães. PUC-Campinas (2018).

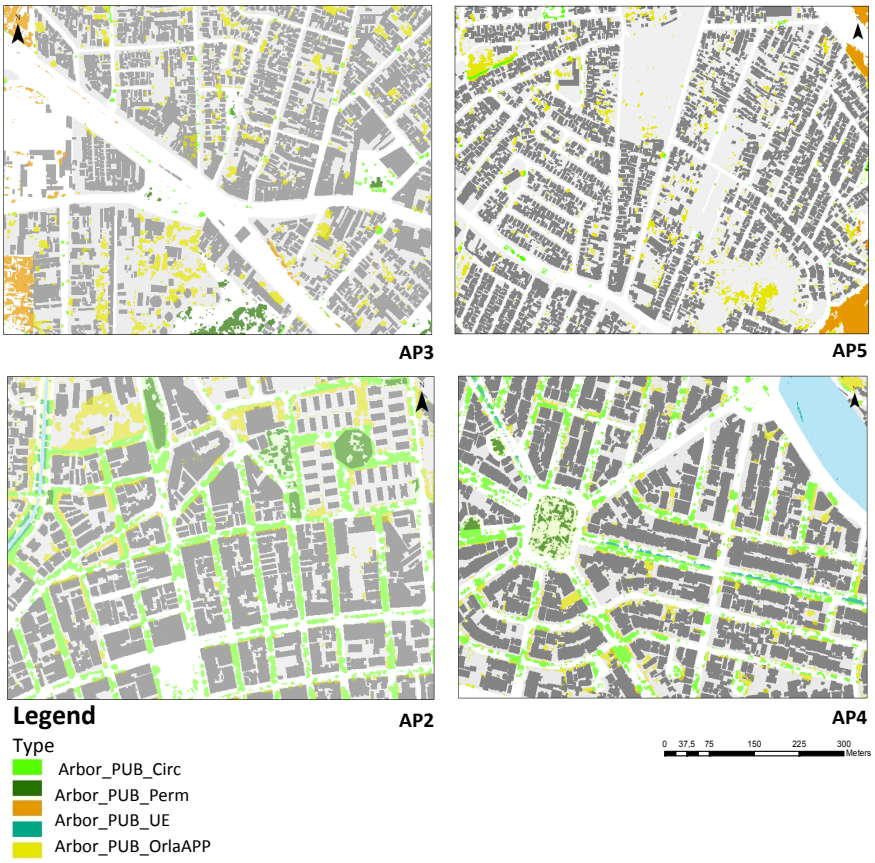

Figure 10: Comparison between tree clustering patterns in different planning areas.

Localizing tree clusters in private open spaces

As previously mentioned, a key finding of this study reveals that in many neighbourhoods within planning areas 3 and 5, where urban greenery is either non-existent or insufficient, tree clusters often occur confined to parcels designated for special uses, such as institutional grounds, and private spaces, rather than being integrated into the broader public realm. This limited and uneven distribution of trees not only reduces the environmental benefits that such element can provide, such as air quality improvement and micro climate regulation, but also restricts residents' access to open spaces that could support mental and physical well-being. However, the preservation of these areas as a compensatory measure for the lack of trees in neighbourhoods where public green spaces are scarce, seems crucial to mitigate some of these environmental challenges and enhance overall urban resilience. In this study, we identified and categorized the types of open spaces where tree clusters, as mapped and summarized in Figure 11.

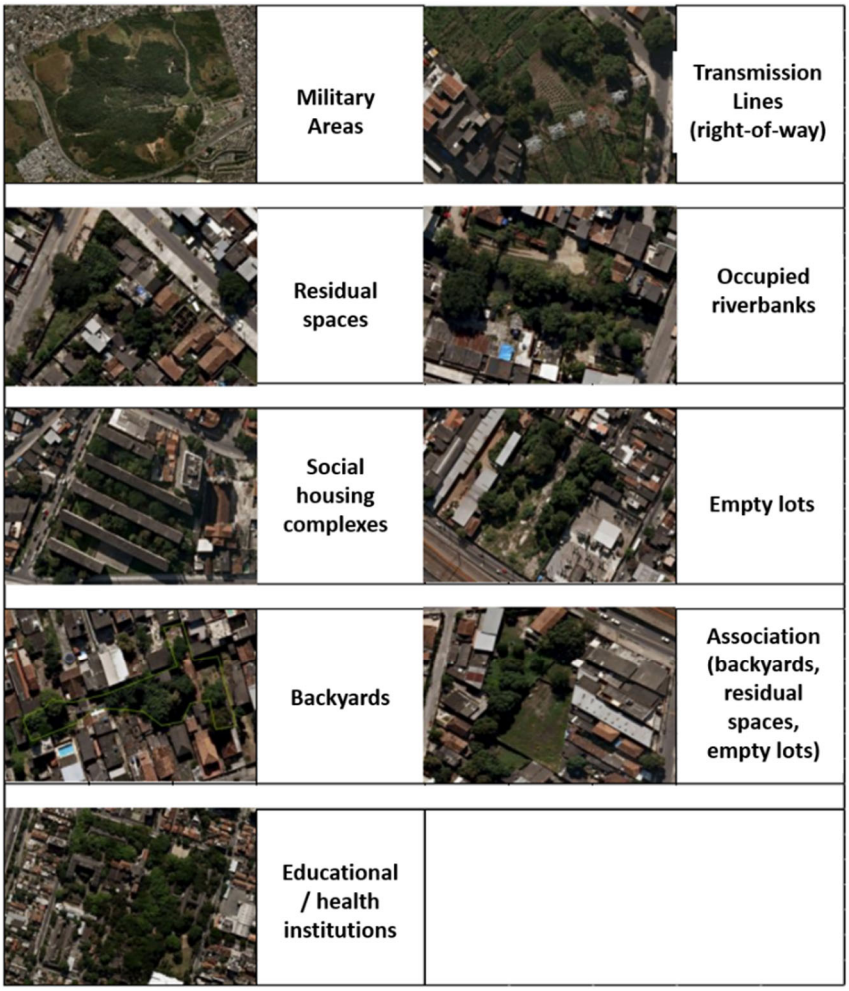

Figure 11: Comparison between tree clustering patterns in different planning areas.

- Military areas: Large, often restricted zones dedicated to defense purposes, where tree cover is typically preserved due to limited public access and minimal development;
- Energy transmission lines (right-of-way): Strips of land beneath power lines where vegetation is managed to prevent interference with the infrastructure, often maintaining a significant amount of greenery;
- Residual spaces: Undeveloped or underutilized areas within the urban landscape that often serve as informal spaces for leisure activities;
- Occupied riverbanks: Urban occupation along rivers and water bodies, informally settled, sometimes resulting in the natural growth of vegetation along these water bodies;
- Open spaces within social housing complexes: These areas often preserve significant green spaces, contributing to the overall greenery of the city;
- Empty lots: Parcels of undeveloped land within the city that may spontaneously or intentionally support clusters of trees and vegetation;

- Backyards: Private open spaces located behind residential lots, contributing to the greenery, especially in neighborhoods where low-rise buildings are predominant;

- Educational/health institutions: These institutions often maintain large campuses where green spaces are preserved or cultivated.

Green infrastructure and urban heat islands

Green infrastructure is crucial in mitigating the challenges posed by urban heat islands, a phenomenon where densely built environments experience significantly higher temperatures than their surrounding areas. As cities expand and develop, the replacement of natural landscapes with impermeable surfaces like concrete and asphalt increases heat retention, intensifying the urban heat island effect (Gartland, 2012). The lack of trees, which offer shade and promote evaporative cooling, further exacerbates this effect, making densely built-up regions noticeably warmer than areas with more greenery (Bowler et al. 2010).

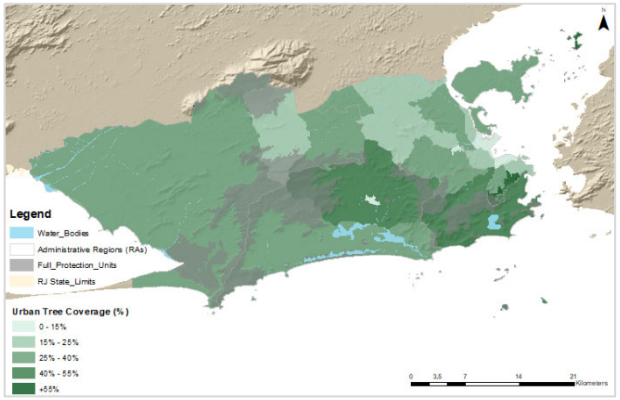

Figure 12: Tree canopy density per Administrative Region (RA).

In Rio, our analysis reveals a clear relationship between tree canopy density, mapped per Administrative Regions (RAs), and the urban heat island effect. Low-lying areas with tree coverage below 25% (Figure 12) consistently exhibit significantly higher temperatures, as shown by the red hues in Figure 13. In contrast, regions with higher tree coverage, particularly in the South, or those adjacent to or intersected by conservation units (covered by dense vegetation), correspond to cooler temperatures, indicated by the lighter yellow shades on the temperature map.

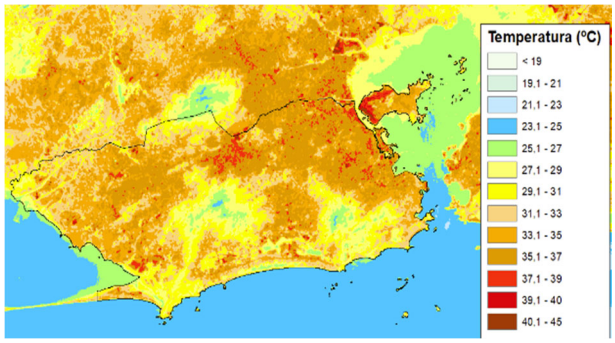

Figure 13: Map of Urban Heat Islands in Rio de Janeiro (12.01.2015) Source: Data.Rio Portal.

CONCLUSIONS

In conclusion, this study provides a comprehensive analysis of the distribution of urban trees in Rio de Janeiro, highlighting how urban sprawl and socioeconomic factors influence tree cover distribution while deepening our understanding of the city's broader environmental challenges. Through comparative analyses and cross-referencing with other indicators, such as education, health, and public safety, the findings can inform the development of public policies focused on planning, implementing, and maintaining urban afforestation. These policies must consider the spatial distribution of trees and their interactions with urban infrastructure, as well as the socio-spatial patterns and conflicts within the urban landscape, to ensure equitable and sustainable urban greening efforts.

Urban trees are critical components of sustainable urbanization, offering a wide range of benefits, from enhancing biodiversity and regulating the climate to improving residents' mental and physical well-being. However, the uneven distribution of green spaces in Rio de Janeiro mirrors broader patterns of urban inequality, where wealthier neighborhoods enjoy greater access to greenery compared to fragmented, lower-income areas. Our findings emphasize the importance of adopting a systemic approach to assessing green infrastructure across both public and private spaces, revealing the uneven distribution of tree clusters in different planning areas. Notably, private open spaces play a crucial role in maintaining urban greenery, especially in high-density areas. This underscores the urgent need for equitable urban planning policies that integrate green infrastructure into all neighborhoods, ensuring that the environmental and social benefits of urban trees are shared more fairly across the city.

In climates characterized by high temperatures and humidity, such as Rio de Janeiro, the presence of tree clusters is essential for heat regulation and well-being. On a local scale, the research highlights the potential of urban trees to mitigate the effects of urban heat islands, which disproportionately affect densely built and less vegetated areas. The correlation between tree canopy density and cooler temperatures in certain regions reinforces the need for strategic urban forestry management to enhance climate resilience. Policymakers and urban planners should prioritize expanding green infrastructure in underserved areas to reduce heat stress and promote more livable urban environments for all residents. Beyond their environmental and climatic advantages, urban trees also provide socioeconomic benefits: neighborhoods with abundant greenery often experience higher property values, attract investment, and foster economic growth. Urban trees also enhance social cohesion by offering communal spaces that promote community interactions and contribute to a sense of well-being.

Ultimately, this study contributes to the growing body of literature supporting nature-based solutions in urban development. The methodology and findings presented here lay the groundwork for future research and urban planning initiatives aimed at fostering sustainable and resilient cities. By bridging the gap between ecological conservation and socioeconomic equity, urban forestry can play a pivotal role in addressing the environmental and social challenges posed by rapid urbanization in Brazil.

Indigenous cities in Brazil: an analysis of urban form and basic health units

ABSTRACT

The migration of indigenous people to cities has been going on for a long time and this movement is experienced with exclusion, marginalization and discrimination, implying vulnerability of this population and harm to their health (Coimbra Jr and Santos, 2000). A study in twenty-eight (28) countries found that indigenous people have less favorable health and socioeconomic indicators than non-indigenous people (Anderson, et al., 2016), and another study found that this is the social group that suffers the most injustice (Rocha et al., 2018). Therefore, indigenous people's access to health facilities is an important factor in reducing their vulnerability. This paper analysis urban form based on the integration measures of Hillier and Hanson (1984) and compactness of Krafta (2014) as an instrument for analysing the accessibility of this population. The method, of a hypothetical-deductive nature, with explanatory analysis and a multi-case study research strategy, is divided into (1) literature review, (2) survey of socio-spatial data and (3) geoprocessing treatment. The sample of cities, totaling 10, was chosen based on the percentage of the population that self-declares as indigenous in the Census (IBGE, 2022). As main results, it was identified that there is a positive correlation between the Integration and Compactness variables, with Pesqueira/PE having the most Integrated system; Tefé/AM having the greatest access and coverage of Primary Health Care and São Gabriel da Cachoeira/AM being the least compact of the cities.

Keywords: Urban Form, Indians, Compactness, Space Syntax and Health

INTRODUCTION

Urban form, Indians, Compactness, Spatial Syntax and Health Difficulties involving the migration of Indians/indigenous people to urban spaces have existed for centuries throughout the world and these dilemmas are experienced through situations of exclusion, marginalization and discrimination, implying greater vulnerability to health problems for these people (Coimbra Jr and Santos, 2000). In addition to health problems, indigenous people face numerous limitations, among which is the lack of professional skills, with the first formal alternative being the job of labor in the construction industry of urban centers (Albuquerque, 2015).

The movement of indigenous populations has had some negative implications, and a study of 23 countries and 28 populations found poorer health and social outcomes for indigenous peoples than

non-indigenous populations (Anderson et al., 2016). The results of a study in Brazil indicate striking differences, with much higher mortality rates for indigenous people in all age groups considered (Campos et al., 2017).

Although indigenous people have gained space and rights in recent years, they appear in first place with 33.67% as the most unfairly treated group in relation to other peoples (Rocha et al., 2018). Along with inequity, health indicators are modest when compared to the investment of 200 million reais in 2003 to more than 1.4 billion reais in 2016 (Benevides Ferreira and Taveira, 2017). That is, even though there has been progress in terms of healthcare assistance and accessibility via the Unified Health System/SUS[67], the data continues to point to enormous gaps between indigenous and non-indigenous people (Mendes et al., 2018).

The injustice is so evident that, when we examine the public health services related to this population in Brazil, we see that these people came to have (indirect) access to health care from 1910 onwards with the Indian Protection Service/SPI, but it was only in 1999 that they had direct access to basic care via the Unified Health System/SUS through the Indigenous Health Care Subsystem of the SUS/SASI-SUS (Benevides Ferreira et al., 2019).

Amidst struggles and conquests, it is known that the Brazilian population, including the indigenous population, has increasingly migrated to the country's urban centers, that is, when considering the total number of indigenous people living in the country, it is noted that 622.1 thousand (36.73%) reside in Indigenous Lands and 1.1 million (63.27%) outside them and the Southeast region has the largest proportion of indigenous people living outside these delimited territories with 101.9 thousand (IBGE, 2022).

However, the city, as a structure shaped by the population that lives there, requires constant monitoring to understand its dynamics and, associated with this, there is the debate about the compact city and its level of accessibility. Therefore, researchers have considered the road network as one of the main elements to contribute to evaluating the performance of the urban form in the city (Ribeiro, et al., 2012).

There are several types of approaches that allow us to analyze urban form, and one of them is the Theory of Social Logic of Space (or Spatial Syntax). This theory seeks to understand human social organization through a spatial configuration. In other words, for the Theory, the structure of the road network, together with land use and population density in cities, determine accessibility patterns, maintaining a relationship of influence between them (Hillier and Hanson, 1984).

For Krafta (2014), the city is the result of the forces that exist within it, in which each element contributes to magnetize, polarize, distribute and conduct activities and flows. For the author, two forces that enhance this phenomenon are given by the road structure and population density; however, it is seen that investigations involving the performance of the urban form through the compactness indicator have been increasingly explored in urban studies (Maia and Netto, 2016).

[67] Universality, comprehensiveness and equality are guiding principles for access to public health services at all levels of care (Brazil, 1990).

A study that investigated the Yanomami population dynamics in four distinct periods identified that health care, through the establishment of health posts, ensured the growth of their population, however, contact with other peoples and epidemics impose the need to expand this care (Nilson and Fearnside, 2017).

A systematic review of indigenous populations in urban areas found a prevalence of physical inactivity ranging from 28.8% to 45.3% (Radicchi and Lima, 2020). Another investigation related to the topic, but with a morphological bias, analyzed spatial patterns of indigenous settlement based on Spatial Syntax, finding spatial associations between morphological and functional centrality. Furthermore, it was possible to understand the construction of alternative paths as a need to adapt the spatial configuration and promote greater spatial integration in the village (Dill et al., 2021).

Andrade and Pereira (2021), who investigated the relationship between the location of the Basic Health Unit/ABS and the urban morphology[68] of the neighborhood based on Space Syntax measurements, found evidence that the permanence of a regular grid implies an intelligible system and that the location of the UBS on the most connected road in the system tends to guarantee favorable accessibility for the neighborhood's residents.

Given studies of urban dynamics and the inequity suffered by the indigenous population, we suspect that more compact cities with coverage by Family Health Teams/ESF and Primary Care/AB tend to provide accessibility and prevention to the health of indigenous people. This study aims to analyze the level of accessibility of the urban form based on the Space Syntax of Hillier and Hanson (1984) and the compactness indicator for urban fabric of Krafta (2014) in relation to the Basic Health Units/UBS of the ten cities with the largest self-declared indigenous population in Brazil. In addition to this introductory part, this study is structured in three stages, namely: (a) method, (b) results and debates, and (c) conclusions.

METHOD

The method applied in this research is hypothetical-deductive and descriptive in nature, with data based on the Brazilian Institute of Geography/IBGE and the Ministry of Health for demographic aspects and on the Open Street Map/OSM for spatial aspects. After the bibliographic review, the method was organized into two stages (1) demographic and (2) spatial.

In the demographic stage, a survey was conducted of the first ten cities - except capitals and cities that are part of metropolitan regions - with the largest self-declared indigenous population in Brazil, considering (a) total population, (b) the percentage of indigenous people in relation to the total population and (3) population density. In the spatial stage, the technical and tool procedures were carried out by importing the road structure via the Open Street Maps/OSM database and then developing the modeling and treatment of the maps in the QGIS® software version 3.22 and processing in DepthmapXnet® version 0.35; adopting the segment map to work with the syntactic measures.

Therefore, the technical and tooling execution began with the extraction of the Spatial Syntax Integration measure and subsequent calculation of the compactness indicator for the urban fabric of individual cities. We emphasize that the integration measure (or proximity) is the main measure of Spatial Syntax and refers to how close or distant a street segment is in relation to all others in

[68] Urban morphology, urban form and spatial configuration are read as synonyms in this article.

topological distance. That is, all axes are directly connected to a given line and are one topological step away from it. The lines directly connected to these axes are two topological steps away from the first, and so on (Hillier et al. 1993 and Saboya, 2007).

The logic behind the calculation of the Theory is that lines closer to other lines in the system are considered more integrated (or shallow) and lines further away from other lines in the system are considered segregated (or deep). The Integration measure of each line is calculated based on the average depth, and lines with Integration values greater than 1.67[69] can be considered highly integrated, while those with values less than 1 are considered segregated. Generally, the values are presented on a chromatic scale, and in this study, darker colors (dark gray leaning towards black) indicate greater accessibility potential and lighter colors (light gray leaning towards white) indicate less potential (Hillier and Hanson, 1984).

After obtaining the Integration measure, we calculated the compactness indicator for urban fabrics, understanding that the compactness index is measured by the ratio between the built-up area and the urbanized area of the city. We chose this indicator because we understand that a compact city is synonymous with efficiency, since in addition to implying greater savings in the implementation and maintenance of infrastructures, compact cities tend to imply greater accessibility to urban services and equipment (Krafta, 2014). Therefore, to operationalize the equation, we considered the most integrated area and/or integrating core (Holanda, 2002) as the built-up area; that region of the map tending towards a darker tone and the polygon around the limits of the road structure as the urbanized area inclined towards a lighter tone (Figure 1).

RESULTS AND DISCUSSIONS

The data analysis is organized into three categories, namely: (a) general population and percentage and health; (b) demographics and built and urbanized areas; and (c) urban form. This organization was chosen to initially offer an understanding of the context of the place and thus, first discuss a set

[69] These values (1.67 and 1) refer to European metropolitan cities. In the Brazilian context, Porto Velho/RO has 2.213 and Florianópolis/SC has 0.262 with Integration values (Medeiros, 2013).

individually and then make the cross-references between sets with an emphasis on measures of urban form.

Thus, we saw that of the 10 cities listed, 9 are located in the North Region and 1 in the Northeast Region. The data indicate that Tefé/AM is the city with the largest population in absolute numbers, however, the city of São Gabriel da Cachoeira/AM is the city with the largest percentage of Indians, with Tabatinga/AM and Barcelos/AM appearing as the largest and smallest demographic densities, respectively (Table 1).

Table 1 – The 10 main indigenous cities in Brazil and the relationship between Family Health Teams/ESF and coverage by Primary Care/AB. Source: IBGE (2022) and Ministry of Health (2024)[70].

	Municipality	**Total population**	**Indigenous people**	**%**	**Number of SF Team**	**Primary Health Care Coverage (%)**
1	São Gabriel da Cachoeira/AM	51.795	48.256	93,17	8	52,5
2	Tabatinga/AM	66.764	34.497	51,67	17	76,59
3	São Paulo de Oliveiça/AM	32.967	26.619	80,74	13	73,12
4	Pesqueira/PE	62.722	22.728	36,24	21	84,65
5	Autazes/AM	41.564	20.447	49,19	8	58,82
6	Tefé/AM	73.669	20.394	27,68	15	95,73
7	Santo Antônio do Içá/AM	28.211	18.882	66,93	8	77
8	Benjamin Constant/AM	37.648	17.811	47,31	9	64,62
9	Jacareacanga/PA	24.042	14.216	59,13	2	51,78
10	Barcelos/AM	18.834	14.178	75,28	7	73,59

It can be seen that the percentage of the self-declared indigenous population has increased in relation to the last Censuses, since the 1991 Census carried out in Brazil limited the counting of the indigenous population to the cities, not collecting data such as ethnic affiliation and language spoken. The 2000 Demographic Census demonstrated the population growth of this indigenous population from 249 thousand to 749 thousand people. This increase in growth resulted from the fact that people identify themselves as indigenous, mainly in urban areas (IBGE, 1991; 2000).

In order to highlight the interrelations between social inequalities and dynamic processes involving health and disease in a given population, reliable information in the form of qualitative and quantitative parameters (Coimbra Jr and Santos, 2000) is necessary to be able to carry out the analyses proposed by the study. In this sense, the city with the largest indigenous population in the country (São Gabriel da Cachoeira/AM) is the one with the least Primary Health Care/PHC coverage, while the city of Tefé/AM has excellent proportions both in terms of the number of Family Health Teams and in Primary Health Care/PHC coverage (Table 1).

[70] These data were consulted by period and by geographic unit with a base date of April 2024 and are available at https://egestoraps.saude.gov.br/

Considering the second category (demographic and built and urbanized areas) to be analyzed, it is worth noting that 9 out of 10 cities are located in the North Region of the country - cities characterized by large areas of territorial extension. It is appropriate to clarify this methodological logic and it is important to understand the context of the place, in order to later discuss the third category that deals with urban form.

Therefore, the city of Pesqueira/PE - the only city located outside the northern region - is the city with the highest population density and Barcelos/AM the lowest. Although Pesqueira/PE has a high density in relation to the 10 cities, it can be seen that its built-up area is smaller than the average of 14.21 km². Another equally important piece of information for the debate concerns the relationship between built-up area and population density of the city of Autazes/AM, that is, this city has both built-up and urbanized areas larger than the average of the cities, however, a density of just over 10% of the average (Table 2).

São Gabriel da Cachoeira/AM and São Paulo de Olivença/AM are the cities with the largest and smallest urbanized areas. The level of urbanization in the northern region is generally linked to exploitation by groups of landowners, mining companies, agribusinesses and others who, when exploiting the forest (in this particular case), end up influencing decisions about the general form of these urban settlements, resulting in a vast urbanized area, with little construction and little population. In addition to these cities having a higher cost due to these exploitations, the city is transformed into several private and closed spaces, preventing more people from circulating and moving around, no longer having time to focus on their own urban morphology (Ribeiro et al., 2008).

Table 2 – Demographic values and areas of the 10 indigenous cities. Source: IBGE (2022), QGIS (2024).

City	Population (hab/km²)	densityBuilt area (Km²)	Urbanized area (Km²)
Barcelos/AM	0,15	2,67	129,77
Jacareacanga/PA	0,45	63,79	4202,80
São Gabriel da Cachoeira/AM	0,47	18,03	4353,77
São Paulo de Olivença/AM	1,68	2,11	28,57
Santo Antônio do Içá/AM	2,28	3,06	64,65
Tefé/Am	3,11	24,99	398,00
Benjamin Constant/AM	4,32	7,64	337,79
Autazes/AM	5,43	186,44	3609,01
Tabatinga/AM	20,48	47,91	905,50
Pesqueira/PE	65,33	10,39	599,39
Média	32,89	14,21	498,69

According to Maia and Netto (2016), it is necessary to be clear between evaluating the 'form performance' and 'measuring the form' based on compactness and density values. Evaluating performance means examining the impacts of the form on dynamics beyond the form, such as social, microeconomic and environmental processes, for example. And, evaluating the urban form means mapping it, based on its attributes, in relation to another universe external to the morphology, generally linked to the city users who live in the city or periodically pass through it (Krafta, 2014).

The choice of the Integration measure and the indicator of compactness of the urban fabric for this work sought to bring together theoretical basis and technical-tool support in order to analyze and reflect on the level of accessibility of the indigenous people to health teams or public facilities in general. Therefore, we see that the city of Pesqueira/PE has an urban system with greater potential for Integration (proximity) and Jacareacanga/Am more distant (or segregated), that is, while Pesqueira/PE tends to have a greater flow of movement (pedestrians and vehicles), Jacareacanga/Am tends to have less flow. We point in this direction because in traditional syntactic studies the integration measure presents a correlation coefficient of 0.547 when related to pedestrian movement on a local scale (Hillier et al., 1993 and Hillier, 1999).

Still in syntactic terms and in comparison to other urban systems, while Florianópolis/SC presents an integration level of 0.262, considered the lowest among Brazilian capitals (Medeiros, 2013), Pesqueira/PE presents a more integrated system than the capital of Santa Catarina and Jacareacanga/PA, an urban network less integrated than Florianópolis/SC. In this perspective, Pesqueira/PE presents an integrated (or close) urban system with 0.627 and Jacareacanga/PA with 0.063 of the selected cities.

Table 3 – Relationship between cities and urban form measures.

City	Integration (NAIN)	I comp
Pesqueira/PE	0,627	0,02
Barcelos/AM	0,585	0,02
São Paulo de Olivença/AM	0,422	0,07
Santo Antônio do Içá/AM	0,373	0,05
Tefé/AM	0,378	0,06
Autazes/AM	0,330	0,05
Benjamin Constant/AM	0,275	0,02
Tabatinga/AM	0,279	0,05
São Gabriel da Cachoeira/AM	0,259	0,00
Jacareacanga/PA	0,063	0,02

Regarding the compactness indicator, none of the 10 cities obtained a value higher than two digits. Only 2 cities presented values above 0.05, namely the city of São Paulo de Olivença/AM with 0.07 and Tefé/AM with 0.06. This value of 0.05 was used as a parameter, a reference value to establish a relationship between the selected cities. Even so, considering that the compactness measures vary between 0 and 1 according to Krafta (2014), the compactness indicators of the 10 main Brazilian indigenous cities can be considered to be of very low levels, as can be seen in Table 3.

When exploring the correlation between the two measures (integration and compactness) intrinsic to the urban form, an exponential trend of 0.240 is observed. Although this may seem like a low value, perhaps due to the number of cities or the regional context in which most of them are located, the truth is that the data points to a positive correlation, that is, the higher the compactness indicator, the more integrated the urban network tends to be and vice versa. These values corroborate arguments that compact cities imply benefits (Krafta, 201), as they tend to have an intensive use of

urban space, avoiding the widespread expansion of urbanization over the natural environment (Graph 1).

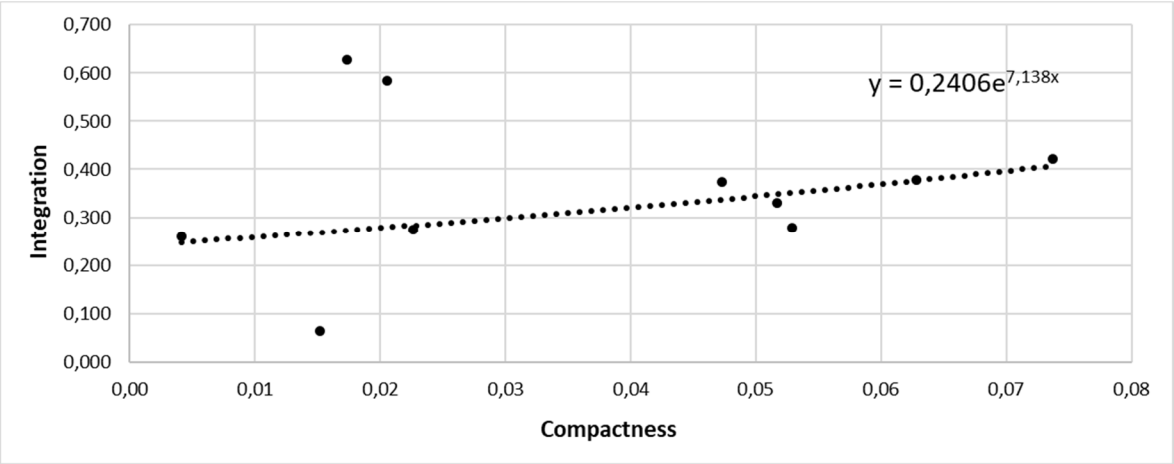

Gráfico 1. Correlation between integration and compactness measures of selected cities. Source: Open Street Maps/OSM road network and processed via Depthmap®. Credit: Authors 2024.

When crossing the results between the suggested categories, it is clear that the city of Pesqueira/PE stands out as the most integrated urban system, the densest and the largest in number of Family Health Teams. However, the findings indicate that this city has a relatively low compactness indicator and the penultimate place in terms of the percentage of indigenous population, characterizing a highly urban profile.

The city of São Paulo de Olivença/AM has the smallest built and urbanized areas, the most compact and the third largest both in terms of integration and percentage of indigenous population. Although it is considered a city with positive morphological attributes, it is a city with relatively low density; however, when observing health-related services, it can be considered of good quality, as the city has just over 73% coverage of Primary Health Care.

Jacareacanga/PA and São Gabriel da Cachoeira/AM are two cities that have the lowest values of Integration, Density and Compactness. In addition to having an indigenous population of over 60 thousand people, the two cities have the largest urbanized areas, with São Gabriel da Cachoeira/AM standing out in first place.

Regarding health care, Jacareacanga/PA and São Gabriel da Cachoeira/AM have cities with just over 50% Primary Health Care coverage for each of these settlements, while Jacareacanga/PA has 2 and São Gabriel da Cachoeira/AM has 8 Family Health Teams each. These results corroborate a scenario that has persisted for decades in which there is an unacceptable gap between several health indicators recorded among indigenous peoples and the rest of the Brazilian population, with the indigenous segment systematically disadvantaged (Mendes et al., 2018).

When analyzing the urban grids (Figure 2), we observe two distinct profiles that we call inter-Amazonian and urban. The urban forms with an inter-Amazonian profile are the 9 cities located in the northern region (images “a”, “b”, “c”, “d”, “e”, “f”, “g”, “h” and “j”) and the one with an urban profile is located in the northeast region (image “i”), including the one discussed at the beginning of this section.

The urban forms with an inter-Amazonian profile, for the most part, present a region (or nucleus) of greater Integration, that is, a place in the system that is easily identifiable, except for the cities of Autazes/AM (image “d”) and São Paulo de Olivença/AM (image “h”), which present a more spread-out system. In the cities where the Integration nucleus is more concentrated, a common characteristic can be seen between them, which are the long road axes intercepted by perpendicular roads over the urbanized area, compromising efficiency and maintenance costs.

The network identified as urban has a radial slope and its integrating core tends to expand east/west. Having a radial network and an extensive core means that the city is more efficient than a more distant and linear network such as the inter-Amazonian network, since the radical form has shorter paths/distances from one point to all others in the road system (image “i”).

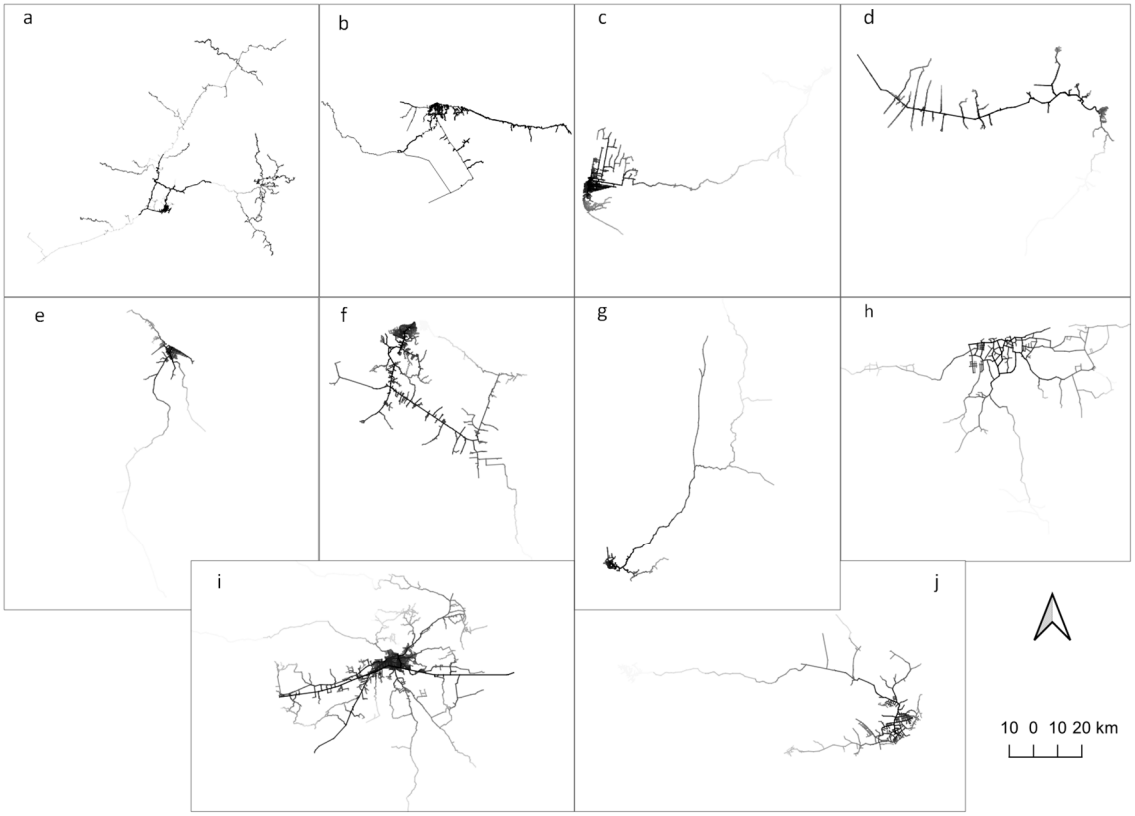

Figure 2. List of syntactic maps of the selected cities. a) Jacareacanga/PA; b) Benjamin Constant; c) Tabatinga/AM; d) Autazes/AM; e) Barcelos/AM; f) Tefé/AM; g) São Gabriel da Cachoeira/AM; h) São Paulo de Olivença/AM; Pesqueira/PE and j) Santo Antônio do Içá/AM. Source: Open Street Maps/OSM road network, developed via QGIS® software and processed via Depthmap®. Credit: Authors 2024.

The study indicates that Pesqueira/PE has the most integrated urban form and is the second city with the highest Primary Health Care/PHC coverage (84.65%). Considering that its urban system is the most integrated and that being integrated is synonymous with potential accessibility (or proximity), the results suggest that the morphological profile of this city contributes to the population in general (including indigenous people) having greater access to health facilities.

Jacareacanga/AP, Barcelos/AM, Benjamin Constant/AM and São Gabriel da Cachoeira/AM are the cities that presented a less integrated morphology and are among the urban fabrics with the lowest

compactness index of the selected cities. In addition to having a linear and distant configurational structure, their indigenous populations, which are between 47 and 93.17%, are minimally assisted by both the number of Family Health Teams/ESF and Primary Health Care/APS, compromising health problems for the indigenous people.

CONCLUSIONS

These structural difficulties (morphological, urban equipment and human resources) of the urban environment compromise the efficient functioning of human life in the city. While we have a human settlement characterized by an extensive road network, low density, less compactness and minimal health care, the results cannot be contrary to the fateful social, economic, ethnic segregation and other types of exclusion associated with scarce health promotion and prevention services in general.

The findings lead us to reflect on the importance of the topic and its limitations as well. That is, we see that it is possible to aggregate other attributes of the urban environment intrinsic to the city, which were not related in this study, such as employment, income, services and mainly which production sectors are predominant in these cities. Another limitation of the study is of a conceptual nature and deals with discussing the spatial guidelines between the built and urbanized areas. A third suggestion is to associate studies of urban form with the health area, such as identifying and quantifying the causes of hospitalizations of the indigenous population; quantifying the number of beds, emergency care units and relating whether these are within the coverage area recommended by the SUS.

Acknowledgements

The first author would like to thank his grandmother Dorvalina Córdula de Oliveira (1932-2018) for the values and principles she taught him. Dorvalina, an honorable woman of indigenous origin, was born in the municipality of Borba in the state of Amazonas/Brazil. She was a great example of courage, perseverance, and resilience during her time among us. She encouraged this author to always seek knowledge and, in her name, the author dedicates this work to all Brazilian indigenous peoples who, like his grandmother, left their habitat to face the challenges of urban life.

ABSTRACT

Urbanization has led to significant changes in the form of cities. Typically, cities that have undergone urbanization have historical areas, modern urban areas, new town areas, and urban expansion areas (suburban areas), each with distinct urban form characteristics and morphological structures. At the same time, different cities have unique historical backgrounds and cultures, resulting in varying strategies for managing urbanization. As a result, a specific urban area may exhibit different urban form characteristics and morphological structures. To clarify the relationship between the historical morphological imprint of the city, urban culture, the stage of urban development, and the town's morphological characteristics and morphological structure, this research conducts a comparative study of three cities with different historical backgrounds, cultures, and stages of development: Shanghai, Nanjing, and Copenhagen. It explores the differences between these cities in terms of characteristics of morphological structure. Six 1km by 1km areas were selected in each of the three cities based on the definitions of historical area, modern urban area, new town area, and urban expansion area. The blocks/streets and buildings were mapped, and numerical statistics on the street patterns and structures, number and size of blocks, and the size and distribution of buildings were carried out using GIS (Geographic Information System), leading to a comparative analysis of the different urban areas from a quantitative perspective. The research finds that the morphological indicators can demonstrate the similarities in urban form between urban areas with similar historical backgrounds and cultures at the same stage of development and the differences in morphological characteristics and structures between urban areas with different historical backgrounds and cultures. Additionally, it has been discovered that specific indicators can describe the morphological characteristics of street patterns and structures.

Keywords: Quantification, Comparative Study, Urban Morphological Character, Morphological Indicator

INTRODUCTION

The shaping of urban form is a complex and gradual process, which is not only profoundly influenced by the historical background and social culture of the city, but also tends to leave behind the products of different eras in the expansion and renewal of the city. On the one hand, urban morphology is related to historical context, laws and regulations, geographic location, population, economy and

culture (Scheer, 2016), and cities with different cultures tend to differ in many ways in their physical form. On the other hand, urban morphology is related to the stage of development of a city. Cities that have undergone urbanisation tend to have a variety of urban areas, including historical areas, city centres, new town areas, and expansion areas. Each of them has different functions and different characteristics of urban forms. In addition, in the context of globalisation and urbanisation, due to the wide application of modern construction techniques and planning concepts, new urban areas with different cultures may also present similar urban forms. Differences and similarities in urban form not only reflect the unique history and culture of cities, but also map the process of urbanisation.

In the past decades, many researchers have studied urban form through comparative studies to understand the differences and similarities of urban form. These studies can be broadly categorised into diachronic and synchronic comparisons (Scheer, 2016). Diachronic comparisons can reflect how the elements of urban form (e.g. street/block, building, plot) change and develop over time, so as to analyse the pattern of evolution of urban form with the process of urbanisation and the motivation. Synchronic comparisons can reflect the differences or similarities of urban form in different areas, so as to analyse the characteristics and influencing factors of urban form. Among comparative studies, although cross-cultural comparisons are relatively rare and challenging due to the diversity of urban forms, the inconsistency of related terminology and cultural differences, they are of great importance in providing a richer set of cases and research methodologies for urban morphology and facilitating an understanding of the ways in which knowledge is accumulated in different cultural contexts (Whitehand et al., 2012; Scheer, 2016).

In established research, approaches such as historico-geographical approaches, process typological approaches and the spatial syntax have been extensively employed in comparative studies of urban form, thereby providing a comprehensive theoretical foundation for urban morphology (Oliveira and Pinho, 2006; Oliveira, 2014; Wardhani and Bahri, 2020). In the 21st century, there is a shift in urban morphology towards evidence-based approaches and the quantitative approach has become an important tool in urban morphology study (Batty, 2008). A considerable number of studies have explored ways to quantify urban form from different perspectives and have used a variety of morphological indicators to measure different features of urban form (Fleischmann et al., 2021).

This study will conduct a cross-cultural comparative study using quantitative approaches to quantify characteristics such as morphological structure and street density, block size, building size and density, etc. Through diachronic and synchronic comparisons, this study reveals how urban form under different cultures is affected by factors such as historical background and culture, and how urban form under the same culture is affected by factors such as urban planning. The findings will contribute to our understanding of the physical form and morphological structure of cities in different cultures and identify effective indicators for comparative studies of urban form using quantitative approaches.

RESEARCH BASE

Most cities have developed from their historical origins, which have been influenced by a combination of geographical and cultural factors, resulting in unique and varied urban forms. The building type and morphological structure of urban areas evolve in a dynamic manner, adapting and transforming in response to many factors, including social needs, technological change and economic conditions.

Western cities have undergone significant changes in building types (Oliveira et al., 2014), a phenomenon that has been reflected in China's urban form, particularly in the housing type (Liu and Ding, 2012). Upon entering the modern pattern of urban development, the morphology of both residential areas and city centres has undergone profound changes. The diversity of urban forms that has resulted from differences in development rates, policies, urban planning and resource allocation in cities not only highlights the complexity of cities but also emphasises the importance of a deeper understanding of the factors that influence urban form.

The evolution and development of the modern city has been significantly influenced by urban planning theories and ideas, particularly those outlined in the Athenian Charter and the fundamental principles of contemporary urban zoning. The theories advocate the separation of the residential, recreational, work and transport functions of the city, and it is under the influence of these theories and ideas that many cities have developed urban residential, commercial, office areas and so on (Athens Charter, 2007). The different zoning not only shape the unique physical form and spatial characteristics of different urban areas, but also influence the functions of them and the daily lives of their inhabitants.

Differences in urban form across cultures and morphological changes during the transition from ancient cities to modern urbanisation can be revealed and understood through comparative studies. Many studies have discovered how historical culture and urbanisation influence urban form through comparative studies of morphological structures, building types, etc. (Whitehand et al., 2014; Whitehand et al., 2016; Wardhani and Bahri, 2020). In recent decades, there has been a clear trend towards the use of quantitative or numerical methods to study urban form, driven by a number of researchers (Moudon, 1997). A number of studies have been conducted using these quantitative methods to carry out comparative studies with the objective of revealing evolutionary patterns and features in urban morphology. Peponis et al. quantified morphological indicators including block size, street and intersection densities, across 118 U.S. areas, revealing a decline in street density due to 20th-century sprawl (Peponis et al., 2007). Porta et al. examined the main street network structure and street lengths in 100 urban areas worldwide, noting that historical streets were significantly shorter than modern ones, which suggests a corresponding increase in block size (Porta et al., 2014).

COMPARATIVE METHODOLOGY

Cases

In order to investigate the influence of different cultural and historical backgrounds on urban form, three cities with disparate cultural and historical backgrounds were selected for the study: Nanjing, Shanghai and Copenhagen (Figure 1). Nanjing and Copenhagen are respectively, representative of a city in China and Denmark. They reflect the cultural differences and urban characteristics between China and the Western Europe. Shanghai's semi-colonial history resulted in a fusion of Chinese and Western cultures. A cross-cultural comparison of the three cities allows for an investigation of the impact of contrasting cultural and historical (Nanjing and Copenhagen) influences on urban form. It also permits an examination of the similarities and differences between Shanghai that influenced by Western culture and Nanjing, as well as the particularities resulting from the fusion of cultures.

Nanjing, one of China's four ancient capitals, is renowned for its extensive history and cultural heritage. It serves as the capital of Jiangsu Province with a population of around 9.5 million, Nanjing has experienced significant urban expansion in recent decades. This includes the development of Hexi

New City, situated to the west of the Qinhuai River, in the early 21st century, and Jiangbei New City, located to the north of the Yangtze River, around 2015 (Figure 1a).

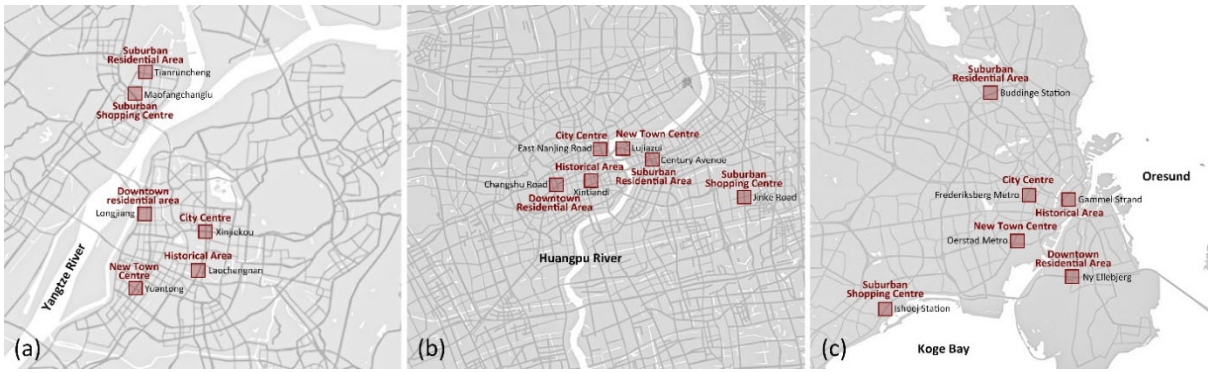

Figure 1. Case Study Selection: (a) Nanjing, (b) Shanghai, (c) Copenhagen, photo credit: all figures except Figure 2 in this paper are drawn by authors.

Shanghai, an international metropolis in China and a globally important economic and financial centre, has a population of around 25 million. From 1843 onwards, Shanghai was semi-colonial and absorbed Western influences, resulting in the blending of Chinese and Western cultures and building types. Since the 1990s, the Pudong New Area has undergone a period of rapid growth, transforming Shanghai into a cosmopolitan city (Figure 1b).

Copenhagen, the capital of Denmark, has a history dating back to the Middle Ages and a current population of around 1.3 million. The city underwent a rapid process of industrialisation and modernisation between the late 19th and mid-20th centuries, with expansion into surrounding regions and the development of new residential and industrial zones (Figure 1c).

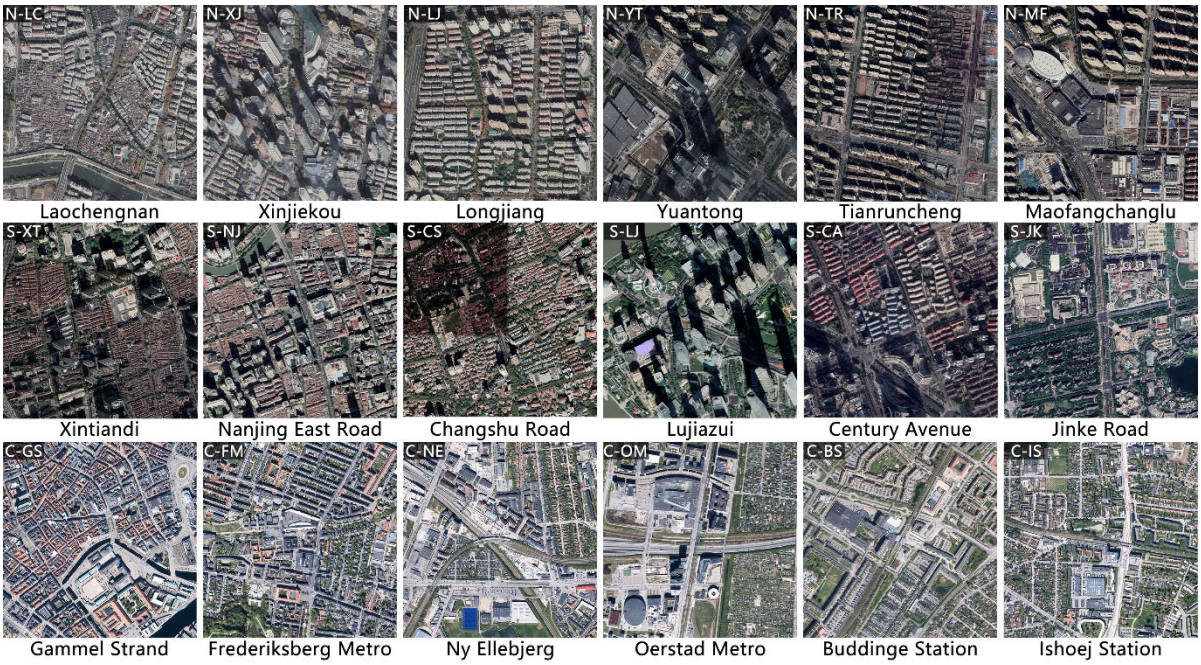

Figure 2. Satellite maps of study area with abbreviations consisting of the initials of the country and the area, photo credit: River Map (a software) and NIRAS.

Secondly, the study selects historical areas, city centres and residential areas from each of the three cities to investigate the influence of the city's stage of development on urban forms (Figure 2). ‘Laochengnan’, ‘Xintiandi’ and ‘Gammel Strand’ are selected as the study cases for historical areas. In particular, Xintiandi’, embodies a blend of Eastern and Western characteristics to highlight the cultural integration in Shanghai's historical area. Based on the location and planning, there are three categories of city centres: city centre, new town centre and suburban centre. ‘Xinjiekou’, ‘Nanjing East Road’ and ‘Frederiksberg Metro’ are selected as the study cases of city centres, which are densely populated, functionally mixed and commercially prosperous. ‘Yuantong’, ‘Lujiazui’ and ‘Oerestad’ are selected as the study cases of new town centres in the three cities respectively, which are characterised by a high concentration of companies and enterprises. ‘Maofangchanglu’, ‘Jinke Road’ and ‘Ishoej’ are selected as study cases for suburban centres. These areas tend to have large shopping malls and a large number of residential areas. In addition, 'Longjiang', 'Changshu Road', and 'Ny Ellebjerg' are selected as study cases for downtown residential areas, while 'Tianruncheng', 'Century Avenue', and 'Buddinge Station' are selected as study cases for suburban residential areas.

Cartographic Methods

The raw materials for all the study cases are collected, which are mainly provided by the research team of Nanjing University, Tongji University and NIRAS participating in the research project entitled ‘Transit-Oriented Development 2 (TOD2) – Public spaces, mobility hubs and climate neutrality toolbox’, including satellite maps, land use maps and footprint maps. The satellite map provides the fundamental features of an area, serving as an important reference material throughout the process of map creation and revision. The land use map reflects the nature of the land use and the mix of functions in an area. The footprint map includes street/blocks and buildings, based on which street/block map, street network maps, building maps (including the number of storeys), and building footprint maps are generated, which are all necessary for the study, together with the land use map, are the fundamental maps required for the study (Figure 3). These maps should be put into GIS and are described below.

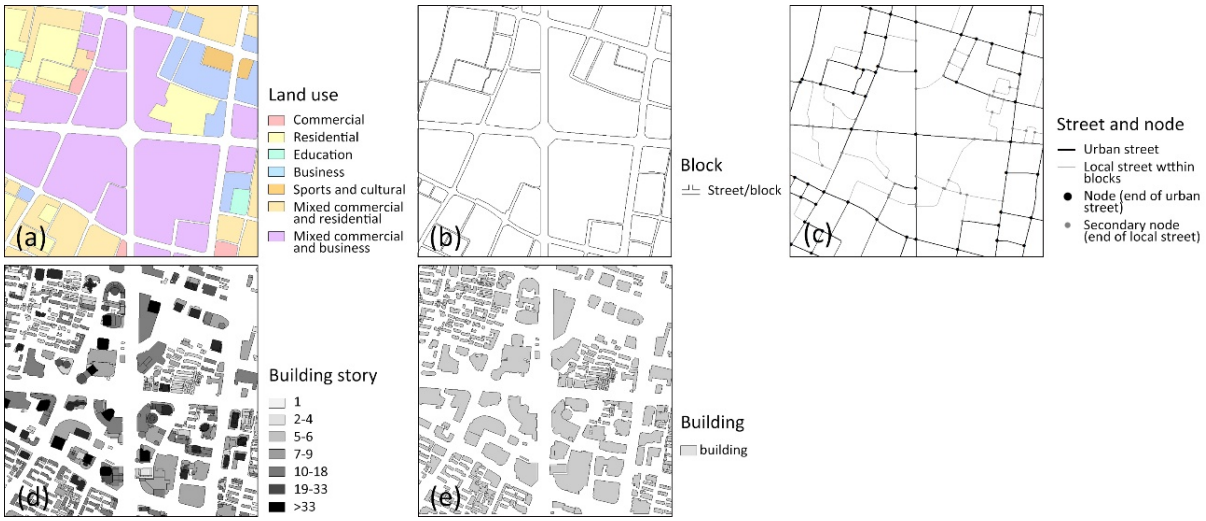

Figure 3. Five Fundamental Cartographic Maps: (a) Land use map, delineates ten distinct functions, with eight dedicated to single-use land types, including commercial, residential, and educational and the remaining two functions designated for mixed-use, comprising commercial-residential and commercial-business combinations.

(b) Map of street/block. (c) Map of street networks. (d) Map of buildings (DIM), includes seven categories according to Chinese standard. (e) Building footprint map.

Due to the influence of planning ideas, modern cities have land use maps, but different countries or areas have different criteria for classification. The study harmonised the classification of land use properties in Nanjing, Shanghai and Copenhagen into ten main functions. Based on this map it is possible to calculate indicators such as diversity and mixing degree of functions (Figure 3a).

Street/block maps and street network maps can reflect street space and street patterns. In the process of mapping, it is necessary to overcome the inconsistency of road classification between China and Denmark to ensure a uniform mapping standard. Based on the street/block map, the number, size and distribution of street blocks can be counted, and based on the street network maps, the number, density, length and connectivity of the street network can be calculated (Figure 3b,3c).

Maps of buildings (DIM) and building footprint maps can reflect the morphological characteristics of buildings. The former one contains information about the number of storeys of buildings, based on which indicators such as the number of storeys, the difference in building heights, and the floor area ratio can be calculated. The later one is based on the former one by integrating different parts of the same building through the tools in GIS. Based on this map, we can calculate the building density, ground area of buildings and other indicators (Figure 3d, 3e).

The elements of each of the five fundamental maps need to be completed in a GIS platform. Based on these, parameters such as length, area and number can be counted, which in turn allows for the calculation.

Morphological Indicators

The study analyses the three elements of streets/blocks, street network and buildings, with the aim of exploring the characteristics of street patterns, building density and building types in different areas. Previous studies have demonstrated that urbanisation has resulted in a reduction in the number of streets and blocks, an increase in the length of streets and the size of blocks, and an increase in the number of storeys and floor area ratio. Concurrently, the street network connectivity and building density have undergone significant changes. The study selects appropriate indicators that can effectively describe these characteristics, thereby enabling an accurate reflection of the impact of urbanisation and culture on urban forms.

Firstly, the Herfindahl-Hirschman Index (HHI) was selected to quantify the diversity of functions, with a value between 0 and 1 (Jiao et al., 2021). A lower value indicates a greater diversity of functions, which is associated with greater ease of living.

Secondly, morphological indicators of streets/block patterns were selected. In consideration of the frequency, clarity and stability of the indicators, the Number of Blocks per sq. kilometre (NB) and Street Density (SD) were selected to describe the density of street/blocks. Additionally, the Average Area of Blocks (AAB) and Average Street Segment Length (ASSL) are selected to describe the size of the blocks and the street length, respectively. In addition, the Connectivity Alpha Index (CAI) was selected for the purpose of evaluating the connectivity of the street networks. It can be adapted for

calculations in one square kilometre, while the resulting data reflect the diversity of actual travel choices, thereby facilitating a more accurate assessment (Song et al., 2013).

Finally, the morphological indicators of the building were selected. The Ground Space Index (GSI) and the Floor Space Index (FSI) were selected as indicators of building density. The Median Ground Area (MGA) was selected to describe the size of buildings, given that the median measure is relatively more accurate at the midpoint of the sample (Porta et al., 2014). The ratio of the FSI to the GSI, i.e., the Area-Weighted Average Storey (AWAS), was selected to describe the average height of the buildings.

Following the screening process, the study select a total of ten indicators, which were subsequently categorised into four categories (Table 1). The first category characterises to the diversity of functions. The second and third categories are concerned with the street/block pattern. The fourth category describes the characteristics of buildings. These indicators facilitate precise comparative analyses from a range of perspectives, including diachronic and synchronic comparisons.

Table 1. Selected morphological indicators to describe the characteristics of urban forms.

Category	Element	Indicator	Code	Formula	Description
1	Street/block	Herfindahl-Hirschman index [-]	HHI	$\sum_{i=1}^{k} {P_i}^2$	Where Pi is the percentage of land use i and k is the number of land-use types.
2	Street/block	Number of blocks per sq. kilometre [-/km²]	NB	/	/
		Average area of blocks [ha]	AAB	$\frac{\sum_{i=1}^{n} A_i}{n}$	Where Ai is the area of each block and n is the number of blocks.
3	Street network	Street density [km/km²]	SD	$\frac{\sum_{i=1}^{n} L_i}{A_T}$	Where Li is the length of each urban street segment and n is the number of urban street segments.
		Average street segment length [km]	ASSL	$\frac{\sum_{i=1}^{n} L_i}{n}$	Where n is the number of urban street segments.
		Connectivity alpha index [-]	CAI	$\frac{u}{2V-5}$	Where V is the number of nodes (end of links). Where u (L-V+p) is the cyclomatic number and p is the number of subgraphs.
4	Building	Ground Space Index [-]	GSI	$\frac{\sum_{i=1}^{n} A_i}{A_T}$	Where Ai is the ground area of each building and A_T is the study area.
		Floor Space Index [-]	FSI	$\frac{\sum_{i=1}^{n} A_i S_i}{A_T}$	Where Si is the storey of each building.
		Median ground area [m²]	MGA	/	/
		Area-weighted average story [-]	AWAS	$\frac{\sum_{i=1}^{n} A_i S_i}{\sum_{i=1}^{n} A_i}$	/

URBAN MORPHOLOGICAL CHARACTERISTICS AND THE INDICATORS

On the basis of the methodology described above, five fundamental maps of the 18 study areas were drawn up and the values of the indicators were calculated, with the following results (Table 2).

Table 1. Quantitative results of nine morphological indicators for eighteen study areas.

Area	HHI*	NB	AAB	SD	ASSL	CAI	GSI	FSI	MGA	AWAS
N-LC	0.21	69	1.1	16.3	0.08	0.25	0.35	1.2	52	3.4
N-XJ	0.19	46	1.8	10.7	0.11	0.15	0.35	3.7	326	10.5
N-YT	0.17	19	4.0	7.4	0.23	0.10	0.19	2.1	710	10.9
N-LJ	0.41	16	5.1	8.3	0.24	0.18	0.21	1.5	611	7.4

N-TR	0.51	8	11.7	4.2	0.30	0.04	0.15	1.2	550	7.9
N-MF	0.23	9	10.0	3.3	0.37	0	0.33	2.4	911	7.5
S-XT	0.31	39	1.7	8.9	0.13	0.35	0.35	2.0	282	5.9
S-NJ	0.14	60	0.9	11.7	0.10	0.20	0.39	2.7	350	6.9
S-LJ	0.19	24	2.5	6.6	0.14	0.10	0.18	3.1	572	17.3
S-CS	0.27	28	2.3	7.2	0.14	0.15	0.35	1.6	258	4.4
S-CA	0.24	17	3.6	5.5	0.22	0.07	0.24	1.7	440	7.4
S-JK	0.21	16	4.1	5.0	0.20	0.07	0.23	1.4	686	6.1
C-GS	0.19	105	0.8	18.2	0.07	0.27	0.42	1.7	177	4.1
C-FM	0.17	53	1.7	13.0	0.11	0.13	0.28	1.3	196	4.5
C-OM	0.18	21	4.2	7.1	0.17	0.11	0.20	1.2	56	5.8
C-NE	0.15	37	2.3	8.2	0.13	0.09	0.20	0.6	95	3.1
C-BS	0.42	34	2.7	8.6	0.15	0.05	0.16	0.3	123	2.1
C-IS	0.38	19	4.8	6.8	0.21	0.04	0.18	0.4	99	2.4

**Note: Since the two categories of mixed-use lands encompass two functions, adjustments are needed for these mixed-use lands when calculating the HHI, that is 〖P_M1/2〗^2 and 〖P_M2/2〗^2. Where P_M1 and P_M2 are the percentage of two mixed-use lands.*

In order to observe the overall trend of the multiple sets of data, the numerical results were normalised by dividing each indicator's value by its maximum value, thus ensuring that all results fell within the interval 0–1. Subsequently, the indicators were reorganised, with the second and third categories of indicators grouped together, both of which describe the street/block pattern. The fourth category of indicators was divided into two categories, with one category (GSI and FSI) describing the density of buildings and the other category (NBU, MGA and AWAS) describing the dimensions of the buildings. Finally, line plots were drawn up for the three cities, with the area defined as the horizontal coordinate and the normalised indicator scores as the vertical coordinate (Figures 4 and 5).

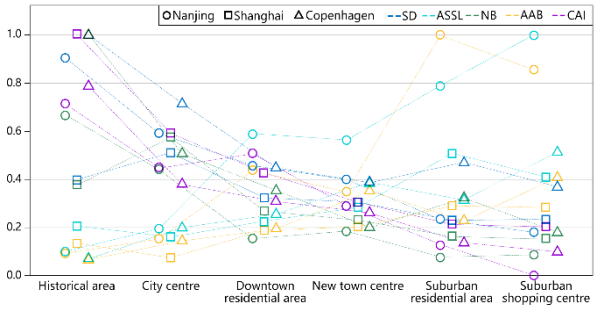

Figure 4. Comparison of quantitative results for street/block patterns.

The figure shows a gradual decrease in the values of NB, SD and CAI, while a gradual increase is observed in AAB and ASSL from the historical areas to the downtown areas to suburbs (Figure 3).

The spontaneously formed street network of the historical areas (N-LC, C-GS) has the highest SD and NB and the smallest ASSL and AAB. In contrast, S-XT was built after planning, and its grid street pattern displays the characteristics of a modern street network. The city centres (N-XJ, S-NJ, C-FM) exhibit the next highest and numerically close SD, NB, ASSL, and AAB, which may be attributed to the necessity of accommodating both pedestrian and vehicular accessibility. New town centres and suburbs are mostly formed under modern planning concepts, with sparse and wide streets, the smallest NB and SD, and the largest ASSL and AAB. In particular, the suburbs of Nanjing and Shanghai have sparser streets and larger blocks than those of Copenhagen. In many of them, the SD is less than half of that in Copenhagen, whereas the values of ASSL and AAB are two to four times higher than that in

Copenhagen, which is consistent with the phenomenon of giant blocks in Chinese cities, which has a negative impact on the pedestrian experience.

As the SD and NB decrease and ASSL and AAB increase, the connectivity (CAI) of the urban street network gradually decreases. In addition, the grid street network pattern was found to favour street connectivity. However, for areas with large ASSL and AAB, even with grid patterns, it is no longer possible to include enough complete block in 1km x 1km areas, resulting in a very small CAI.

The quantitative results of the street/block pattern demonstrate a regularity in urban development. In modern cities, there is a sparser street layout compared to historical areas, accompanied by an increase in street lengths, block sizes and a decrease in connectivity. These elements are in line with the findings of numerous established studies, which empirically demonstrate that the evolutionary patterns of urbanisation in Chinese cities (Nanjing and Shanghai) are in a consistent state with Danish cities, with a much stronger magnitude of change. They also provide quantitative evidence for understanding the differences in morphological structure between modern and traditional cities.

The population density of a city is closely related to its building density. A clear downward trend in FSI is observed in Copenhagen, with the city's population distribution is characterised by a dense population in the centre and a relatively sparse population at the edges. Conversely, the suburbs of Nanjing and Shanghai still have large populations, and in order to meet the residential needs of these people, these areas still have high GSI and FSI.

Urban building patterns are influenced by the urbanisation process and urban culture. In this process, the building types in Nanjing and Shanghai have undergone significant evolution, which is reflected in the changes in the values of the NBU and MGA indicators. Conversely, Copenhagen shows less variation in building scale and related indicators, indicating a smoother development.

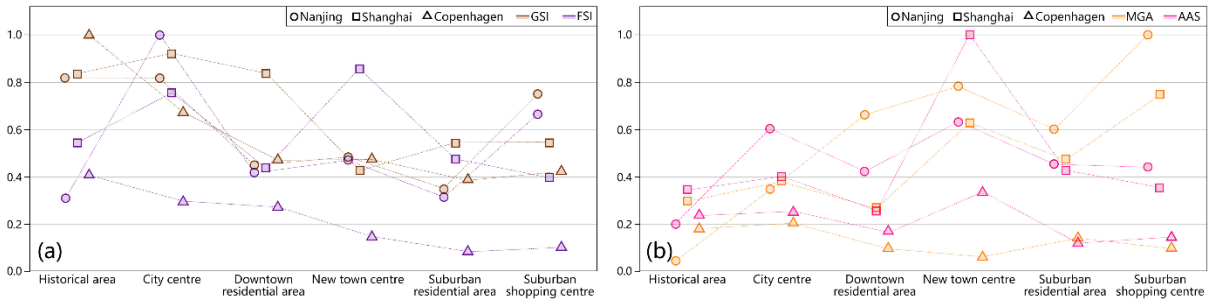

Figure 5. Comparison of Quantitative Results for buildings: (a) building density, (b) building size.

The study finds that NBU serves as an effective indicator to differentiate between historical areas and CBDs in new town, as shown in the figure, the N-LC area has an extremely high value of NBU, while the N-YT and S-LJ areas have a low value of NBU. In addition, the study points out that MGA can indicate the residential building type in one area as the individuals with MGA are usually residential buildings, and the significant differences in the MGA values for the N-LC, S-XT, C-GS, N-LJ, and S-CS areas indicate that these areas have different building characteristics. Quantitative analyses of the MGA metrics provide a direct representation of the scale characteristics of the types of residential buildings, and their validity needs to be further empirically research to verify its validity. The quantitative analysis of MGA provides a direct representation of the size characteristics of building types. However, further empirical research is required to verify the validity of it. In addition, AAS was

found to reflect the development strategy of the city. Most other parts of Nanjing and Shanghai have significantly higher AAS compared to historical areas, due to the fact that China's urbanisation tends to adopt ‘Vertical Growth pattern’ through the concentration of high-rise buildings.

COMPARISON AND ANALYSIS

The study will undertake a comparative analysis of historical areas, residential areas and city centres in Nanjing, Shanghai and Copenhagen, respectively.

The urban form of historical areas and the building type

The morphological characteristics of each city's historical areas are distinctive, and comparative analyses of building types can reveal the respective histories and cultures. However, within the 1km x 1km study areas of historical areas, only some of the buildings have been preserved in their historical forms. To accurately analyse the characteristics of urban forms and the relationships between the buildings and the morphological structure, it was necessary to redefine the study area within the original study area. The newly defined study areas are carefully screened to ensure that over 80 percent of the area are with historical forms, and was bounded by the axes of the urban streets to form the calculation area (Figure 6a).

N-LC preserved some Ming and Qing buildings and streets, and the main building type is the traditional Jiangnan houses. They are laid out in a courtyard style, with the scale of the building limited by the size of the timber and the legal requirements for residential buildings. Most dwellings comprise three ‘Jians’ (bay-room), the width of one ‘Jian’ is about 3 to 4 metres, and the depth of the dwellings is mostly 3.6 to 4.2 metres. Most buildings have a single storey, with the construction of two-storey buildings only becoming common after the end of the Qing Dynasty. The courtyard's layout is primarily symmetrical along an axis, with the central 'main room' serving as the primary activity space for the family. The ‘main room’ on the axis is the primary living and meeting space for the family, while the ‘side room’ on either side are typically used as bedrooms and auxiliary rooms. In some instances, due to the constraints of the plot's width, there may be no ‘side rooms’ or only one. The boundaries of the family plot are delineated by walls, and the ownership of the plot is distinguished.

Figure 6. Comparison of three historical areas: (a) 1km × 1km area, (b) reselected historical area, (c) one typical block, (d) elevation of the building type, (e) plan of the building type.

Shanghai's lilong houses originated in the 1950s as refugee housing and evolved with the growing property market. This resulted in the construction of a unique building type that reflected a fusion of Chinese and Western cultures (Whitehand et al., 2014). Lilong houses are densely built, constructed in close proximity to each other, with a collection of dwellings, usually 2 to 4 storeys, and with unit sizes ranging from 60 to 105 square metres to accommodate diverse resident needs (Gregory, 2015).

Danish classical buildings are usually four to five storeys high with sloping roofs, set out in rows. The buildings have narrow frontages measuring approximately 15 metres and long sides, enclosing multiple internal public courtyards. Most of the ground floors are occupied by shops or bars, with flats and offices located on the upper floors.

The numerical results for some of the updated indicators are presented in the table (Table 3).

Table 3. Quantitative results of three morphological indicators for the new study areas of three historical areas.

Area	NBU	MGA	AWAS
N-LC	148.0	31	1.4
S-XT	13.1	278	2.8
C-GS	16.5	174	4.1

The urban forms of N-LC and C-GS are both the result of natural evolution, and they are different in building types, but there are some similarities in their formation logic and morphological structure. In terms of building scale, the quantitative results of N-LC indicate that most buildings have ground areas of around 30 square metres and are one or two storeys in height, which is highly consistent with the building scale of traditional Chinese Jiangnan houses. The living units of people in N-LC are situated within courtyards comprising two and twelve buildings. Families with more people and higher economic status tend to have more buildings. The quantitative results of C-GS demonstrate that most

buildings have ground areas of around 170 square metres and are around four storeys in height. This result reveals the basic scale of Danish classical buildings. In terms of morphological structure, the courtyards in the N-LC and the buildings in the C-GS are typically aligned along the longer side of the blocks. The length of the block is typically determined by the number of courtyards or buildings in that direction, which is usually an integer multiple of the number of courtyards or buildings. The width of the block is typically determined by the number of 'Jin' in the courtyard (reflecting the size of the family) or the depth of the building, as well as the number of courtyards or buildings in that direction. Despite the differences in building types and living units across cultures, the similarity in layout patterns indicates a common underlying logic in the organisation of living space.

The buildings in S-XT are constructed according to a planned street network that considers the fundamental scale and layout pattern of lilong houses. They can vary in length by adjusting the number of dwelling units. Furthermore, the distribution and the number of units are planned according to the size and shape of the site. The quantitative results indicate that most buildings have ground areas of around 380 square metres and are two to three storeys in height. This suggests that the number of units contained in most buildings in the area is calculated to be between seven and twelve.

Residential area and morphological characteristics

The residential areas of the three cities exhibit distinctive morphological characteristics, reflecting their distinct economic and cultural contexts. There are many slab apartment in N-LJ, N-TR and S-CA, which are a typical residential building type that has entered the modern Chinese cities. These buildings are generally orientated east-west to gain more sunlight, with the spacing between adjacent north-south buildings increasing with the number of storeys. Each building usually contains a number of dwelling units, and each dwelling unit usually consists of 2-4 living units (Liu and Ding, 2012). The buildings in S-CS are mainly garden houses and attached houses built in France from the 1910s onwards, and present a variety of architectural styles such as classical European and Lilong houses. The buildings in C-NE and C-BS are mainly villas and each building is suitable for one family (Figure 7). As with the historical area, the study areas must be redefined to ensure that they are populated with residential buildings and to update the relevant indicator results (Table 4).

Figure 7. Elevations of typical types of six residential areas: (a) Slab apartment buildings in N-LC, built in 1999-2002, (b) garden houses in S-CS, built in 1941. (c) Villas in C-NE. (d) Slab apartment buildings in N-TR, built in 2010-2014. (e) Slab apartment buildings in S-CA, built in 1999, (f) Villas in C-BS.

Table 4. Quantitative results of four building morphological indicators for the new study areas of residential areas.

Area	GSI	FSI	MGA	AWAS

N-LJ	0.23	1.5	597	6.6
N-TR	0.15	1.2	550	7.9
S-CS	0.32	1.4	275	4.3
S-CA	0.24	1.5	475	6.3
C-NE	0.19	0.6	80	3.4
C-BS	0.15	0.2	120	1.6

In Chinese cities entering modernisation, the type of residential building, the number of storeys and the given FSI are highly correlated. A combination of building codes and economic factors has resulted in the predominant use of 6, 11, 18 and 33 storeys in slab apartment buildings. Property developers often choose the appropriate number of storeys and building type based on the FSI constraints in the site. Typically, economic efficiency, land price and FSI are highly correlated, and the higher FSI, the higher the number of storeys of the building (Zhang and Ding, 2013). Land prices in Chinese cities are often related to the stage of development and locations, and similar construction years tend to have similar FSIs. A comparison of the quantitative results for three residential areas, N-LJ, N-TR and S-CA, which are dominated by slab apartments, reveals that although S-CA is in the suburban area of Shanghai, it was developed in a similar era to N-LC, located in the downtown of Nanjing. Consequently, as areas developed in the same period of time in China, they have similar land prices as well as similar FSIs, which lead to their similar morphological characteristics. The quantitative results of the comparison between the residential areas of Nanjing and Copenhagen demonstrate that Copenhagen has experienced suburban developments with a low population density, which has led to the C-BS having a low GSI and FSI. This development is a result of factors such as steady economic growth, increasing popularity of villas, and a long urbanisation period. In contrast, the rapid urbanisation rate, high urban population density and the 'Nanjing villa construction ban' (posted in 2021) have resulted in Nanjing continuing to develop in a high-density pattern in the suburbs.

Shopping Centre and Commercial Configuration

Different lifestyles give rise to different commercial configurations and forms of shopping centres. The study calculated the proportions of major functions and HHI in the city centres (including city centres, new town centres and suburban shopping centres) (Table 5).

Table 5. The functional proportion of the city centre areas in three cities.

Area	Commercial	Residential	Office	Mixed commercial and residential	Mixed commercial and office	Other functions	HHI
N-XJ	2%	12%	10%	19%	54%	3%	0.19
N-YT	2%	11%	15%	0	33%	39%	0.17
N-MF	32%	32%	10%	9%	17%	0	0.23
S-NJ	11%	18%	5%	25%	36%	5%	0.14
S-LJ	1%	0	12%	0	44%	43%	0.19
S-JK	21%	23%	19%	0	10%	27%	0.21
C-FM	6%	22%	3%	43%	0	26%	0.17
C-OM	17%	34%	4%	0	16%	29%	0.18
C-IS	17%	58%	0	13%	0	12%	0.38

A statistical analysis of the data reveals that, despite significant cultural differences, the functional diversity of urban business districts in all three cities decreases with distance from the city centre (HHI increases). The city centres exhibit a high level of mixed land use, high diversity, and a wide range of commercial distribution, predominantly in the form of ground-floor businesses along the street. This

results in a high level of living convenience and urban vibrancy. The commercial activities in new towns and suburban centres are concentrated in large shopping malls, which limits residents' commercial options. Furthermore, many people are forced to use cars to get to the shopping centres in these areas due to the large scale of the blocks.

CONCLUSIONS AND DISCUSSIONS

This study reaches the following conclusions.

Firstly, the cross-cultural comparative study reveals the general characteristics and patterns of urban forms that emerge as a result of the transition to a modern mode of urban development. The diachronic analysis verifies that as the distance from the city centre increases, all three cities demonstrate a tendency for the street network to become increasingly sparse, with an accompanying increase in the length and size of blocks. This, in turn, leads to a decrease in connectivity. Concurrently, the influence of the planning concept of functional zoning has resulted in the formation of specialised commercial and residential areas in all three cities. The scale and configuration of the commercial areas in these areas are designed to meet the needs of the neighbouring residential areas they serve. It is also noteworthy that, despite their disparate cultures, the historical areas of Nanjing and Copenhagen show significant similarities in the relationship between building types and block sizes, as well as the morphological structure. This observation suggests that the morphological structure of historical areas may possess a cross-cultural universality, reflecting the limited influence of cultural factors on it.

Secondly, this study further examines the differences of urban morphological characteristics that influenced by urban history, culture and urbanisation processes. A comparative analysis of historical areas demonstrates that, despite their similar morphological structures, the building types observed therein exhibit variation according to their historical and cultural contexts. The traditional Jiangnan houses in Nanjing and the Copenhagen classical buildings reflect their unique cultural and historical backgrounds. In contrast, the lilong houses in Shanghai represent a cultural fusion, exhibiting a combination of Western planning concepts and the characteristics of the traditional Chinese courtyard in their building and room layouts. A comparative analysis of the suburbs reveals that the differing rates of urbanisation and the establishment of administrative boundaries between China and Denmark have resulted in notable differences in the density and capacity of the urban suburbs. The process of urbanisation in Danish cities has been extensive, and the low population density, has resulted in a current urban population characterised by a dense central area with sparse edges. This has led to the predominant development of low-density villas in its suburban areas. In contrast, in the 1950s, China's urban-rural dichotomy led to a massive influx of people from rural to urban areas. During this period, the population of Nanjing and Shanghai's originally designated urban fringe areas continued to grow. As a result, both cities chose to address the housing needs of these people by building high-rise housing in the fringe areas of the city, leading to the high density and capacity of the suburban areas identified in this study.

Thirdly, the quantitative approach of this study provides an objective assessment method and analytical framework for understanding the universal laws and differences of urban form. It also enables the morphological characteristics of a particular area to be described, thus allowing the

definition of urban area attributes. To illustrate, the Century Avenue area, which was previously considered suburban residential area, was found to be similar to the downtown residential area of Nanjing through quantification. This led to the conclusion that they belonged to architectural products of the same period. Furthermore, this study employed quantitative and comparative analyses to identify key urban morphological indicators, specifically street density (SD) and median ground area (MGA), which are useful for describing the morphological structure and the characteristics of building types. SD demonstrated significant differentiation ability in assessing the morphological structure and walkability within 1km × 1km areas. Its values were able to map the urbanisation of different stages of urbanisation, with SD exceeding 20 km/km² in historical areas, SD being about 10 km/km² in downtown areas, and SD usually being less than 8 km/km² in new town and suburban areas. Further research indicates that areas with SD values exceeding 8 km/km² tend to exhibit enhanced connectivity, a finding that provides a reference for planning authorities when designing the street network system in new districts. MGA is capable of accurately characterising building types across different areas by quantifying the building ground area, as individuals with a median building ground area often represent the typical building type observed in a given area. The universality of it has been demonstrated through its application in the identification of building types in historical areas.

The subsequent discussion section of this paper will focus on the experiences and strategies encountered during the research process, offering insights for future studies. The selection of typical cases and refined and standardised mapping are two crucial aspects when using quantitative approaches for comparative studies. The study selects several Western-influenced areas in Shanghai as samples of urban forms where East meets West. Although they are capable of revealing the characteristics of urban form under the influence of different historical cultures in synchronic comparisons, the S-XT and S-CS exhibit atypical characteristics in diachronic comparisons, which are mainly due to their unique historical backgrounds, and they do not represent the patterns of urban development in general. In addition, in order to ensure the accuracy of the quantitative study, the original maps must be supplemented, corrected and updated to meet the requirements of different quantitative indicators on map fineness. In cross-cultural comparative studies, unified mapping standards are particularly important, such as in the case of China and Denmark, where unified standards for the division of land use properties, street grades, etc. are needed to ensure the consistency and validity of quantitative comparisons.

ABSTRACT

Railway hubs, as mega-scale transportation complexes, play a pivotal role in urban areas due to their vast scale and significance as key nodes within and outside cities. Previous studies have shown that promoting pedestrian accessibility is crucial for enhancing the vitality of hub areas and promoting regional development. Therefore, this research aims to explore which morphological forms are more effective to enhancing pedestrian accessibility from mega railway station areas to various urban functions, thereby improving the integration between mega hub stations and cities. This paper selects Tianjin station as old station and Shenzhen North Station as the new one compare with three other stations which have similar platform scale and average daily passenger flow but significant differences in pedestrian connections between the station and the city, as well as surrounding area morphology. Using tools such as sDNA, the study evaluates pedestrian accessibility of the station area in different aspects. Through the analysis of pedestrian accessibility and the morphology of the area, the research aims to identify existing issues and propose corresponding solutions of the mega railway station area in China.

Keywords: railway station, pedestrian accessibility, sDNA, station-city integration, morphology

INTRODUCTION

High-speed rail (HSR), with its powerful space-time compression effects, has restructured the spatial patterns of cities and regions. As a critical node in China's transportation network, HSR stations possess significant potential for development and redevelopment due to their high regional accessibility and the large volume of human activity they attract.

The concept of Station-city Integration is rooted in the systematic integration and organic coordination at the urban, regional, and nodal levels. At the station area level, effective pedestrian accessibility not only enhances the connection between the station and surrounding areas geographically, allowing for the rapid dispersal of large passenger flows to adjacent districts, but also promotes low-carbon station development. More importantly, it enables the station to truly function as a catalyst for regional growth.

Currently, the rapid development of mega railway station areas in China has been hampered by traditional large-scale, rapid development models which prioritizes fast car access over pedestrian accessibility in transportation approaches. This paper analyses pedestrian accessibility and the surrounding area morphology of both domestic and international cases to provide recommendations for enhancing pedestrian accessibility in existing and new-planned mega railway station areas in China.

Case selection

This study selects Shenzhen North Station and Tianjin Station in China, Utrecht Central Station in Europe, Fukuoka Hakata Station in Japan, and Liverpool Street Station in the UK as research subjects. These five stations share similar numbers of platforms and daily passenger volumes, which face comparable challenges in pedestrian flow management and have high requirements for pedestrian accessibility. However, due to differences in geographic location and development patterns, these stations exhibit distinct surrounding area morphologies. Comparative analysis of these cases will help identify pedestrian accessibility characteristics and issues under different conditions.

Table 1. Platform size and daily passenger volume of five cases, self-drawn.

Station	Location city	Construction years	Surrounding city development	Platform and track size	Average daily delivery volume
Shenzhen North Station	Shenzhen, China	2011	Planning sub-centers	20 tracks, 11 platforms	275000
Tianjin Station	Tianjin, China	1988/ 2008	regeneration city center	18 tracks, 10 platforms	110000
Utrecht Central Station	Utrecht, Netherlands	2016	Planning sub-centers	16 tracks, 8 platforms	207400
Fukuoka Hakata Station	Fukuoka, Japan	1960/ 2011	regeneration city center	14 tracks, 7 platforms	200328
Liverpool Street Station	London, Britain	1992	regeneration city center	17 tracks, 9 platforms	183471

Shenzhen North Station, which began operations in 2011, represents a later-developed station in China. It was the first to eliminate the traditional large station square, allowing passengers to transfer between various modes of transportation without leaving the station. This makes it one of the most efficient and convenient mega stations in China. By comparing Shenzhen North Station, a newly planned area, with Tianjin Station, a more maturely developed area in China, and other foreign stations with well-established pedestrian systems, this study can more effectively reflect the current pedestrian conditions around two generations of mega-stations in China.

According to the TOD (Transit-Oriented Development) model, the influence area of HSR stations can be divided into core, impact, and peripheral impact zones (Cao et al., 2020). Building on Sorensen's methodology and conclusions (Sorensen, 2000), Peter M.J. Pol redefined the potential impact areas of HSR stations into three zones and the primary one is within a 5-to-10-minute walking distance (Pol, 2002). Therefore, a 5-minute walking radius and a 1000-meter radius (approximately 15 minutes) from the station entrance is used to define the area for pedestrian accessibility studies. Additionally, a 2000-meter radius is employed as a buffer zone for modeling pedestrian pathways.

Figure 1. Core area of five station with a radius of 1000-meter, self-drawn.

Literature review

Walking is an essential component of sustainable travel and healthy, low-carbon living (Giles-Corti et al., 2016). Pedestrian accessibility specifically reflects the ease with which people can walk from one location to another. Studies indicate that areas with higher accessibility and pedestrian-friendliness increase the likelihood of residents choosing to walk (Kang et al., 2017).

Early studies on train station accessibility primarily focused on measuring walking distances to stations (Currie, 2010; El-Geneidy et al., 2014; Lin et al., 2014) or walking time (Mavoa et al., 2012; Transport for London, 2010; Yigitcanlar et al., 2008). More recent research has expanded these analyses. For instance, factors such as walkability, accessibility features, and the slope of pathways to stations were taken into consideration (Kizawa and Takami, 2008; Kita et al. 2012). Japanese researcher employed random utility theory to model the choice of nearest train stations, assessing station accessibility and finding that improving station accessibility and rail service frequency can increase resident rail usage (Terayama et al., 2015).

Another body of literature focuses on case studies. One approach analyses the design methods for individual hub-based pedestrian systems, such as Qingdao Station (Ma et al., 2021), Xuzhou Railway Station (Wang et al., 2017), examining key design features, existing issues, and planning optimizations towards it. Another approach compares multiple stations, broadening the accessibility concept including environmental factors, to establish a more comprehensive pedestrian accessibility assessment frameworks (Wu et al., 2017; Li et al., 2023; Gui et al., 2024;).

Current pedestrian accessibility assessment methods utilize new tools, such as GIS network analysis and sDNA, to evaluate the quality of facility layouts (Zhao and Zhang,2024; Fan,2024) and pathways design (Fan,2020). For example, Liu constructs an “O-D cost matrix” alongside sDNA spatial syntax models to assess street network accessibility and indicator correlations in studies analyzing Guiyang’s central district (Liu et al., 2022). However, network analysis and sDNA methods are often applied to single cases or specific areas, limiting broader insights.

Existing researches often overlook the diverse accessibility needs of urban populations and passenger groups in station area. Many studies focus on single-station evaluations, making it challenging to compare stations with varying passenger volumes, which limits the potential for generalizable findings. In this paper, we analyze both new and existing stations in different countries, incorporating population and centrality distinctions to establish refined accessibility metrics. Using new tools to conduct multi-station comparisons, this study enables more effective visualization and quantification of accessibility differences across stations, thereby identifying their unique features and issues, ultimately proposing a more specific suggestion

METHOD

This study begins with the analysis of the urban morphology surrounding five station areas that impact pedestrian accessibility, focusing on station layout, road network structure, and pedestrian connectivity patterns.

In the second step, pedestrian accessibility in mega station areas is studied in two parts based on different population attributes. First, passenger groups are key participants in enhancing the vitality of areas surrounding railway stations. Therefore, the first part uses network analysis to assess the pedestrian accessibility centred on the station. This involves analysing the reachable areas and functions based on real pathways and walking time of the travellers. The second part focuses on non-passenger groups, where movements may not have the station as the start or end point. Here, sDNA analysis is used to comprehensively evaluate the pedestrian accessibility of the whole station area, reflecting the overall pedestrian accessibility of the surrounding area and the impact of the high-speed rail station on the pedestrian network.

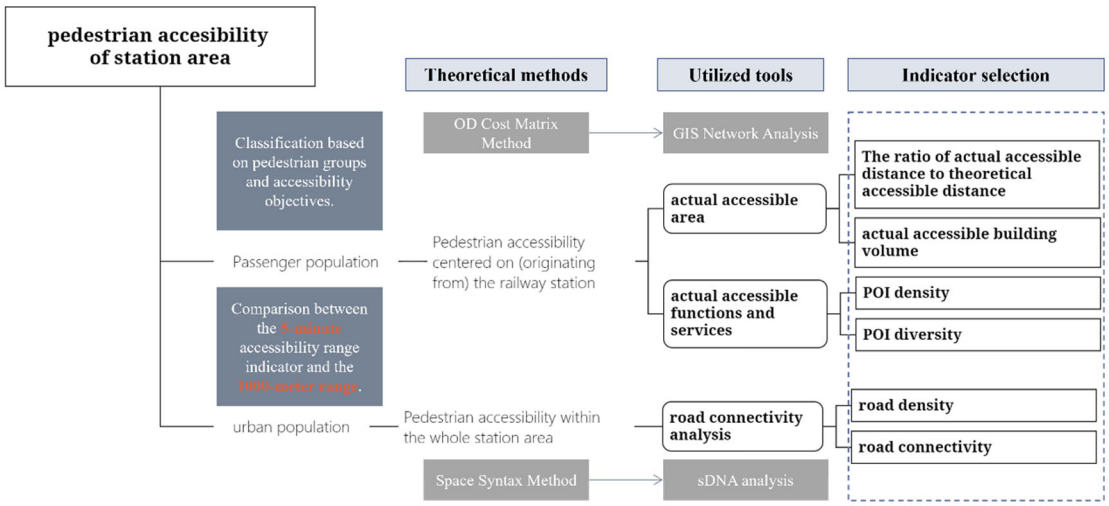

Figure 2. The research frame and selected indicators of pedestrian accessibility, self-drawn.

By comparing pedestrian accessibility across different station morphologies in a radius of 5-minute walking time and one in 1000 meters, the study identifies the characteristics and challenges of each type. Also, specific suggestions are given to Tianjin station and Shenzhen North Station as the representative of mega station area in China.

Data sources and processing

This study utilized road network data from Open Street Map (OSM) to analyse pedestrian accessibility in the mega station areas. The data were imported into ArcGIS 10.8, where road types were filtered and refined using Google/Baidu street Maps for error correction and data supplementation.

As for the accessibility of diversity functions and services, it is assessed using Points of Interest (POIs) data. Data sources vary according to case study locations. For Shenzhen North Station and Tianjin Station, Gaode Map is preferred as it provides one of the most complete datasets with minimal manual editing. For the other three stations, data is obtained from OSM which is more complete.

Analysing tools

OD Cost Matrix

The OD Cost Matrix is a time-based matrix created between supply and demand points, calculated using real travel paths based on ArcGIS's Network Analyst tool. The analysis uses the average minimum impedance, which can be expressed by the following formula:

$$MI_i = \frac{1}{n-1} \sum_{j=1, j \neq i}^{n} (d_{ji})$$

where MI represents the overall accessibility of the network, $\boldsymbol{MI_i}$ is the accessibility of node i on the grid, and $\boldsymbol{d_{ji}}$ is the minimum impedance between nodes j and i.

In this study, the analysis starts from the entrances and exits of mega stations, including height information and considering the connections between the station and external urban spaces via bridges and underground passages. A normal walking speed of 5 km/h is assumed, and the actual accessible area, reachable services and functions based on the POIs are calculated.

sDNA

The sDNA (Spatial Design Network Analysis) tool developed by Cardiff University is used to analyze accessibility and centrality in the street network. Based on the ArcGIS platform, sDNA supports the analysis of 3D networks, including vertical connections such as stairs, elevators, and escalators.

For this study, a walking radius of 500 meters is chosen, which is commonly considered a comfortable walking distance. The analysis focuses on two primary metrics: Network Quantity Penalized by Distance of Angular (NQPDA) and Two Phase Betweenness (TPBt). "Angular" (minimizing turns and intersections) is used as the measurement standard.

NQPDA measures the total number of street network topologies within a certain radius, reflecting the integration of a particular space in the system and its potential for traffic attraction. TPBt is a measure of betweenness centrality, representing the probability of traffic flow through the network within the search radius. Higher betweenness indicates stronger through-traffic potential, corresponding to higher vehicle and pedestrian flow in reality.

RESULTS AND DISCUSSIONS

Quantitative analysis of morphology

The initial step is to summarize differences in station morphology, divided into three main aspects: station form, road network, and pedestrian mode.

For the road network, scale differences can be ex/tpressed through block size. According to their structural patterns, networks can be categorized into grid, hybrid, and free-form types. (Gui and Li, 2015).

Table 2. Station form, block size and pedestrian mode of five cases, self-drawn.

Station	Station Form	Station Form	Station Site Area	Average Block Area	Road Network	Pedestrian Mode
Shenzhen North Station	Through Station	Planar (Ground-level) Station	82612	187481	Large, Grid	Passageway Connection Model
Tianjin Station	Through Station	Planar (Ground-level) Station	39636	35397	Large, Hybrid	Metro Transit Model
Utrecht Central Station	Through Station	Planar (Ground-level) Station	26030	9950	Small, Hybrid	Passageway Connection Model

Fukuoka Hakata Station	Through Station	Elevated Station	22000	6622	Small, Grid	Multi-level Connection Model
Liverpool Street Station	Terminal (Dead-end) Station	Underground Station	22900	5650	Small, Freedom	Metro Transit Model

In terms of pedestrian mode, the study classifies the connectivity between station blocks and surrounding blocks based on structural typologies: 1. Flat Monolithic Model: Stations and nearby blocks are connected on a single plane, with no additional elevated or subterranean pathways.

2.Layered Connections (2 levels): Connections are achieved through another elevated level in addition to the surface, such as footbridges, underground passages, and subway links, which includes most of the mega station cases.

3.Multi-Level Connections: Fukuoka's Hakata Station exemplifies this, with a sophisticated network of elevated walkways and underground passages. Besides functional subway exits, this category includes underground shopping streets that connect various blocks within the region.

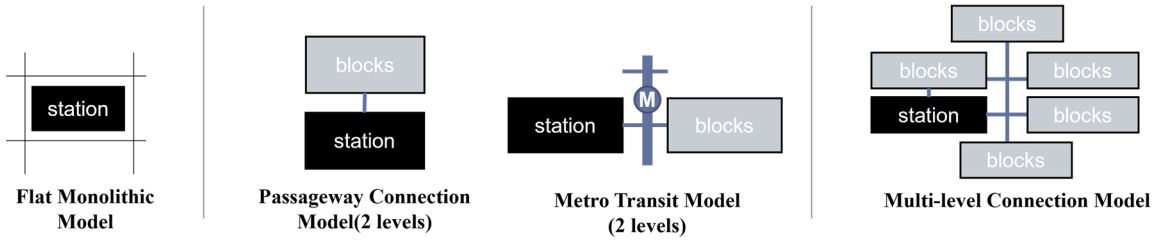

Figure 3. The pedestrian mode, self-drawn.

These differences in station form, road network, and pedestrian connectivity are primary contributors to varying levels of accessibility. It is evident that stations in China generally have much larger plot and station sizes when managing comparable passenger flows.

Actual accessible area

The actual accessible areas of the five stations are difficult to compare directly due to the involvement of numerous variables. To eliminate the impact of the number of mega station entrances and exits, as well as the presence of non-development land such as rivers and forests, focusing on station layout, road network and pedestrian connectivity patterns, this paper introduces the concept of the Actual Accessibility Ratio. The actual accessible area is calculated using the OD cost matrix based on a walking speed of 1.4 m/s over 5, 10, and 15 minutes. The theoretical accessible area is the envelope formed by circles drawn with radii calculated from this walking speed and time, subtracting non-urban land. The Actual Accessibility Ratio is the ratio of the actual accessible area to the theoretical accessible area.

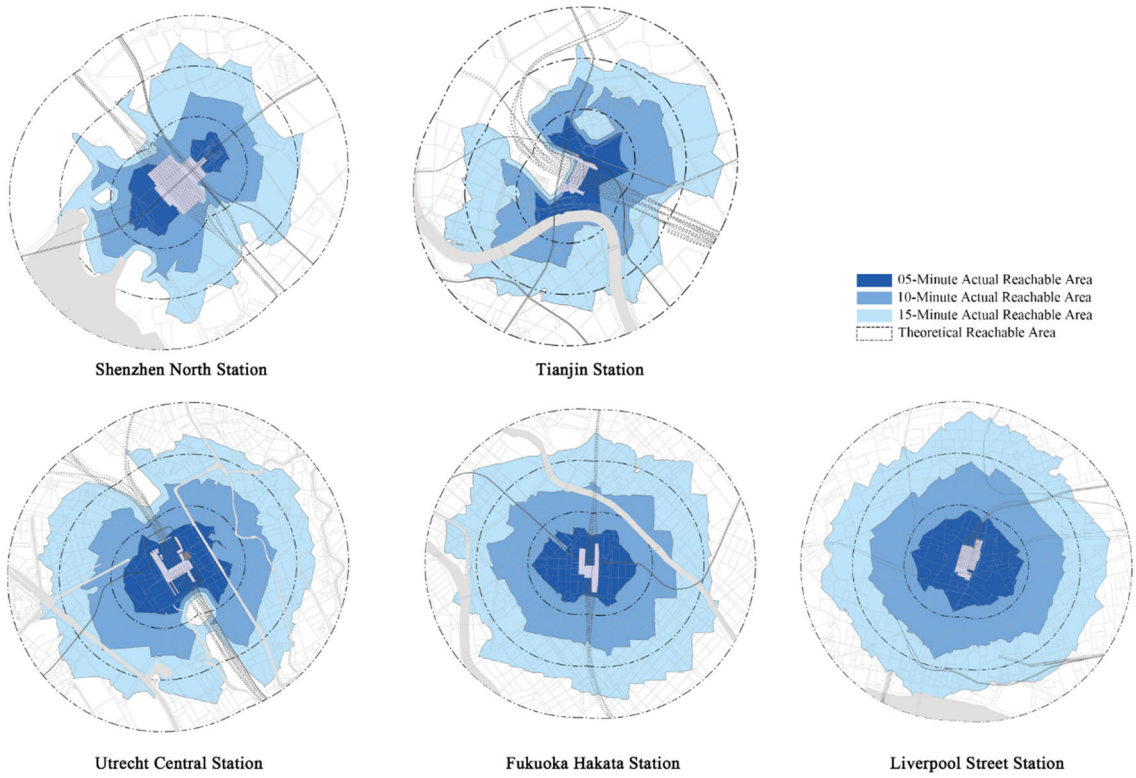

Figure 4. The accessible area of 5 stations in 5/10/15- minutes' walk, self-drawn.

According to the figure 4, all stations exhibit a spindle-shaped accessible area because of the separation between train platforms and railways. This effect is more pronounced in areas like Tianjin Station, where there are few paths crossing or near the railway tracks. Both Shenzhen North Station and Tianjin Station demonstrate poorer accessibility and balance between different directions compared to the other three stations, largely due to the design of large road networks and the lack of pedestrian paths within blocks surrounding the stations. In fact, it is difficult to walk to the theoretical 10-minute walking area around these stations.

Table 3. Actual accessible area and Accessible Ratio of five cases, self-drawn.

Station	Actual 5-Minute Reachable Area	5-minute Accessible Ratio	5-minute Accessible volume	Actual 15-Minute Reachable Area	15-minute Accessible Ratio	15-minute Accessible volume
Shenzhen North Station	265368.9	30.64%	1800780.51	2488610.3	45.71%	3575703
Tianjin Station	267503.5	36.31%	1688032.00	2745412.1	50.31%	4160000
Utrecht Central Station	421865.8	53.71%	4251124.71	3262989.5	60.02%	6363564
Fukuoka Hakata Station	362323.6	51.60%	3706798.06	3384202.2	65.38%	13338150
Liverpool Street Station	489461.0	66.42%	9434195.00	3779752.7	70.28%	15073781

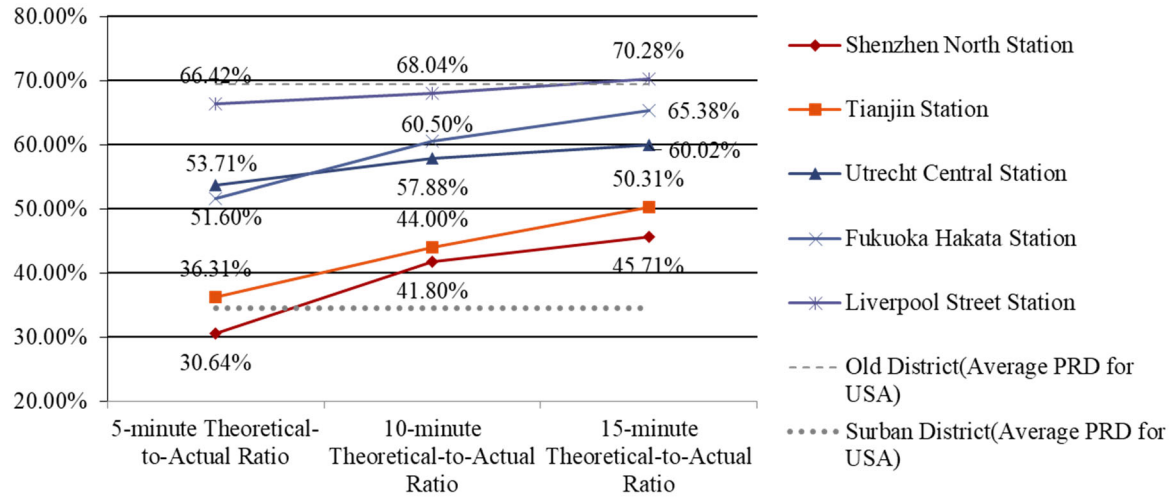

Figure 4. Actual accessible ratio of five cases, self-drawn.

For planar stations, Utrecht Central Station also displays a spindle-shaped accessible area, but the width and length of the impact caused by the tracks are smaller than those of domestic stations in China. As a result, it achieves relatively good accessibility, especially in its core area where the internal connections over the tracks are appropriately spaced.

The PRD (Pedestrian Route Directness) is the ratio of the actual walking path length to the straight-line distance between two points. Its calculation principle is consistent with the pedestrian accessibility area, meaning that the Actual Accessibility Ratio can also be derived from the PRD coefficient. According to research (Gui et al., 2023), PRD in older urban areas in the U.S. is about 1.2, and around 1.7 in newer areas, corresponding to actual accessibility ratios of approximately 69.4% and 34.6%, respectively. In contrast, the actual accessible area within the 5-minute core walking zone of Shenzhen North Station and Tianjin Station is significantly lower, nearing suburban neighborhood levels in the U.S. This is mainly due to the construction of large road networks designed for rapid car dispersal and the lack of connections across large road networks and stations.

Accessible functions and services

To enhance station-city integration and boost the vibrancy of areas surrounding mega stations, having sufficient and diverse functions is essential. As walking commuters need destinations, the density and diversity of these functions affects their choice of travel modes.

This study classifies and quantifies eight major types of functions. In the accompanying figure, we can see significant differences in POIs (Points of Interest) clustering across the five major stations in the radii of 200m, 500m, and 1000m. Newly planned stations, such as Shenzhen North Station and Utrecht Central Station, show more concentrated POIs distributions, primarily within the station area and nearby mature development zones. In contrast, older mega station areas not only have a greater number of functions but also exhibit a more dispersed distribution. Fukuoka Hakata Station, however, is bordered by a large residential area on the opposite side of the river. Given that high-speed rail in Japan often plays a more significant role in daily commuting compared to other countries, residential areas have become important destinations. Additionally, discrepancies in the number of functions may be due to incomplete map data.

Figure 5. Distribution of facilities of five cases, self-drawn.

Using Shannon's entropy formula, which measures diversity, we calculate the diversity index of functional facilities around different stations. Following the figure 6 from top to bottom, the diversity indices for each station, starting with Shenzhen North Station, are 1.48, 1.48, 1.28, 1.67, and 1.28. This shows that the differences between stations are relatively minor, indicating that intentional configurations or gradual developments have led to a fairly diverse range of functions around each station.

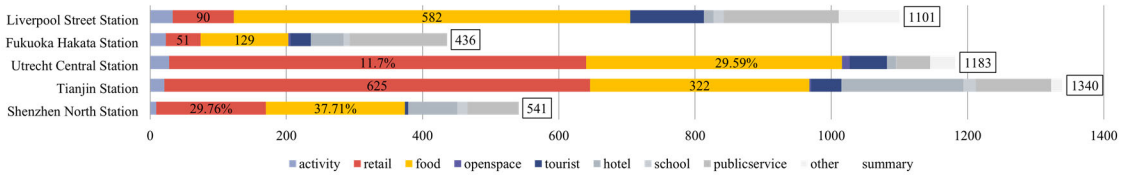

Figure 6. Numbers of different facilities of five cases, self-drawn.

After conducting an OD cost matrix analysis of these functions, they are divided into four categories: within the station, within a 5-minute walk outside the station, within a 10-minute walk, and beyond 10 minutes. Comparing the five station areas, there is little variation in the quantity and diversity of on-site service facilities. The primary differences in station function development occur in the 5–10-minute intermediate concentric layer.

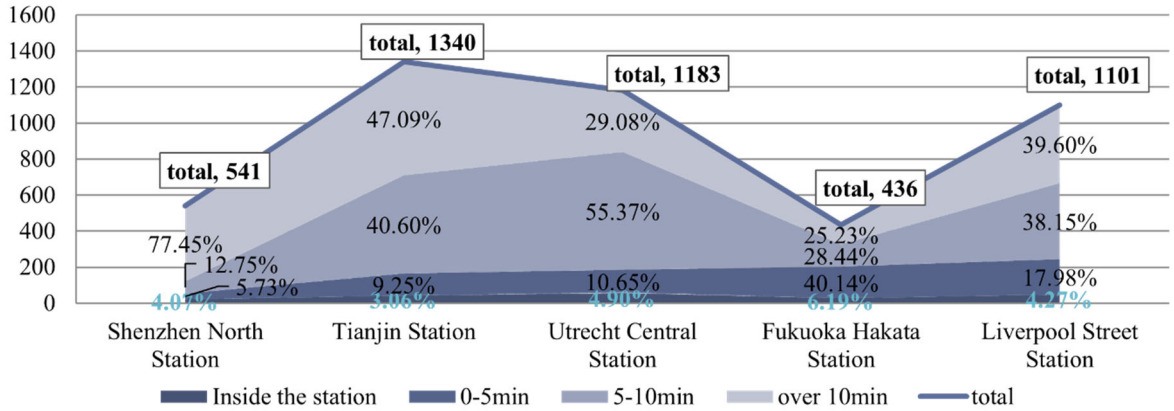

Figure 7. The portion of facilities in Iso-time zones, self-drawn.

Assuming an even distribution of POIs, based on mathematical geometric proportions, the proportion of POIs within 5 minutes/5-10 minutes/1000m should be 18%, 53%, and 29%, respectively. In terms of distribution, Utrecht Central Station closely aligns with this distribution. Fukuoka Hakata Station and Liverpool Street Station, however, exhibit a stronger "concentrated" clustering effect of station-related functions. In contrast, outside of Shenzhen North Station's station area and adjacent plots, the next layer is largely comprised of gated communities and large green spaces. Given that high-speed rail still plays a relatively minor role in daily work commutes in China, it is evident that newly planned stations like Shenzhen North Station do not prioritize station-centric function distribution in the 5–10-minute core zone.

Road connectivity analysis through sDNA

Using the sDNA tool, a walking network analysis was conducted with a radius of 500 meters, employing the natural breaks classification method for presentation. Utrecht Central Station shares similar characteristics with Tianjin Station and Shenzhen North Station. Because of their planar station layout, the pedestrian accessibility surrounding these mega stations is relatively poor.

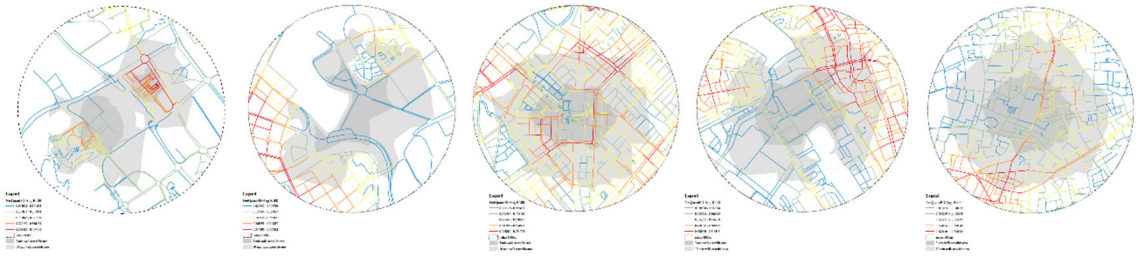

Figure 8. NQPDA500 figure of five stations using sDNA, self-drawn.

Figure 9. TpBetweeness500 figure of five stations using sDNA, self-drawn.

The analysis results from sDNA indicate that direct comparisons of values are challenging due to the different characteristics of road networks. After applying the natural breaks classification method, the accessibility values for each segment reflect its relative standing within the station area. By statistically analysing the lengths of roads within each accessibility tier, it becomes evident whether the roads surrounding the train stations are below or above the average performance within the holistic urban area.

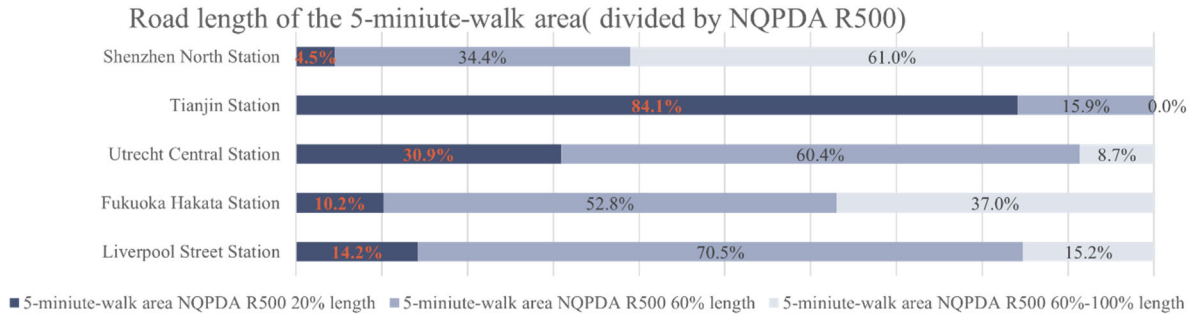

Figure 10. The portion of roads in different connectivity levels in 5-minute-walk area, self-drawn.

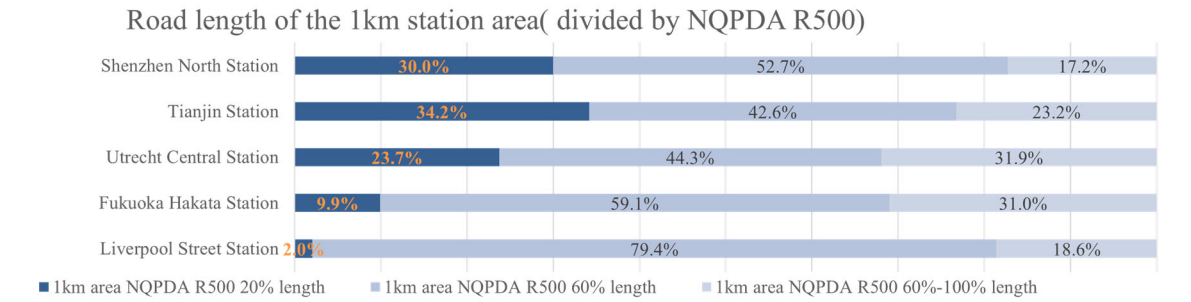

Figure 11. The portion of roads in different connectivity levels in 1km area, self-drawn.

Tianjin Station, as an older station, has a weaker pedestrian system compared to Shenzhen North Station, despite both having similar station layouts. The excessive length of underground passages in Tianjin Station significantly reduces pedestrian accessibility. Within the 5-minute walkable area, the roads falling within the lowest 20% accessibility tier—represented by the darkest blue on the map (figure 8)—account for a staggering 84%. Conversely, Shenzhen North Station, as a new station, greatly improved the pedestrian network in its vicinity but lacks external connections, currently limited to nearby commercial facilities without further extensions. In the case of Fukuoka Hakata Station and Liverpool Street Station, the road networks adjacent to these stations exhibit high levels of pedestrian accessibility.

Within the 1 km analysis range, all three planar stations display a high proportion of roads falling within the lowest 20% accessibility tier, as indicated by the darkest blue roads. Compared to the two domestic stations, which suffer from the effects of enclosed residential communities leading to dead-end roads and a large-scale road network, Utrecht Central Station demonstrates comparatively better performance.

Pedestrian accessibility evaluation

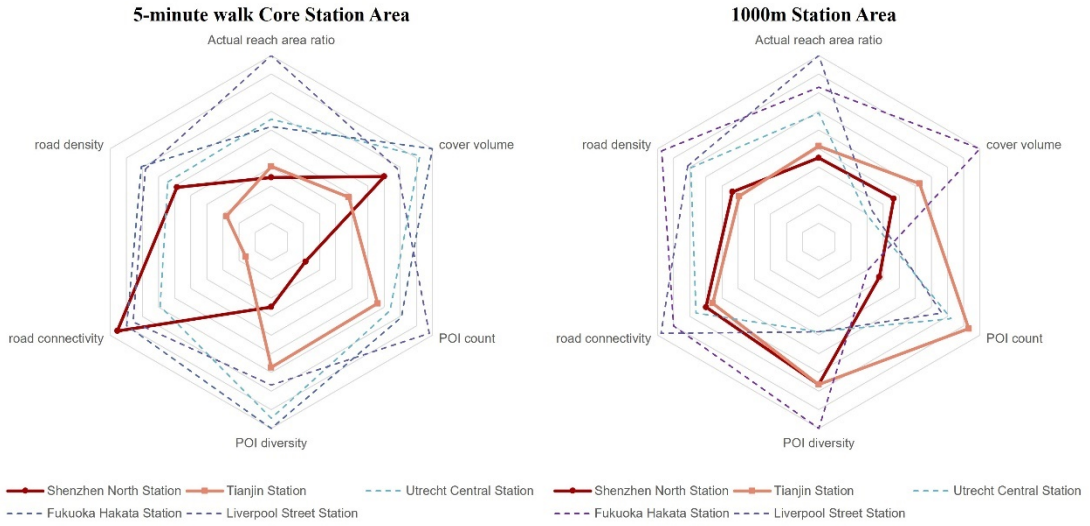

Figure 12. Comparison of the pedestrian accessibility in five stations, self-drawn.

Finally, integrating the evaluations across six accessibility dimensions, the data was normalized and presented using radar charts. In the 5-minute-walk core area of the mega station, Shenzhen North Station shows a higher design standard for pedestrian infrastructure and larger building volume. However, there are significant shortcomings in facility configuration and the extension of accessible areas. Tianjin Station, being an older station, suffers from excessively long and singular pedestrian paths across and near the station, resulting in lower connectivity in its core area compared to external regions.

To address these issues, Tianjin Station—representing existing older railway stations—should focus on enhancing connectivity through the construction of cross-station passages, improving the northern square, and better linking the station to the external city centre.

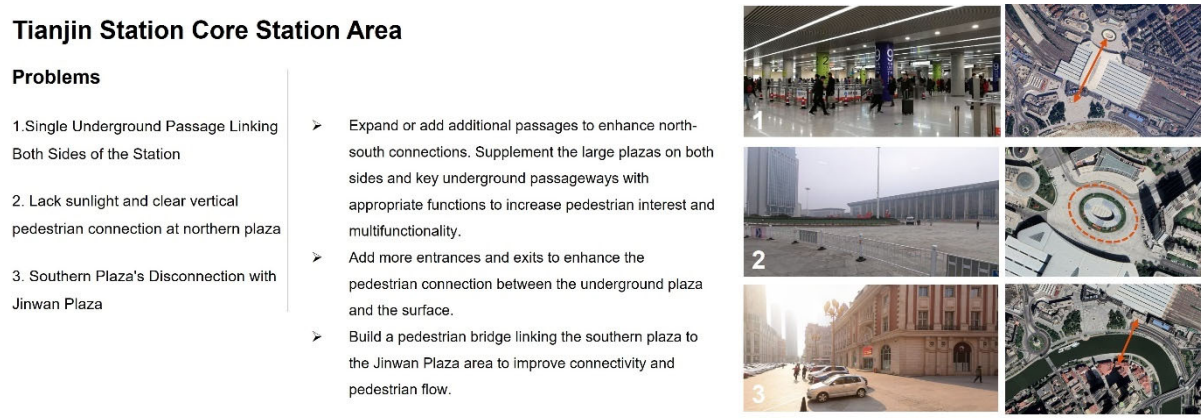

Figure 13. Suggestions to Tianjin Station, self-drawn.

In the 1 km influence range of the station, mega stations in China exhibit poor pedestrian accessibility due to differences in road network density and structure. This poor connectivity, coupled with high building volumes, may lead to a reduced choice for walking among users. Moreover, the service facilities around newly planned stations tend to be overly concentrated, lacking the development of mature commercial districts, which should be a focus for future improvements.

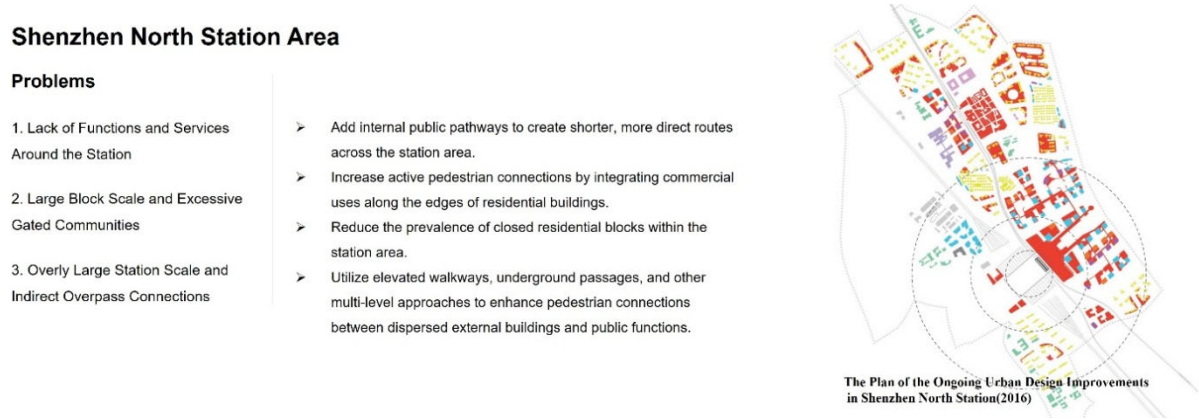

Figure 14. Suggestions to Shenzhen North Station, self-drawn.

CONCLUSIONS

After summarizing the station layout, road network, and pedestrian connectivity patterns of the five selected stations, this study evaluates their accessibility features across six dimensions. This evaluation highlights the factors driving each station's accessibility characteristics and uncovers the underlying morphological features shaping them.

The three planar stations showed relatively poor performance in accessibility assessments related to road networks. Utilizing elevated or subterranean solutions could effectively mitigate the barriers presented by tracks and platforms, thus enhancing performance in core station areas.

Chinese railway stations exhibit variability in accessibility due to differences in road networks and station scales, which is normal resulting in weaker data performance. But it can still remind us to address these accessibility challenges. Tianjin Station, as a representative older station, should focus more on its inner circle of the station, improve its accessibility to meet passenger needs and avoid becoming a walking void in the city centre. Recommendations include adding crossing passages and engaging in urban renewal to incorporate more service functions, drawing from examples of the other four stations.

For newly planned stations, like Shenzhen North Station, there is potential for improved infrastructure, yet more focus should be placed on controlling station scale and enhancing the density and diversity of functions in the surrounding area. The limited extension of the walking system beyond adjacent blocks and weak surrounding accessibility may hinder the development of the 1 km area. Therefore, urban design should not only focus on connections with adjacent blocks but also consider the overall walking system of the urban area, appropriately positioning gated communities and adjusting block scales to avoid negative impacts on pedestrian accessibility.

Limitation

This paper emphasizes qualitative research, as the relationship between morphological features and accessibility assessments is multifaceted. The limited number of case studies and significant differences in planning and station construction across countries complicate direct definitions of specific morphological impacts. Future research can expand in three directions:

1. Increasing the case database, focusing on diverse geographic regions, and conducting quantitative analyses of multiple morphological features against specific accessibility indicators to derive stronger correlations.

2. Enhancing accessibility evaluation metrics through methods such as hierarchical analysis and entropy methods to develop a more comprehensive and applicable station accessibility scoring system.

3. Comparing new and old domestic stations, addressing their distinct morphological differences and varying accessibility challenges, to further consolidate understanding in this area.

ABSTRACT

Brazilian favelas face chronic infrastructure and urban services deficiencies, safety against hazards, housing quality, and access to green spaces. Often occupied by low-income populations, improving it aligns with Sustainable Development Goals (SDGs) 6 and 11. However, a critical obstacle is effectively diagnosing their needs and setting priorities for intervention. Slum upgrading programs aim to address the built environment deficits based on precise field surveys to support projects and works for infrastructure provision and safety against geotechnical and flooding risks. However, surveys covering all precarious areas of the city are costly and rare, becoming shortly obsolete given the dynamics of constant and incremental growth of favelas. This paper presents a low-cost method for mapping the transformations of the housing fabric in all favelas of a city or region, considering a pre-established time frame. Changes are verified through visual analysis of images from the Google Earth Pro application. Comparing two aerial images from different dates, transformations are identified and classified according to type (removal or expansion) and intensity (moderate or intense). Transformations can then be mapped, highlighting typology, intensity, and spatial distribution as a basis for further analysis of their impacts on urban and environmental quality and identification of general trends. The results reveal issues such as the impact of road infrastructure on transformations and the increase of precarious housing in environmentally protected areas such as riverbanks, water bodies, or forests, among others. The increase or reduction of slum-type housing fabric shows the efficiency of urban and housing policies. It is also an indicator for measuring the trend toward achieving the SDGs directly related to the phenomenon. The method was tested in Campinas (SP) and Macapá (AP), cities with distinct urban characteristics and spatial data availability, demonstrating its potential for replication in other contexts.

Keywords: Deprived urban areas, Morphological analysis, Cartography of transformation, Data-driven interventions, Social Urbanism

INTRODUCTION

Like many cities worldwide, contemporary Brazilian cities exhibit a diversity of urban quality and form across their territories, partly driven by the phenomenon that Caldeira (2017) defined as “peripheral urbanization.” This model of urban development has resulted in numerous neighborhoods self-built by their residents, providing housing for a significant portion of the urban population for decades (Abramo, 2012; Davis, 2006; Maricato, 1979, 1996). Within this realm of urban informality lies a particular type of housing: the favela. According to UN-Habitat, the number of people living in suboptimal housing has never been higher (Rowe, 2022). Despite decades of efforts to urbanize and improve living conditions in favelas, the trend has been one of expansion rather than reversal in many parts of the world (UN-Habitat, 2018). As a result, global commitments such as the 2030 Agenda and the achievement of the SDGs are severely jeopardized, along with the ability to monitor their progress.

The need for more understanding of the causes behind the housing crisis in many cities and the lack of precise data hinder assertive action to recognize residents as rights-bearing subjects who require effective public policies to meet their urban housing needs. In Brazil, despite changes in urban legislation aimed at recognizing and upgrading precarious neighborhoods, and the existence of policies involving all three levels of government that could shift this scenario, the lack of consistent investment in cities (exacerbated by the Covid-19 pandemic) has hampered efforts to transform urban areas into healthier and more inclusive environments.

This article aims to shed light on the growth and spatial transformation of favelas over the past decade, drawing on case studies from two major cities: Campinas (SP) and Macapá (AP) (Figure 1). The first city is located in the Southeast region of Brazil, where urbanization began much earlier than in Macapá and has stabilized in terms of population growth. Macapá, on the other hand, is the capital of the state of Amapá, located in the Northern region, experiencing rapid population and urban growth since the late 20th century. The objectives are: a) to present a method based on visual analysis of aerial images to capture spatial transformations in favelas and b) to reveal the different growth trends in these two urban contexts, along with their impacts on urban and environmental quality.

The article begins with a review of contemporary efforts to quantify the population living in favelas, emphasizing the Brazilian trajectory. Based on available official data, it then describes the two cities in terms of their geomorphological context, urban development processes, and deficits in infrastructure and urban services. Since the two cases are part of distinct research projects, the “Method” section presents and justifies the procedures adopted in each case.

As a result, the study demonstrates the replicability potential of the method and provides an overview of recent transformation trends in both cities. While the term “favela” can be broadly applied across different contexts, the realities of these areas are particular, as the transformations they undergo. The adopted procedures successfully capture this phenomenon. With this, we aim to highlight the importance of a more careful approach in formulating strategies to address urban challenges, ensuring more efficient and appropriate outcomes.

Figure 1. Location of the cities of Campinas (Southeast region) and Macapá (North region) in Brazil. Map credit: National Online Project, 2024

The extent of housing precariousness captured by census surveys and aerial imagery

Like many in the so-called Global South, Brazilian cities have historically faced significant barriers to providing broad segments of the population with access to adequate housing through the market or public policies. The causes of the phenomenon of exclusionary urban development in Brazil are complex and will not be explored here. However, one of its territorial consequences is the emergence of neighborhoods composed of houses, streets, and urban services that the residents partially or entirely build.

Different names across Brazilian cities know self-built neighborhoods, but the term "favela," which originated in the Southeast region and adopted in cities like Rio de Janeiro and São Paulo, has become predominant. Beyond regional variations, favelas display significant morphological diversity, influenced by the biophysical characteristics of the sites they occupy, the development processes of their respective regions, their location within the city, and the degree of urban precariousness that defines them (Silva, Samora, 2020).

In Brazil, the Brazilian Institute of Geography and Statistics (IBGE) conducts census surveys every ten years. It has been developing and refining methods to quantify the number of households in favelas since 1950. In 1991, the IBGE began classifying census tracts containing favela-type housing as “subnormal,” enabling a more precise definition of the population living in these areas. The most recent data for this category is from 2010, which recorded 1.4 million people residing in subnormal census tracts—about 6% of the country’s population (Agência IBGE, 2011; Instituto Brasileiro de Geografia e Estatística, 2013).

However, due to the methodological limitations adopted, the IBGE data presents a significant underestimation. Some studies compare local data with IBGE databases (Brueckner et al., 2019,

Castro, 2018; Catalá & Carmo, 2021; Ferreira et al., 2016; Souza et al., 2020), while others attempt to assess, based on a sample of cities, the population living in favelas that resides in areas not classified as subnormal, revealing nearly double the number of people living in favelas (Marques et al., 2007). Since 2010, the IBGE has considered local surveys conducted by municipalities to delineate subnormal tracts and correct these distortions. In this process, municipalities provide the IBGE with the favelas' boundaries, preventing census enumerators from classifying these areas in the field. However, at least in the case of Macapá, this procedure has not prevented underestimation, as we will see.

Advancements in georeferencing and access to updated satellite imagery have enabled significant progress in understanding the phenomenon of deprived urban areas or favelas (Abascal et al., 2024; Kuffer et al., 2016, 2020). Research initiatives such as SLUMAP and IDEASMAP utilize these images to produce global assessments of the population living in favelas, supporting monitoring the Sustainable Development Goals (SDGs). The analysis can be performed automatically through machine learning techniques or by trained individuals who interpret the visual aspects of the phenomenon. A notable example of systematic monitoring in Brazil is the Mapbiomas Project, which tracks the increase in land occupied by favelas based on Landsat imagery (Souza et al., 2020). The accessibility of these images allows for increasingly precise identification and measurement of favelas, uncovering settlements in remote areas that are rarely included in traditional surveys.

In Brazil, the National Housing Policy, established in 2005, promoted the production of assessments of local housing needs (for cities with populations over 20,000) by conditioning the allocation of federal resources on the development of Local Social Housing Plans (PLHIS). Drawing from successful experiences in favela urbanization undertaken by local governments since the late 1980s—a practice recognized by the UN—the national policy acknowledges that many favelas' households suffer from a "qualitative deficit". It means that, through slum upgrading and land regularization, self-built dwellings can achieve the status of decent housing.

The concept of "housing needs" aims to address two distinct situations: housing deficit, which refers to the need to increase the stock of homes for families without housing, and qualitative deficit, which assesses the number of homes lacking urban services and legal status (Fundação João Pinheiro, 2021). To this end, the PLHIS diagnoses these needs, revealing the number and location of favela households classified as experiencing qualitative deficit.

Thus, many municipalities surveyed the existing housing stock in favelas or other types of precarious housing, as seen in the cases of Campinas and Macapá. The assessments included in the PLHIS were expected to reflect local realities more accurately than the censuses produced by the IBGE had managed to do so far. However, since 2016, the Federal Housing Policy has ceased to foster the development of local diagnostics. As a result, the national census, despite all its limitations, has become the only data source available to capture the reality of urban precariousness in many cities. The lack of accuracy and consistency in the quantitative assessments of the number of households in favelas hinders systematic monitoring of territorial transformation. It complicates the measurement of the effectiveness of policies aimed at overcoming housing precariousness.

City of Fields, City of Waters: Context and Universe of the Favelas of Campinas and Macapá

Campinas and Macapá are two Brazilian cities that developed at distinct historical moments, occupying natural sites with unique characteristics. The urban processes in both locations have resulted in spaces with diverse characteristics, which is reflected in the typology and conditions of housing precariousness, as presented below.

Campinas, SP: favelas in the City of Fields

Campinas is located in the state of São Paulo, in the Southeast region of Brazil. It serves as the headquarters of the Metropolitan Region of Campinas, which is part of the São Paulo macro metropolis, the territory with the highest Gross Domestic Product in the country. It is fully integrated, through processes of conurbation, with the metropolitan areas of São Paulo, Vale do Paraíba, Santos, and Sorocaba, as with the urban agglomerations of Jundiaí, Bragança Paulista, and Piracicaba. The city developed in 1850 in a geographic space characterized by rolling topography occupied by two biomes: the Cerrado and the Atlantic Rain Forest. In these higher topographic areas, the lush Atlantic Forest, primarily found in the floodplains, gives way to the fields of the Cerrado that name the city.

The economy of coffee production was the main driver of the urbanization process in Campinas. The accumulation of resources in the hands of local landowners enabled the economic and political elite to invest in railways to transport their produce, marking the region as an important railway hub. This advantageous condition regarding regional infrastructure availability was crucial for many industries to settle around the traditional urban site in the 20th century, shaping what Farah (2024) referred to as the “first historical periphery” of Campinas. After 1950, the country began investing in road transport, Campinas also benefited from highways such as the “Anhanguera”. This road significantly impacted the local urban morphology of the city by acting as a segregation element, increasing the value of land in the northern portion of the city. From the second half of the 20th century onward, it would be primarily to the south of the Anhanguera highway that working-class neighborhoods would concentrate, whether built through public policies or self-construction, determining “the place of the poor in the city” (Rolnik et al., 2015).

Throughout the 20th century, Campinas experienced significant urban expansion through the development of low-density housing neighborhoods, interspersed with urban voids. Starting in the 1980s, in the context of a severe economic crisis preceding the deindustrialization of the following decade, the city saw a growth in its favelas and the emergence of another specific housing type: segregated condominiums for the middle and upper classes.

In the 2011 Local Social Housing Plan (PLHIS), the City Hall of Campinas presented its first and only diagnosis of the housing conditions of low-income families, revealing that the city had 194 favela-type settlements, comprising a total of 29,078 households (Prefeitura Municipal de Campinas, 2011, p. 299). A year earlier, the census recorded the total population of Campinas at 1,074,659 people, of which 148,278 lived in subnormal census sectors, resulting in 153 subnormal clusters (AGSN), in turn containing 40,099 households (Instituto Brasileiro de Geografia e Estatística, 2010). These sectors are not limited to the favela typology but encompass other forms of precarious housing, such as those found in irregular subdivisions. In the diagnosis conducted by the city hall, this typology accounted for 40 neighborhoods, with an estimated 24,287 households.

In 2020, the IBGE released a preliminary announcement of the perimeters of subnormal clusters (AGSN) encompassing all Brazilian cities, estimated for the census scheduled for that year. In Campinas, for the year 2019, the IBGE estimated 149 AGSN in the city (a decrease compared to 2010), with 41,344 households showing low growth compared to 2010. Since no other housing diagnosis has been conducted and the data from the 2022 Census has yet to be presented with a breakdown of the favela typology, these are currently the most recent available data to portray precarious housing in Campinas, which justifies studies aimed at understanding the current situation of this universe, such as those we will report next.

Regarding spatial morphology, many favelas in the city are located on land that is not suitable for occupation according to urban legislation, typically along watercourses, in flood-prone areas of the city's rivers, abandoned railway beds, and vacant land neglected by the real estate market operating in the city. These are very dense occupations, with self-built houses that can reach up to three stories. The open spaces within the settlements are used for the circulation of people and vehicles, as illustrated in Figure 2. Most houses are connected to water and electricity networks; however, they lack sanitation systems, with wastewater being disposed of in septic tanks and rainwater flowing directly into the streets.

Figure 2. Viela com infraestrutura urbana precária na região do Parque Oziel/Jardim Monte Cristo. Campinas, photo credit Google Street View, março de 2020.

Macapá, AP: Stilt Houses in the Ressacas of the Water City

According to Carvalho (2020), the urban site of Macapá is characterized by "ressacas" (floodplains), a regional term used to describe areas of water accumulation influenced by river and rainfall regimes that drain internal and surface waters into the Amazon River basin and play an essential role in regulating the microclimate, serving as habitats for diverse fauna and flora. The most recent survey identified 24 floodplain areas (see Figure 3), which form a sizeable interconnected water system. The classification distinguishes between rainfall-influenced, river-influenced, and those affected by both systems, all protected by federal environmental legislation.

In the 1950s, Macapá began its expansion to the south, and between 1961 and 1973, new neighborhoods were established following the urban grid (SEMDUH, 2011). This growth soon encroached upon the floodplains, which began to be altered through filling, constriction, sedimentation, and the construction of infrastructures such as wooden stilt houses and access walkways for internal circulation. These changes impact the ecological characteristics and water quality, a situation worsened by lacking basic sanitation (Carvalho, 2020; Takiyama et al., 2012), exacerbating flooding (Sousa et al., 2021).

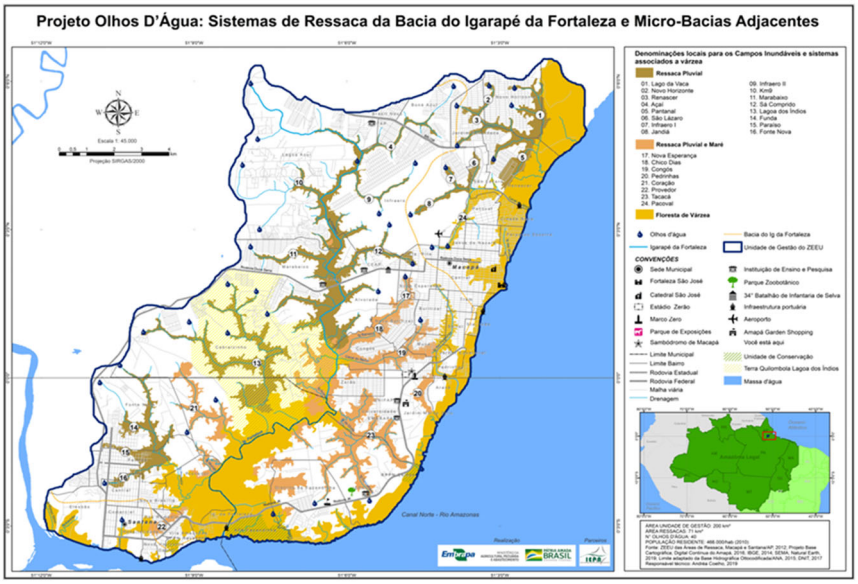

Figure 3: Olhos D'Água Project. Source: EMBRAPA, 2022.

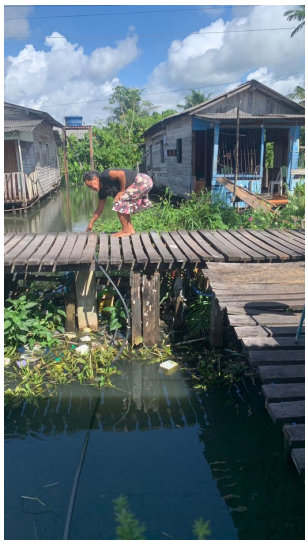

Figure 4: Stilt ways to the stilt houses in the Ressaca Chico Dias Community, Congós, Macapá (Brazil). Source: Authors' Archive, 2024.

As highlighted by Carvalho (2020), the communities that settle in these territories, which are the only areas accessible to large segments of the population in Macapá, face severe vulnerability conditions, mainly due to insufficient infrastructure and deprived housing conditions, further exacerbating the risks associated with human occupation. In these flooded areas, stilt houses predominate, accessed by wooden walkways— elevated paths over the water—constructed by the residents.

Whitouth municipal data on the universe of housing occupying floodplains, the IBGE data regarding subnormal clusters (AGSN) is the only available source. An estimated 16,757 households were identified in 84 AGSN in 2019. There is no clear differentiation between how many of these areas consist of settlements on dry land or in flooded areas, which is why the method described below outlines the procedures for estimating the number of neighborhoods with stilt houses in the floodplains (figure 4).

METHOD [Heading 1]

The research group "Territorial Policies and Water in Urban Areas" employs the method of "Transformation Cartography" to develop cartographic products derived from analyses of transformations within a specific area. After defining the temporal and spatial scopes of the transformations to be observed, analytical categories are established based on the study's objectives. The data used for analyzing transformations are satellite images collected on different dates and compared. The main indicator for determining visible transformations in the satellite images is the presence of slabs or roofs, which are counted as corresponding to a building. However, particularly in Campinas, it is impossible to associate each building with a single household, as many consist of more than one floor and may contain multiple households.

The cases of Campinas and Macapá address the transformations of the same urban phenomenon, the favelas, but they integrate research with different purposes. As a result, in each case, the dates of the images and the territorial scope adopted varied. Moreover, the data sources used come from different origins. Since the studies do not cover all favela neighborhoods in both cities or all households in these conditions, the results obtained cannot be interpreted as quantitative data but rather qualitative. While both cities have developed their housing plans, only Campinas has made the diagnostic data by neighborhood publicly accessible. Macapá's plan is more general and does not provide locational and population data for its favelas. The only available data containing the perimeters of the subnormal clusters (AGSN) come from the IBGE for the years 2010 and 2019.

Campinas, SP

Two distinct analyses were conducted to capture favelas' transformation and to characterize the related databases in Campinas. The first analysis involved comparing aerial images from 2010, 2011, and 2019, along with the perimeters of favelas (according to the PLHIS) and subnormal clusters (according to the IBGE). The objective was to identify coincidences and discrepancies and to understand the causes of variations between the municipal and the IBGE data.

The second analysis investigated how the 194 favelas mapped in 2011 by the PLHIS transformed over a ten-year period, using human interpretation techniques of satellite images for each favela in 2011 and 2021. We classified the transformations according to the categories in Table 1, and a summary of the results is presented in Table 3.

In this process, we excluded some areas due to limitations of the available material, resulting in 188 classified favelas. We mapped the results for further analysis regarding the environmental impact of the transformations, vulnerability to disaster risk, and urban infrastructure deficits, among others (SAMORA et al., 2024). The results discussed in this work come from the second evaluation, specifically the one that assessed the transformations of the perimeters mapped by the municipality in 2011.

Table 1. Transformation Categories used in the case of Campinas.

Transformation Category	Description
Consolidation	No growth or increase in dwellings by 10%

Minor Partial Removal	Up to 30% removal of dwellings
Moderate to High Partial Removal	30% to 50% removal of dwellings
Severe Partial Removal	Removal greater than 50% of dwellings (but not total)
Total Removal	100% of dwellings removed
Low to Moderate Expansion	10% to 30% increase in the number of dwellings
Moderate to High Expansion	30% to 50% increase in the number of dwellings
High Expansion	Increase greater than 50% of lots

Macapá, AP

Macapá lacks a municipal survey detailing the perimeters of wetlands occupied by stilt houses. Therefore, the only available territorial database comes from the IBGE, using proxies from subnormal clusters (Instituto Brasileiro de Geografia e Estatística, 2020).

The analysis in Macapá aimed to understand how the city's stilt house occupations transformed over time. Thus, the territorial scope focused on subnormal clusters formed entirely or partially by stilt houses located in wetlands or any existing floodplain areas. To exclude clusters established on "solid ground" from the sample, we needed to establish a procedure to define the study universe. Since the IBGE does not differentiate stilt house settlements from others, the first step involved examining each of the 84 subnormal clusters listed in the 2019 database. Out of these, 13 contained the word "ressaca" in their identification. In addition to this nomenclature, we selected other areas through typological assessment to include in the research universe. This procedure resulted in selecting 69 areas that exhibited characteristics of neighborhoods formed by stilt houses, thereby establishing the sample size.

The next step established the transformation categories for analyzing the selected subnormal clusters (Table 2). As in Campinas, we compared two images from each location (2010 and 2019), described the results in data sheets for each subnormal cluster, and summarized them in Table 4.

We identified significant differences in the perimeters from 2010 and 2019, leading to the development of a case study in the subnormal cluster named “Ressaca Chico Dias,” an area that experienced substantial growth in the number of precarious dwellings during this period. The case study aimed to understand the origins of the perimeter differences and determine the underreporting of existing stilt houses in 2010 that were not included in the subnormal cluster perimeter established at that time.

Table 2. Transformation Categories used in the case of Macapá

Transformation Category	**Description**
New occupation	Area not occupied in 2010
Moderate expansion	Up to 10% increase
High expansion	10% to 50% increase
Severe expansion	+50% increase

RESULTS AND DISCUSSIONS

Tables 3 and 4 present, respectively, the summary of transformations in both cities

Table 3. Transformation of Campinas Favelas 2011-2021 by category

Transformation Category	**Settlements**

Consolidation	129
Minor Partial Removal	12
Moderate to High Partial Removal	4
Severe Partial Removal	5
Total Removal	7
Low to Moderate Expansion	16
Moderate to High Expansion	2
High Expansion	13

Table 4. Transformation of selected subnormal clusters in Macapá 2010-2019 by category.

Transformation Category	Description
New occupation	1
Moderate expansion	13
High expansion	32
Severe expansion	23
Total	69

Types and Trends of Transformation

Using the same technique, we identified different transformation trends in the favelas of Campinas and Macapá. In the first city, the category "consolidation" best describes the transformations of favelas, while in the Amazonian city the transformations are much more intense, characterized by the "expansion" of stilt dwellings, a trend evident in all areas.

The consolidation of favelas observed in Campinas indicates that there was no expansion of households in the 129 perimeters where this trend is evident. However, further studies are necessary to analyze the growth of new perimeters after 2011, which was not the focus of this research. Additionally, the analysis of the urban characteristics of areas classified as "consolidated" shows that, despite the stability in the number of buildings, there are no significant transformations in the quality of infrastructure, as demonstrated by the image in the Oziel Favela (figure 1).

In Campinas, the category "consolidation" refers to areas with little modification regarding horizontal expansion within the perimeter, specifically a growth of up to 10% in the constructions observed in the aerial image. The morphology of these areas has little or no space between buildings, preventing excessive expansion that would extend the original boundary of the settlement. Thus, labeling a space as "consolidation" makes sense when the resulting form allows for little or no horizontal expansion. The local needs for population growth in many of these areas are addressed by the vertical expansion of households, meaning an increase in the number of stories of the buildings. However, this vertical expansion cannot be captured by aerial imagery, demanding other procedures not included in this research but reported in other works by the group, such as Bastos (2023).

In Macapá, we classified situations where the growth of buildings was up to 10% into a category called "moderate expansion." Unlike in Campinas, these settlements feature generous spaces between the buildings, allowing for almost unlimited horizontal expansion without being confined to a predetermined perimeter. Additionally, because they consist of stilt houses, the vertical growth of households is more complex than in the masonry and reinforced concrete structures that characterize the favelas of Campinas.

Macapá did not experience transformations resulting from the "removal" of households (either total or partial), but this phenomenon affected 28 locations in Campinas. These removals can be attributed to urbanization interventions in favelas, financed by the federal government, between 2007 and 2016 (Bianco, Bueno, 2019). By mapping these transformations, we can see that the favelas near the removal areas experienced expansions, which may indicate increased housing precariousness for the residents. Macapá did not receive any interventions similar to those in Campinas. However, the city is investing in places like Ressaca Chico Dias to replace wooden walkways with concrete ones and improve access to electricity. It demonstrates that, at least for now, there is no intention to remove the stilt settlements.

Considering the stilt settlements, the analysis concluded that the category "high expansion" best characterizes the transformations we observed in Macapá, followed by "severe expansion." This situation contrasts sharply with what we saw Campinas.

Underreporting of the Phenomenon in Macapá

Another relevant fact concerns the underreporting of the phenomenon in Macapá. In 2010, IBGE recorded 24 subnormal clusters (AGSN), but by 2019, it mapped 84 locations, doubling the number of areas identified in the previous survey. However, many of these neighborhoods existed in 2010 but did not receive AGSN classification in that year's census. Only one of the 69 areas analyzed in this research can be considered a new occupation emerging after 2010. In consultation with the IBGE office in Macapá in June 2024, officials informed us that the municipality is consulted to validate the AGSN perimeters used in the census survey.

The Ressaca Chico Dias favela case in the Congós neighborhood exemplifies the challenges of comparing the AGSN perimeters from 2010 and 2019. Figure 5 shows two images from Google Earth Pro of this favela for 2010 and 2019, with the perimeters labeled as “Ressaca Chico Dias” delimited in the two surveys. The yellow line represents the 2010 perimeter, while the red line indicates the perimeter defined in 2019. In 2010, many dwellings fell outside the yellow perimeter and were not included in any other subnormal cluster. The 2019 perimeter appears more accurate than its former counterpart, even though it excludes an entire alley in the lower left corner of the image that was part of the 2010 perimeter. This variation highlights the difficulty of conducting a comparative analysis, as situations that existed in 2010 were overlooked. As a result, these were counted as new households in the 2019 base, even though they had been present since at least 2010. Nevertheless, considering the 2010, we concluded that the category that best represents the transformation is “high expansion.”

Among the 69 areas analyzed, only one case represents an occupation that occurred after 2010, an indicator that reinforces the underreporting present in the 2010 base, which included only 24 AGSN perimeters.

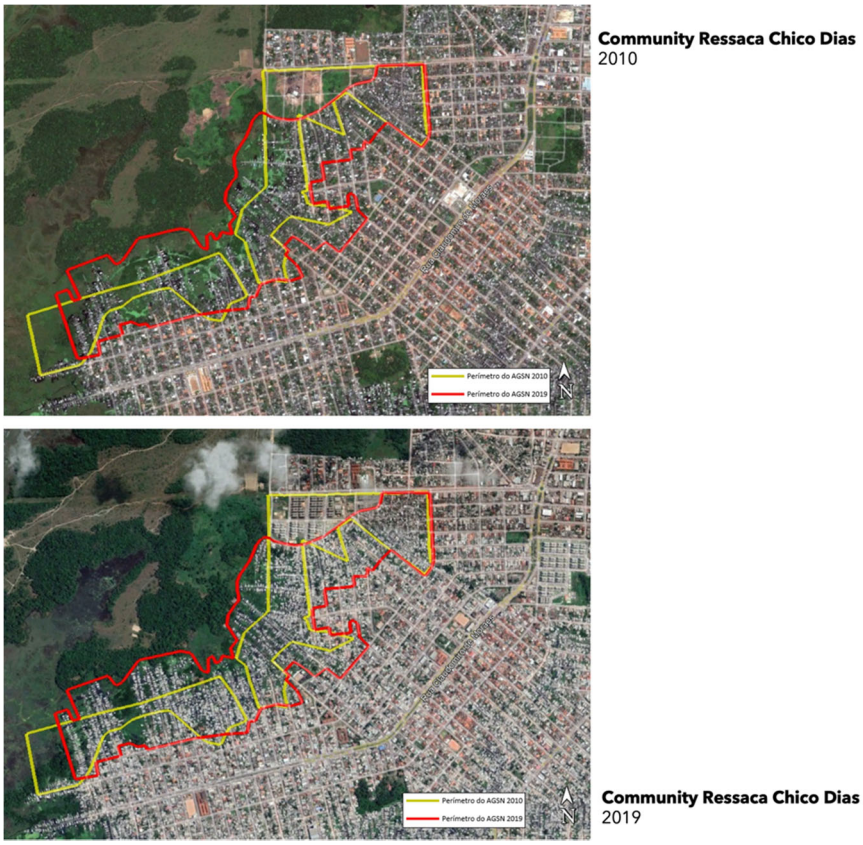

Figure 5: Case Study in Ressaca Chico Dias 2010 - 2019.

CONCLUSIONS

The method for analyzing transformations proved to be quite versatile, applicable in contexts as distinct as those of Campinas and Macapá. The different histories of urbanization in these country country partly explain the predominance of consolidated favelas (or, more precisely, favela perimeters) in Campinas, and the strong growth of dwellings in Macapá.

The insufficiency of data in Macapá's 2010 census base is not new, underscoring the importance of producing local data. The census cannot serve as the only source of housing data, or we risk underestimating the country's precarious housing conditions.

Regarding actions to address infrastructure in these areas, Macapá has been expanding primary networks and consolidating walkways, yet still fails to provide satisfactory access to water and sewage treatment. In the context of unlimited housing expansion in areas of permanent preservation, neglecting sanitation places both residents and the environment in precarious conditions. Thus, it is worth noting that many communities in Campinas still lack adequate sanitation, even after being established for over a decade, which presents additional challenges for these cities in achieving the Sustainable Development Goals (SDGs).

The analyses reveal significant differences between Campinas and Macapá regarding favelas transformations and the challenges faced by each city. In Campinas, the predominance of "consolidation" indicates stabilizing existing settlements without significant expansion. This situation contrasts sharply with Macapá, where the "high expansion" category highlights a notable increase in precarious housing, particularly in the form of wooden stilt dwellings. The findings underscore the

importance of addressing the data discrepancies from previous censuses, as the lack of accurate information in both cities contributes to ongoing challenges related to urban infrastructure and housing conditions. These differences reflect not only the unique historical contexts of urbanization in each city but also emphasize the need for tailored policy interventions to address the specific needs of their respective populations.

Acknowledgements

The authors would like to thank Capes and CNPq for the scholarships and financial support they provided for this work. They also thank the residents of Ressaca Congós for receiving us on the field visit and the IBGE technicians for clarifying doubts about the 2010 and 2019 surveys in Macapá

ABSTRACT

Since the 1988 Brazilian Constitution the sectoral policies have as a pressure mechanism the offer of resources for municipalities to plan and implement sectoral policies at the municipal level. If, on the one hand, this sectoral view helps to face certain issues that are difficult to prioritize local policies, such as environmental sanitation, urban mobility, housing, disaster mitigation, among others, on the other hand, it ends up generating a deterritorialization of demands, since resources are allocated by sector and not by territorial needs. Given the scope and regional differences of the Brazilian territory, there is a difficulty in planning territorial-based national policies. It is necessary to create arguments that strengthen territorial-based public policies in order to consider the typologies of Brazilian cities. Some efforts have already been made by researchers from different areas of knowledge to build a typological study of cities that makes it possible to establish specific programs defined by national policies. The present research aims to contribute to the typological studies of cities by adopting knowledge accumulated by research carried out in the area of urban morphology. Specifically, the objective is to verify whether it is possible to identify patterns of urban forms existing in the municipal territories of different Brazilian regions. Through previous research, we were able to apply the method of characterization of urban occupation over the municipal territory in 62 small and medium-sized cities located in the interior of the State of São Paulo. It is now intended to expand it to other regions of the country and to verify if it is possible to identify patterns that help in the studies of typologies of Brazilian cities. The results obtained make it possible to quantify the degree of dispersion and fragmentation of cities.

Keywords: Urban Form, Morphology, Territorial Policies, Typologies of Cities, Federative Structure

INTRODUCTION

To understand the relevance of this research, it is necessary to make a small preamble about the option taken, since the 1988 Constitution, to adopt National Policies of a Sectoral nature. We will briefly present the obstacles to its elaboration and continuity, as well as the difficulties that Brazil has been facing in attempts to implement it.

It should be noted that this debate is not new. Technicians and researchers have been working on creating strategies to foster territorial-based policies. The implementation of the Ministry of Cities in 2003 was a hope to treat cities through territorial-based policies where, for example, housing would

not be reduced to the provision of housing units. Unfortunately, the hopes for the action of the Ministry of Cities were not realized in that period (MARICATO, 2011).

In 2019, the Ministry of Regional Development (MDR) absorbed the technicians of the former Ministry of Cities (MC). Despite the times of dismantling of public policies, which devastated the country between 2018 and 2022, the National Urban Development Policy (PNDU) continued to be discussed in the MDR, which is characterized by being a State policy and not a Government policy, that is, a discussion that goes beyond the management of this period, after all, the formulation of the PNDU had been debated since the 1988 Constitution.

> "A existência da PNDU no Brasil é controversa. Diferentes atores-agentes, gestores e pesquisadores do campo do planejamento urbano divergem sobre a existência da PNDU e sobre sua efetividade (COSTA; GOMES; ADRIANO, 2017). A inexistência de uma política formalizada enquanto tal, por meio de norma específica, significa, para alguns, que não há uma PNDU. O capítulo constitucional da política urbana deixou a questão em aberto e o EC, ao trazer as diretrizes e instrumentos da política urbana, regulamentou aspectos da política urbana em geral, especificando o que havia sido estabelecido pela CF 88, mas não tem a envergadura esperada de uma PNDU que trouxesse maior objetividade e permitisse operacionalidade para efetivar tal política."
>
> (Ipea, 2020, p. 14)

Technicians from the former Ministry of Cities and researchers linked to INPE – National Institute of Economic Research with support from IBGE – Brazilian Institute of Geography and Statistics and ANPUR – National Association of Urban and Regional Research, had been debating in seminars the research developed that investigated the methods for the creation of the typologies of Brazilian cities. It is expected that with the next administration, through the resumption of processes that will strengthen institutions, this debate will gain strength. Therefore, we are going through a historic moment, where efforts to understand the Brazilian territory can contribute to territorial-based public policies.

Since the 1988 Constitution, sectoral public policies have been formed, strongly driven by National Policies that define national plans for each sector (sanitation, housing, mobility, etc.), establishing programs and resources. This structure induces municipalities to follow sectoral policies as they place the formulation of municipal sectoral plans as a condition for receiving resources from the sector. In view of the scarcity of resources that municipalities face, especially when since the 1988 constitution there has been an imbalance between the obligations and the resources allocated to the municipalities (TOALDO & HERMANY, 2013).

If, on the one hand, this sectoral vision helps to cope with the distribution of resources, on the other hand, it ends up generating a deterritorialization of demands. The ongoing research, which resulted in the present publication of preliminary results, problematizes this process through the analysis of some national public policies and their impact on the municipalities and analyses the spatial configuration of urban occupation on the municipal territory in different contexts and regions. It is not intended to establish a direct relationship between the practice of sectoral policies and the resulting urban territorial configuration, however, it is worth reflecting on how much this practice, which results

in the deterritorialization of local policies and actions, does not end up creating obstacles to territorial planning.

Sectoral policies have been developed since the 1988 constitution. A set of national policies were painstakingly built through extensive debates between 1988 and 2015, we can highlight: Water Resources (1997); National Risk Reduction Plan (2012); National Basic Sanitation Plan (2007); National Housing Plan (2009); National Mobility Plan (2012); Ten-Year Energy Expansion Plan (2012); National Plan for Integrated Solid Waste Management (2010). It is also worth remembering that many changes to these sectoral policies emerged between 2016 and 2021 after the coup, weakening them even more (BASTOS, 2017).

The formulation of a national policy is costly in terms of time, negotiation and construction of the concepts and principles that guide it. Take, for example, the National Water Resources Policy, a sector that has several correlations with the others. Law No. 9,433/1997, which institutes the National Water Resources Policy, creates the National Water Resources Management System and regulates item XIX of article 21 of the Federal Constitution, establishing the national water resources management system and defining criteria for granting rights to use water, which is fundamental for the sector's programs and policies. The continuity of this debate is put at risk 22 years later with Law No. 13,844/2019, which changes the composition of the National Water Resources Council. We take this sector only as an example, to demonstrate the difficulty in continuing the debate.

Another example is the National Urban Mobility Policy. In 2008, Brazil aligned itself with the international mobility policy through the European Union-Brazil Sector Dialogues Support Project with the objective of fostering the transfer of experiences, knowledge and consolidation of the social pacts of the Sustainable Urban Mobility Plans from European to Brazilian cities. Four years later, in 2012, through Federal Law 12.587, which establishes the guidelines for the National Urban Mobility Policy, the premise is taken as the sustainable development of cities in order to prioritize federal investments in non-motorized means and collective modes, in addition to establishing the regulation of services and fare policy. In this context, the Urban Mobility Plan became the instrument for implementing the National Mobility Policy (PMU) stipulating the obligation of municipalities, with more than twenty thousand inhabitants, to develop the PMU. The development of the municipality's PMU becomes a condition for it to receive federal resources for urban mobility projects. In addition to being integrated into the city's Master Plan, the PMU should establish the actions, objectives and concrete goals that meet the demands of the population in a participatory way, including the different agents

Despite the technical assistance offered by the Federal Government, the lack of technical, financial and technological resources found in most Brazilian municipalities proved to be obstacles to face the technical complexities involving the PMU (OLIVEIRA, 1972).

In January 2016, the then Ministry of Cities carried out a survey of the 3,342 municipalities that, by May 2015, should have prepared the PMU, to compete for federal financial resources. Of the 2,066 respondents, only 189 municipalities had prepared the PMU. Of these, 142 (83%) are located in the South and Southeast regions (Brasil, 2016) and 133 (78%) have up to 250 thousand inhabitants.

The low adherence of municipalities to compliance with Law No. 12,587/2012 prompted the proposition of Bill No. 7,898/2014, which ended up becoming, in 2016, Law No. 13,406/2016,

postponing the PMU deadline to 2019. However, a new law, in 2020, (Law No. 14,000/2020) extends the date of delivery of the Urban Mobility Plans (PMU).

The research of Laura Machado, Lívia Salomão Piccinini (MACHADO; PICCININI, 2018) develops a table that lists 43 cities that declared to have prepared the PMU, and in 29 of these (68%), it was found that the plans do not define concrete actions, postponing decisions for more specific plans, such as: bicycle paths, public transport, sidewalks, urban forestation, universal accessibility or public lighting plan. In this way, the Urban Mobility Plan is no longer effective and hinders the desired integration between modes.

In Brazilian cities, characterized by socio-spatial segregation (SILVA, 2016; VILLAÇA, 2011), the search for public resources for the implementation of concrete actions on the territory, within a sectoral logic, end up deterritorializing the look and time of the place. National and local agendas are not always aligned and compete for the resource without clearly evaluating the city that is being formed. (CARDOSO et al., 2016).

The data presented demonstrate the difficulties in implementing national sectoral policies. It happens that territorial-based policies favor electing actions that normally demand different sectors, however the difficulty lies in the management in view of the continental scale of the country and, mainly, the regional differences and between the types of existing municipalities, either from the dimensional point of view of population and territory, or their insertion in the network of cities, or even the financial and technical capacity of the local public staff.

Given the scope and regional differences of the Brazilian territory, there is a difficulty in planning national policies based on territory. It is necessary to create arguments that strengthen territorial-based public policies in order to consider the typologies of Brazilian cities.

It should also be noted that the search to strengthen territorial-based policies is of great importance for the adaptation of cities to climate change. The process of occupation and transformation of the Brazilian urban territory is characterized by socio-spatial segregation, and the urban form reflects these processes (SANTOS, 2014). Without territorial-based programs, it is impossible to intervene in a systemic way in order to avoid the impacts that are to come.

Some efforts have already been made by researchers from different areas of knowledge – involving universities and institutions such as IBGE (2020), IPEA (2020), etc. – to build a typological study of cities that makes it possible to establish specific programs defined by national policies.

In 2018, the IBGE publishes the REGIC - Regions of influence of cities 2018, updating the references of the Brazilian urban network. It would be the fifth version of this line of research that establishes the hierarchies and links between the Cities and delimits their areas of influence.

The previous versions were published in 1972, 1987, 2000 and 2008, which makes it possible to understand the historical evolution of the urban phenomenon in Brazil. This line of research helps to identify the networks, the nuclei and the isolations. These data were considered in the proposed typology of cities; however, they are not sufficient for their establishment.

In turn, IPEA (2020) contributes to this discussion with economic parameters, analysing the different financial capacities of municipalities and the relationship with the network system and parameters to establish the typologies of cities.

It is not enough to characterize these differences by population size, or by the five regions (South, Southeast, Center, Northeast and North). As we have presented, the studies on the typification of cities have been working with a set of approaches: management capacity (IPEA, 2020), position in the network of cities (IBGE, 2020). However, these approaches are still insufficient. The present research investigates how an analysis of the degree of dispersion or concentration of urban areas in the municipal territory can help in the typification of cities. Cartography is used and from the cartographic data a graphic synthesis is drawn that favours comparative analysis and perception of patterns.

The objective of the ongoing research is to contribute to the typological studies of cities by adopting knowledge accumulated by research carried out in the area of urban morphology. Specifically, the objective is to verify if it is possible to identify patterns of spatialization of existing urban forms in municipal territories.

The research intends to apply a cartographic method of analysis that results in a graphical synthesis making it possible to identify similarities and dissonances. To do so, it uses morphological reading as an instrument of analysis.

METHOD

With a view to the quantitative and qualitative reading of the process of urban dispersion, we undertook two stages of research. The first, through the interpretation of images from Google tools: Earth, Maps and Street View; the second by field observation work. The quantitative form measures the number of dispersed urban fabrics found, as well as their dimensions. Dispersed fabrics are defined as those that are not part of the main urban area of each municipality. The qualitative form typifies each of these occurrences.

In the first stage of the work, satellite images were initially analysed, made available by Google Earth, between the second half of 2020 and the first half of 2021. We sought to identify the entire urbanized area, both in the main urban area, which we refer to as the city, as well as the other areas separated from the main area and identified as urban, due to the presence of some of the urban morphological elements such as: blocks, roads, lots and buildings. The criterion adopted was to consider urban area any occupation greater than 2ha, with road access other than a highway and parceling in lots less than 2,000 m2. For the purpose of this research, this is the minimum urban cell, equivalent to about two blocks in a common urbanization, where some relationship of neighbourhood and locality begins to be established.

When there was doubt in identifying the locations, we also consulted Google Maps with the resources of markers and user information, and finally Google Street View, which, when available, is very effective in identifying the type of occupation. The relevance of typological characterization lies in providing elements for the interpretation of the factors that generate the dispersion process.

From this observation, we first mapped the main urban sprawl and all the fragments outside it. With Google Earth's polygon drawing feature, each of them was saved as a file, named, and numbered. The same resource allows us to extract the area and perimeter information and assign a color, with which we identify the typology of the occupation, as exemplified in figure 1. To make the structure of urban

dispersion more visible and to make it comparable between cities, diagrams were drawn up, converting the previous information into a schematic graphic representation (figures 2 and 3).

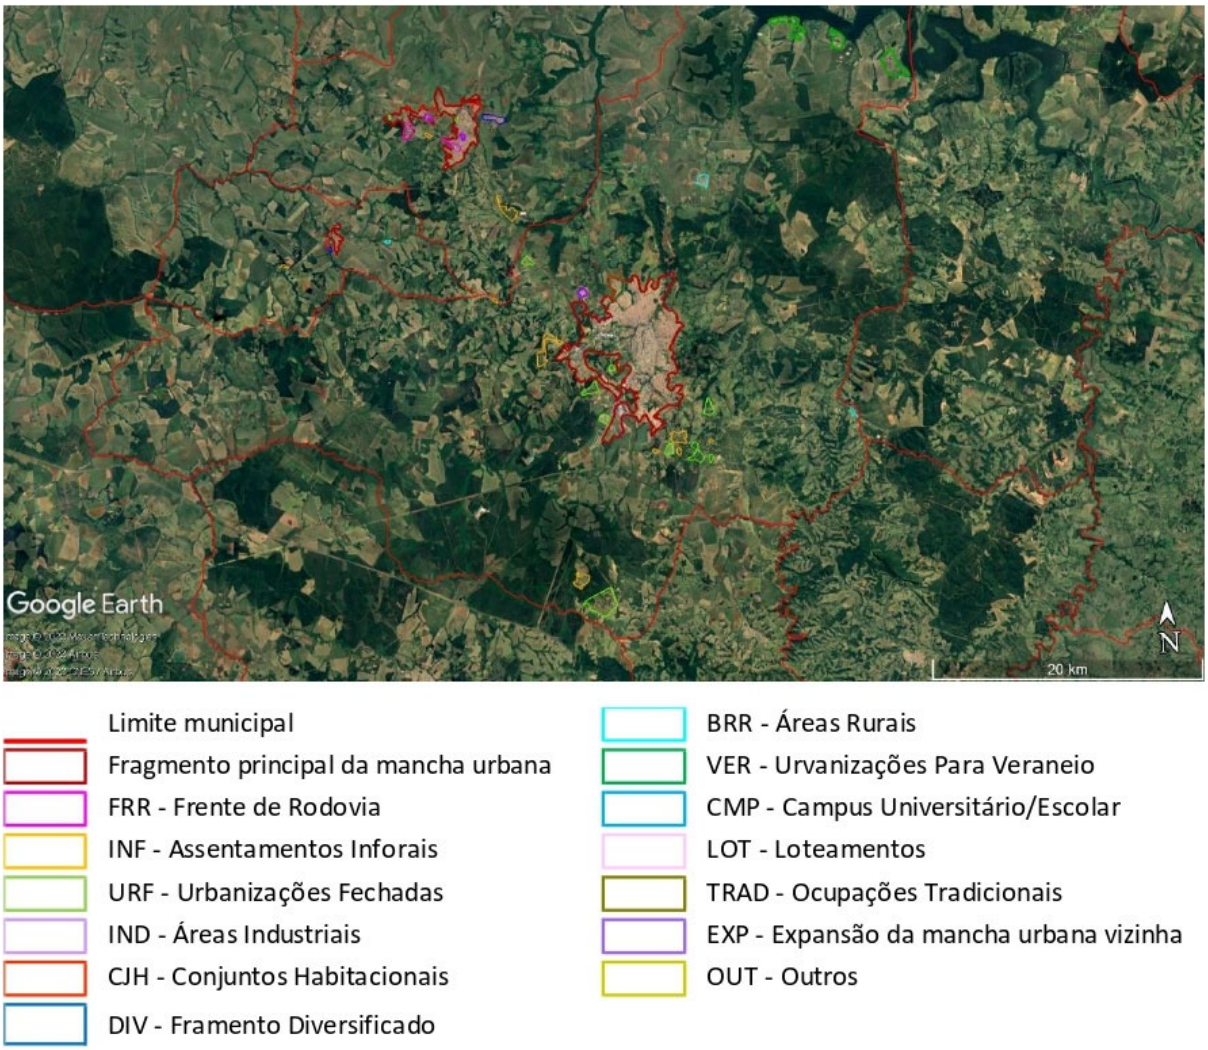

Figure 1: Analysis of urban dispersion in the municipalities of Botucatu, São Manuel and Pratânia. Source: Almeida Filho, 2024.

The identification of dispersed urban areas and their delimitation effectively contains the information desired by the research and provides the numerical data that we will analyse later and allow the interpretation of the reality of dispersion in the municipalities analysed. However, its visualization is difficult, due to some factors: a. the scale of the maps, which cover the territory of the municipality in its entirety; b. the small size of some dispersed urbanizations and c. the competition with the other elements of the satellite image in the background. In addition to these factors, it was observed that the morphological diversity of the spots identified in each municipality makes the comparison itself difficult. A first possibility of observation would be to work with two images. The first as shown in figure 1 and the second where the image in the background would be suppressed, highlighting the drawn polygons. It was perceived that there would still be losses in the interpretation of the result, as the difficulty arising from the competition with the image in the background would be circumvented, but not the one that comes from the diversity of forms. There are still other factors and one of significant importance is that the distance that is relevant to understand the degree of isolation of a dispersed urban sprawl is much more road than geometric. To explain: if an urban area is two kilometres, in a straight line, from the main area, it is close. However, if there is a geographical

accident that makes direct access impossible, such as a mountain range or watercourse, and the contour requires a journey of ten or more kilometres, it is far away.

Faced with this situation, we chose to create diagrams that support the analysis of the result. By reducing the information to the essential in graphic terms, we were able to observe in a direct and intuitive way the situation of urban dispersion. To this end, all urban spots, main and dispersed, are represented as circles, with an area equivalent to that measured in the analysis of satellite images. Considering the angle between the center of each urban area and the main urban center, the direction in which each circle will be inserted in the diagram is defined. The distance is represented by the shortest road distance between each spot and the center of the main urban area, informed by the Google Maps route query tool. The axes that connect the circles represent schematically the road system that connects them, reduced to straight lines with as few derivations as possible. Finally, a second circle, in a dashed line, was thrown around the circle that represents the main area, which represents the area equivalent to the sum of all the urban areas found in each municipality, in order to perceive the total degree of dispersion in each municipality. For information on the typology of each stain, colour legends were used. Figure 2 explains the elaboration of the diagrams:

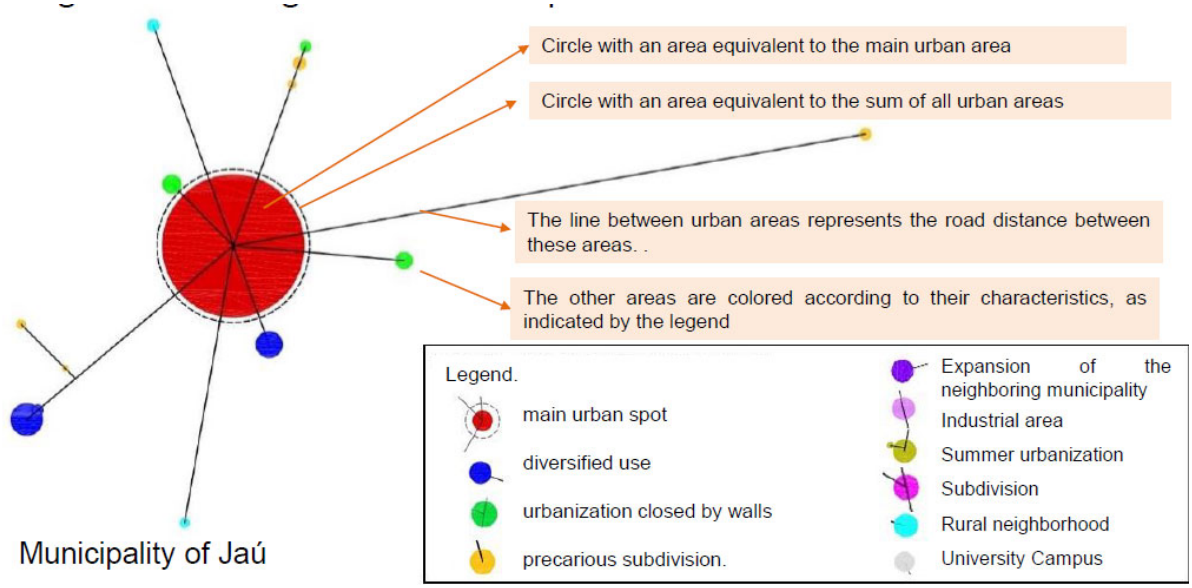

Figure 2: Interpretation of images by the construction of diagrams – Diagram from Jaú/SP. Source: Almeida Filho, 2024.

We can now examine, in figure 3, the diagrams that represent the three municipalities depicted in figure 1, and perceive not only the dimension, but also the structure of the dispersion.

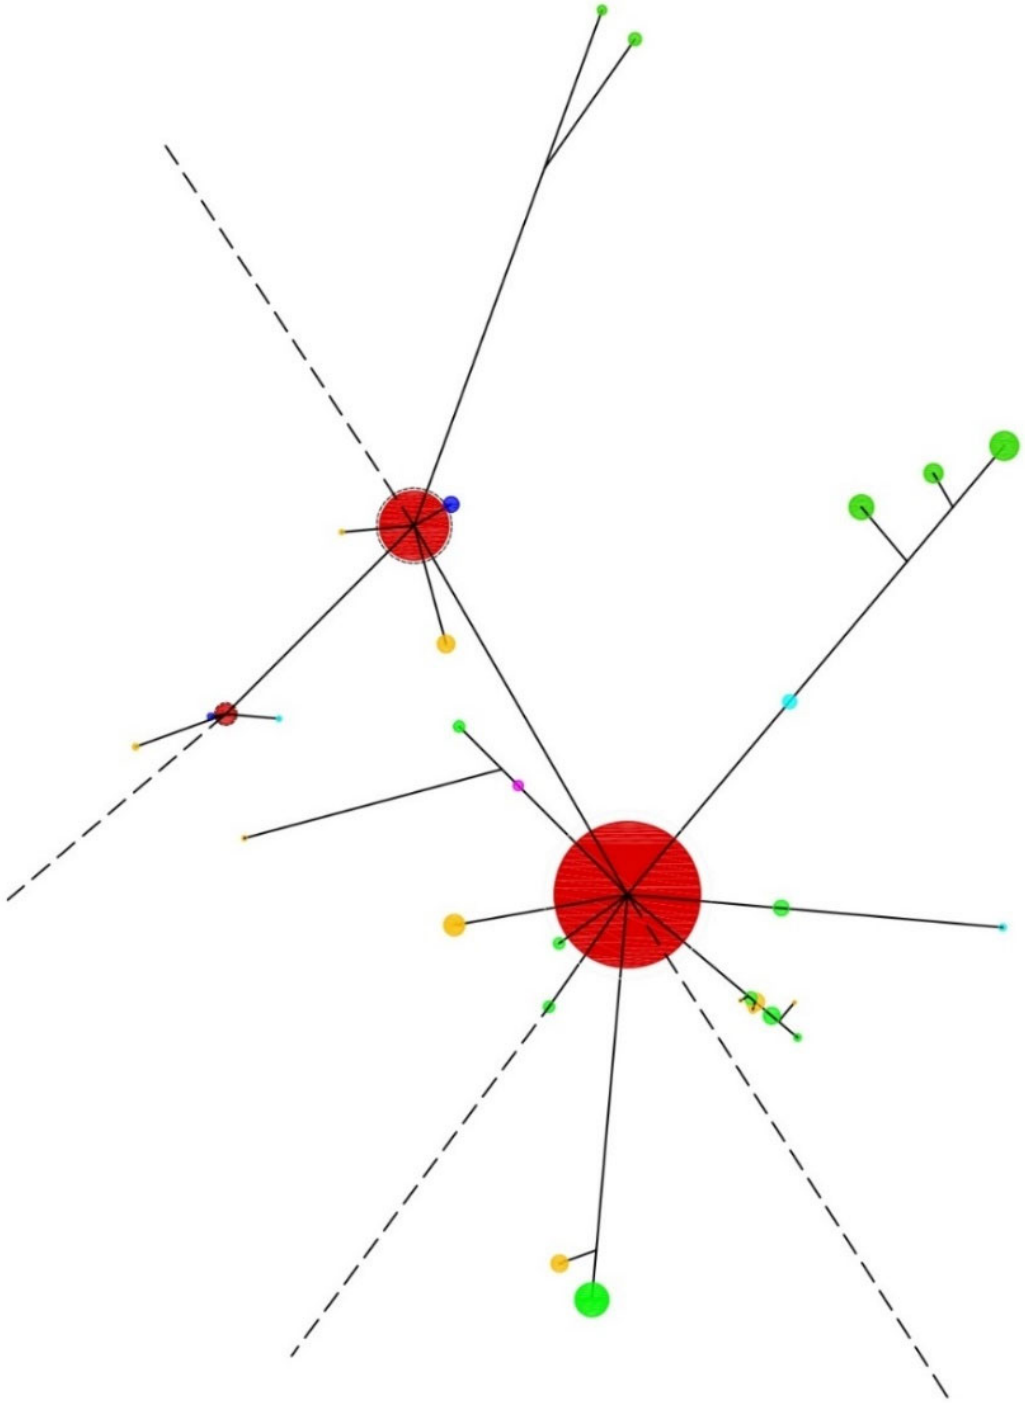

Figure 3: Scatter plots of the municipalities of Botucatu, São Manuel and Pratânia. Source: Almeida Filho, 2024.

It should be noted that we assume an action research methodology in which the researcher's experience, culture and professional experience directly affect the perception of the place Lakatos (1985, pg.193). Therefore, this reading was confirmed, case by case, in the second stage, by the field view. To this end, we visited, throughout the second half of 2021, 40 of the 62 cities in the sample, including all those with an urban population of more than 20 thousand inhabitants and 10 among the 32 cities with less than that.

RESULTS AND DISCUSSIONS

The method was applied to a sample of 62 small and medium-sized cities in the interior of São Paulo, selected based on a socioeconomic reading from a previous survey (Almeida Filho, 2019), presented in figure 4:

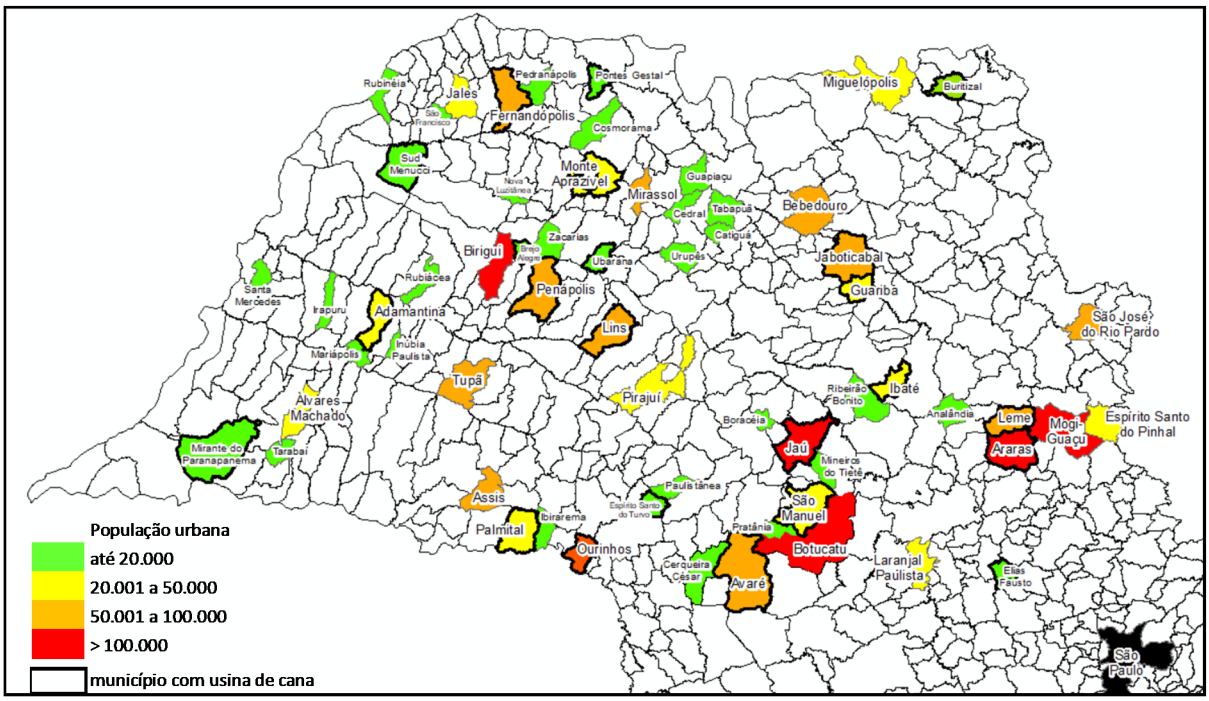

Figure 4: sample of 62 cities. Source: Almeida Filho, 2024.

The dispersion analysis consists of verifying the proportion of the area occupied by the external fragments in relation to the area of the main urban area (Table 1). This indicator contemplates the process of dispersion of urbanization and presented very different results: from a group of eight cities where we did not find any urban area outside the main area to the other extreme, also with eight cities, where the dispersed occupations make up an area greater than that of the main area. That is, in the first case, the city remains absolutely cohesive within the municipal territory and, in the second, there is more than another city dispersed in this territory. As the main urban area, we adopted not necessarily the largest, but the one that houses the main urban center. Among the various situations, it is certain that the process of dispersion of urbanization is not exclusive to large cities, as several studies point out, but also affects medium and small cities.

	Município	Proporção	região do Estado (1)	Distância rodoviária à capital (2)	População urbana (3)

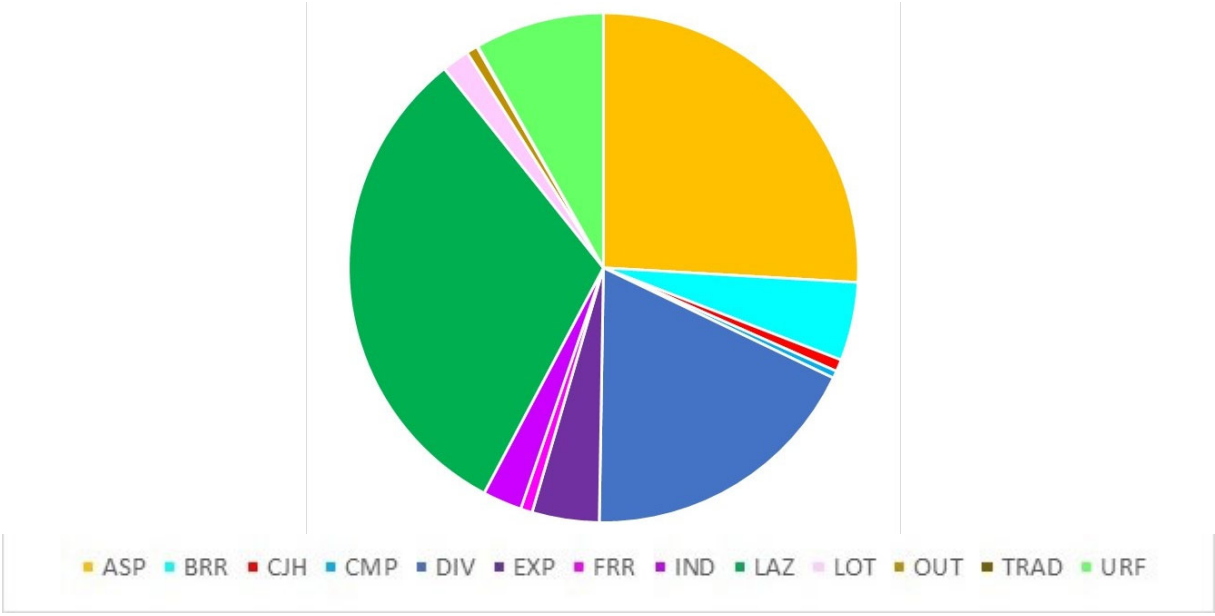
Table 1 – Dispersion of the urban area: proportion between the area of the dispersed spots and the main area. Source: Almeida Filho, 2024

Regarding the typology of the external fragments (graph 1), both in number and in occupied area (148 and 36.77 km2), informal settlements (inf) emerge as a preponderant factor in the process of dispersion of urbanization. In the urban universe researched, precariousness means the non-compliance with the legislation on subdivision and, therefore, with the guidelines of a possible municipal urban planning, but not necessarily precariousness in the socioeconomic sense, associated with social vulnerability.



Graph 1 – External fragments by typology – area. Source: Almeida Filho, 2024.

There are 72 rural neighborhoods, whose occupied area is not very expressive (7.06 km2). They all have an evident hierarchical relationship with the main urban center. Diversified fragments, on the other hand, have a priori an opposite meaning. They are less numerous and more expressive in area (31 and 25.74 km2) and almost always closer to the main urban area and the main road structure. These are places that have lately attracted various activities, on the initiative of various agents. They are growth poles of the cities disconnected from the main area, possibly with more regional than local articulations.

Included among the closed urbanizations, the gated communities have a very marked impact throughout the interior of São Paulo, and it is no different in the medium and even small cities of the sample (35 and 11.63 km2). It is not difficult to infer that they constitute the most ostensible form of denial of the city, ideally understood as a place of encounter between people. They are recent and visibly expanding structures, conceived, on the contrary, precisely to segregate people.

The other typologies found make up 27 fragments and an area of 9.91 km2. They are housing complexes, University Campuses, Highway Fronts, Industrial Districts, allotments, Traditional Occupations and others, not defined.

Regarding the dispersion process of the main urban area, we observed that the surface of urbanization outside this area reaches about 18% of its area, sometimes reaching almost four times larger than it. Considering both the number of occurrences and the extent of the occupied areas and in descending order of importance, the main causes found in the sample are:

- the growth of cities along the highway fronts and their relationship with these linear structures, especially radial highways, connecting the capital and the interior;
- the disarticulation between regional and local, industrial and residential, large or small uses in these portions of the territory; the barrier effect of these structures;
- informal settlements, implanted visibly outside the standards of federal legislation on land parceling, according to satellite image analysis, in isolated, sometimes remote locations;
- urbanizations aimed at leisure, practically all on the banks of rivers and dams, often have large extensions, low density and, in some cases, also very low occupation of lots;
- diversified expansion nuclei, when a growth pole is detached from the main urban sprawl;
- closed urbanizations, in a process similar to what occurs in the intra-urban sphere.

SCATTER AND TYPIFICATION DIAGRAMS

The view of the set of diagrams allows us to rehearse a first discussion about the typification of cities in terms of the mode of dispersion. For the sake of space in this article, we have selected some significant diagrams for this first digression.

First, we identified medium-sized cities, where dispersion is intrinsic to the growth process itself. In them, we perceive tissues dispersed in different directions and typologies, seeming, at first glance, to be the result of an expansion that is not established by a single or preponderant factor.

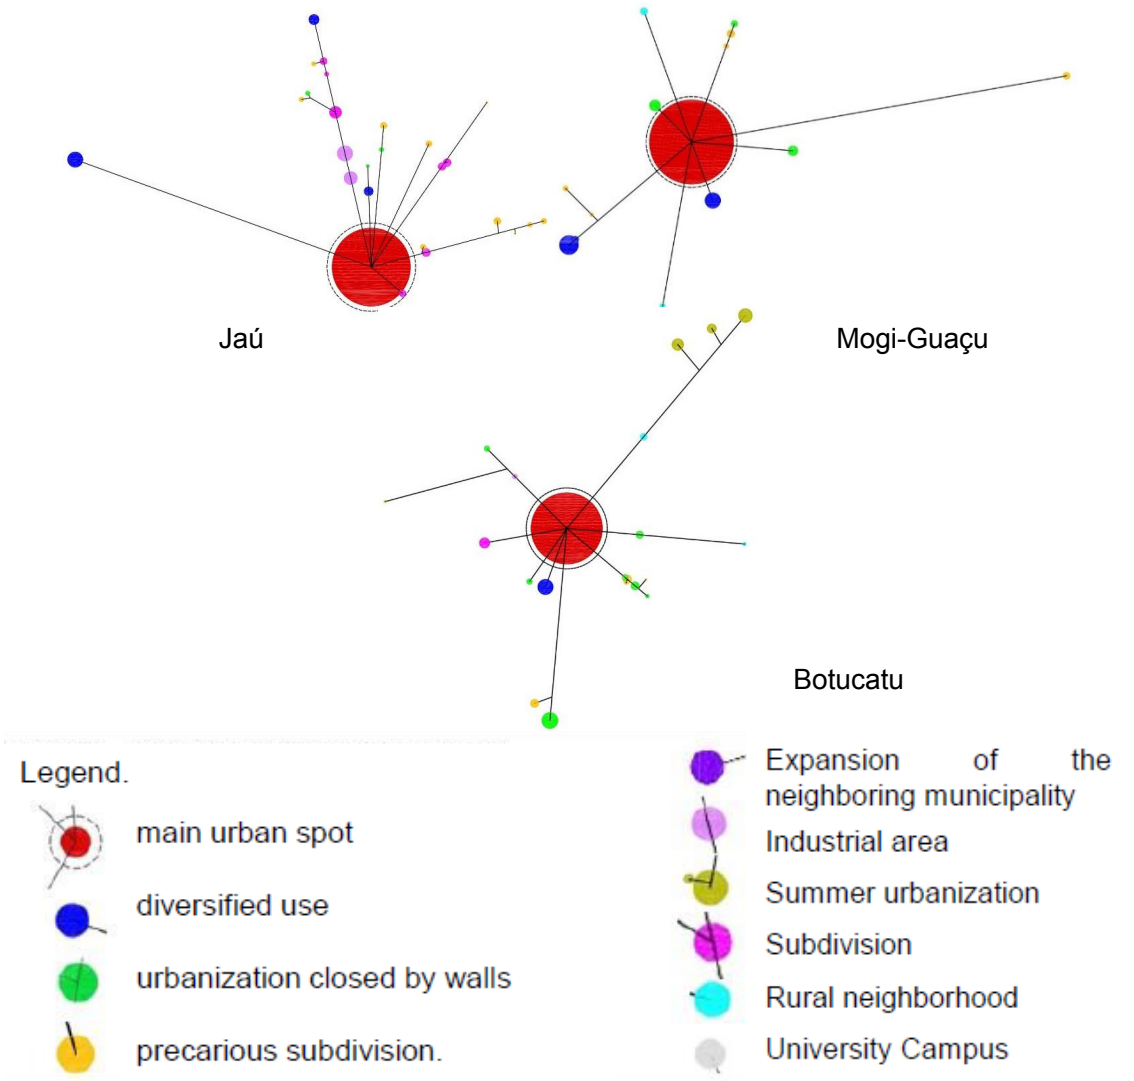


Figure 5: Diversified scatter plots in medium-sized cities.

We identified another group of small cities that, being neighbors of regional capitals or metropolitan areas, behave like satellites and see their expansion conditioned to the process of the main city, detached from its own center. Dispersed fabrics of a residential nature predominate. These are the cases, among others, of Álvares Machado (bordering Presidente Prudente), Guapiaçu (São José do Rio Preto) and Elias Fausto (Piracicaba). In the first two, the dispersion occurs predominantly towards the pole of attraction.

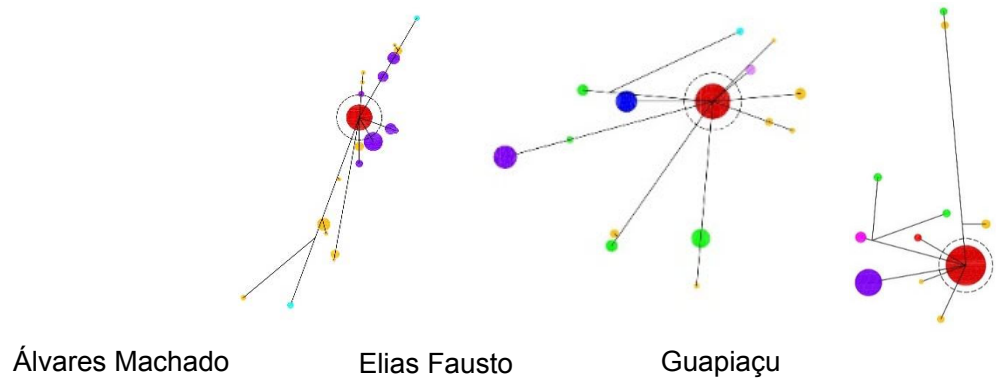

Figure 6: Scatter diagrams in cities neighbouring regional capitals and metropolitan region.

There are cases in which dispersion results from geographical aspects, such as the presence of rivers and hills, as in São José do Rio Pardo:

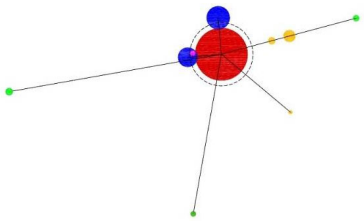

Figure 7: Scatter diagram resulting from geographical accidents. Source: Almeida Filho, 2024

In the state of São Paulo, the process of dispersion linked to tourist attractions or second homes is also remarkable. Whether in municipalities marginal to rivers and dams, such as Miguelópolis, where subdivisions at the water's edge predominate, or closer to the capital, such as Laranjal Paulista, where condominiums and informal subdivisions with large lots, the so-called "chacreamentos", appear.

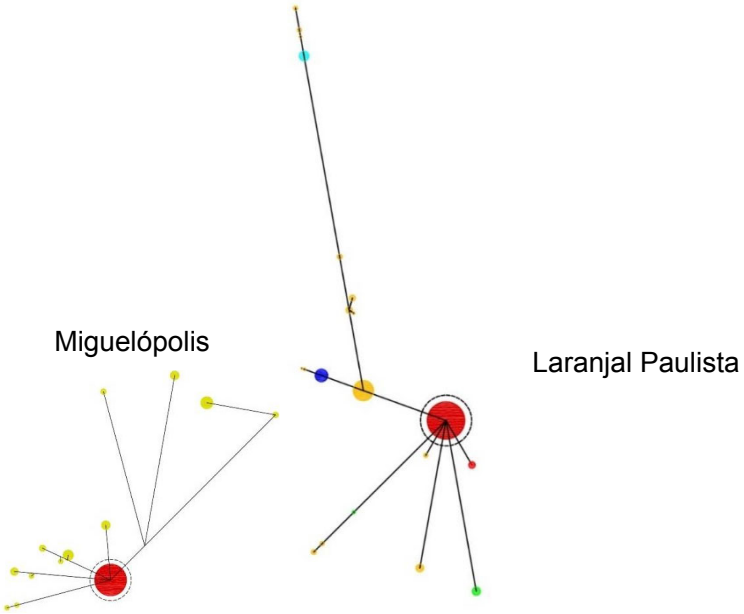

Figure 8. Scatter diagrams and tourist cities.

Finally, there are medium-sized cities that, contrary to the general tendency to disperse, remain cohesive.

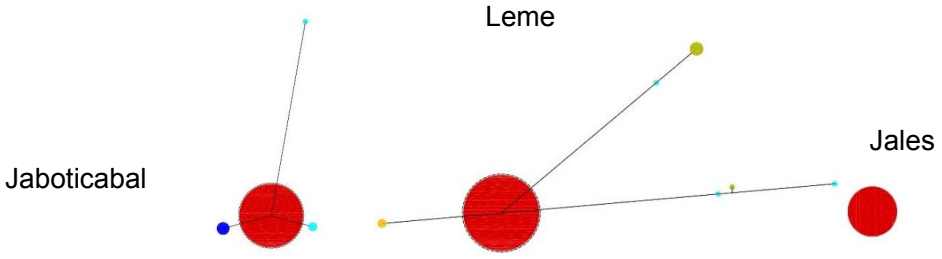

Figure 9: Scatter plots of municipalities with low or no dispersion:]

CONCLUSIONS

The present research aims to contribute to the typological studies of cities by adopting knowledge accumulated by research carried out in the area of urban morphology. It is expected as a result the preparation of the diagrams of the cities analyzed and the verification of the existence of patterns of the existing urban forms in the municipal territories of different Brazilian regions. It is expected to contribute to the development of a cartographic analysis method that results in a graphic synthesis of the spatial distribution of urbanization over the municipal territory.

ABSTRACT

The study takes a historical approach to the production of housing in three South American countries – Argentina, Peru and Uruguay – and compiles a qualitative and quantitative overview of the contributions and challenges of each of the main experiences. In addition, for the nine most significant case studies, the insertion of housing into the urban fabric was investigated. The results showed obstacles and the lack of funding sources, the importance of pluralizing actions and the different demands of the actors, as well as the continuity and conclusion of some experiences.

Keywords: housing, South America, socio-spatial equity

INTRODUCTION

Latin America is one of the most urbanized regions in the world, with around 79.5% of the population living in cities (ECLAC, 2017), especially in metropolises. The existence of common structural conditions brings the urbanization process in these countries closer together. These include colonial inheritance, which was decisive to produce an oligarchy of landowners whose was in the land a source of primitive accumulation, on the one hand, and the formation of an immense mass of excluded people who were not served to by an agrarian and urban reform policy, on the other. Furthermore, the way in which rapid urbanization took place, based on peripheral industrialization and low wages, led to the formation of a macrocephalic interurban network based on the creation of an immense informal fabric around the formal city. Historically, despite a popular housing market and the existence of important state provision policies, some of them applying experiences produced in the central countries and carried out by strong, populist governments, they were not accessible to the economic standard of the families or were not sufficient to satisfy the immense demand, so that precarious settlements have been consolidated as an important form of access to housing, forging the so-called informal city. These processes are exacerbated by a clandestine market for the sale of plots and the difficulty of the families ascending to the formal renting of qualitative properties. In numbers,

23% of South America's territory is made up of precarious settlements (Lopes, 2023), while public production reaches 8% (Lopes, 2023) and market production 13.1% of regional GDP (Habitat, 2024).

Despite these obstacles, the subcontinent has stood out for successful experiences in access to housing. These include the regularization of precarious settlements, carried out by multidisciplinary teams with an accumulation of knowledge, through participatory practice and the originality of the solutions found on a case-by-case basis. Part of these discussions were captured by the United Nations Habitat (UN-Habitat) and by funding from multilateral agencies, which encouraged this action as a policy to confront the fiscal adjustment to which these countries were subjected in order to adhere to neoliberalism. In addition to mutual aid actions, which have proven to be a qualitative response to the promotion of well-located housing, despite the numerical limitations of the action. In such a way that the historical challenge of confronting this immense problem persists, linking housing well located in the urban fabric within an urban planning process that is able to consolidate instruments that are adhere to the social, economic and environmental conditions of this sui generis type of urbanization. No wonder, the Latin American Urban Planning Congresses were spaces for reflection and proposing these ideas, with the 1968 Andes Charter being an important document for disseminating these principles.

In this way, the aim of this work is to promote a historical reflection on the production of housing in three South American countries – Argentina, Peru and Uruguay – and compiles a qualitative and quantitative overview of the contributions and challenges of each of the main experiences. To do this, the method included a theoretical analysis of the historical trajectory of housing production (item 1) followed by an empirical analysis of nine important cases of access to housing in these three countries (item 2). The empirical analysis sought to explorer the insertion of housing into the urban fabric was investigated, in terms of diversity and density of existing typologies, links to urban mobility and the physical environment, and the provision of collective facilities and participatory decision-making bodies. Finally, sought to draw up a conclusive balance of alternatives and challenges in tackling the immense problem.

Housing policy in Argentina, Peru and Uruguay

Observing the particular case of Latin America, Abramo (2011) shows that the provision of social housing can take place through three logics – the typical promotion of the formal, popular market, selling plots on installments; through state housing policy, by the provision of subsidized or financed new housing; the logic of informal occupation of land, usually public and environmentally fragile, as a solution to the compulsory and immediate need for housing of those segments who are not solvent in the market and who are not reached at scale by the state. The author also identifies subsystems in the interface between these logics – the operation of a clandestine market for the subdivision and sale of grabbing plots, generally acquired by the excluded segments, even without the title of property, followed by the self-construction of housing; and the corrective action of the state, in the sense of promoting titling, as well as other socio-urban improvements in these informal and illegal territories occupied by the excluded families. In such a way that own home, even if not recognized by law, is a “magic formula” for families' budgets, in the context of an economy based on low wages and/or informal/unstable employment; the informality of housing is thus the most immediate

reflection of precarious work, something that covers around 50% of the Latin American population (WB, 2019).

Abramo also extends these three logics for access to social housing through rent – with the operation of a formal, popular and peripheral market; through state policy, by rental assistance, electronic vouchers to reduce the excessive burden of rent, urban stimulus for popular market rentals or the construction and maintenance of a state rental park. Likewise, the author recognizes subsystems at the interface between these logics – with an informal rental market operating in precarious settlements, through densification (tenement) or for the rental of rooms; and with the action, albeit restricted, of the state in partnership with communities, in the sense of making abandoned properties available for retrofitting and occupation. In such a way that renting is still a fragile policy in Latin America, as it is not seen as a way out for families, as it would mean subjecting a limited and uncertain family budget to a fixed monthly obligation.

The trajectory of social housing in Argentina, Peru and Uruguay reflects the complexity of the actions of these agents and forms of housing provision (see table 1).

Table 1. Déficit nos países estudados. Source: 1- Cippec-ACIJ-TECHO Argentina, 2023. 2- MVOT, 2020. 3- INE Encuesta Continua de Hogares, 2022. 4- Ministerio de Vivienda, Construcción y Saneamiento, 2024.

Countries	Precarious Housing (Quantitative Deficit)	Excessive Rental burden	Precarious Settlements	Total
Argentina	1.3 million[1]	1.6 million (80% of all[1] rented properties)	2.6 million[1]	4 million[1]
Uruguay	51,889[2]	152,806[3]	169,573[2]	221,462[2]
Peru	378,000[4]	---	1.44 million[4]	1.8 million[4]

In the case of Argentina, the import substitution industrialization that began in the 1930s boosted urbanization, which had already been taking place since the mid-19th century. This rapid urban growth was supported by a popular market for the sale of plots on installments, while the excluded segments formed villas de emergencia, the way precarious settlements are known in the country. The production of new housing by the state (“turnkey” policy) only began in the 1930s, when the first bodies dedicated to this issue were created – the Institutos Provinciales de Vivenda (IPVs), including the one in the province of Buenos Aires, and the Banco Hipotecario (BH), created in 1937 and 1886 respectively. These structures are associated with the establishment of a Welfare State, which accompanied the first developmental phase, led by military governments (1930-1946) and the populism of Juan Perón (1946-1955).

Given Argentina's tradition of conducting housing policy at provincial level, from 1972 were created the other IPVs, as well as the Fondo Nacional de Vivienda (FONAVI) by Law nº 19.929. The first IPV actions accounted for a small number of units produced (Manes, 2016). Between the 1950s and 1976 (when the military government began), Argentina experienced its second development phase, marked by the introduction of foreign capital and the alternation of unstable governments, with the return of Peronism (1973-1976). The creation of large technocratic structures – such as the Comisión Nacional de la Vivienda (1955), the new Buenos Aires IPV (1956), the Fondo Federal de la Vivienda (1959), the Secretaria de Estado de Vivienda (1965) e the FONAVI (1972) – gave support to the centralized policy.

Despite this apparatus, the period saw the construction of few units, with more comprehensive actions, under the influence of modernism.

It was curiously at this moment of the country's most violent dictatorship that the first actions to regularize the villas de emergencia emerged, in response to the 1976 United Nations Habitat. In this context, the instability created by the coup resulted in an increase in rental prices and a reduction in mortgage credit, contributing to the exponential growth in the number of precarious settlements created by the population not served by the "turnkey" policy (Wagner, 2005). Despite these initiatives, in the province of Buenos Aires, a policy along the opposite lines prevailed, with the compulsory removal of villas de emergencia, through the Plans for the Eradication of Precarious Housing, financed by the central government. Di Virgilio et al. (2014) note that the creation of more specific rules for the implementation of subdivisions by the market, through Law nº 8.912 of 1977, would have contributed to the retraction of the popular market in the period.

The country's return to democracy was accompanied by a political and economic crisis, with inflationary pressure and a fiscal deficit (Wagner, 2005), ushering in a long period of fiscal adjustment and adherence to neoliberalism. The result of this situation was a further increase in the number of villas de emergencia.

The neoliberal transition meant decentralization. It is in this context that the Sistema Federal de Vivienda was created, through Law nº 24.464 of 1995, consisting of a holistic structure formed by FONAVI, IPVs and Consejo Nacional de la Vivienda (CONAVI). The Law guaranteed greater powers to the provinces, not only in the use of resources (as was already happening through their co-participation in FONAVAI), but in deciding the allocation of resources. In this restructuring, the provinces were obliged to allocate funds to FONAVI to cover the deficit caused in the financing system, while BH was privatized.

The combination of the reduction in the transfer of funds and the increase in average construction prices meant that the policy of promoting new housing throughout the country came to a standstill. Thus, the policy of improving precarious settlements and building smaller housing complexes, putting individual credit programs into operation to keep the system functioning (Realini et al., 2019), became the prevailing programs. Wagner (2005) points out that this is the time of the greatest increase in urban poverty in the country.

In this context, it was enacted the Economic Emergency Law, Law nº 23.697 of 1989, which gave the National State the prerogative to transfer ownership of tax land declared not necessary for management to private individuals. In addition to Decree nº 1.001 of 1990, which enabled the transfer of tax land in the precarious settlements of Buenos Aires and Decree nº 2.411 of 1990, which extended this same condition to the other precarious settlements of Greater Buenos Aires (Di Virgilio et al., 2014). In addition, the regulation of Law nº 24.374 of 1994, known as the "Pierri Law", allowed private land to be titled to occupants.

More recently, the legal titling of properties passed an important moment with the enactment of Law nº 2.639 of 2008. This new legal framework established the Single Provincial Housing and Habitat Register (Registro Único Provincial de Vivienda y Hábitat), which allowed municipalities to carry out

comprehensive urban planning projects, financing the construction of new homes, housing improvement modules and infrastructure, thus reinforcing decentralization. Despite these initiatives and the large qualitative deficit (table 1), Argentina does not have a unified methodological procedure for land regularization, even though the period saw the implementation of important actions in precarious settlements through the Programa de Melhoramento de Bairros (PROMEBA). Created in 1997, the program aims to make systemic improvements in these territories, with land titling, infrastructure and environmental sanitation works, actions to reverse social vulnerability, in a financial agreement with the Inter-American Development Bank (IDB). Between 2003 and 2024, PROMEBA financed 39,068,518,614.47 dollars, covering 760 projects and 40,533 families, of which 690 projects, benefiting 39,198 families, have already been completed (SDTHV, 2024).

The state's promotion of new housing in this neoliberal phase began in 2003, when housing was chosen as a strategy for leveraging the economy in the face of the crisis, in a context in which the majority of the population did not have access to long-term financing on the private market (Barenboim, 2021). This restructuring took place with the re-centralization of the system, starting with the drafting of the National Housing Plan in 2003, and the creation of the Programas Federales de Vivienda (PFV), in which the Construcción de Viviendas I subprogram is included. This subprogram aimed to build 120,000 homes in phase 1, from 2003 to 2007, and a further 300,000 homes in phase 2, from 2007 to 2009. The third version took place with the launch of Techo Digno in 2009, with the aim of guaranteeing the continuity of existing infrastructure works and carrying out other complementary works essential to housing (Barenboim, 2021).

The Program currently in force for the production of new housing in the Casa Propia, governed by Resolution nº 16 of 2021, with the objective of financing 120,000 housing in the period 2021 to 2023, under the management of SDTHV. The Program Argentino de Crédito do Bicentenário para Habitação Unifamiliar (Pro.Cre.Ar.), created by Decree nª 902 of 2012, also currently in force, aims to finance the construction of new housing for the low-income and lower-middle-income segments; according to its operational design, the State makes tax land available for the location of developments, for those who do not have their own site, and finances the units to the beneficiaries, at reduced interest rates, from its own fund, linked to the Banco Hipotecário, and also constituted by the sale of tax land assets (Barenboim; Elinbaum, 2017). Is worth noting that the Programa de Incentivo a la Construcción Federal Argentina y Acceso a la Vivienda, created by Ley 27.613 of 2024, aims to grant credit to complete housing works that were paralyzed in the country.

Regarding the promotion of housing through mutual aid, Law nº 14.449 of 2012, called Fair Access to Habitat Law of the Province of Buenos Aires, represents an important current effort to strengthen the capacity of the state (provincial and municipal) and social organizations to promote fair access to habitat. The law, through credit at a subsidized rate, for the purchase of the land, the construction of the building and the hiring of an interdisciplinary technical team that accompanies the cooperative throughout the process. Zapata (2022) shows that there are currently 110 properties bought by cooperatives in the heart of urban Buenos Aires, with 45 cooperatives having already completed the construction work and almost 1,300 families currently living collectively in these housing estates. However, the program still has fewer resources than the others. Another important measure, the publication of the Plan Nacional de Solo Urbano, by Resolution nº 19 of 2020, consists in make urban land available for the promotion of housing, coordinating technical advisory actions.

In terms of rent, the worsening of the housing crisis, especially after the pandemic, has resulted in a situation where 80% of families who rent in Argentina commit 41% of their budget to paying rent (Encuesta Nacional Inquilina, 2024), an impactful value for the general poverty situation. This lack of plurality in actions, which are highly dependent on limited public funding, means that the problem is becoming more complex in the country, despite some successful initiatives.

In the case of Peru, urbanization began in the 1940s with the influx of migrants from the Andean region to Lima, but it intensified during the late process of industrialization by import substitution, which only took place during the Belaúnde Terry government (1964-1967) and reached its peak during the Velasco Alvarado dictatorship (1968-1975). The peripheral technological level of this industrialization did not favour the integration of the internal market, so that urban growth was not absorbed by the traditional mechanisms of the market for the sale of plots on installments, nor by the state's housing policy, causing barriadas, the way precarious settlements are known in the country, to become the main type of housing.

In fact, the state's housing policy, which began in the 1930s with the construction of barrios obreiros according to the principles of modernism (Romero et al., 2005), had a number, design and price of units that were not in line with the needs of the low-income segments (Castro; Riofrío, 2013). The Corporación Nacional de la Vivienda (CNV) was the body responsible, between 1940 and 1960, for the construction of some qualitative housing estates, in the body of ideas brought by the deputy, architect Belaúnde Terry (Espinoza, 2014).

Faced with urban growth from the 1950s onwards, Lima's traditional barriadas, which had been restricted to the hills of the central areas in previous decades, expanded into the peripheral, desert areas, the banks of the Rímac River and the Andean slopes, as discussed in classic studies (Matos Mar, 2012; Driant, 1991). In this context, the state began to support the barriadas, instead of eradicating them, as had been the case until then. Thus, the populist government of Manuel Odría (1948-1956), through the CNV, gradually set up modular urban centers, with plots and services, so that families could build their own homes (Castro; Riofrío, 2013). That this symbiosis between the state and the population represented a sui generis case of the formation of a spontaneous city, by the hands of the population, but with state provision of the necessary facilities.

The liberal government of Prado Ugarteche (1956-1962) represented a new attitude towards barriadas. The understanding was that self-construction, facilitated by the state, would be a low-cost solution to the housing problem (Castro; Riofrío, 2013); thus, through the Comisión para La Reforma Agraria y La Vivienda (CRAV), an intervention methodology was adopted based on holding technical advisory workshops so that families could build homes in mutual aid schemes, under the guidance of the state (Collier, 1978). The enactment of the Barriadas Law, Law nº 13.517 of 1961, represented a legal milestone so that these precarious settlements, as long as they were not located in inappropriate areas, could be subject to “physical and legal sanitation”, although the formation of new barriadas was not allowed.

The Prado Ugarteche government was also responsible for creating the Instituto Nacional de Casas Populares (INVI) in 1960, with the aim of building “satellite cities” based on the idea of “elemental housing”, according to which the state would be responsible for producing minimum housing modules

and providing technical support so that families could progressively complement the self-construction of their homes (Kahatt, 2015).

With the great urban growth of the 1960s, bodies were created to finance new housing, especially for the middle class, such as the Banco de la Vivienda del Perú (BVP), inaugurated in 1962, and the Junta Nacional de la Vivienda (JNV), created in 1963, with the task of managing the system and building the new units. Contradictorily, the balance was that the Belaúnde Terry government directed more resources to the middle class (91%) than to the popular sectors (9%), so that the JNV's own performance in these territories, at this time, was marked by total discredit, contrasting with the expectations brought about by the Barriadas Law.

It is worth noting that the barriada policy of the 1970s was taken over by the JNV, incorporating the ideas put forward by John Turner. The architect, after years of research and action on Peru's barriadas, advocated a methodology of neighborhood consolidation by the hands of the population itself, in its freedom to self-construct the space, as opposed to the rigidity of state planning and housing measures (Maldonado, 2015). FONAVI, created in 1979, was responsible for the housing policy of the period, with the intention of increasing the role of the construction sector within the BVP. FONAVI's resources came mainly from the compulsory contribution of formal and informal workers, but its actions were mainly directed at the middle class.

With the political and economic crisis of the 1980s, the country went through a somber period of armed struggle between extremist groups – the Tupac Amaru Revolutionary Movement and the Sendero Luminoso – and harsh repression by the police forces. The rise of Alberto Fujimori's dictatorship (1990-2000), as an unfortunate consequence of these conflicts, resulted in a rigid neoliberal transition in the country. It is in this context that the regularization of precarious settlements emerged, in line with the neoliberal thinking of Hernando de Soto and funding from multilateral agencies. So through the Comisión para la Formalización de la Propiedad Informal (COFOPRI), the country promoted the world's largest legalization programme, issuing more than 1.6 million public tiles. Ramírez and Riofrío (2006) show that this policy of widespread distribution of property titles in the short term, to the detriment of more comprehensive qualifications, has meant the legalization of fabrics outside the urban network and in situations of environmental and geotechnical risk.

The neoliberal adjustment of the Fujimori government meant that the policy of producing new housing almost disappeared, delegating the resolution of the issue to the private market (Calderón, 2015). The market's own pressure to resume financing resulted in the reconstruction of the system, with FONAVI being abolished in 1998 and replaced by the Mi Vivienda Fund (FMV), created by Law nº 26912 of 1997. The Mi Vivenda Program is a mortgage credit that allows the purchase of housing between 65,200 and 464,200 Soles, for different low-income groups, requiring the beneficiary to make a 7.5% down payment. Techo Proprio, created by Ministerial Resolution nº 054 of 2002, is the arm of the policy aimed at the lowest income segments (family groups between 2,706 and 3,715 Soles a month), with a one-off bonus granted by the state of 44,805 Soles for the purchase of housing, 30,900 Soles for construction and 11,845 Soles for housing improvements.

Calderon points out that Mi Vivenda reached its peak during Toledo's transitional government (2001-2006), directing resources towards financing new housing for the middle class, in a format in which

construction companies are responsible for selecting the land, designing and approving, building and selling the developments, while the government provides a subsidy to the private sector. The author points out that the 2008-2015 Housing Plan itself assumes the objective of reducing the deficit, placing the market as a facilitator of the process, which still represents the view that the sector is responsible for economic activity.

The period 2002-2006 saw great numerical success, with the state injected approximately 600 million dollars into the banking system (Caldéron, 2015). The program's actions meant construction for the middle class in the central area of Lima, with very few resources going to the lower class (7,111 bonuses), of which 7,037 were for new housing and only 74 for their own homes. This was because families did not have the minimum conditions to access the financing, due to job instability, so that the policy had difficulty competing with the illegal land-grabbing market and even with COFOPRI's own titling policy (Caldéron, 2015).

The program was restructured in 2006, under the García government (2006-2011), and began to target the lower classes, still with the primacy of private initiative, something that led to the vertical growth of cities based on real estate mortgages (Caldéron, 2015). The policy was thus divided into three modalities – new housing, construction on one's own site and housing improvements. Calderon notes that while first modality is led by construction companies, the second has attracted small construction companies (Technical Entities), usually made up of an engineer and a lawyer, working to regularize informally occupied areas or those acquired through land grabbing, although the processes are slow (Caldéron, 2015). And the third is the one that has received the least funding, with little interest from private companies, large or small.

Concerning the regularization of precarious settlements, the Programa de Mejoramiento Integral de Barrios (PUI), launched in 2007, is the current policy for intervention in these territories. The policy loses the aim of carrying out comprehensive improvements in each of the precarious settlements separately, in order to carry out a large number of small interventions in several settlements simultaneously, focusing above all on improvements to the road system, the placement of squares and community facilities, and the stabilization of risks, within the strategy of gaining scale in the overall impact on the population's living conditions. Medina et al. (2011) show that by 2010, the Program had worked in 1,363 settlements, with a total of 476,600 families served. One line of action within this framework is the Barrio Mio Program, created by Ordinance nº 1625, with the aim of implementing projects in vulnerable areas of Lima, based on the construction of geotechnical containments, stairways, squares and green spaces, designed in an integrated way with community leisure and circulation spaces; the identification and implementation, with community participation, of a portfolio of community equipments (culture, sport, health, leisure), which make it possible to improve the quality of life in the neighborhoods; and the implementation of social projects in these territories. Despite the tradition of self-construction of homes and cities, based on the historical buttom-up consolidation of the barriadas, the country does not have a tradition of mutual aid construction sites, with entities and cooperatives taking on the role of coordinating and technically supervising the work fronts. And although renting represents a small proportion of the housing stock, within the paradigm of home ownership as a magical housing solution for peripheral economies, the country has no tradition of a rental policy.

In the case of Uruguay, urbanization began at the end of the 19th century and especially in the first half of the 20th century, more as a way of applying agrarian rents to urban modernity than as a change in the direction of this main vocation towards industrialization. This growth was absorbed by the market production of installment lots and rental houses (Barenboim; Agudelo, 2010), while the excluded segments went on to form the country's first precarious settlements, the conventillos as they are known. One of the first initiatives, the Conventillos Law of 1878, aimed to improve the sanitary condition of these settlements and tenement houses. It was only with the creation of the Banco Hipotecario del Uruguay (BHU) in 1892 that the country's first policy of financing new housing began, which resulted in housing being built near factories (Barenboim; Agudelo, 2010). Subsequently, the Housing Rights Act of 1921 encouraged workers, military personnel and civil servants to obtain loans for housing construction (Barenboim; Agudelo, 2010).

An important milestone in housing production, within the formation of a relatively well-established Welfare State in the country, was the creation of the Instituto Nacional de Viviendas Económicas (INVE) in 1937, with the aim of building low-income housing for workers, with infrastructure for essential urban services, for rent or sale (Barenboim; Agudelo, 2010). However, the political and economic crisis from 1955 to 1958 had a major impact on housing production and it was precisely in this context that the country's landmark housing policy was approved, the Vivenda Law, Law nº 13.728 of 1968. Through it, housing was recognized as a right and an institutional structure was created to deal with the issue, made up of the Dirección Nacional de Vivienda (DINAVI), the BHU (financial body), INVE (central policy body) and the Fondo Nacional de Vivienda. The Law also established the need to plan housing demand and supply, through Five-Year Housing Plans, linked to economic plans, with housing targets to be achieved (Nahoum, 2008).

The law was responsible for institutionalizing cooperativism in housing policy, stipulating that cooperatives would be one of the forms of housing production (Nahoum, 2008). The law guarantees not only technical support through Technical Assistance Institutes (IATs), but also the provision of financing channels (around 22% of the housing fund) and the provision of land by municipalities (Nahoum, 2008). According to the Law, different types of cooperatives can be formed, depending on the format (head office or branch), the property situation (collective or owned), and the construction condition (with third-party labor or own labor – self-construction or mutual aid). In self-construction, each family builds its own house and on the construction site, through mutual aid, everyone works to build the units, which are then allocated by lottery.

According to the Law, municipalities must participate in the process by reserving land for acquisition by cooperatives, through the Cartera de Tierras (Decree nº 24654 of 1990), which also allows for better housing locations in the city, linking housing policy to urban policy. By utilizing various types of land (central voids, retrofitting abandoned buildings), cooperative production is diverse. The financing for the works comes from the National Housing Fund, which covers approximately 85% of the total cost of the work; families can commit a maximum of 20% of their family income to paying the financing (Nahoum, 2008). The Law provides for some types of subsidies, the most widely used currently being the amortization quota, in which the State pays the difference in monthly payments if families are unable to pay the full amount. In terms of numbers, more than 12,000 homes have already been built through cooperatives in the country, and the houses produced in cooperatives were the cheapest (according to data from 1969) (Nahoum, 2008).

The expansion of precarious settlements in Uruguay only occurred later and in smaller numbers than in other Latin American cities (Rivadulla, 2014). Most of the occupations were consolidated after the neoliberal opening up of the country, which, in a way, affected the tradition of a welfare policy, with the very retreat of the BHU, and exposed work to greater informality, which ended up accentuating poverty and, consequently, precarious settlements. As a result, the lowest-income segments, not served by the mechanisms of the market and the state, will find a way out of housing in the organized collective or individual occupation of public land, followed by self-building. The state's relationship with these occupations covers a myriad of situations: from non-recognition and removal, to recognition, titling of plots and progressive improvements.

It is in this context that the Programa de Integración de Asentamientos Irregulares (PIAI), launched by the MVOT in 1999, represented the first significant intervention policy in these areas. Carried out with resources from the IDB, as part of the prevailing policy of multilateral agencies to finance land regularization on a larger scale in Latin America in the context of fiscal adjustment, the program aimed to comprehensively improve the neighborhoods. The institutional design of the Program consists of the coordination of actions by the national government in conjunction with the departments. Thus, through the Planning and Budget Office (OPP), the departments submit the projects and the national government selects those eligible to receive the funds. The PIAI also assumed that the settlements would be on public land and with a minimum housing density; other versions of the Program allowed for action on land of private origin, but which had been expropriated by the government for regularization. The Programa de Mejoramiento de Barrios continued the PIAI using a mix of resources from the national government (30%) and the IDB (70%) (MVOT, 2020). The PMB has a more comprehensive approach than the PIAI, seeking to include the population in society. Between 2005 and 2019, 80 barrios were regularized, while between 1999 and 2004, 11 projects were approved (MVOT, 2020). Uruguay has a national social housing policy, provided for in the Quinhenal Plan. Thus, the rent can be given by value supply, so that the beneficiary can rent housing in the market, or from the rent of the state stock, built within the BSF. Between 2015 and 2019, 8,719 rental guarantee contracts were signed (MVOT, 2020).

Critical analysis of important housing experiences in Argentina, Peru and Uruguay

In Argentina, faced with the immense challenge of producing new low-cost housing, one of the significant programs is Pro.Cre.Ar., among them the one located in San Miguel, a municipality in the Northwest region of the province of Buenos Aires. The project consisted of land subdivision of around 125,000 m² for the construction of housing; and, although the selection of the land was the responsibility of the state, this meant the peripheral extension of the fabric. The presence of government teams, or in ad-hoc arrangements, are responsible for designing the project and construct the basic infrastructure, in this case of an entire new neighborhood, and building the complexes. Pro.Cre.Ar San Miguel consisted of 96 two-bedroom apartments and 136 two- and three-bedroom detached houses, ranging from 60 to 98 m² each, six of which are adapted for people with special needs; the units have a pantry, kitchen, bathroom and bedrooms (figure 1). The typological variation and the good use of concrete allowed for a better quality of the whole, despite the cost-saving prerogative inherent in this type of project. Nevertheless have a central area with green spaces and community leisure, the neighborhood lacks commercial areas. The project offers few collective equipment in the surrounding area. The units cost 454 million pesos and were distributed to

beneficiaries registered as eligible for the Program, with financing from the Pro.Cre.Ar Fund (Argentina, 2018).

Figure 1. San Miguel aerial view (i), typologies (ii), location (iii). photo credit: Argentina, 2018 (i-ii) authors (iii).

Argentina also has a major land regularization challenge and one of the most significant programs on the subject is PROMEBA. The Program's operational design determines that municipalities must present the most pressing local projects for regularization, while the national government is in charge of selecting the proposals that will receive the funds. One of PROMEBA's most significant experiences was the Vila Tranquila, located in the municipality of Avellaneda, which is part of the Buenos Aires metropolitan area. The area experienced rapid growth in the second half of the 20th century as a result of industrial activities and the existence of the railroad and dock port in El Partido (Bettati, 2008). However, with the stagnation of the region's industrial fabric, Villa Tranquila became a place where 40% of the population was unemployed and 80% of families were below the poverty line, resulting in a serious situation of social vulnerability and violence (Bettati, 2008). The regularization of Villa Tranquila was an attempt at multisectoral action, for which an executive unit was created, with representatives from various bodies, and with prominent popular participation.

Figure 2. Villa Tranquila typologies (i-ii), location (iii). photo credit: Argentina, 2018 (i), GoogleMaps®(ii) authors (iii).

The regularization involved funds from the Federal Government, for the construction of 730 new homes, and from PROMEBA, for urban infrastructure works (Bettati, 2008). There was also municipal funding for technical assistance, through an agreement with a university, and for complementary works. The intervention project covered an area of 374,907 m² and included urban redesign, with the conformation/reorganization of new blocks, the definition of public and private spaces, as well as the improvement of basic infrastructure; the installation of community equipments (mainly through the transfer of abandoned industries to the state); the creation of opportunities for professionalization,

employment and income for the community (figure 2). The urban improvement works were carried out in stages, due to the limitations of the occupation. Existing homes were also improved and new ones built, in order to relocate the families affected by the urban remodeling of the subdivision, with the release of the non-aedificandi strip protection from the railroad and the opening of new roads. It should be noted that new constructions, semi-detached buildings, have been undergoing various modifications to adjust to the needs of families. In addition, there was the titling of the properties.

Argentina has little tradition of cooperativism, but the institution of Law 341 of 2000, which created the Programa de Autogestión de la Vivienda (PAV) in the province of Buenos Aires, have enabled some actions with mutual aid. One of the Program's recent experiences is the building Amancio Alcorta 1601/07, located in Barracas, in the southeast of Buenos Aires. The project was carried out by the Alto Corrientes Cooperative, which was responsible for commissioning the architectural design, carried out in 2002, and the construction company, which carried out the work between 2006-2009. The site, with an area of 131.00 m², is very well located in the urban fabric, with a significant range of commercial and institutional areas and, therefore, employment options in the surrounding area, as well as green areas. The project consisted of converting an old hotel into 14 residential units. As it was not possible to make use of the existing equipaments, the building was demolished and the new building was erected on the site, consisting of 4 duplex units and 10 single-room units plus mezzanine. The collective areas are restricted to circulation spaces and a courtyard inside the building (figure 3). The technical team did some training work, but the project was not carried out by mutual aid. Despite the cooperative initiative, ownership of the units is individual. Each unit cost around $ 30,000.

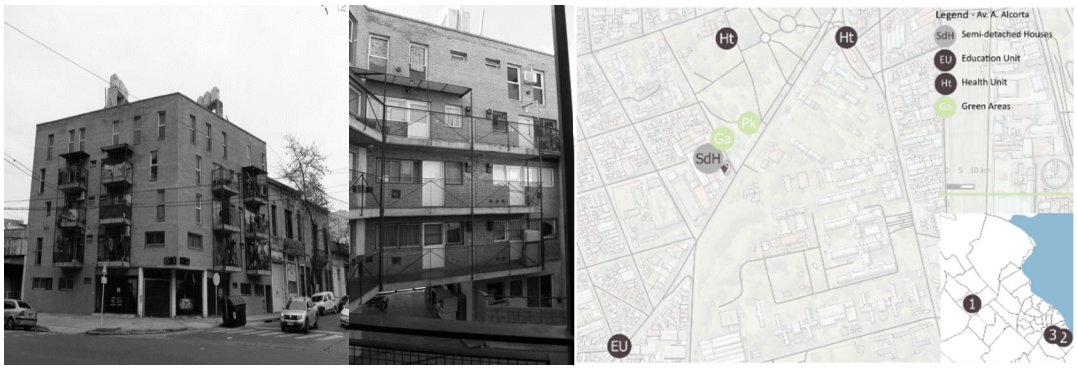

Figure 3. A. Alcorta typologies (i-ii), location (iii). photo credit: Zapata, 2022 (i), GoogleMaps®(ii) authors (iii).

In Peru, the policy of producing new housing has traditionally been insufficient and discontinuous, and a typical example of the current program MiVivenda, is Ciudad Sol de Collique, located in Comas, north of Lima.

Figure 4. CidSol de Collique typologies (i-ii), location (iii). photo credit: Zapata, 2022 (i), GoogleMaps®(ii) authors (iii).

The very prospect of land and scale gains determines the peripheral location of the land, a former airfield, acquired from the public authorities at a low price (Calderón, 2015), and the choice of the mega-ensembles, showing the difficulty of reconciling housing and urban policy. The project has 16,000 units, 5,000 linked (with 8-storey buildings) to Techo Próprio and 11,000 (with 12-storey buildings) to Mivivienda, in a total of 15 blocks (2 for commercial use). The housing units consist of a kitchen and laundry room, 2 bedrooms, a living room and a bathroom. There are collective uses such as a playground, squares and bike paths. Housing costs 43,200 soles in Techo Próprio and between 60,000 and 103,000 in MiVivenda (figure 4).

Peru, following the Latin American context, has precarious settlements as an important form of access to housing. One of the most emblematic cases of land regularization is Vila El Salvador (VES), located 23 km south of Lima. The site was regularized in the 1970s and, with the reproduction of informality, there was a new intervention under the PUI, so that it can be examined through two generations of programs. The VES was occupied as part of the formation of the Velásco government's assisted barriadas in the 1970s, when a group of 200 families settled on an extensive desert site; the next day there were already 9,000 occupants and two months later 20,000 families (Bocanegra, 2009). There has thus been a long history of mobilizations and conquests, with the site receiving various interventions, promoted by different actors, until it became one of the main popular fabrics in the metropolis of Lima. The process began with essential works and the recognition of the Comunidad Urbana Autogestionaria de Villa El Salvador as responsible for conducting the qualifications together with the government. The project consists of a basic nuclei for the organization of community life; initially, 100 residential groups were built, each made up of 16 blocks with 24 plots and the neighborhood's collective equipments were allocated in the center of these, designed to be collective properties and products of the cooperative work of the residents of each “residential group”. This sorganization would also form, at the top level, a self-organization by sectors.

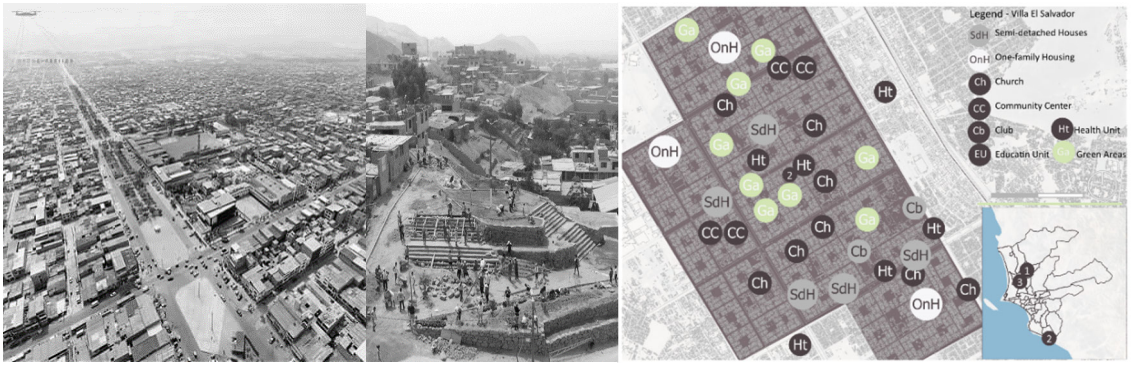

Figure 5. VES aerial view (i), Barrio Mío (ii), location (iii). photo credit: Zapata, 2022 (i), Zapata, 2022 ii), authors (iii).

The social struggles continued in the following decades, especially in the face of the retreat of government support under the Bermúdez government and the dark period of penetration of the Sandero Luminoso movement in the VES. The site was also the object of work by various organizations and technical assistance workshops in working class neighborhoods. More recently (2012-2014), VES was one of the 17 areas of Lima that received the actions of the Barrio Mío Program, with the improvement of squares and public spaces and investments in social equipments (figure 5).

In Peru, one of the historical experiences of self-managed production is the Proyecto de Vivienda Experimental (PREVI), carried out in Lima in 1965, as part of a joint initiative between the Peruvian government, UN-Habitat and the BVP (Land, 2008), seeking to place the housing issue within urban planning. So four projects were proposed, the first plan focused its efforts on disseminating debates on housing and proposed a housing complex with experimental residential typologies. The second aimed to redevelop housing and urban areas in precarious sectors of the city and the third created a plan for self-built plots and services, expanding social networks. The fourth plan was dedicated to developing construction procedures capable of withstanding earthquakes. PREVI is part of the first plan, representing the questioning of the large modernist housing estates advocated in the post-war period by the second CIAM. According to the competition, each typology had to comply with the limits of built area, set at between 120 and 60 m², with one or two floors, with the potential for expansion up to the third floor, to meet the needs of the families. The housing concept consisted of “courtyard homes” that would allow for future extensions (figure 6). The plan includes 24 residential groupings designed by different architects, with public facilities and communal spaces. The various layouts of the residential groupings formed a densely occupied neighborhood, rich in cultural diversity, integrated with mixed uses. The PREVI Plan interpreted the demand for housing in a self-sufficient way, giving the user back the leading role in articulating with the built space. The initiative allowed each family to have control over the construction of their homes and future extensions were assured in the guidelines imposed for all typologies (Land, 2008). Many typologies were modified, de-characterizing the original architectural proposals, mainly with new colors and interventions on the façades.

Figure 6. PREVI mockup (i), typologies (ii), location (iii). photo credit: Zapata, 2022 (i), GoogleMaps® ii), authors (iii).

In Uruguay, the experience of producing new housing through the market is less significant, given the tradition of cooperatives and the choice of small units sprayed on the fabric. The main program in this area is carried out by the Banco de Previsión Social (BPS), aimed at retirees, pensioners and lower-income social groups, in the form of direct allocation (with 6754 houses), subsidizing rent in units similar to the BPS for those enrolled who have not yet been offered housing (with 102 houses); granting subsidies or paying for housing services in homes for the elderly enrolled in the Program (with 746 houses); however, the number of units offered by the BPS Program covers only 10% of total demand (MVOT, 2020). According to the Program's design, the MVOT is responsible for constructing the buildings through bidding from construction companies, which become part of the BPS residential stock; the beneficiaries are selected by the MVOT and the Organización de Jubilados y Pensionistas, registered in the Program. A case of construction of new units under BPS policy is the Parque Riviera Building, located in the east zone of Montevideo. The 1500 m² plot is located in a predominantly residential area, with availability of equipment. The project consists of a three-story building with 40 one-bedroom apartments, as well as a multipurpose space.

Figure 7. Parque Riviera typologies (i-ii), location (iii). photo credit: Zapata, 2022 (i), GoogleMaps® ii), authors (iii).

The regularization of precarious settlements in Uruguay has been addressed through specific programs. However, it was the PIAI which played a more significant role in these territories. One of the most significant examples of PIAI is Boix y Merino, located in the eastern part of Montevideo. The urban intervention covered an area of 106,577 m² and benefited 1133 families (282 lots). The process unfolded from 2005 to 2012 in three stages: project preparation, execution of works and post-intervention actions. The development of the project was preceded by a Participatory Social Diagnosis of the site carried out in 2005, in which the total number of homes and people (282 and 1133 in 2005

respectively) were mapped, the legal situation of the lots, the existing infrastructure and urban equipment, the buildings and existing environmental problems. Approval of the project depended on validation by at least 70% of the local community and the technical and economic viability of the solutions, according to the available resources, and, from there, a bidding process followed. The urban interventions included improving roads so that children could access school and ambulances could enter, in addition to opening passages to provide access to sports courts, and installing a sewage system, which had not existed until then. The land titles were also issued. The Diagnostics identified that almost 40% of the houses did not have a bathroom and that 55% did not have sanitation. Thus, mutual aid efforts were carried out to improve housing, primarily installing bathrooms. The work was supervised by the Sindicato Único de la Construcción (SUNCA), which also worked to professionalize the work fronts so that, in addition to improving their own homes, the population could receive a Training Certificate at the end of the works. Families that needed to be relocated were assisted by policies for the acquisition of new units or existing ones.

Figure 8. Boix y Merino aerial view (i), typology (ii), location (iii). photo credit: GoogleMaps® (i-ii), authors (iii).

In the case of Uruguay, housing cooperatives are based on the country's already deep-rooted vocation for self-construction. They emerged in the wake of the workers' and cooperative movements (Nahoum, 2008), and thus went through a long history of struggles until they were granted legal provision in the 1968 Vivenda Law. One of the most virtuous cases of the work of housing cooperatives was the recent construction, in 2011, of the cooperative neighborhood “Juana de América” (Mesa 5), located in the center of Montivideo. The meetings are occasions when a group of cooperatives come together to promote the construction of the complex. The neighborhood, located in the western area of Montevideo, has a total of 420 homes, divided into four-story semi-detached housing blocks. The neighborhood was built with a regular orthogonal urban layout.

CONCLUSIONS

Despite the complexity of the problem, South America has virtuous solutions to address the quantitative deficit, such as the recent attempt to associate the supply of urban land with the financing policy for new housing (Argentina), something important compared to the typical peripheral and homogeneous solutions characterized by market production (Argentina in the PFVs and Peru), or the policy of public stock for sale or rent (Uruguay). However, it is necessary to cross housing policy with urban policy, applying instruments to capture plus values and subsidies for better located developments. It also has a long tradition in land regularization, whether in methodologies that allow for scale-up of interventions (Peru) or holistic actions in each project (Argentina and Uruguay), although it requires greater innovations for property titling and scale-up of actions, also favoring housing improvement policies, based on reform assistance programs with technical advice from entities. Very structured around the magic formula of home ownership, renting is still fragile in the subcontinent, and it is worth highlighting the successful experience of Uruguay.

ABSTRACT

The last decades of urban expansion have resulted in significant spatial changes on a global scale. Greater intensity of these spatial shifts has been observed in Global South contexts, particularly on the African continent. These changes are caused by demographic, economic, and political shifts. Cities in Sub-Saharan Africa exhibit fragmented morphological patterns in terms of urban development. These patterns include planned and unplanned areas. Informal settlements, once peripheral to mainstream urban studies, now demand critical engagement as part of the broader urban landscape. Understanding the spatial evolution of these areas is vital to formulating urban strategies. This research seeks to clarify how emerging urban morphologies in informal areas can inform current urbanization trends in the Global South through the use of systematic and analytical spatial observation. The paper aims to analyze the morphological evolution of street patterns in informal settlements, testing a proposed methodology on Kibera, Nairobi, over a 20-year period. The objective is to understand how incremental changes in access networks reflect on broader urban dynamics, contributing to discussions on infrastructure planning and urban integration. The study applies GIS and Space Syntax to analyze the spatial changes in Kibera's street network over a 20-year period (2004–2024), using satellite imagery at five-year intervals. By focusing on measures such as integration and betweenness, the study tracks incremental changes in street connectivity and accessibility. Results indicate that Kibera has become increasingly integrated into Nairobi's broader urban network over time. Infrastructural developments related to the city's masterplan have improved connectivity, though they have also led to the displacement of residents. It is argued that while infrastructural improvements can enhance connectivity, they also risk marginalizing local communities. The study illustrates that GIS and Space Syntax methods are potentialy capable of capturing the dynamic, evolving nature of informal settlements, providing insights into their spatial transformations. The findings suggest that systematic spatial analysis can improve the understanding of informal settlements' morphologies and their relation to the broader urban fabric. These methods offer a tool for analyzing urbanization trends in informal areas, with potential applicability in other cities.

Keywords: Informal Settlements, Space Syntax, Kibera, Nairobi Spatial Integration

INTRODUCTION

Global urban expansion has significantly increased the extent of urban areas, driven by of population growth, economic development, and socio-political factors (Seto et al., 2011). This expansion has broad about significant changes in the way cities are structured, particularly in the Global South, where urbanization is characterized by rapid city growth, significant inequities in access to services, and the enduring impacts of colonial legacies (Myers, 2003). As a result, informal settlements have proliferated, becoming a defining characteristic of many urban areas. These settlements, characterized by spontaneous, incremental growth and a lack of formal planning, present unique challenges. Understanding how these emerging urban morphologies evolve over time is crucial for addressing broader urbanization trends in the Global South. While much of the existing urban research has focused on formal city development, there is an increasing acknowledgment that informal settlements demand specialized analytical approaches to effectively capture their dynamic characteristics (Lall, et at., 2017; Gutu Sakketa, 2023).

Urban informality, far from being an exception, has become a consistent mode of urban space production (Dovey et al., 2020). Although informal urbanization is not a recent phenomenon, it has historically been overlooked in urban morphological studies. In recent decades, scholars have called for a better understanding of informality but a challenge remains in terms of how we can better understand these urban forms and the processes that shape them. Recent scholarship highlights the importance of adopting a systematic, analytical approach to studying these settlements, one that goes beyond simply describing them as deficient or irregular (Gilbert, 2007; Zarate, 2016; Dovey et al., 2018). Informal settlements share common physical characteristics across diverse contexts. Their growth is typically self-organized and incremental, leading to a fragmented urban morphology that alignes newer additions with more stable cores of earlier settlement (Iranmanesh and Kamalipour, 2023). Developing strategies to address the challenges of informal settlements and incorporating them into the wider urban environment requires a deep understanding of how these settlements evolve over time.

The study seeks to address this question: How can the study of emerging urban morphologies shaped by informality help clarify current urbanization trends in the Global South?. The paper argues that this can be achieved through the systematic observation and analysis of urban forms and their dynamics. The study employs Geographic Information System (GIS) techniques and Space Syntax analysis to establish a methodological framework for understanding the evolution of spatial configurations of informal settlements evolve over time. Kibera, Nairobi's largest informal settlement, is used as a test case to assess the applicability of these methods in studying informal urban morphologies. The importance of the research lies in its potential to provide analytical approaches for urban planners and policymakers in rapidly urbanizing cities. By systematically mapping changes in the selected informal settlement's street network over a 20-year period (2004–2024), the study tests whether Space Syntax and GIS techniques can effectively capture the incremental spatial changes typical of informal settlements. The findings can potentially inform broader discussions on how such methods could be used to address the challenges posed by urban informality. Thus, the aim of this paper is not only to examine the morphological changes in the selected case but to demonstrate the value of systematic spatial analysis in understanding informal urban growth. The methodological approach applied in this study can be a tool for understanding the broader urbanization trends in other cities facing similar challenges.

This paper is organized as outlined: The first section reviews existing literature on urban morphology and informality as well as the applicationof space syntax in studies dealing with informal areas. The second section describes the methodology, focusing on the use of GIS and Space Syntax for spatial analysis. The results section presents findings from the 20-year analysis of the test case's street network, followed by a discussion on the broader applicability of these methods in understanding informal settlements. Finally, the conclusion reflects on the potential and pitfalls of these analytical tools to inform urban planning.

Urban Morphology and Informality

The field of Urban morphology, which studies the form and structure of urban spaces (Oliveira, 2016), provides valuable perspectives into the dynamics of informal urban areas, which emerge as spontaneous and incremental responses to local conditions and needs. Unlike formally planned urban areas, informal settlements evolve without the guidance of master plans or regulations, leading to complex, often irregular spatial structures (Dovey and King, 2011). Despite this apparent disorder, the spatial configurations of informal settlements are shaped by adaptive processes that reflect the ongoing negotiation between residents and their environment. These areas often feature small building increments, narrow pathways, and uneven access routes that form in response to resource availability and immediate social needs (Dovey et al., 2020). The gradual densification of informal settlements leads to morphological consolidation, where once-peripheral areas become integral to the settlement's internal structure, as well as to the broader urban system (Tessari, 2020). Despite the significant role of informal settlements in urban development, the morphological study of these areas has often been overshadowed by other relevant discussions on economics, land tenure, and infrastructure (Owen et al., 2013). Recent scholarship has shifted focus towards the spatial characteristics and developmental logics of informal settlements. Researchers are increasingly recognizing that the form and structure of these areas reveal underlying spatial patterns and urban dynamics that are crucial to understanding broader urbanization trends (Kamalipour and Dovey, 2020).

Traditionally, urban morphology has been dominated by three major schools of thought—the British, Italian, and French schools—that focus on the historical and typological evolution of cities (Oliveira, 2016). These schools offer insights into formal urban environments, emphasizing historical cartographic analysis, building types, and street layouts (Conzen, 1968; Caniggia and Maffei, 2001). However, the fluid nature of informal settlements challenges these conventional approaches, as these areas operate outside of regulatory frameworks. To address this gap in urban morphology, scholars have begun incorporating morpho-analytical tools to explore the spatial logic of informal settlements particularly those utilizing space syntax (Karimi et al., 2007; Loureiro, 2017; Cutini et al., 2019; Iranmanesh and Kamalipour, 2023) and historico-geographical and process-typological approaches (Maretto et al., 2014; Iovene et al., 2017).

Challenges of studying the morphological aspects of informal settlements have been recognized as related to availability of high-quality spatial data. Acquiring maps and cartographic data on informal settlements has become feasible in recent decades. Busgeeth et al. (2008) outline several reasons for the difficulty in obtaining spatial data for informal settlements, including unclear municipal boundaries, the lack of formal plot boundaries, challenges in conducting in-situ surveys, and the ever-changing nature of the settlements. Information designed for city planners, technicians, or military use was once restricted and required bureaucratic access. As Fabricius (2008) points out, details about

a city's spatial relationships, such as proximities, densities, and inhabited areas, were closely guarded. The constraints in gathering data on informal settlements have been mainly addressed through the use of remote sensing technologies (Musakwa & Van Niekerk, 2015) and approaches and technologies that include open-source software, mobile applications, and volunteered geographic information.

Space Syntax as methodological tool for informal settlements

In physical terms, cities are networks of streets and open spaces that connect buildings and blocks, forming a backbone of urban life. Socially, these spaces facilitate movement, interaction, and activities, creating a dynamic urban environment. Space Syntax, developed in the 1960s offers a methodological tool for examining the relationship between the spatial configuration of urban environments and social and economic dynamics. By focusing on the connections between spaces rather than their physical attributes, Space Syntax provides insights into how spatial configurations influence movement patterns, land use, and social behaviors within a city (Van Nes and Yamu, 2021).

The core measures of Space Syntax, angular integration and angular betweenness (choice), provide quantitative data on spatial relationships that relate to how spaces are connected and accessible. The first measure, angular integration, is considered a "to-space" measure. It refers to how easily one can reach other parts of a spatial system from a given location, considering the angular change in direction required to move through space. A space with high angular integration is typically more central, indicating that fewer angular deviations are needed to reach it from other spaces. It is a key indicator of how integrated or accessible a particular space is within a network. The second one, angular betweenness, is considered a "through-space" measure. It refers to the extent to which a particular space lies on the shortest paths between other pairs of spaces. A space with high angular betweenness is often a critical connector in the network, frequently used as a route between other spaces. This measure is crucial for understanding how traffic or movement might flow through a network (Hillier 1996). These measures can be calculated at global - referring to the entire network- and local scales- referring to subsections of the network- offering different insights of potentialities of places and networks.

Space Syntax has proven useful in understanding the underlying spatial structures of informal settlements (Karimi, 2012, Cutini et al., 2019; Tufek-Memisevic, 2023). Studies using this methodology have shown that despite their seemingly chaotic appearance, informal settlements often exhibit structured networks that facilitate social and economic interactions (Cutini et al., 2019). The application of these quantitative spatial tools has allowed the mapping, analyzing, and interpretation of connectivity of street networks and the ways in which informal settlements are integrated into or remain isolated from the broader urban system. The emerging focus on the morphogenesis of informal settlements—the process by which their form changes over time—reveals that as informal street networks grow, they often become more hierarchical and structured (Iranmanesh and Kamalipour, 2023). The incremental development process is critical for understanding the spatial evolution of these settlements and their potential integration into the formal city (Karimi et al., 2007).

Examples of applications offer insights into how these areas evolve, adapt, and integrate with broader urban systems. Although limited to some studies, this methodology has been effectively employed in various contexts to understand the structural and social dynamics of informal areas. Results obtained by applying space syntax enable topological and statistical analyses, revealing underlying urban

patterns. Such studies have been used for the identification of areas with low integration pointing to suggestions on targeted interventions (Karimi et al., 2007), or evaluation of proposals for interventions in such settlements (Tufek-Memisevic, 2023); recognition of discernible patterns in the morphology of informal areas (Cutini et al., 2019); influence of street accessibility on the distribution of small businesses (Mohamed et al., 2022); and explorations on the morphogenesis of street patterns (Iranmanesh and Kamalipour, 2023).

METHOD

This study developed a street network model for a whole city and a 15 km buffer around it, using road center line (RCL) data obtained from OpenStreetMap (OSM) datasets (data downloaded in March 2024). The use of RCL maps in Space Syntax analysis allows for the systematic representation and analysis of the spatial configuration of urban street networks. The methodology for creating this model involved two key steps, the first step was a general inquiry into the entire site, which included simplifying the citywide network through predefined Space Syntax methods, including error removal and data generalization (Kolovou et al., 2017). The generalised RCL data was then used to create a segment network, on which centrality analysis was conducted to calculate integration and choice values for each segment using the Place Syntax Toolkit (PST). The analysis was carried out across various radii, allowing the identification of integrated and segregated areas at both global (total, radii 10 km, 15 km) and local scales (radii 1 km, 2 km). These calculations involved determining topological depth and normalizing the integration values to account for the size of the network, which provides a picture of the relative spatial importance of different areas within the city's urban fabric.

The second step of the methodology focused on a specific area of the city, an informal settlement, to perform diachronic mapping of network modifications within and around the settlement. Figure 1 and Figure 2 depict the proposed methodological approach for the study. The systematic mapping was developed using historical satellite imagery from Google Earth. A database of satellite images obtained at regular intervals (2004, 2009, 2014, 2019, 2024) was created by georeferencing the images in QGIS. Urban mapping techniques were then applied to map modifications in the settlement's street network. Mapping informal areas with satellite images has been effective in studying the morphology of such settlements (Kuffer et al., 2016; Dovey and Kamalipour, 2018; Samper et al., 2020; Ricchiardi, 2022). The resulting networks for each time interval were analyzed using Space Syntax to compare spatial configurations across the five periods. Visualization of the results were then created through color-coded maps that highlighted areas of high and low integration. These visualizations aided in the interpretation of spatial dynamics, helping to identify trends in accessibility and movement patterns within the settlement over time.

The case study selection for testing the proposed methodology was primarily driven by the availability of data. Kibera, located in Nairobi, stands out as a particularly significant case study due to the extensive data gathered for the settlement. It is not only one of the most well-known informal settlements in Nairobi but also one of the few where street network data and building foorprint has been comprehensively mapped through the collaborative Map Kibera Project (Map Kibera, n.d.). This initiative facilitated the addition of Kibera’s street data to OpenStreetMap (OSM), making it an exceptional case for urban analysis. The documentation and mapping effort in Kibera provides a stark contrast to the data scarcity typically associated with informal settlements, making it a valuable subject for testing the methodology central to this research.

Application of the methodology - Nairobi & Kibera

As with many cities in the Global South, Nairobi presents a complex case study of contradictions and contrasts. The city exemplifies the design and structural tensions typical of Sub-Saharan African cities, where rapid urban growth often occurs alongside significant socio-economic disparities. Frequently cited as a model of a colonial city, Nairobi also embodies a hybrid post-colonial identity found in most major urban centers across the region (Myers, 2016). Its population has surged from approximately 30,000 in the late 1920s to over 5.5 million by 2024 (United. Nations, 2024). The city's rapid expansion is marked by a stark contrast between modern infrastructure and sprawling informal settlements. Studies on urban development plans in Nairobi reveal widespread non-compliance with zoning regulations over the past few decades, further compounding city's challenges (Karanja and Achola, 2021).

Nairobi originated along a caravan route connecting Kenya's interior to the Indian Ocean. As a British colonial railway town, the city's spatial patterns were shaped by a political framework of imperial extension (White et al., 2015). The layout of the city followed a segregated urban plan, which allocated distinct functions to different zones, a legacy that persisted well into the post-independence era (Owuor and Mbatia, 2012). Although official segregation was abolished after Kenya's independence, new forms of discrimination—based on income, ethnicity, and religion—emerged, influencing the urban fabric (Otiso, 2005). Colonial spatial strategies have continued into the post-colonial period, but alternative spatial strategies have also emerged, particularly in informal settlements (Myers, 2003). These settlements have appeared in areas historically designated for "Africans," such as the eastern side of the colonial city, but have also emerged in wealthier western neighborhoods (Médard, 2010). Responses to informal areas have varied widely, ranging from indifference to harsh demolitions (Murunga and Nasong'o, 2006). By 2008, Nairobi had around 150 informal settlements, covering only 5% of the city's residential land but housing over 1.8 million people—more than 50% of the city's population (Slum Dwellers International and Pamoja Trust, 2009). Many of these informal settlements are located near the central business district (Figure 3).

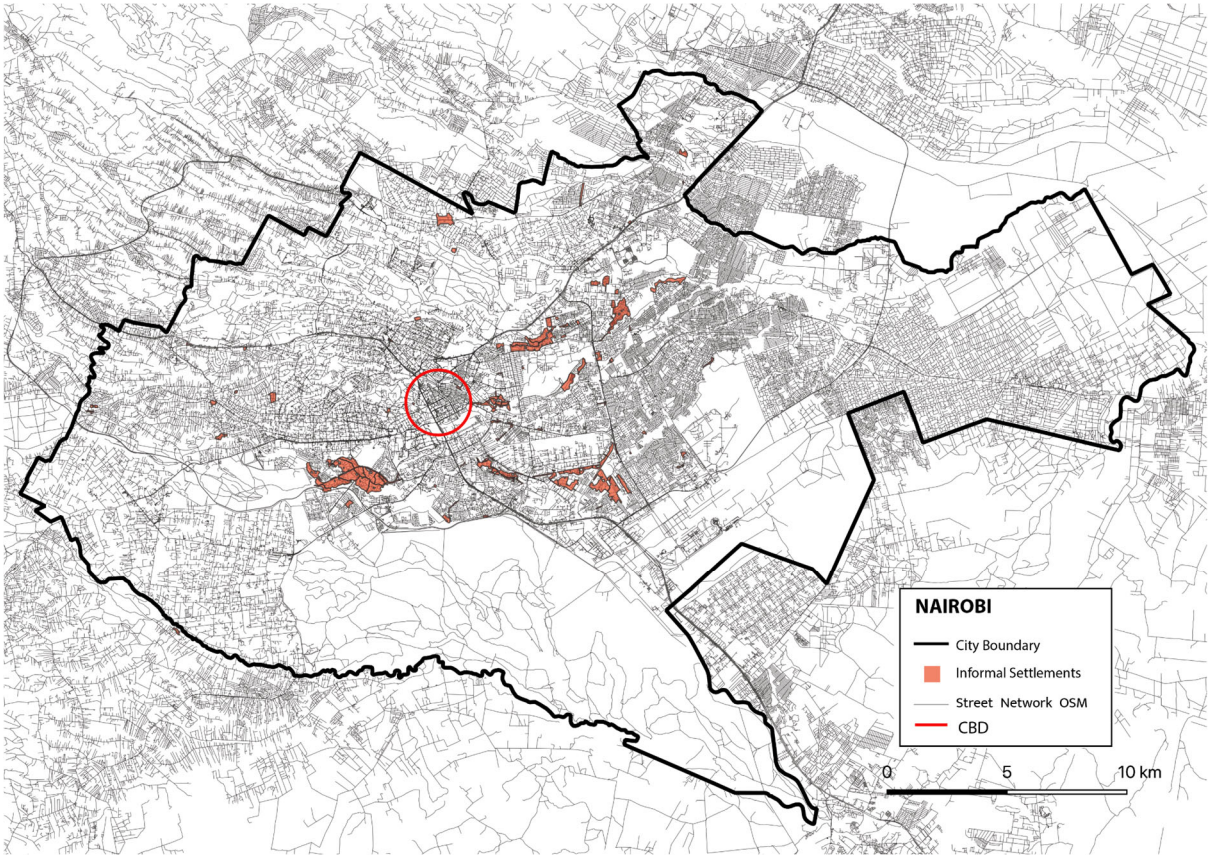

Figure 3. Informal settlements in Nairobi as 2010 from Kenya Land Use. Data Source: Columbia University's Center for Sustainable Urban Development. Visualisation by Authors.

As colonialism set the foundation for urban development in Nairobi, post-colonial nationalism, globalization and urban neoliberalism have since reshaped the city's urban identity. The hybridity of Nairobi's urban form reflects these multiple layers of influence (Myers, 2016), as the city's urban fabric continues to extend far beyond the boundaries of Nairobi County (OECD/SWAC, 2020). Structural adjustments imposed by international financial institutions have further entrenched these contradictions, contributing to the rapid construction within informal settlements (Huchzermeyer, 2011). At the same time, the rise of gated communities and upscale apartment complexes for Nairobi's affluent population adds another layer of inequality. Nairobi's most recent urban strategy, the Nairobi

Integrated Urban Development Masterplan (Nairobi City County, 2014), aims to address many of the city's challenges. The plan outlines priorities such as the renewal of Eastlands, the redevelopment of the railway city, and the integration of a greater central business district with sub-centers involving changes in the street network of the city.

Kibera

Established in 1912, Kibera is located approximately 5 kilometers from Nairobi's city center. The name "Kibera" comes from the Nubian word 'Kibra,' meaning "wilderness" or "bush" (Bodewes, 2005). Following Kenya's independence, when colonial restrictions on indigenous Africans' movement were lifted, Kibera experienced a wave of rural-to-urban migration. Unable to afford formal housing, many migrants settled in Kibera, constructing makeshift homes. Today, the settlement has become very consolidated in the city and is now surrounded by upper middle-class housing estates. The Nairobi Integrated Urban Development Master Plan (NIUPLAN) has significant implications for Kibera. While the plan includes infrastructure upgrades such as roads, water, and sanitation that could improve living conditions, these improvements have carried the risk of displacement as zoning regulations and land use planning are not managed to protect residents' rights (KDI, 2018). The tension between upgrading infrastructures and maintaining the social fabric of informal settlements like Kibera is a recurring theme in Nairobi's urban planning discourses.**RESULTS AND DISCUSSIONS** **[Heading 1]**

Provide a concise, clear and precise description of the results and their interpretation. You may use tables, drawings, figures, and diagrams to illustrate your findings. Make sure to dedicate enough space for discussing your results and to reflect on how they can be interpreted from previous studies' perspectives and the working hypotheses/research questions. The findings and their implications should be discussed in the broadest context possible, and the limitations of the work should be highlighted. **[Text body]**

RESULTS AND DISCUSSION

The Space Syntax analysis of Nairobi provides insights into the city's hierarchical urban structure (Figure 4). At the local scale, areas with high integration, highlighted in red, suggest that certain neighborhoods and streets are more accessible within their immediate surroundings. These zones likely act as critical nodes for local movement, serving as hubs where pedestrian and vehicular traffic converge. On the global scale, the analysis reveals a broader pattern of connectivity across the city. The red zones in the global integration map point to areas that are not only locally accessible but also central within the entire urban system. These areas, primarily consisting of major roads and central districts, facilitate city-wide movement and serve as key destinations for people from various parts of Nairobi. The contrast between the well-connected areas and the less accessible peripheral zones underscores the disparity in spatial accessibility within the city. The central and eastern parts of Nairobi emerge as highly integrated both locally and globally, suggesting a concentration of activities and movement in these regions. This likely stems from a combination of historical development patterns and infrastructural investments. Conversely, the peripheral areas, particularly in the western and southern parts of the city, exhibit lower levels of integration, indicating a more fragmented urban fabric.

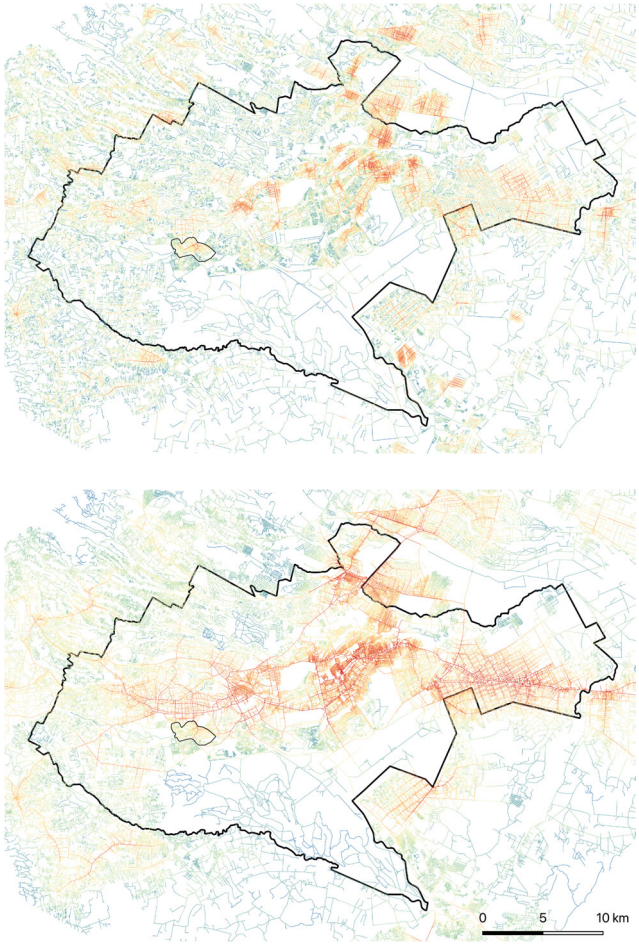

Figure 4. Up, Local angular integration. Down, Global angular integration results in Nairobi.

The incremental Space Syntax analysis of Kibera from 2004 to 2024 demonstrates significant transformations in both local and global spatial integration, as well as betweenness values. These changes reflect Kibera's evolving connectivity and accessibility, both within the settlement itself and in relation to Nairobi's broader urban network. (Figure 5 and Figure 6)

Local Scale Analysis: In 2004, Kibera exhibited relatively low local integration, with few areas displaying high levels of accessibility within the settlement. However, by 2024, local integration has markedly increased, particularly in the northern sections of the settlement. This suggests that infrastructural developments over the past two decades have significantly improved local movement networks, making certain streets and areas more central and accessible within Kibera. The increase in choice (betweenness) values, though modest, indicates that certain routes are becoming increasingly important for local navigation and movement, particularly those that cut across the settlement in an east-west direction.

Global Scale Analysis: From 2004 to 2024, Kibera's integration within Nairobi's urban fabric has notably increased, signaling the settlement's consolidation. In 2004, Kibera appeared relatively peripheral, with only a few routes showing high global integration. These routes served as primary connectors between Kibera and the rest of Nairobi. By 2024, the analysis indicates that Kibera is becoming more integrated into the city, with increased global integration values along its northern and central axes. This suggests that Kibera has transitioned from a somewhat isolated informal settlement to a more connected and accessible part of Nairobi's urban system. Two major

infrastructural changes—the Southern Bypass and the Lang'ata Link road—have played crucial roles in this shift, though these developments also led to the displacement of thousands of residents and the demolition of several community facilities, such as schools (KDI, 2018). The integration of unplanned areas like Kibera into the broader urban context poses challenges that go beyond infrastructural adjustments. While such integration is often framed as necessary for urban development, it can prioritize superficial connectivity over the social, cultural, and economic dynamics inherent in informal settlements.

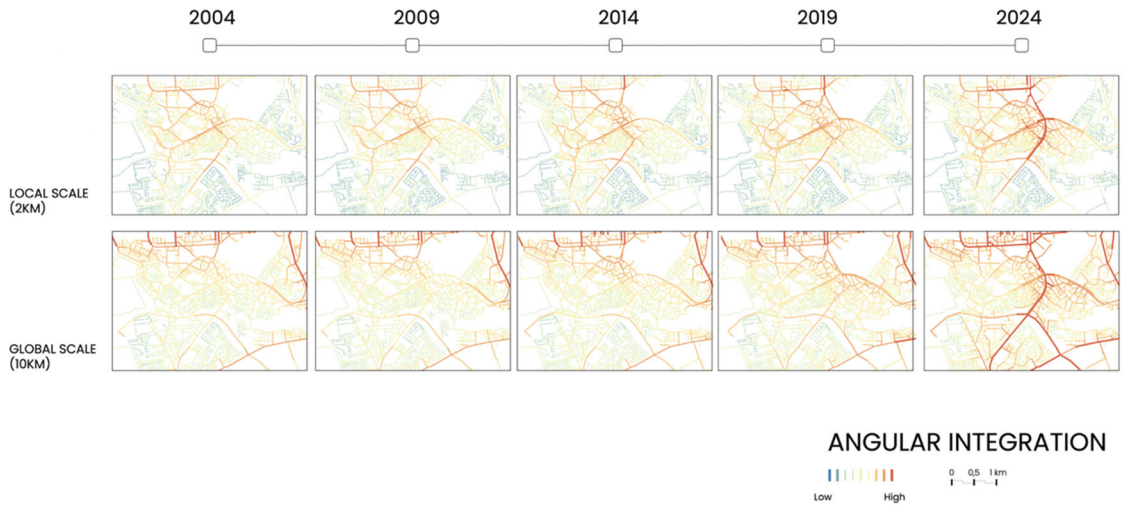

Figure 5. Local and global angular integration analysis results for Kibera.

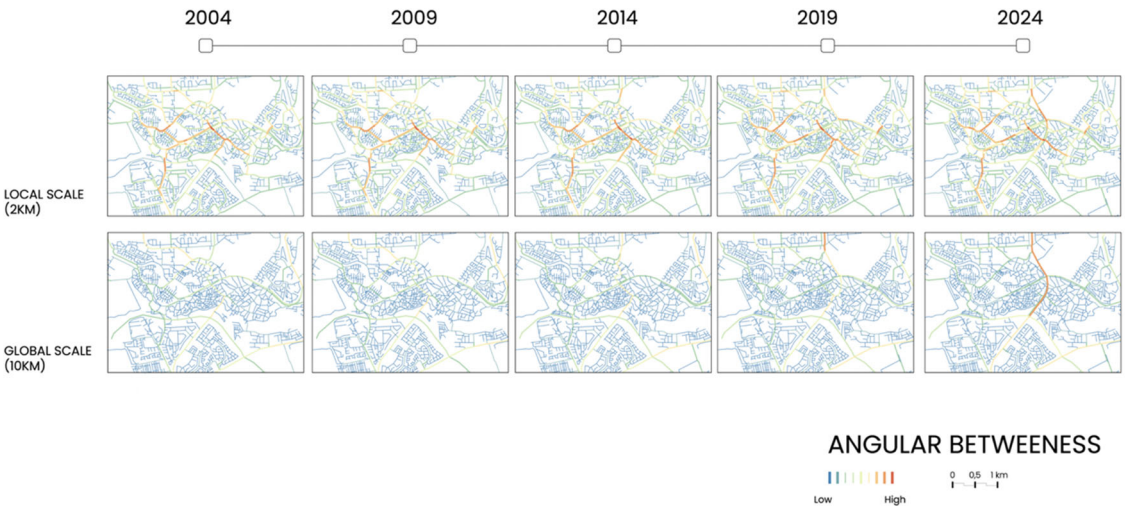

Figure 6. Local and global angular betweeness analysis results for Kibera

The analysis of incremental processes in this particular case reveals both the potential and pitfalls of using Space Syntax as a tool to study the development of street networks in these contexts. One pressing concern in integrating informal settlements is the tendency to create "pass-through" infrastructures—roads, highways, and transit systems that facilitate movement but fail to engage with local communities (KDI, 2018). These infrastructures serve broader urban agendas rather than catering to the needs of residents, which can lead to further marginalization of communities in informal settlements.

Space Syntax emerges as a valuable tool that can uncover configurations that often go unnoticed in conventional surveys for planning. By highlighting areas of varying integration and connectivity,it can potentially enable a more informed approach to urban planning and development, identifying zones that require specific attention. However, relying solely on Space Syntax introduces limitations. The lack of reliable and detailed spatial data in informal settlements can influence results, while the dynamic and complex nature of informal areas makes it difficult to capture stable findings over time. In this sense, and given the context-specific nature of informal settlements, ground verification becomes critical. Many informal networks are obscured by physical structures, such as roofs, making accurate mapping and analysis challenging. Combining quantitative tools like Space Syntax with qualitative assessments is essential for a better understanding of such settlements. Engaging local communities in the research process can provide insights that purely analytical methods might miss, such as lived experiences and community-driven dynamics that inform the spatial layout. Qualitative assessments can explore important factors such as place identity and community character, which go beyond what spatial analysis can capture helping with the limitations encounter in the study.

CONCLUSIONS

This study addressed the spatial dynamics of informal settlements, with a focus on how they could inform broader urbanization trends in the Global South. The central question guiding this research was how the study of urban morphologies shaped by informality can help clarify current urbanization patterns. By using Kibera as a case study, the research demonstrated how the application of tools like GIS and Space Syntax allows for a systematic observation of urban forms and their transformations over time. The study validated the methodological framework proposed. By analyzing Kibera's spatial configurations over a 20-year period, the research revealed how the settlement changed in relation to infrastructural interventions in terms of integration to the broader urban fabric. This emphasizes the importance of viewing informal settlements as dynamic spaces that contribute to the overall urban system, rather than as peripheral or isolated areas.

The exploration of unplanned urban areas emphasizes the need for a fundamental change in how interventions are approached in such settlements. Understanding the spatial dynamics of these areas is crucial for addressing the challenges of rapid urbanization. The findings highlight the significance of ongoing research into informal settlements, not only as a pressing academic concern but as a critical component of creating more adaptive urban policies. Morphological studies of informal settlements offer valuable insights into how communities adapt. This study reaffirms the notion that informal settlements embody unique spatial characteristics that are often overlooked in traditional urban planning frameworks. Urban planners and policymakers must recognize these characteristics and their potential to inform broader urban development strategies.

The complexity of informal settlements requires researchers to develop tailored methodologies that capture their evolving nature. The need for continued exploration and engagement with informal settlements is clear. The future of urban planning depends on our willingness to learn from and adapt to the realities of these critical city spaces. Transformative approaches that incorporate both formal and informal urban growth patterns will be essential for creating cities that serve all residents, particularly in rapidly urbanizing regions.

ABSTRACT

Global South Metropolitan Regions are experiencing significant growth and transformation, characterized by rapid urbanization and extensive conurbations. In these regions, satellite cities often face problems stemming from the external dynamics with local impact, such as the presence of metropolitan transportation infrastructure, and housing demand. The objective of this study is to analyze some impacts of the metropolisation from the point of view of a peripheral city's spatial structure using network analysis. Specifically, we focus on Embu das Artes municipality, in the Metropolitan Region of São Paulo, to examine the distribution of intra-urban centralities for population and economic activities, considering the metropolitan road infrastructure and the proximity to São Paulo peripheral urbanization. Two network measures are modelled using GAUS (Graph Analysis of Urban Systems), a set of scripts for calculating configurational metrics in QGIS: accessibility and centrality, weighted by population and local economic activities. Among the main findings, the analysis reveals clustered and hierarchical internal spatial structure tensioned by the metropolitan process. Topographic features, associated with the metropolitan transportation infrastructure, act as barriers, inducing the formation of two clusters: one around the traditional downtown and another closer to São Paulo's border. A population cluster distant from the historic center indicates a concentration of metropolitan commuters living in low-standard urbanization. In conclusion, this study provides an approach to the investigation of the underlying intra-urban spatial structure of cities, offering insights to support decisions in urban and regional planning.

INTRODUCTION

Metropolitan regions in the Global South are experiencing rapid growth and transformation, driven by accelerated urbanization and the emergence of extensive conurbations. These regions, also referred to as urban-regional arrangements (Moura, 2012), have become critical hubs of population and hold significant economic, social, and technological importance. Characterized by high urban

density, strong regional integration, and intricate complexity, they are shaped by multidirectional flows of people, goods, knowledge, and power. However, the process of metropolization affects municipalities unevenly. Those with the necessary technological, scientific, institutional, and cultural capacities to participate in the agglomeration process tend to prosper, while others remain excluded from these developmental gains.

Morphologically, metropolitan regions expand by incorporating urban centers along with their surrounding urban and rural areas, forming either continuous or fragmented spatial units. This expansion enhances connectivity and promotes shared functions with adjacent agglomerations, contributing to a more complex urban structure and an extended regional scope. The genesis and growth of this phenomenon are driven by two key factors: the search for locations with greater access to economic opportunities and the peripheralization of urban poverty, a process influenced by real estate market dynamics.

Satellite cities frequently face challenges stemming from external dynamics with local implications, such as the expansion of metropolitan transportation infrastructure, increasing housing demand, and the growth of large private developments, including gated communities. In contemporary urbanization, the historical trajectory of regions significantly shapes both their form and dynamics (Moura, 2004: 86). The inherited geographical conditions constrain the development of regional systems, as emerging dynamics often reinforce and intensify pre-existing relationships, further shaping their morphological evolution.

Understanding the morphology of contemporary urbanization requires the adoption of new methodological approaches, particularly those that are systemic and multi-scale. Regions should be conceptualized as interconnected networks comprising social and spatial elements in constant interaction and flux. One promising method for addressing this complexity is through urban modelling and configurational studies (Batty, 2013; Crucitti et al., 2006; Hillier and Hanson, 1984). These approaches treat cities and regions as spatial systems, facilitating their representation and quantitative analysis, especially regarding hierarchies and properties such as accessibility and centrality.

The objective of this study is to analyze some impacts of metropolisation on the spatial structure of a peripheral city using network analysis. Specifically, we focus on the municipality of Embu das Artes, located in the Metropolitan Region of São Paulo, to examine the distribution of intraurban centralities in terms of population and employment. This analysis considers the influence of metropolitan road infrastructure and the city's proximity to the peripheral urbanization of São Paulo.

Configurational methodologies have been applied to regional-scale studies, as demonstrated in the works of Serra and Pinho (2013), Krenz (2017), and Kaplan et al. (2022). These studies use configurational accessibility and centrality in a multiscale assessment of natural or emerging centralities. In Brazil, Ugalde (2013) focused on the Porto Alegre Metropolitan Region, analyzing how the spatial structuring of the conurbation shapes movement routes across different regional scales. Colusso (2015) examined the influence of regional systems on urban forms, proposing a regional tension model based on spatial interaction and betweenness centrality. Other studies employ spatial models to identify emerging hierarchies in regional systems using weighted centrality measures (Espínola, 2003; Calvetti, 2016; Maraschin et al., 2021).

Ribeiro et al. (2016) applied configurational models to the city of Embu das Artes, utilizing centrality measures and performance indicators such as Accessibility, Betweenness, Spatial Convergence, and Spatial Opportunity (Krafta, 1994; 1996). Their analysis involved the development of two distinct spatial scenarios / two geographical scopes to assess the city's urban structure and its performance in terms of configurational efficiency and equity.

In this paper, we build on these previous studies by employing a weighted centrality model to investigate the impacts of metropolitan processes on the spatial structure of a peripheral city. The next section outlines the methodology, followed by the results and discussion of the case of Embu das Artes.

METHOD

To examine the spatial structure and dynamics of the distribution of employment and residential locations we use configurational models. These models employ methodologies that break the city down into components (e.g., elementary spatial units, spatial attributes) and their relationships (e.g., topological descriptions, adjacencies, centrality). Graph theory serves as the analytical foundation for calculating various measures and properties of the urban network. The models are based on the shortest path hypothesis, assuming that connections between cells in the network will always occur via the shortest routes. As a result, cities exhibit spatial differentiation, forming a hierarchy where certain cells (spaces) stand out due to their relative position and/or the number of connections with others.

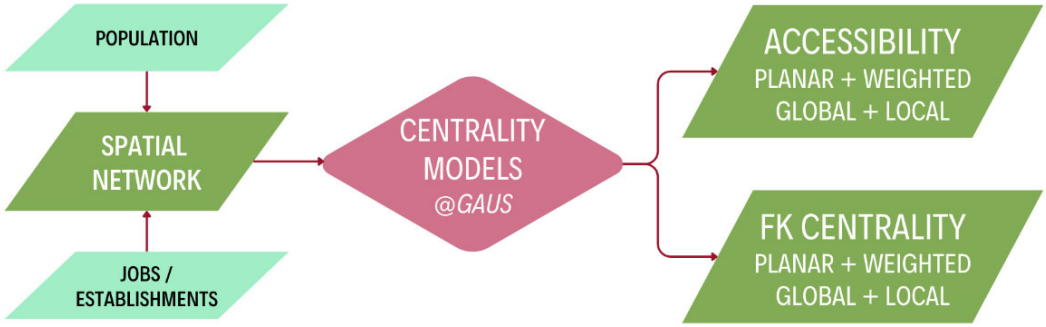

Figure 1. Methodological strategy. Credit: authors (2024).

Modeling process involves the transformation of city street grids into urban spatial networks. We adopt a spatial representation by street segments (Batty, 2004; Krafta, 2014; Kruger, 1979), which consists of a set of lines representing street segments or portions of streets situated between pairs of corners or road intersections (Krafta, 2014). In this graph, each street segment functions as a node, and the connections between them are the links. This representation allows for a fine level of spatial disaggregation, making it well-suited for studies focused on intra-urban scale. Resulting street network is composed of 24,890 segments, including a 5 km buffer to minimize edge effects — which was later removed for further analysis.

It is important to highlight that the configurational software utilized – GAUS (Dalcin and Krafta, 2021) – allows distance computations with edges having lengths equal to the actual distances between the midpoints of adjacent street segments. This correction ensures that the length of these edges accurately reflects the real distances they represent.

In the following step, the network is loaded with specified attributes: population and non-residential establishments (i.e., institutional, commercial and services establishments, industry, etc.). Population data is sourced from the 2022 Population Census, survey by the Brazilian Institute of Geography and Statistics – IBGE (2024b). For non-residential establishments, we used data from the National Register of Addresses for Statistical Purposes, survey by IBGE (2024a).

Geoprocessing resources facilitate the transfer of population quantities from the census tracts polygons, and non-residential establishments quantities, represented as points, to the street segments. Influence areas are determined for each street segment using Voronoi polygons (Kolahdouzan and Shahabi, 2004). Influence area "captures" point data located within it. Concerning polygonal data, we clipped the polygon inputs (census tracts) with influence areas to determine the total counts of inhabitants spatially coincident to each street segment. This procedure resulted in the street segments network weighted with the origin and destination attributes (Ribeiro, 2017).

Network measures are modelled using GAUS – Graph Analysis of Urban Systems (Dalcin and Krafta, 2021), a set of scripts for calculating configurational metrics in QGIS: Accessibility and Freeman-Krafta Centrality, weighted by working-age population and local jobs.

In the context of graph theory and network analysis, different centrality measures for a vertex in a graph indicate its relative importance, or in urban networks, how significant a road is within the system.

- Accessibility is broadly defined as ease of access or the ability of a node in the system to be reached (Ingram, 1971). It represents a measure of proximity between two points, which in this case is quantified by the relative distance of each urban location to all others.

- Planar Freeman-Krafta Centrality considers only the configuration of the spatial network, disregarding any attributes assigned to the network nodes. This centrality measure uses the concept of shortest paths and the interaction between non-adjacent elements, placing greater emphasis on nodes positioned along these paths. Such nodes gain strategic significance due to their role in facilitating connections between many other nodes, thereby indicating their relative importance within the network. Typically, higher centrality values tend to be found near the geometric center of the network.

- Weighted Freeman-Krafta Centrality incorporates the concept of weighting by assigning values to the tension between each pair of nodes, with a fraction of this value distributed across the nodes forming the shortest path between them. In this study, the attributes of population (IBGE, 2024b) and non-residential establishments (IBGE, 2024a) are applied to the network nodes to weight the centrality measures.

This approach provides a nuanced understanding of how central nodes function both in terms of spatial configuration and their demographic and economic importance.

RESULTS AND DISCUSSIONS

Contextualization

Established in 1973, the São Paulo Metropolitan Region is the largest urban agglomeration in South America, ranking sixth among the largest in the world. The region comprises 39 municipalities, with a population of over 20 million inhabitants (IBGE, 2024b). Embu das Artes is a historic municipality located in Metropolitan Region of São Paulo, with a population of 250,691 inhabitants (IBGE, 2024b) is 36 km from the capital, São Paulo (Figure 2). Embu is considered a touristic destination due to the concentration of artists, among painters, sculptors, musicians and singers living in the city and a renowned Arts and Crafts Fair that occurs in the Historic Center.

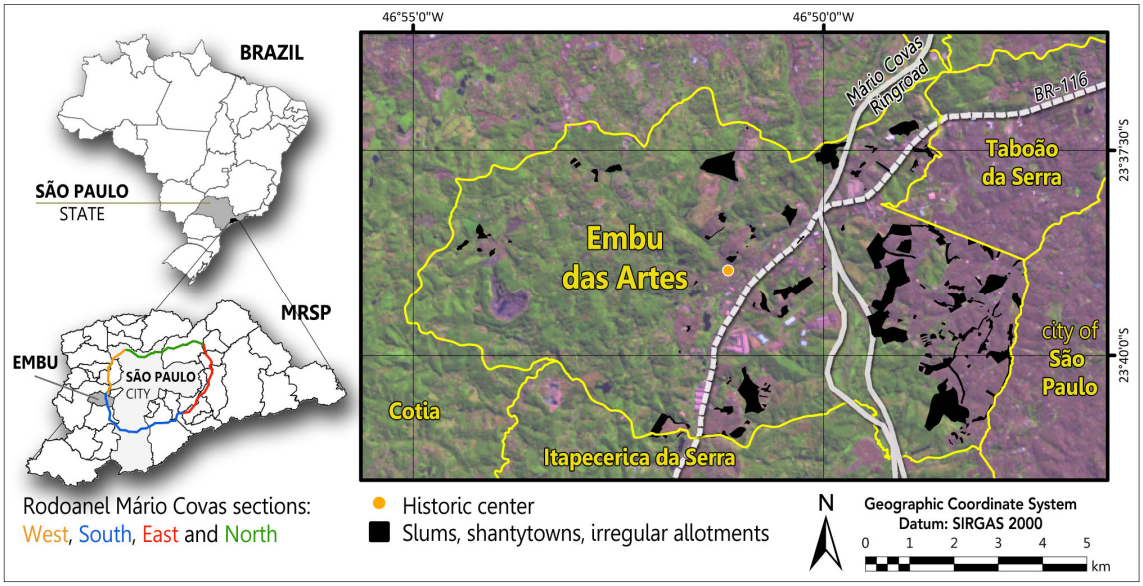

Figure 2. Location of Embu das Artes in Brazil and in the Metropolitan Region of São Paulo (MRSP). Source: authors (2024).

Embu experienced a disorganized urbanization process and a significant increase in population, primarily as a result of the sprawl of the São Paulo metropolitan area. The opening of the Régis Bittencourt Highway (BR-116) in 1961 significantly contributed to the population growth in the area. In this period, the occupation of existing subdivisions was consolidated, along with the availability of new subdivisions. Additionally, there was the beginning of migratory movements towards São Paulo, reinforcing the suburbanization process in the region (Azevedo, 2017). The commuting flows were intensified by the construction of an important ring road (Rodoanel Mario Covas) in 2002.

Embu das Artes is considered to have a very high level of integration into the dynamics of the São Paulo Metropolitan Region (Ribeiro et al., 2012). This classification was based on criteria such as population size, economic and functional aspects, degree of urbanization, density, land use, and population mobility (Figure 3).

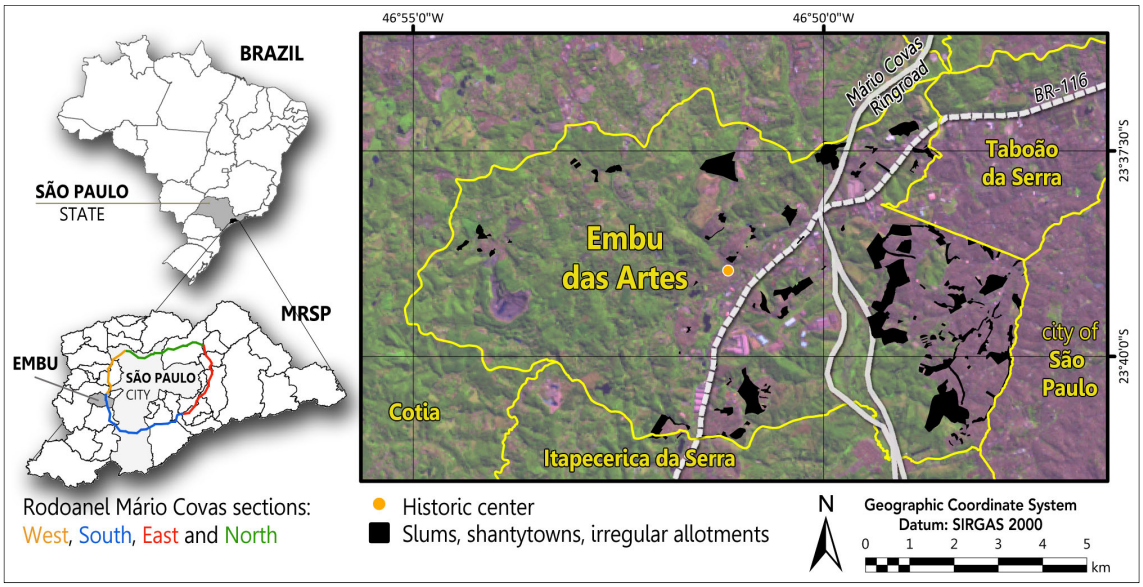

Figure 3. Levels of integration into the dynamics of São Paulo Metropolitan Region in 2010. Source: authors, based on Ribeiro et al. (2012).

The rural area of Embu das Artes was increasingly utilized by the population of São Paulo as a leisure destination, with the establishment of small farms and vacation homes. The eastern area, closer to São Paulo, experienced greater development of residential lots for low-income commuters, as well as the construction of homes through self-build initiatives. This process was facilitated by lower land costs, which were significantly cheaper than those in the city of São Paulo (Azevedo, 2017). This author identifies a dichotomy between the western and central regions and the eastern region, referring to them as the "two Embus" (op cit: 109). The following sections aim to investigate this dichotomy and its impact on the spatial structure of the city.

Network Centrality in Embu das Artes

The analysis of the accessibility of Embu's road network (Figure 4-A) highlights the street segments that result in shorter relative distances within the spatial system. It can be observed that the regional highways are the most accessible areas, followed by the eastern portion, which also includes the historic center and partially the western region. When this measure is weighted by the population per road segment, the results change significantly (Figure 4-B). Beyond the highways, the importance of the eastern sector becomes evident, demonstrating the influence of the high density of residents in that area. In this case, the historic center is perceived as "distant" from areas with concentrated populations.

The measure of centrality assesses the relative importance of segments within the interconnections of the spatial system. Planar Freeman-Krafta Centrality (Figure 4-D) highlights the significance of highways in regional connectivity. Other roads also play important roles, particularly in the eastern portion. When the population is included in the measure (Figure 4-E), there is a notable increase in the hierarchical importance of the roads in the eastern area.

Figure 4. Results obtained from the centrality models: [A] - Planar accessibility, [B] - accessibility weighted by population, and [C] - by economic activities. [D] - Planar Freeman-Krafta centrality, [E] - FK centrality weighted by population, and [F] - by economic activities. Source: authors (2024).

When analyzing the urban network, it is important to highlight the influence of urban barriers, which create discontinuities in the street network and in the urban fabric. These barriers often result from transportation systems but can also arise from landscape features shaped by natural phenomena or engineering projects, such as highways or railways. In the case of Embu, its terrain is highly diverse, with steep hills to the west, plains along the rivers in the central area, and rolling hills to the east. This

topography influences the street layout and generates difficulties in the road connections. Regarding the barriers related to the transportation system, the two major road infrastructures (BR-116 and Rodoanel) create a significant separation between the east and west sides. These are highways with extremely high traffic volumes, featuring complex intersections, tunnels, and associated roadworks, which discourage local and pedestrian movement in their vicinity. Along these highways, there is large-scale urban development, including industries, logistics activities, and other services.

A complimentary analysis of the FK centrality measure is presented in Figure 4-F: economic activities are loaded to the network to calculate the weighted FK centrality. Once again, there is an increase in centrality values in the eastern portion when compared to the planar measure, revealing areas of more intense centrality than the historic center itself.

When these previous model results are discussed in light of some socio demographic data, certain findings are reinforced. Population density is significantly higher in the eastern portion (Figure 5-A), while per capita income is higher in the western portion (Figure 5-B).

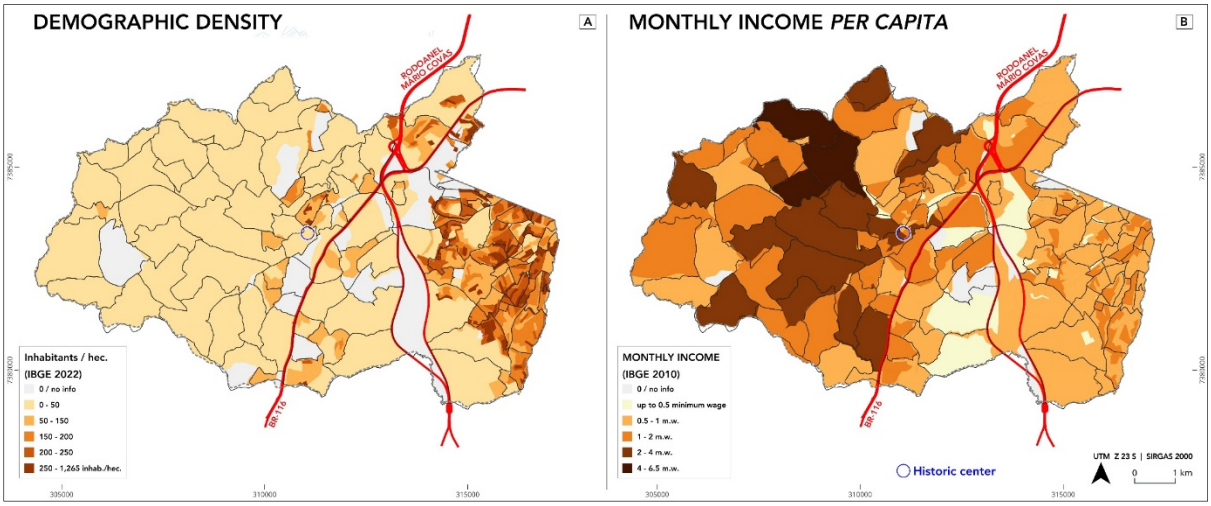

Figure 5. Demographic data aggregated by enumeration area: [A] - Demographic density, and [B] - Average monthly income per capita. Neighborhoods are outlined in black. Source: authors, based on data from IBGE (2024b; 2011).

Analyzed data reveals a city that is highly unequal in terms of both population density and income distribution. The eastern portion of the municipality, closer to São Paulo, exhibits a high concentration of inhabitants, with Embu functioning as a dormitory city. Additionally, the population is concentrated near the Historic Center and along the northern and southern borders.

The analysis of the spatial distribution of economic activities (Figure 6) highlights the role of the Historic Center in concentrating some economic dynamics. However, it is surpassed by the eastern portion, which emerges as an autonomous area with its own economic activity.

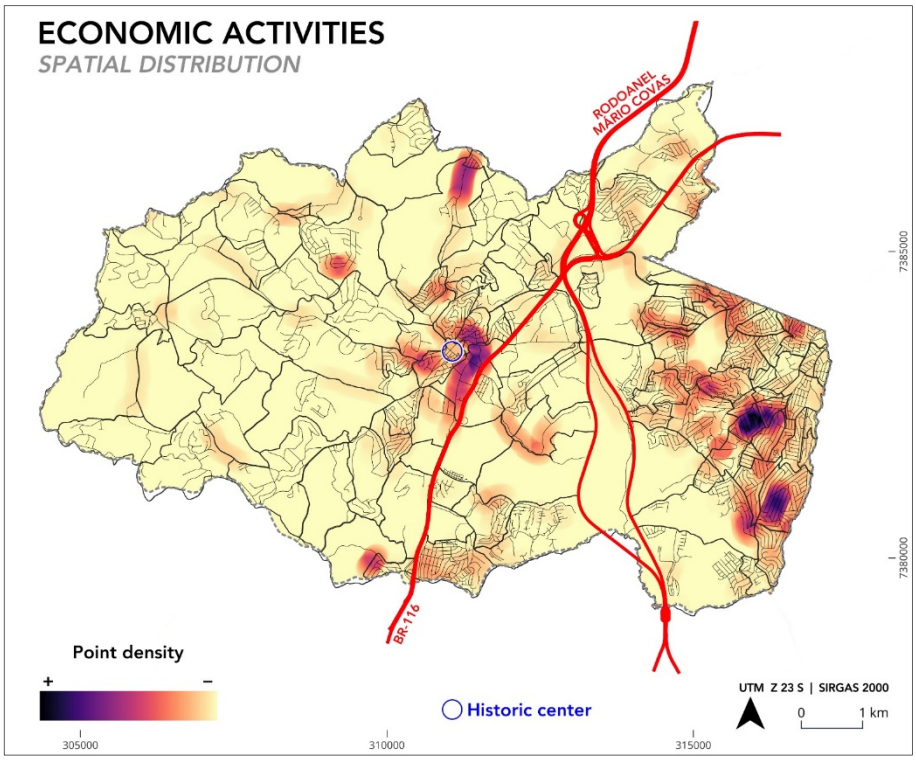

Figure 6. Density of economic activities in Embu das Artes. Source: authors, based on data from IBGE (2024a).

The urban configuration of Embu both reflects and amplifies the existing metropolitan socioeconomic tensions. Regional highways shape and reinforce the system's centrality, impacting mobility and access. The eastern portion, marked by lower income levels and high population density, remains highly dependent on São Paulo for economic opportunities. In contrast, the western portion, characterized by higher income levels and lower population density, experiences less reliance on external economic centers. Meanwhile, the Historic Center has lost its significance in a city fragmented by these socioeconomic and spatial disparities.

The distance between residents and workplaces can be viewed as a matter of equity, reflecting a spatial mismatch between residential areas and employment centers (Gonçalves, 2011). However, when considered from an efficiency perspective, this distance or dispersion of non-residential activities becomes undesirable. From the standpoint of economic efficiency, agglomeration—or the closer proximity of these activities—is preferable, as spatial proximity can reduce costs associated with internal interactions (Netto, 2014).

CONCLUSIONS

The configurational analysis of Embu revealed a process of spatial centralities shifting from the historic center toward the metropolitan highways and to the east, closer to São Paulo. This process has led to a fractured and unequal spatial structure. This clustered and hierarchical internal spatial structure is shaped by metropolitan processes. Topographic features, combined with metropolitan transportation infrastructure, act as barriers, fostering the formation of two distinct clusters: one around the traditional downtown and another closer to São Paulo's border. A significant concentration of the working-age population, distant from jobs and schools, suggests a high number of metropolitan commuters residing in areas of lower-quality urbanization.

In recent years, São Paulo Metropolitan Region has evolved into a “macrometropolis” (Bogus, Magalhães and Pasternak, 2021), a metropolitan complex spanning 200 km around the capital, São Paulo, formed through the conurbation of various metropolitan centers. The development processes and territorial structuring in this region are marked by internal inequalities, both in terms of human development indices and existing infrastructures, presenting significant challenges for local and regional management and planning.

To contribute to this task, the present study provides a methodological framework for investigating the underlying intra-urban spatial structure of cities, offering insights to support decision-making in urban and regional planning. The adopted method employs a quantitative approach, enabling the description of the socio-spatial impacts generated by the metropolis on the local system of a city. The conducted modelling facilitated the integration of the spatial system configuration (street network) with various social attributes (population, income, jobs etc.). This enhances the models' suitability for representing the complexity of urban environments.

Morphological characterisation of informal urban gardens in residential neighbourhoods of Piura, Peru

Stella Schroeder[1]
[1] School of Architecture, Faculty of Engineering, Architecture and Design, Universidad San Sebastián, Chile, stella.schroeder@uss.cl

ABSTRACT

The emergence of informal activities has long been a part of urban life, filling up unused land in large and mid-sized cities worldwide. They routinely occupy or appropriate urban spaces, revealing new functions of these places, such as urban gardening. With these activities, the inhabitants move beyond the limits of formal strategies in terms of occupation, urban design, planning, and construction. However, the issue of informal gardening has rarely been formally discussed at the governmental level in the Global South. Based on a case study of three neighbourhoods in Piura, Peru, this research explores patterns of form, accessibility, and visual interaction for urban gardening. The study aims to reveal similarities and particularities in the configuration of individual objects, analysing equipment, materials, and the structural environment. Using a qualitative approach, morphological characterization is considered as an analytical key to interpret the connections between the elements that make up a space. These observations include data gathering and analysis, mapping, sketches of the gardens, as well as aerial photographs as a complementary method. Through graphic representations of floor plans, the results demonstrate the physical appearance and accessibility of the gardens and their relation to the built environment. The gardens vary in size, and have multiple functions, such as storage, parking, or drying laundry, in addition to gardening. The vegetation consists of a variety of plants, including decorative flowers, vegetables, and fruit trees. The gardens also feature water infrastructure, furniture, and designated areas for plants and vegetables, providing spaces for relaxation and family gatherings. The findings provide valuable insights into the design possibilities and potential benefits of incorporating informal gardening practices into urban planning and development strategies.

Keywords: informal practices, public space, urban gardening.

INTRODUCTION

The presence of informal activities has been a longstanding aspect of urban life, occupying vacant areas within cities worldwide. Such activities related to informal occupation often repurpose urban spaces and introduce new functions. Inhabitants engage in these practices, surpassing the boundaries set by formal strategies in terms of occupation, urban design, planning, and construction.

The term "informal" is often understood as the opposite of "formal" (Huchzermeyer, 2011). Debates on informality in cities focus mainly on two interrelated but often separately addressed aspects:

debates on informal employment and debates on spatial informality. The first refers to economic activities outside regulated markets. Since the 1940s, these activities have been studied from three main approaches. One is technocratic, represented by authors such as Germani (1973), who focus on national modernisation projects and the eradication of the informal sector. Castells (1973), on the other hand, criticises this approach and seeks to dismantle the myth of marginality by analysing the causes of informality with arguments based on dependency theories and Marxist approaches. A more recent stream, represented by De Soto (1989), adopts a dualist approach that sees the informal sector as a source of value that must be integrated into the formal sector in order to promote forms of popular capitalism. Parallel theories have focused on spatial informality, particularly as manifested in the unplanned settlements of Latin America in the 1950s. These theories examine the activities that affect land use, land values, and its physical expansion within developing cities. The studies by Matos Mar (1957) and Turner and Fichter (1972) on such settlements in Peru are examples of this work, viewing informal settlements as the initial stage of an incremental construction process. Other studies have attempted to analyse these human settlements using concepts of self-help and self-construction, as well as different political perspectives. Davis (2006) is considered one of the seminal works in this tradition.

In more recent studies, both aspects have been combined, focusing on urban informality in general as well as the growth of cities in the Global South. In addition to these approaches, primarily academic research has focused on the socialisation and daily life experiences in informal settlements, as well as their capacity to generate forms of resistance and alternative urbanisation. Some examples include the work of Holston (2008) on insurgent citizenship, and the work of Roy and AlSayyad (2004), which incorporates ethnographic and anthropological aspects to study informality as a way of life. In this sense, Gilbert (2004) highlights the challenge of defining informality due to its interconnectedness and relationships with formality. Informal urbanisation can be defined as urban development that occurs outside the established legal frameworks, planned procedures, and regulatory processes of city development, generating uncertainties regarding spatial property. According to Azuela and Tomas (1996), the concept of irregularity is subordinate to the presence of norms. The authors state that "irregularity enters our consciousness at the moment when the State decides to normalise practices previously considered marginal" (Azuela and Tomas, 1996, p. 234).

However, despite the resurgence of interest in community gardening in the United States driven by growing attention to issues of health and urban food systems, the topic of informal gardening has received limited formal recognition and attention at the governmental level, particularly in the Global South. Urban gardens are multifaceted spaces that foster creativity, activity, and a sense of identity and belonging within a specific environmental context (Crouch and Wiltshire, 2005). Contemporary theory suggests that the positioning of gardens relative to other green spaces is a crucial characteristic. Atkinson (2007) posits that the garden has arisen as a preferred spatial type over the park, which can be understood by examining the divergent modes of production associated with these spaces. Specifically, the notion of a "garden" implies both a productive activity and a physical entity, whereas a "park" is an object that people primarily engage with as consumers.

There are various reasons behind the emergence of new gardening initiatives. Each region and country have its own unique context, and the social actors involved approach their projects from their own distinct concerns. However, there are some recurring urban and social processes that can be observed.

One key factor is the link between the crisis and the rise of urban gardens. This can be seen in the case of the community gardens that appeared in New York City during the oil and financial crises of the 1970s (Matesanz Ventura, 2018). A grassroots movement led by a group of artists and activists called the Green Guerrillas was inspired by concerns related to human well-being, community building, and the improvement of everyday living spaces in neighbourhoods (Eizenberg, 2012). These community gardens and urban farms served as models that were later replicated in the UK and the Netherlands, where counterculture and environmentalism also played a role (McKay, 2011). Additionally, in this period, some European countries also saw people's demands for greater participation in urban development decision-making, as well as dissatisfaction with the traditional planning system (Cabral and Weiland, 2016).

Informal gardening refers to gardening without official permission, on property that belongs to someone else, typically a municipal authority. As noted by Hou (2014), the informal nature of community gardens has been both an asset and a challenge for community gardeners and their supporters. On the positive side, the informal and open-ended character of these spaces allows communities to transform underutilised urban areas into productive landscapes at relatively low cost. It may enhance the built environment in situations where the civil society perceives the government and other development actors to be falling short. Community gardens have enabled residents to organise and take collective action to address issues such as neighbourhood improvement, safety, food production, and the need for green spaces and social gathering places. Informal urban practices, therefore, have far-reaching implications for both local communities and broader urban policies (Douglas, 2014). However, the perception of community gardens as temporary or interim uses, coupled with a lack of institutional and legal support, often leaves them vulnerable to displacement or eradication. The informal status of these spaces can put them at risk, despite the important roles they play for local communities. Contemporary urban theory suggests that it is crucial for urban planning to support and accommodate informal gardening practices. This is because no future scenarios for the development of urban gardens can be adequately planned, controlled, or predicted without a proper understanding of these community-driven initiatives.

As a spatial practice, urban gardening in the public serves to build social capital, assert the right to the city, and catalyse community capacity building in the context of neighbourhood improvement (Chase, Crawford and Kaliski, 2008; Lydon and García, 2015; Hou, 2020). While studies of urban morphology have mainly focused on the typology of buildings, the space between buildings, i.e., public space, has received much less attention (Han, Xu and Wang, 2014), with some exceptions such as studies by Conzen (1960), Jacobs (1967), Hertzberger (1991), Caniggia and Maffei (2001) or Gehl (2011). A certain consensus has been reached on the formal and spatial character of public space typologies. However, research has mainly focused on formal public spaces that are within the scope of official planning, such as parks and squares.

Urban morphology deals with the knowledge of the logic of form, in this case, the urban form. As an established field of study, urban morphology focuses on urban forms by examining the patterns of the constituent parts, as well as the agents and processes that influence their transformation. It also addresses the historical influences, such as spatial organisations, principles, components, relationships, structure, and configuration of physical elements at different levels of resolution (Moudon, 1997). This approach is addressed across multiple disciplines and focuses on observing the physical characteristics, structure, relationships, and transformations of objects and their constituent

elements. There is no common definition of urban morphology, and the research of the International Seminar on Urban Form (ISUF) has been heavily influenced by three main schools of thought: the Italian typological process structured around the work of Muratori et al. (1963) and Caniggia and Maffei (2001), the British historical-geographical approach consolidated by Conzen (1960), and the mathematically-oriented space syntax of Hillier and Hanson (1984).

The typomorphological approach of the Italian School, as developed by Muratori and Caniggia in the early-to-mid 20th century (Cataldi, Maffei and Vaccaro, 2002), is the most relevant for this study. This method involves exploring the physical and spatial structures of cities, which are both typological and morphological, describing urban form (morphology) through detailed classifications of buildings and open spaces by type (typology). The Italian School's approach involved empirically observing the forms and productive processes of urban habitats at multiple scales, including urban circulation, building layout, land subdivision, infrastructure, and building typologies. In this way, the different types of urban fabric were considered the results of various economic, social, cultural, and political factors (Maretto, 2013).

The examination of morphological characteristics in informal urban areas has primarily focused on informal settlements, from a global perspective and based on certain spatial criteria. Over the past few decades, researchers such as Dovey and King (2011), Dovey (2012), Kamalipour (2016), and Jones (2019) have highlighted how the study of informal urban forms can greatly contribute to the understanding of key and emerging urban processes. These studies help explain how informal settlements emerge within the spatial morphology of the city and how perceptions of informality develop within the discursive realm of public space and urban life. Dovey and King (2011) argued that informal settlements have a formal morphological structure, but exhibit differences in their interactions with the formal city, as well as in their topography, climate, culture, materials, economics, and politics. Suhartini and Jones (2020) defined rules as principles that contribute to the existing spatial order, distinguishing between defined norms and implicit norms, such as accepted protocols and unspoken conventions. These rules emerge through processes of self-organisation and coexist, as well as co-evolve, with modern and traditional rules as the settlement grows. Despite the significant progress in the field of spatial forms of urban informalities, none of these studies have specifically focused on the form of public spaces or the informal urban gardens themselves.

Based on a case study of three neighbourhoods in Piura, Peru, this research explores patterns of form, accessibility, and visual interaction for urban gardening. The study aims to reveal similarities and particularities in the configuration of individual objects, analysing equipment, materials, and the structural environment.

METHOD

This research is part of a broader investigation into the morphogenesis of informal public spaces. It encompasses the identification of spatial characteristics found in informal urban gardens in three residential neighbourhoods of Piura, Peru.

Side selection

Piura is the fifth largest city in Peru. In different phases since the 1960s, the urban form has experienced growth driven by the need for housing and the occupation of urban land (through

invasions or illegal land markets) which, combined with the use of various mechanisms established by law, give the actor a certain legality (e.g., obtaining a certificate of possession or being registered) (Calderón Cockburn, 2019). This process is not recognised by official planning, but is considered as a marginal urbanisation process. Another aspect is the informal occupation and use of public space. Neighbours look after the few existing parks with their own resources and add elements such as benches or vegetation or suitable abandoned and empty spaces. What emerges from the analysis is the need for the community to build meeting and recreational spaces, aspects that, historically, have not been considered for the consolidation of public space.

Three initiatives of informal urban gardens, products of residents' involvement in three different neighbourhoods were selected (Figure 1): (1) AH Santa Rosa, Parque San Judas Tadeo Sector 5B, (2) Urb. Santa María del Pinar, Parque Las Fresas, (3) AH Túpac Amaru III, Humedales Santa Julia.

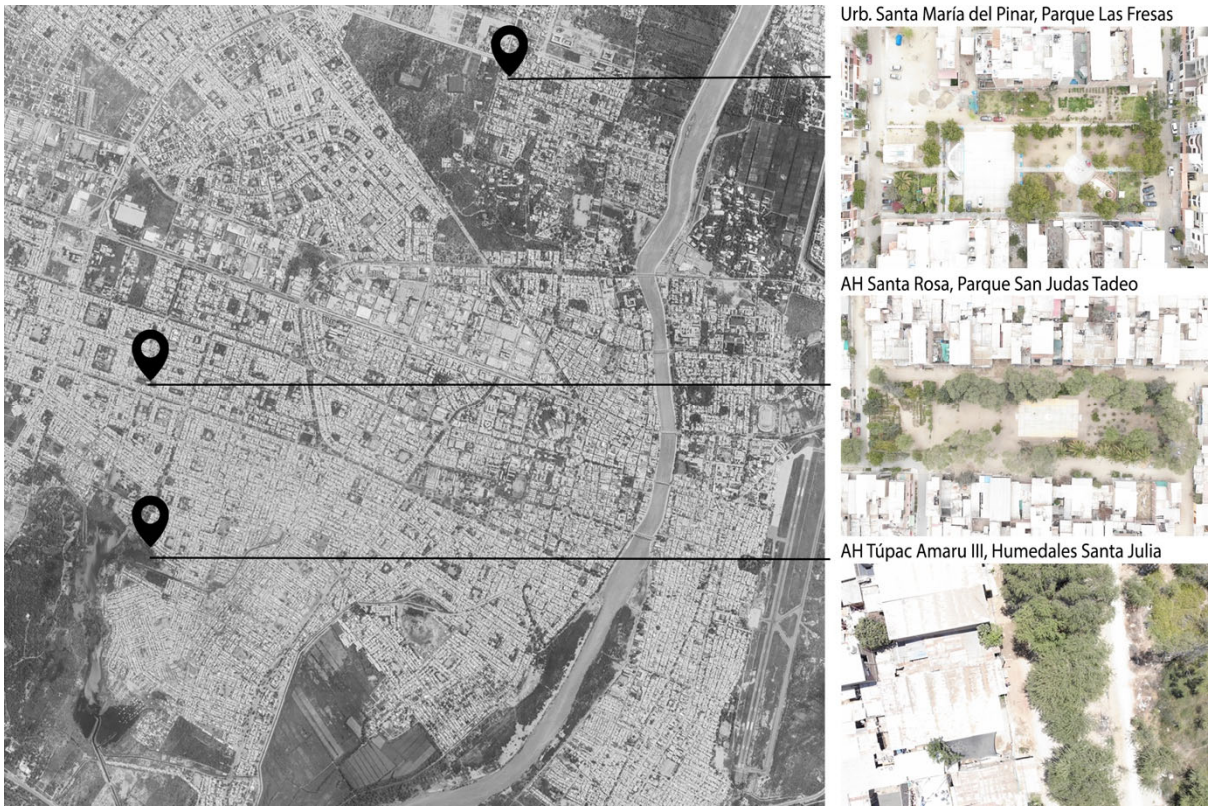

Figure 1. Location and aerial photo of the three case studies in the city.

The criteria for selecting these communities followed three principles: (1) the presence of a neighbourhood-initiated informal gardening initiative, which was confirmed by pre-exploration fieldwork; (2) a different composition of residents living in each of the selected initiative neighbourhoods, in relation to their socio-economic status; (3) the location in a relatively central part of the city, where urban gardens are less common, as opposed to the outer suburbs. Furthermore, it is worth mentioning that the three neighbourhoods of the initiatives show very different characteristics in terms of the years of construction of the buildings within the urbanisation process of the city and include neighbourhoods built in different decades of the last 60 years. Furthermore, there are differences with respect to the origin of the neighbourhood, whether it followed official standards or is part of land occupation with neighbourhood or informal characteristics, and its level

of consolidation. The table 1 shows the main characteristics of each neighbourhood where the urban gardens are located.

Table 1. Information about each neighbourhood with urban gardens analysed in this study

	Urb. Santa María del Pinar	**AH Santa Rosa**	**AH Tupas Amaru III**
Urban growth	1983-2000	Before 1962	1975-1990
Urban density (Inhabit. /block)	181	237	254
Consolidation state	Asphalt street & pavement	Mainly asphalt street & pavement	Mainly only asphalt pavement
Household income	High	Medium / medium high	Medium low
Origin of neighbourhood	State planning	Formalised neighbourhood	Informal / Formalised neighbourhood

Data collection

Using a qualitative approach, the spatial characteristics are considered as an analytical key to interpret the connections between the elements that make up a space. These observations include data gathering, mapping, sketches of the gardens, as well as aerial photographs as a complementary method. Through graphic representations of floor plans, the results demonstrate the physical appearance of the gardens and their relation to the built environment.

Based on observations, a table was used that included a set of categories derived from these: 1) size, 2) equipment, 3) material and 4) comments. In terms of equipment, the parameters included recreational elements that referred to games installed in the space, furniture such as benches and tables, shade that referred to facilities that provided protection from the weather, sports elements such as exercise equipment; as well as cultural elements such as religious elements with local relevance or constructions such as cabins or workshops, for example. In addition, it was documented whether the space has trees or green areas. The most available, cheapest, most intelligible and most appropriate materials of today are those with which informal spaces are constructed. Referring to Coxito (2014) these materials are: hidden materials, industrial materials or recycled materials. In addition, the option of natural materials from the area such as bamboo or reeds and vegetation is added. It is important to note that it was allowed to tick more than one option in each category.

RESULTS

Initial observations revealed a logic in the production of informal urban gardens in Piura's neighbourhoods. In the three initiatives, it was possible to map 36 gardens (Urb. Santa María del Pinar: 7 AH Santa Rosa: 19 y AH Tupac Amaru III: 10) generated with varied uses, methods of execution, activities, and elements. These spaces differ in size, level of development, availability of green areas, facilities, and furniture. However, some similarities can be observed in both similar equipment and use. Table 2 shows the information collected.

Table 2. Information collected on mapped spaces.

	Size			Equipment								Materials			
	< 20m2	m2	> 100m2	Playground elements	Furniture	Shadow	Sports equipment	Cultural elements	Shelters	Tress	Grass / Flowers	Hidden	Industrial	Recycled	Natural
C.	4	22	10	3	24	12	2	2	5	29	36	12	7	16	31
%	11%	61%	28%	8%	67%	33%	6%	6%	14%	81%	100%	33%	19%	86%	97%

The informal gardens are located in spaces that, according to the urban development plan, are considered recreational areas (parks) or natural spaces. It was observed that the gardens tend to have sizes ranging from 10 to 200 m2. The width depends on the available space and can vary, however, the length is oriented to the length of the lots, as shown in Figure 2. People tend to use an area on the site opposite their house.

Figure 2. Distribution of informal gardens in the three case studies.

Many spaces are delineated by fences, and the materials used in these places have included wood, bamboo, and recycled materials such as corrugated metal sheets or tires. Other spaces show a clear delimitation through vegetation, such as natural hedges or living fences. In some cases, the space is closed off with a lock, making it more private, for reasons that vary (private use, plant protection, or protection against animals). The ground material is soil, but with vegetation such as vegetables and fruits.

The gardens have an internal organisation with separate zones for different types of plants, such as a vegetable garden area and a flower area. Figures 3, 4, and 5 provide plant layout drawings of exemplary cases from the three initiatives.

Figure 3. Exemplary plant layout drawings, Urb. Santa María del Pinar, Parque Las Fresas.

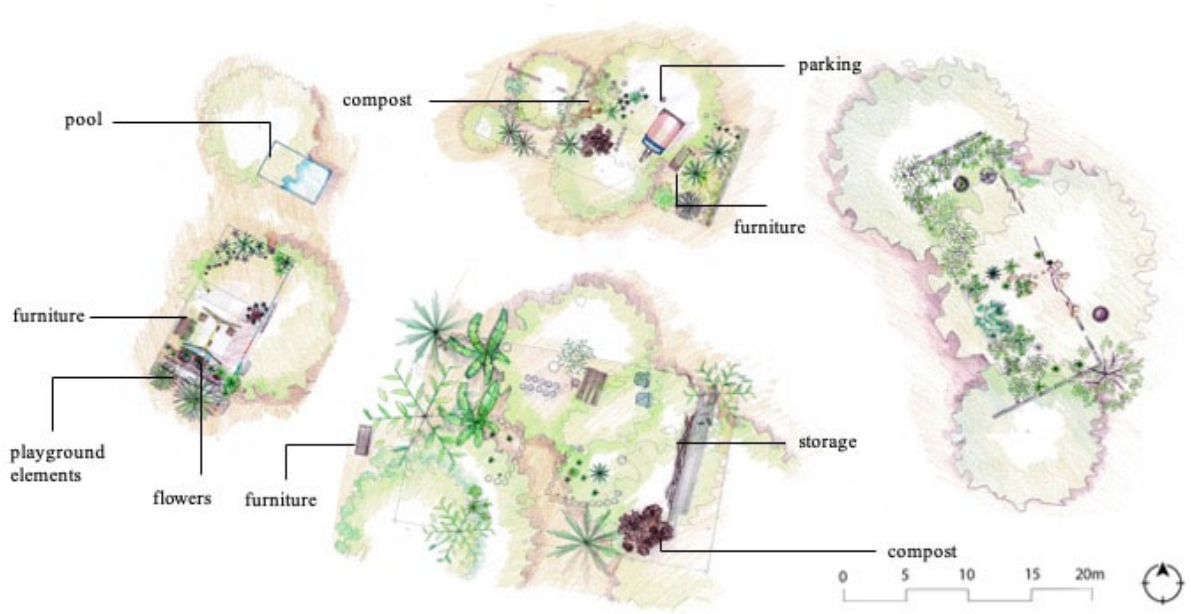

Figure 4. Exemplary plant layout drawings, AH Santa Rosa, Parque San Judas Tadeo Sector 5B.

All these spaces share an abundant presence of plants distributed throughout the surface. Trees provide shade in all the examples. The vegetation varies from decorative flowers to productive plants such as corn, squash, tomatoes, or fruit trees. The differences between the gardens and the surrounding neighbourhood are quite interesting. Spaces located in formal urban development's often have grass on the ground and decorative plants, such as flowers. In the spaces of formalised settlements, there are more fruit trees and vegetables, generally within the space. Some examples include a composting area surrounded by vegetation. Generally, the taller plants and shrubs are found at the boundaries of the space to delineate it, while the smaller plants, vegetables, and herbaceous

plants are protected within the space. Regarding water infrastructure, only one of the spaces has its own water connection, while water from the houses is usually used for the maintenance of the spaces.

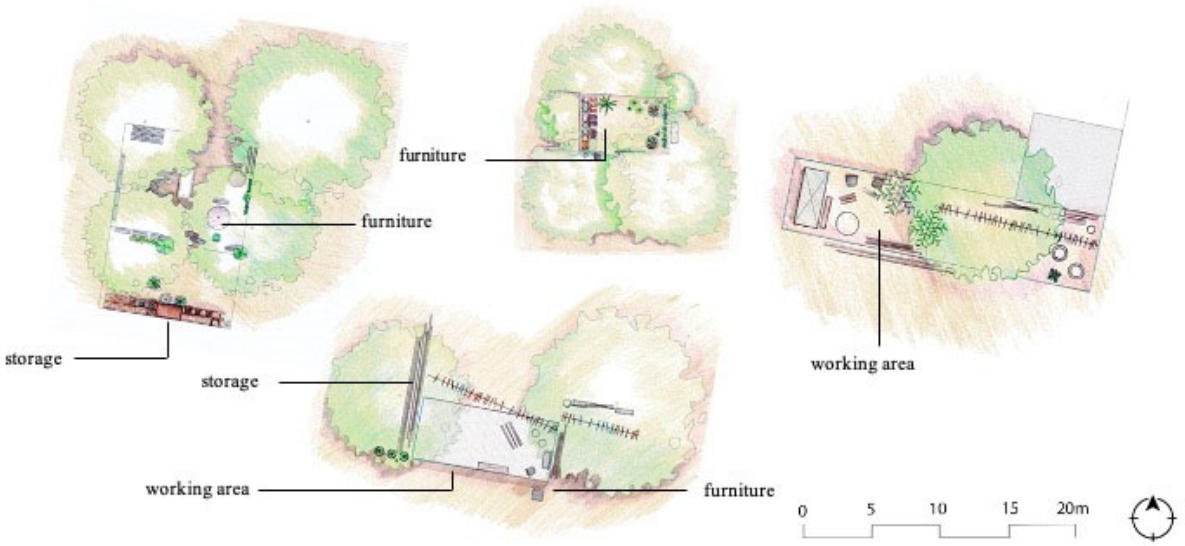

Figure 5. Exemplary plant layout drawings, AH Túpac Amaru III, Humedales Santa Julia.

Many of these spaces have furniture such as benches, chairs, or tables. The furniture is often strategically placed, in the shade of the trees or under a structure that provides shade. People use these spaces to sit, relax in the evenings, or have family gatherings on weekends. The type and conditions of furniture varies by neighbourhood, with Hollywood swings or garden furniture sets being more common in formal urban developments, while in the formalised neighbourhoods, recycled or old furniture is used. Additionally, old elements integrated into the space, such as play equipment like swings or metal climbers, now serve other functions.

Although the primary activity in all the examples is gardening, many of them also have benches, chairs, and tables. The spaces are sometimes equipped with small additional structures, such as sheds or storage units. The functions depend on local needs, but they are mainly related to workshops like carpentry. Additional functions are added, such as car parking or private uses. The parking is generally located in a central part of the space, either using the main access or providing a rear access. Furthermore, people use the space for functions that cannot be accommodated inside the house due to lack of space, such as washing and drying clothes. Some parts of the space are used as storage for construction materials. Materials such as wood, bamboo, old furniture, and industrial materials are stored in a part of the space, in some cases in the back or by separating a corner for this purpose.

Characteristic data about the typology and size of plots, plants etc. may be seen in Table 3.

Table 3. Data about urban gardens in the three selected sites.

Location	**Parque Las Fresas** **Urb. Santa María del Pinar**	**Parque San Judas Tadeo** **AH Santa Rosa**	**Humedales San Julia** **AH Tupac Amaru III**
Surface area total	3.500m2	6.000m2	1.500m2
Date of establishment	2014	2000	2010
Users	Direct residents	Direct residents	Direct residents

Cultivated plants/crops	Nim, ficus, cypress, papaya, poinciana, croton, aloe vera, coconut palm, bougainvillea, acalypha, hibiscus, rose, elephant's ear	Cactus, aloe vera, carob tree, mango, neem, lemon, corn, banana, coconut palm, soursop, croton, bay laurel, hibiscus, guava, marigold, palm tree, arrowroot	Orange, lemon, papaya, tamarind, aloe vera, mango, guarana, coconut, epazote Almond, soursop, mamey, tangerine, pomegranate, cactus, prickly pear, plantain, guava, carob, chinaberry
Ways of garden usage	Gardening, gatherings, rest	Gardening, sports, picnic, recreation, gatherings, rest, walking pets	Gardening, gatherings, rest
Garden equipment	Water, electricity, benches	Compost, benches, garden fences	Garden fences

DISCUSSION AND CONCLUSIONS

In urban studies, informality is a form of fluid, resilient, and flexible urbanisation that fills the gaps left by the state's incapacity or indifference (Fawaz, 2017; Marx and Kelling, 2019). The three case studies describe how (parts of) public spaces have slowly been transformed into what is described in various ways as a garden. Through the activities of local users, these plots have been transformed into lived spaces.

Informal gardening activities often emerge in response to a lack of community management, neglected public infrastructure, and disregard for residents' living needs, such as personal well-being, social activities, and access to green spaces. These grassroots efforts have become spontaneous expressions of an urban counterculture, aimed at resisting the perceived power of technocratic and bureaucratic planning. This phenomenon demonstrates that inadequate planning principles can result in ad-hoc solutions, negotiation of different interests, and the emergence of innovative forms of "producing" meaningful spaces through everyday life practices. The informal nature of the studied gardens allows them to be temporary, flexible, and adaptable to various social and political contexts, thereby challenging traditional notions of urban development with their hybrid character.

The objective of this work was to explore patterns of form, accessibility, and visual interaction for urban gardening. It aimed to reveal similarities and particularities in the configuration of individual objects, analysing equipment, materials, and the structural environment. Through the representations of these spaces, the results demonstrate the implementation of urban gardening spaces that arise from the population's own initiatives.

The spaces exhibit distinct constellations of activities that are generally rare in the public realm (though not particularly unusual in private spaces), such as gardening, installing benches, painting, grilling, and planting trees. These activities are often restricted to private realms, like backyards (or perhaps allotments). However, in the informal space, all of these activities seem to be "permitted". By analysing the specific elements, materials, and structural configurations of these informal garden areas, the research aimed to uncover both the commonalities and unique features present.

Finally, questions related to urban design and urban gardens are examined. This poses an apparently contradictory challenge: What can we learn from informal production in gardens? Additionally, there is a reflection on how the presented patterns can possibly facilitate future ways of formalisation and/or improvement. However, as observed in the study by He and Zhu (2018), many people remain

opposed to informal community spaces, primarily because they view them as a misuse of public resources and believe that informally transforming the space could diminish their quality of life.

Devlin (2018, p. 4) argues "that for planners to engage with urban informality in a progressive way, they need a conceptual compass undergirded by normative values of inclusiveness and economic and socio-spatial justice." Many cities have unused spaces, such as parking lots, abandoned buildings, or vacant lots. These spaces can be transformed into parks, community gardens, and other types of urban infrastructure. The case studies confirm that urban gardens integrated into the urban fabric and densely populated areas, as well as within the wider green landscape, have the potential to serve a variety of functions, resulting in benefits to the population (UK Green Building Council, 2015). Municipalities and local authorities can embrace and facilitate this type of activity across the city, enabling more residents to participate in informal initiatives and feel empowered to revitalise the urban environment. However, a disconnected sequence of poorly managed green infrastructure elements delivers far fewer public benefits than their potential (European Environment Agency, 2011).

The findings contribute to a deeper understanding of the role that the temporary use of public space can play in urban planning and development strategies. The definition of synergy, ultimately, allows for the interpretation of how informal production in public space - in this case, urban gardens - influences the built environment. The growing acceptance of these practices and recognizing their determinants would, consequently, raise awareness of this concept in the city, along with the adoption of appropriate regulations, which would undoubtedly be of immense relevance in formalised planning systems for greater flexibility and timely change. Design criteria must take into account the dynamics of communities and the identities of citizens, and be flexible enough to adapt to as many variables and conditions as possible over time. There are several possibilities for future research opportunities to build upon the work already done. The most obvious is to continue monitoring the ongoing production of the case study site as it evolves and changes over a longer period.

However, the case study results are inevitably partial. The gardens stand out in contrast to the broader area, which is worth exploring further. This also supports the concern that different approaches must be taken to understand informality in urban gardening in the city context. It is a cross-sectional, multidimensional study, heavily correlated with other aspects of society.

ABSTRACT

The cities that typically inform the international theoretical debate about urban form are in countries of the Global North. Expanding urban morphology to countries of the Global South implies recognizing the structural nature of informality in peripheral cities. Fortaleza, capital of the state of Ceará, is one of the largest and most socially unequal cities in Brazil, with more than 40% of its population living in informal settlements. Since 2009, Fortaleza has designated special zones of social interest (ZEIS), which, when implemented, redefine land use and occupancy parameters to encourage or allow social housing. Although progress has been slow, the city has seen important advances in implementing some of these zones, with data production, planning, and special regulations. Building upon this progress in data production regarding informal areas, this paper aims to comparatively analyze the urban form of three of these zones, located in different parts of the city (central, peripheral, and intermediary). We seek to understand the diversity of occupations and contribute to the discussion on the regulation of informal settlements in Fortaleza. To achieve this, we applied a qualitative methodology that includes a literature review, secondary data collection, and production of relevant georeferenced primary data for morphological analysis, followed by cartographic production using geoprocessing software. The results indicate that the zones' location within the city, and consequently the population's income and land prices, significantly impact their urban form. Additionally, factors such as the urban form of the surroundings and the duration of occupation also play a role. The findings support the idea that informal settlements cannot be seen as homogeneous, especially when developing public policies that impact these territories

Keywords: urban form, informality, ZEIS

INTRODUCTION

The Special Zones of Social Interest (ZEIS) have the potential to foster more inclusive cities by recognizing diverse urban occupations. In Fortaleza, ZEIS were established through the PDPFor after advocacy from local social movements. However, their implementation continues to face challenges (Freitas and Pequeno, 2012). ZEIS Type 1, which is the focus of this project, comprises 45 designated areas characterized by irregular settlements with unplanned occupation. These areas, primarily inhabited by low-income populations, are located in public or private spaces and are considered

precarious in terms of urban and housing conditions, intended for land, urban, and environmental regularization.

Despite some advancements, the implementation of ZEIS has been slow compared to the interests of the real estate market. While distributed across the city, ZEIS are few relative to the numerous precarious settlements. Currently, only 10 ZEIS have developed their Integrated Land Regularization Plans (PIRF), with two others still in the early stages.

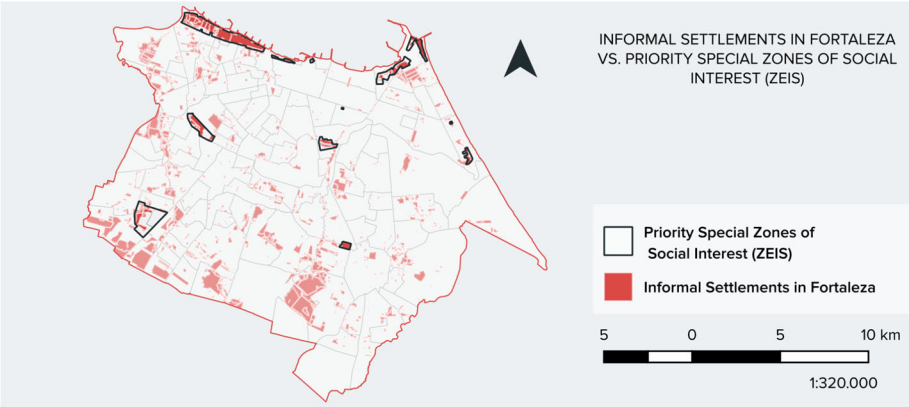

Figure 1. Map of informal settlements versus Priority Special Zones of Social Interest (ZEIS) in Fortaleza, based on the PLHIS-FOR (2013) and ZEIS SEUMA (2018) classifications. Credit: Compiled by the authors (2024).

To assess the potential impact of urban instruments across different territories, it's essential to grasp the specific dynamics of spatial production in each context (Santos, 2008). A thorough understanding of local realities, supported by accurate representation, is indispensable. Investigating these dynamics uncovers the diversity of territorial characteristics, which are often oversimplified by generalizing frameworks, potentially limiting the applicability of these instruments. Therefore, adapting to the unique features of each territory is crucial for effective implementation. Pequeno and Freitas (2012) emphasize this by stating that:

> [...] well-located favelas, equipped with infrastructure and mobility, tend to be more densely and intensely occupied, in order to supplement income, even as a resistance strategy by their residents to remain in the area. On the other hand, areas that are more distant and in precarious conditions have larger areas, fewer people per domestic unit and, consequently, a larger area per inhabitant (Pequeno and Freitas, 2012: 45, own translation).

Figure 2. Map of the selected ZEIS in Fortaleza—one central, one peripheral, and one intermediate—illustrating informal settlements per PLHIS-FOR (2016) and ZEIS SEUMA (2018). Credit: Compiled by the authors 2024.

Urban morphology is a vital tool for analyzing urban differences, providing a framework for interpreting cities as physical constructs. Although traditionally focused on historic European cities, this approach is increasingly relevant for cities in the Global South, revealing both commonalities and unique features. This research conducts a morphological analysis of three priority ZEIS in Fortaleza—Bom Jardim, Mucuripe, and Lagamar—each exhibiting distinct spatial characteristics. Bom Jardim, situated in the southwestern periphery, contrasts with Mucuripe, closer to the urban core, while Lagamar is smaller yet densely populated and centrally located. By comparing these areas, the study aims to explore the diversity of occupations and contribute to discussions on regulating these zones, enhancing our understanding of urban space production within Fortaleza's ZEIS.

The research employs an exploratory, qualitative approach. The first phase establishes a theoretical foundation on urban morphology and informal settlements through extensive bibliographic research. The second phase involves collecting georeferenced data for morphological analysis, which will be used for cartographic outputs and geospatial analysis using QGIS software.

LITERATURE REVIEW

Urban Morphology

Morphology is the study of form. Lamas (2010) defines it as the science that examines the structure and configuration of objects, considering the forces that shape them. In urban contexts, urban morphology focuses on the physical structure of cities and the historical and social processes behind their development. Lamas emphasizes the interdisciplinary nature of this field, which is crucial for understanding and planning urban environments. This analysis provides key insights into urban space development (Del Rio, 2000).

Moudon (2017) outlines three core principles of morphological analysis: form, scale, and time. This framework examines the distribution of buildings, roads, and public and private spaces, along with the social and economic relationships within these contexts.

In urban design, this approach serves as a crucial analytical tool, enabling the identification of principles, patterns, and typologies that inform future city interventions (Del Rio, 2000). Lamas (2010) emphasizes the close relationship between urban form and city design:

> At this point, urban form can be defined as: an aspect of reality, or the way in which the morphological elements that make up and define urban space are organized, in relation to the materialization of functional and quantitative organizational aspects and qualitative and figurative aspects. Form, being the ultimate goal of all design, is in connection with “drawing”, that is, with lines, spaces, volumes, geometry, planes and colors, in order to define a mode of use and figurative communication that constitutes the architectures of the city. (Lamas, 2010: 44).

To effectively interpret urban form, it is essential to investigate its fundamental components. Rego and Meneghetti (2011) emphasize that the city can be "read" and analyzed through its physical structure, and researchers agree that morphological analysis should focus on the basic elements of urban form.

Panerai (2006) defines "urban fabric" as the intricate interactions among blocks, streets, buildings, and public spaces that shape cities, identifying the road network, land parcels, and buildings as its core components. Lamas (2010) further categorizes urban form into three dimensions: sectorial, urban, and territorial. The sectorial dimension includes elements like façades and vegetation; the urban dimension focuses on neighborhood structures such as streets and parks; and the territorial dimension examines urban form at a larger scale, including transportation networks and geographic zones.

Historically, three main schools of urban morphology have emerged: the English School, led by Conzen (n.d.), emphasizing cognitive understanding; the Italian School, shaped by Muratori and Caniggia (n.d.), focusing on typological analysis; and the French School, influenced by Lefebvre and Chastel (n.d.), which adopts a critical perspective on urban life (Moudon and Oliveira, 2017). Research in Global South cities highlights the relevance of these methods, though local challenges, such as informal settlements, must be considered. Santos (2023) points out that formal cities adhere to planned infrastructure, while informal cities develop spontaneously.

To enrich this analysis, four key studies on urban form were selected: two examining urban settlements broadly and two focusing specifically on the typomorphological development of informal settlements.

Urban morphology applications

In Urban Morphology in Planning Practice: Towards an Integrated Methodology for City Analysis and Proposal, Ana Cláudia Monteiro (2020) introduces the Methodology for Analysis and Proposal (MAP), focusing on Porto's urban form by integrating various morphological perspectives into urban planning. She compares three approaches—historical-geographical, typological process, and space syntax—examining elements such as scale, representation, and results to identify convergences and divergences in morphological regions and typological processes.

Rosaneli (2009) applies Conzen's theory to Brazil's coffee frontier in Urban Morphology as a Methodological Approach to the Study of the Form and Landscape of Urban Settlements. Her analysis focuses on the urban project and the detailed morphology of plots, blocks, streets, and public spaces, revealing patterns in public and private domains through block geometry and plot orientation.

Fabiana Izaga et al. (2022; 2023) conduct a typomorphological analysis of informal housing in Rio de Janeiro's Planning Area 3 (AP3). In Typomorphology of Favelas, they examine transformations in

communities like Morro do Céu and Vila N. Sra. da Glória, categorizing favelas based on Panerai's (2006) urban fabric elements—road networks, land parcels, and buildings—into four types: enclave, line, block, and grid, linking urbanization processes to changes in urban form over time.

Farias (2019) explores factors influencing urban form in favelas, particularly Rocinha, Rio de Janeiro. She references Santos's (1985) concept of urban morphology, viewing it as shaped by land use and spatial organization, along with Kostof's (1991) Configuration Factors, which emphasize patterns, topography, and types of expansion.

Based on these studies, a morphological analysis methodology for the ZEIS was developed, integrating elements from each reference to establish categories for analysis. The following section outlines these categories and their contributions to understanding urban form

METHODOLOGY: CATEGORIES OF MORPHOLOGICAL ANALYSIS

The following methodology is primarily based on the analyses of Monteiro (2020) and Farias (2019), who employed summary matrices to compile and compare various morphological approaches. The analysis will focus on the following categories: (1) Location within the city; (2) Road system; (3) Land division (including blocks, plots, and open spaces); (4) Buildings; and (5) Typomorphology.

Table 1. Summary of Morphological Approaches. Credit: Compiled by the authors (2024).

CATEGORY	DESCRIPTION	AUTHORS
Location In The City	Proximity to the urban center has a certain influence on the development and infrastructure of peripheral spaces.	Santos (1985), Panerai (2006), Farias (2019)
Street System	Road networks can connect and limit urban spaces, influencing circulation and accessibility.	Lamas (2010), Panerai (2006), Moudon (2017), Conzen (2009), Rosanelli (2009), Izaga Et Al (2022, 2023), Farias (2019)
Land Subdivision (Blocks, Plots, And Open Spaces)	The organization of plots, blocks, and open spaces helps to understand the urban structure and its transformations over time.	Panerai (2006), Moudon (2017), Conzen (2009), Rosanelli (2009), Farias (2019)
Buildings	Physical elements such as height, shape, and use of buildings can shape the urban landscape and influence city functionality.	Panerai (2006), Moudon (2017), Conzen (2009), Monteiro (2020), Farias (2019)
Typomorphology	Classification of urban typologies such as enclaves, line, block, and grid for understanding spatial configuration and organization of the urban fabric.	Panerai (2016), Izaga Et Al (2022, 2023)

Santos (1985) explores the center-periphery dynamic, noting that city centers concentrate economic activity, while peripheral areas often lack infrastructure. Panerai (2006) adds that urban elements influence growth based on their location and the city's development stage, particularly focusing on Fortaleza's Bairro Centro, its oldest and densest area, while considering natural features like topography and hydrography.

Lamas (2010) emphasizes the critical role of the road system in shaping urban spaces, a perspective supported by Panerai (2006), Moudon (2017), and Rosanelli (2009), who highlight its hierarchical structure and impact on circulation. Izaga et al. (2022, 2023) and Farias (2019) further stress the importance of roads as connectors between formal and informal areas.

Panerai (2006) also views land subdivision—plots, blocks, and open spaces—as essential for understanding urban form. Moudon (2017) and Conzen (2009) discuss how land division shapes urban evolution, while Farias (2019) links land parceling in favelas to power dynamics.

Buildings play a vital role in the urban fabric, affecting both perception and functionality (Panerai 2006; Moudon 2017). Monteiro (2020) analyzes building characteristics to identify urban patterns, while Farias (2019) considers building height an indicator of urban consolidation in informal areas. Izaga et al. (2022, 2023) focus on typomorphology to understand favela growth, classifying ZEIS typologies as enclaves, lines, blocks, or grids, reflecting various stages of urban development influenced by topography.

Table 2. Morphological categories. Credit: Compiled by the authors.(2024)

CATEGORY	DESCRIPTION	REFERENCE
Enclave	Space Included In A Larger Territory With Divergent Characteristics, Not Easily Accessible Or Isolated, Usually With A Main Entrance.	
Line	Growth Around A Linear Urban Infrastructure, Such As Rivers, Walls, Or Roads, With A Rectangular And Linear Form.	
Block	Space Delimited By Streets, Understood As A Block Intended For Building Or Open Space.	Grid	A Set Of At Least Three Blocks, With Both Regular And Organic Sections, Over A Variable Terrain.	

Note: Enclave is an isolated area (Morro do Teixeira, ZEIS Mucuripe); Line shows growth along infrastructure (Sapori, ZEIS Mucuripe); Block represents street-defined spaces (Rei do Gado, ZEIS Bom Jardim); Grid consists of interconnected blocks (Lagamar, ZEIS Lagamar).

In view of the above, the categories defined will be submitted to the three selected ZEIS: Bom Jardim, Mucuripe and Lagamar, in order to carry out the analysis and draw a comparative pattern.

RESULTS AND DISCUSSIONS

The Bom Jardim ZEIS spans 285.68 hectares across the Bom Jardim and part of the Siqueira neighborhoods in southwest Fortaleza. This peripheral area has a lower Human Development Index (HDI) and income levels, along with limited infrastructure coverage (Costa Lima, 2017). It is situated approximately 12-15 kilometers from the city center, translating to a travel time of 30 to 45 minutes by car. In contrast, the Mucuripe ZEIS covers 84 hectares in the northeastern part of the city, encompassing the Varjota, Mucuripe, Vicente Pinzon, and Cais do Porto neighborhoods. This highly sought-after area is close to the waterfront, located just 6 to 10 kilometers from the city center, allowing for a travel time of about 25 minutes by car. Lastly, the Lagamar ZEIS, the smallest at 48.42 hectares, is situated between the São João do Tauape and Alto da Balança neighborhoods, approximately 5 kilometers from the city center.

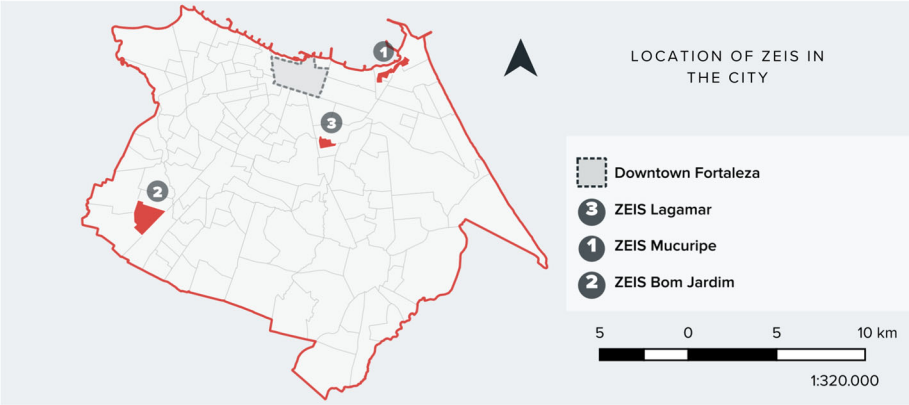

Figure 3. Location of the Bom Jardim, Mucuripe, and Lagamar ZEIS in the city. Credit: Compiled by the authors based on data from SEUMA (2018).

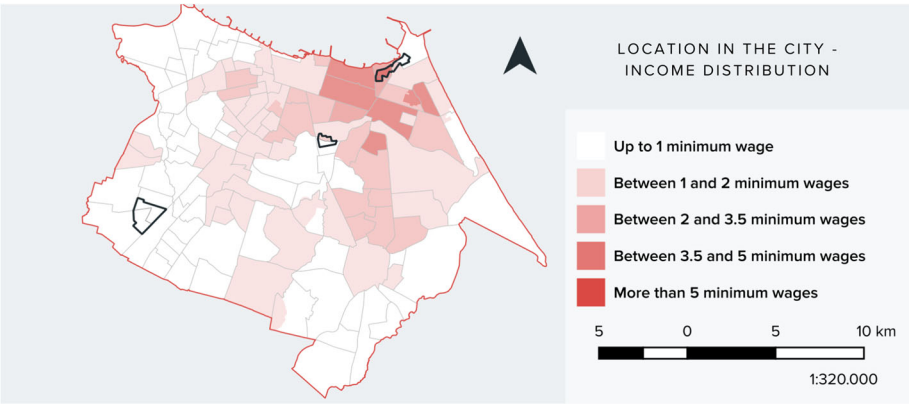

Figure 4. Location of the Bom Jardim, Mucuripe, and Lagamar ZEIS along with income distribution. Credit: Compiled by the authors based on data from SEUMA (2018) for ZEIS and PLHIS (2013) for settlements, and IBGE (2010) for income distribution.

The Mucuripe ZEIS (Figure 5) has 8 precarious settlements: (1) Castelo Encantador, (2) João Arruda, (3) Praça do Coqueiro, (4) Rua João Arruda, (5) Santa Edwirges, (6) Saporé, and (7) Terramar. These settlements vary in size, with the largest located in the eastern part of the territory. The Maceió stream crosses the area and meets the sea. The Bom Jardim ZEIS (Figure 5) has 15 precarious settlements within its territory. They are: (1) Comunidade Canal Leste, (2) Comunidade Parque Santo Amaro, (3) Irmã Dulce, (4) Veneza/Daniel Batista, (5) Rua General Rabelo, (6) Rua Cesarina Batista, (7) Rua Alexandra, (8) Rei do Gado, (9) Travessa Itú, (10) Favela Pantanal/Nova Friburgo, (11) Ocupação

da Paz, (12) Marrocos/Invasão Urucutuba, (13) Mutirão da Urucutuba, (14) Rua Francisco Machado, and (15) Rua Indiara. It is noteworthy that most of these settlements are located along the water resources of the Maranguapinho River, indicating a level of environmental fragility in the occupation. The Lagamar ZEIS (Figure 5) has two precarious settlements: Lagamar (1) and Santo Expedito (2). Lagamar is significantly larger than Santo Expedito.

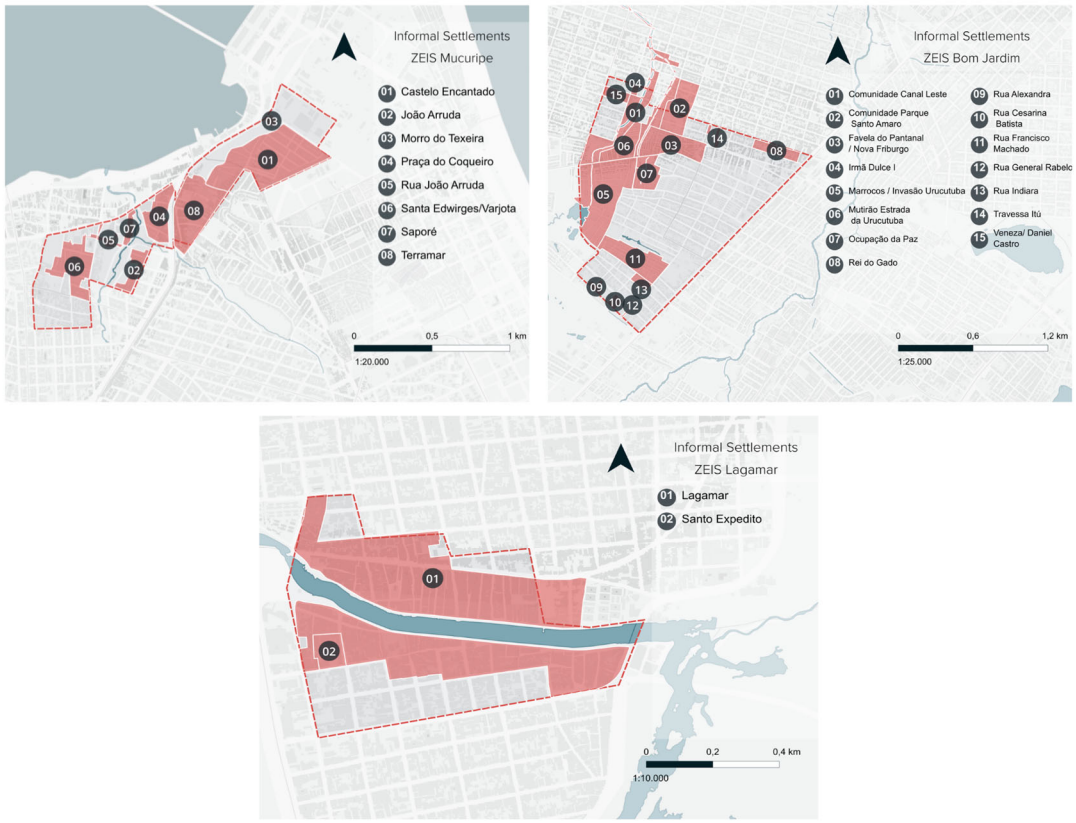

Figure 5. Map illustrating the precarious settlements within the ZEIS of Bom Jardim (right), Mucuripe (left), and Lagamar (below). Compiled by the authors based on data from PLHIS (2013) for settlements and SEUMA (2018) for ZEIS boundaries.

In the Bom Jardim ZEIS (Figure 6), most settlements are located in lower areas where water resources are concentrated, putting them at risk of flooding. In contrast, the Mucuripe ZEIS (Figure 6) features settlements along its length, with a significant portion occupying higher regions characterized by steep slopes. This illustrates a clear relationship between the concentration of settlements and areas with low real estate interest. In the Lagamar ZEIS (Figure 6), the terrain shows relative uniformity around water resources, where smoother contour lines indicate areas with less slope.

The street system (Figure 7) in each ZEIS presents its own challenges. The older settlements of Mucuripe and Lagamar have a more consolidated street network, but with irregular layouts due to the informal nature of the occupations that started in the 1930s. Meanwhile, Bom Jardim, with its more recent occupation, shows a more fragmented and less planned street system, contributing to the area's accessibility issues and the disconnection from the formal urban grid.

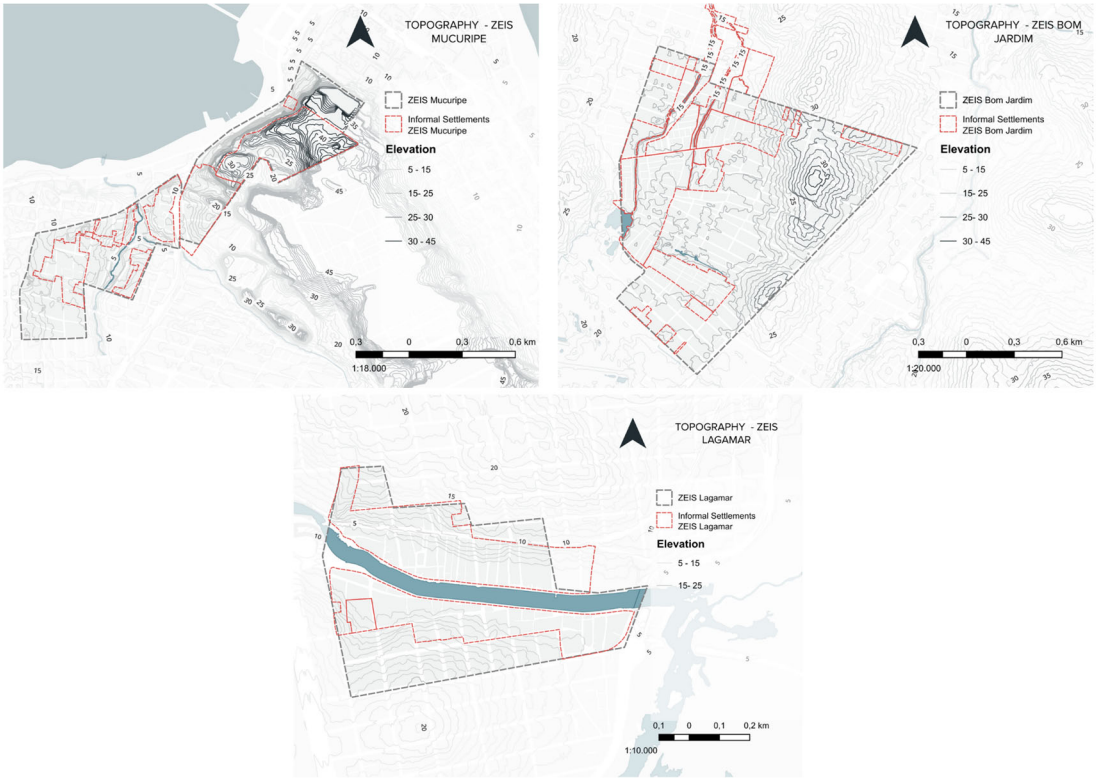

Figure 6. Map illustrating the topography of the Mucuripe ZEIS (left), along with the Bom Jardim ZEIS (right) and Lagamar ZEIS (below). Compiled by the authors based on data from SEFIN (2016).

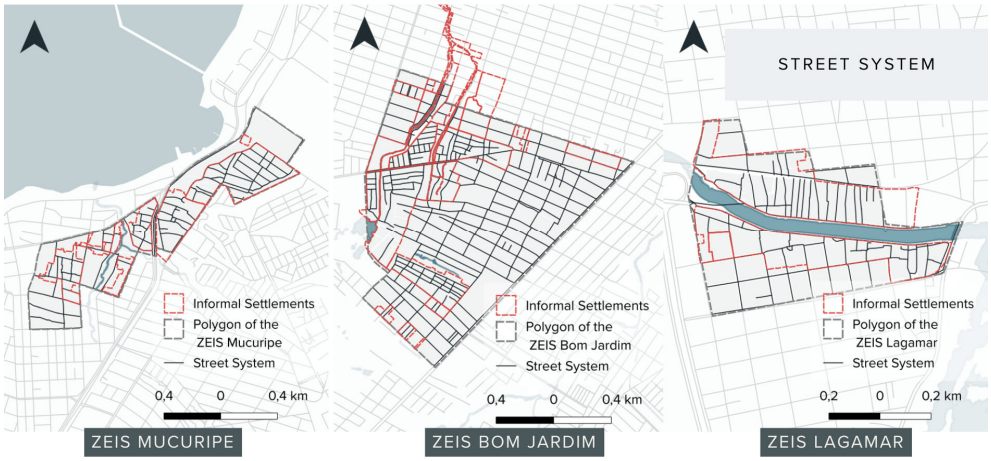

Figure 7. Map showing the street system. Compiled by the authors based on data from SEFIN (2016).

The differences in building occupancy among the three ZEIS significantly impact their composition (Figure 8). The Mucuripe and Lagamar ZEIS, which date back to the city's first informal settlements in the 1930s, exhibit a higher density of buildings. Notably, Mucuripe still contains large vacant areas, primarily walled plots resulting from real estate speculation. In contrast, the Bom Jardim ZEIS, with informal occupations emerging more recently in the 1990s and 2000s, features a sparser built environment characterized by larger backyards.

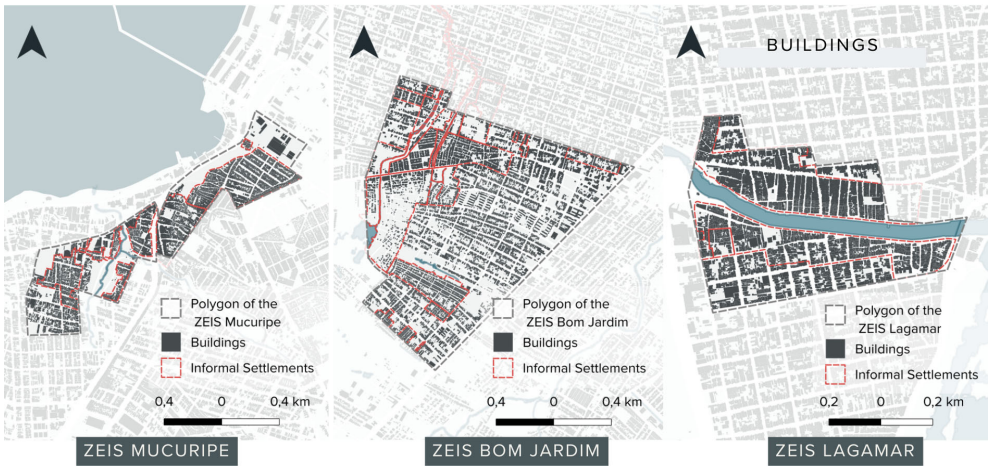

Figure 8. Map showing the buildings. Credit: Compiled by the authors based on data from SEFIN (2016).

An analysis of solids and voids reveals distinct patterns across the three ZEIS. Bom Jardim has densely built-up areas interspersed with significant urban voids, while the Novas Canudos and Pantanal communities are almost entirely developed. Mucuripe, in comparison, has a greater density than Bom Jardim, reflecting its historical context. The analyzed settlements in Mucuripe include Castelo Encantado, Santa Edwiges, and Saporé. Although the plots in Castelo Encantado are irregular, they maintain a cohesive layout. In contrast, Santa Edwiges and Saporé feature more haphazard plots, with some located far from the formal road network, leading to poor access.

In Bom Jardim, open areas are limited to two small squares and one green space, highlighting a significant lack of public leisure facilities (Figure 9). In contrast, the Mucuripe ZEIS offers more options, enhanced by the Maceió stream and Otacílio Teixeira Lima Neto Park (Bisão). The Lagamar ZEIS similarly suffers from a scarcity of free spaces, with its largest water resource lacking infrastructure for quality use.

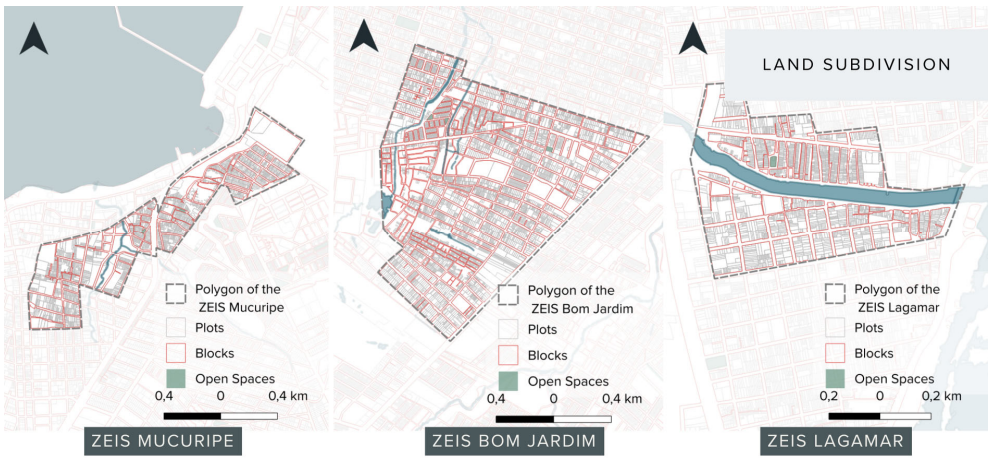

Figure 9. Map showing the land subdivision. Credit: Compiled by the authors based on data from URBFOR (2019) for green areas and SEFIN (2023) for lots and blocks.

The analysis of plots (Figure 9) highlights the complexity of the urban fabric, revealing significant diversity in sizes and shapes across the ZEIS. This contrasts the urban form of precarious settlements with the formal fabric of the city. Three settlements from each ZEIS were selected for closer examination: in Bom Jardim, Marrocos, Ocupação da Paz, and Mutirão da Urucutuba. Among these, Mutirão da Urucutuba, a housing complex, features more regular and orderly plots, while Marrocos

and Ocupação da Paz predominantly consist of irregular plots with notable variations in area and shape. Overall, the ZEIS displays a wide range of plot formats, yet a degree of regularity persists within the settlements, even if they do not conform to the surrounding formal fabric.

Figure 10. Map showing the building height . Credit: Compiled by the authors based on data from SEFIN (2016).

Regarding height (Figure 10), the Mucuripe ZEIS showcases taller buildings compared to Bom Jardim. However, these taller structures are not part of the precarious settlements, which, like those in Bom Jardim, primarily exhibit horizontal development. Similarly, the Lagamar ZEIS also trends towards horizontal growth, with minimal vertical expansion throughout the area.

Based on the work of Izaga et al. (2022, 2023), four typomorphological categories were established: (E) Enclave, (L) Line, (Q) Block, and (G) Grid. Settlements like Comunidade Canal Leste, Irmã Dulce I, Rua General Rabelo, and Travessa Itú in the Bom Jardim ZEIS, along with Saporé in the Mucuripe ZEIS (Figure 11), were classified as lines, reflecting their linear development along infrastructures such as roads and waterways. For instance, Comunidade Canal Leste is defined by the route of the canal it shares its name with.

Figure 11. Maps illustrating the typomorphology of the Lagamar, Bom Jardim, and Mucuripe ZEIS, highlighting their unique urban configurations. Credit: Compiled by the authors based on Izaga et al. (2022, 2023).

In contrast, Comunidade Parque Santo Amaro, Veneza/Daniel Castro, Rua Cesarina Batista, Rua Alexandra, Rei do Gado, and Rua Indiara in Bom Jardim were classified as blocks, enclosed by streets and consisting of one or two blocks designated for building or open spaces. Notably, no such cases were found in the Mucuripe ZEIS. For example, the Rei do Gado settlement features two well-defined blocks resembling formal ones, despite being classified as a precarious settlement (Figure 12).

Figure 12. Maps showing the Morphological Type Analysis for the Mucuripe, Bom Jardim, and Lagamar ZEIS. Credit: Compiled by the authors (2024).

The settlements Favela do Pantanal/Nova Friburgo, Ocupação da Paz, Marrocos/Invasão Urucutuba, Mutirão Estrada da Urucutuba, and Rua Francisco Machado (Nova Canudos) in the Bom Jardim ZEIS,

along with João Arruda, Praça do Coqueiro, Rua João Arruda, Santa Edwiges, and Terramar in the Mucuripe ZEIS, were classified as grids. This classification reflects the formation of continuous urban complexes comprising at least three blocks and characterized by a degree of heterogeneity. For instance, Rua Francisco Machado (Nova Canudos) in the Bom Jardim ZEIS exemplifies this typology.

No enclaves were identified in the Bom Jardim ZEIS, but Castelo Encantado and Morro do Teixeira in the Mucuripe ZEIS were classified as enclaves due to their isolation, limited access, and distinct physical and social characteristics compared to their surroundings. Notably, Morro do Teixeira features a steep slope that complicates access, as indicated in the topographic analysis map. In the Lagamar ZEIS (Figure 12), the Lagamar settlement was classified as a line due to its extension along the water resource, while Santo Expedito was classified as an enclave.

CONCLUSIONS

The study of morphological diversity in Fortaleza's priority ZEIS—Bom Jardim, Mucuripe, and Lagamar—reveals a complex and dynamic landscape of urban occupation shaped by historical processes and urban interventions over time.

In the Bom Jardim ZEIS, diversity is marked by various self-constructed housing types, reflecting spontaneous occupation. The differing shapes and sizes of buildings, along with the presence of open spaces, suggest an ongoing spatial reconfiguration. This underscores the urgent need for public policies that promote land regularization and enhance infrastructure, ultimately improving social inclusion and residents' quality of life.

Mucuripe, located near high-value real estate areas, exhibits a mix of precarious housing and larger buildings. This spatial heterogeneity results from real estate pressures and socio-economic disparities. The findings emphasize the need for interventions that balance urban development with the preservation of the local community's social and cultural identity.

In the Lagamar ZEIS, situated in an intermediate area of the city, occupation follows the banks of the Lagamar Creek. The urban fabric combines regular areas near main roads with fragmented zones featuring alleys and narrow streets, highlighting occupation in an environmentally vulnerable region where many homes are at risk. Urgent urban interventions are needed to upgrade these areas, improve infrastructure, and ensure residents' safety and quality of life.

In conclusion, well-located ZEIS with adequate infrastructure and mobility, such as Mucuripe and Lagamar, tend to be more densely populated. In contrast, Bom Jardim, located on the city’s outskirts and facing precarious conditions, has more open spaces and larger areas per inhabitant.

The morphological diversity seen in Bom Jardim, Mucuripe, and Lagamar underscores the necessity for inclusive and participatory urban planning. Urban policies must account for each area's specific characteristics, promoting integrated solutions that address residents' needs and foster urban sustainability. Understanding these morphological dynamics is essential for guiding actions toward a more just and equitable city, where all citizens have access to adequate infrastructure and a decent quality of life.

ABSTRACT

This study discusses the response to the demand for housing in the context of population and economic growth in medium-sized Brazilian cities, considering the urban morphology of vertical housing areas. The objective is to analyse the current local discourse, reported by the press, based on the resulting urbanity in an area of recent verticalization. The case study is presented, the city of Sorocaba, one regional capital of the state of São Paulo, which has supported large numbers of vertical constructions, that occasionally illustrate news headlines related to the city's growth. Investigations were carried out in newspaper reports on the topic, published by the city's main newspaper, to obtain an understanding of these narratives. The aim is to discuss the quality of the area of recent verticalization based on the analysis of its urban form in the connexion between the implementation of the towers and the consolidation of streets, and the diagnosis was possible through mapping of the urban fabric. It is possible to point, through this examination, that the process of consolidating vertical areas has generated public spaces without urban quality, despite being seen as positive in the absorption of an expanding housing demand by the press. These spaces are the result from practices that prioritize the real estate market to the detriment of urbanity, in other words, the narrative presented to the population does not serve the collective sphere of the city. It also highlights the effectiveness in shaping a narrative that, instead of providing citizens with access to information, resigns itself to being another advertising tool for the real estate market.

Keywords: verticalization; medium-sized cities; public place; housing; real estate market

INTRODUCTION

This study focuses on reflections on meeting housing demand in the context of population and economic growth in Brazilian cities, considering the urban form of new housing areas. Research into current settlement cores is necessary to understand communities, their relationships with urban form, the natural environment, and quality of life and sustainability conditions.

In an increasingly urban society (UN-Habitat, 2022), it is pertinent to examine the effects of urban growth from the perspective of people's access and opportunities in spaces designed to accommodate such expansion demands. Data on population and households from the Brazil's last Census

demonstrate national growth in the 2010-2022 intercensal period with different regional, state, and municipal spatial dynamics that, however, demonstrate the robustness of population displacement in this period (IBGE, 2023). Furthermore, when examining the highest absolute growth rates, there is an increase in the number of apartment households in cities classified as regional capitals by the latest report on Regions of Influence of Cities – REGIC, 2018 (IBGE, 2020 and IBGE, 2023).

Verticalization can be a competent resource in responding to the demands of urban growth, from the perspective of instrumentation in a planning that seeks articulation between different factors that build up cities. Verticalization can be an instrument in promoting opportunities so that a greater number of people can live in spaces with better urbanity indices, access to jobs and public infrastructure (Rolnik, 2014), simply by maximizing the use of the appreciation of urban land (Ayoub et al, 2021). In addition to establishing new ways of living, urban networks and offering the possibility of land multiplication, the verticalization process has the potential to enable proximity and reduce travel time (Silveira; Silveira, 2014). From the perspective of urban sustainability, it can be an important ally in curbing expansion and increasing densities, building more compact territories (Roso; Oliveira and Beuter, 2021). However, what we see in many Brazilian cities is the persistence of peripheral expansion, together with the verticalization of other areas, whose urban development pattern is inadequate to support public life, that is, incapable of encouraging people's presence, coexistence and appropriation of public spaces (Yunda; Sletto, 2020). This pattern of vertical occupation is added to the unequal conditions of access to goods, services and infrastructure in cities by different groups in society, generating segregation, exclusion and the sprawl of the city, including over environmentally fragile areas. The current economic system is interested in reinforcing these modes of production and reproduction that, through neoliberal logic, promote systemic urban chaos (Smith, 2009).

Furthermore, the recent verticalization process does little to promote urban vitality and the use of existing infrastructure, as it does not emphasize permeability, the connection with the surrounding public space, the quality of pedestrian space, among other benefits provided by greater urban density (Gonçalves et al, 2008; Symmes, 2017; Rios et al, 2022). However, the current pattern of vertical developments largely declines connection with public space, occupying large plots of land and characterized by walled extensions, marking the urban landscape with the volumes of the towers and/or the enclosures of the various parking floors next to the sidewalk (Holanda et al, 2012; Alas, 2013). Such implementations reject the values of urbanity and vitality in public space and, despite being equipped with cameras, access controls and barriers, do not result in security (Whyte, 1980; Bentley et al, 1999; Carmona, 2021).

Public spaces can offer something essential to urban life: the freedom to come and go, to use and appropriate them by any citizen. They enable unexpected encounters between people from different groups, ideologies or social classes, and that is why they play a fundamental role in this urban dynamic (Innerarity, 2010). It is possible to say, therefore, that public spaces play a fundamental role in urban life, because, without them, a dense and highly built-up terrain does not constitute a city (Sassen, 2013). The urbanity of a place refers to its characteristics and capacity to welcome people (Aguiar, 2010). Thus, the synthesis of architectural and urban attributes that, together, facilitate interaction and appropriation of people with places, is expressed in the different degrees of urbanity, to the

extent that it presents a greater or lesser capacity to welcome people. In turn, urban vitality comprises the flow and permanence of people in public spaces (Holanda et. al, 2012). Within this dimension, urbanity is something that the urban environment offers through its main morphological elements. Therefore, a high degree of urbanity corresponds to high levels of accessibility, density, diversity and spatial continuity.

The phenomenon of the emergence of new vertical neighbourhoods as result of the logic of the real estate market raises the question addressed by this research, namely, understanding the effects of urban form resulting in a territory that is shaped by the implementation of buildings that reject the relationship between the private and the public, observing the information transmitted to the population about this context. This work addresses the context of verticalization in Brazilian regional capitals with significant population growth rates, in dynamics that expose urban conflicts between the actors that produce intra-urban space and the citizens. Thus, the objective of this study is to analyse the current local discourse, reported by the press and by the municipal government, considering the quality of the resulting urban spaces in an area of recent verticalization, guided by the diagnosis of the conditions of block sizes, road network, connectivity, permeability and accessibility. To achieve the intended scope, we present a diagnosis of a case study in the city of Sorocaba-SP, headquarters of the Sorocaba Metropolitan Region (RMS), highlighted as one of the geographic reference points for population growth in the interior of Brazil in the intercensal period (IBGE, 2023). The arrangements of blocks and lots, the connectivity of the street layout and the alternatives for displacements in the urban form of Parque Campolim were examined, in the perimeter where the urban fabric is in the process of consolidation through the processes of construction of the verticalized landscape, in contrast with the diagnosis of the consolidated area of the Center, also verticalized

Quality of urban form and verticalization

Topics such as urban form, land use, traffic, community, built environment, citizens, urban economy, sociocultural environment and facilities are inextricably linked to urban vitality through certain characteristics and conditions (Liu et al, 2022). Urban vitality is a possible contribution to the establishment of community social ties, at the interface between the built environment and social cohesion, as a prerequisite for a safe and successful city in terms of street life, being conceptualized and evaluated as urban spaces have life and animation (Mouratidis and Poortinga, 2020).

To achieve responsive environments, it is imperative to ensure spaces provided with urban vitality, with attention to the attributes of permeability, variety, legibility, robustness, visual appropriation, richness and personalization for the development of urban area projects (Bentley et al, 1999). Urban design should contribute to the well-being of individuals, considering the reality of the current context, in which opportunities are constrained by the economic market and legislative political articulations. The design, as a process, should be seen as an activity of common integration for all those involved in the generation and maintenance of areas so that they have characteristics that guarantee successful spaces for the use and coexistence of people (Carmona et al, 2021).

Different forms of urban and landscape expansion, land use and occupation, building patterns, different degrees of population density, mobility and population diversity have different effects and provide different stimuli in urban life. The connectivity of the road network, traffic accessibility and the density of intersections – which are closely related to land use – improve the mobility of the population of the blocks and increase their vitality (Liu et al, 2022). Ignoring issues of connectivity,

accessibility and flexibility of use leads to the reproduction of less sustainable urban forms, with lower levels of social equality and obstacles to long-term economic viability (Carmona et al, 2021). The new centralities have the functional density of the historic centers but are not as physically dense. The new areas tend to be shaped by the logic of the automobile and the privilege of their space requirements, rather than the distances travelled by pedestrians (Russin, 1999).

In relation to urban verticalization, it constitutes processes that determine landscapes, resulting in new residential values, location, security and infrastructure. Therefore, their connections in relation to city spaces should guarantee urban evolution that generates wealth, environmental quality and life for people. In recent terms, housing verticalization has translated into a form of urban precariousness at first, but with the prospect of future housing precariousness, in a process similar to what occurs in other countries (Symmes, 2017), implying hyper densification.

In Brazil, from the 1970s onwards, cities classified at lower levels of urban hierarchy (when compared to large metropolises) began to attract investments and undergo socioeconomic changes. Federal development public policies for medium-sized cities were implemented to reduce metropolitan migration. Thus, medium-sized cities have shown growth and transformations generated with horizontal and vertical urban expansion (Oliveira; França, 2012).

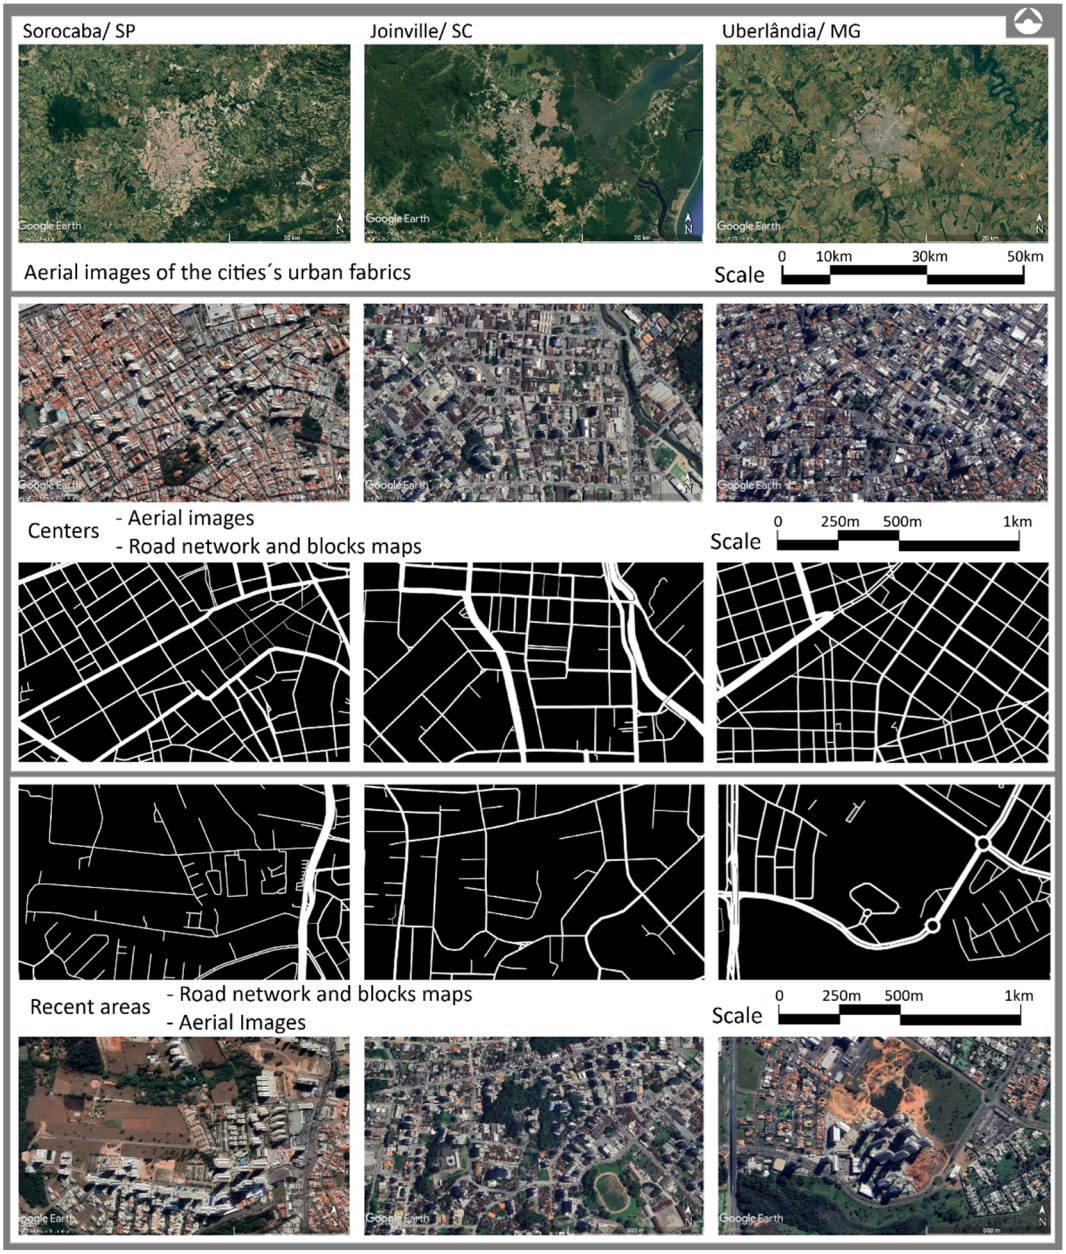

Figure 1. Sorocaba, Joinville, Uberlândia. Prepared by the authors based on Google Earth, 2024.

Figure 01 demonstrates, using satellite images, the urban areas of the cities of Sorocaba/SP, Joinville/SC and Uberlândia/MG – three expanding regional capitals, experiencing processes of urban verticalization. The diagrams (Figure 01) indicate the differences in the road networks of central areas, already consolidated, and areas that are currently undergoing consolidation processes. Figure 02 brings together three reports from local newspapers about the verticalization of these cities and the association of these processes with economic and population expansion.

Figure 2. News about verticalization in Sorocaba, Joinville, Uberlândia. Prepared by the authors .

In this context, this work is guided by the deepening of the conditions of road permeability and connectivity of the street fabric, combinations of blocks arrangements, accessibility and comfortable walking distances and the opportunities for choices and multiplicity of possible paths for people, through analyses of the urban form and layout – in land and subdivision patterns, dimensions of blocks and lots and connections with the road system in the vertical urban fabric of Parque Campolim and Centro in Sorocaba-SP.

Verticalization in Sorocaba

Sorocaba is in the interior of São Paulo (Figure 03), has 723,574 inhabitants, and is the 7th most populous city in the state of São Paulo and the 27th most populous in the country (IBGE, 2023). In addition to the population increase of 23.3% in relation to 2010 Census data, there is economic growth, occupying 7th place in the national ranking of interior cities. Furthermore, the Gross Domestic Product (GDP) of the Metropolitan Region of Sorocaba (RMS) grew 0.7% in the first quarter of 2023, being the highest GDP in the interior regions of São Paulo in this period (IBGE, 2023; SEADE, 2023).

The institutionalization of the RMS, in 2014, accelerated the processes of local metropolitan consolidation and expansion of its area of influence. The city of Sorocaba receives people who seek better living conditions, coming from smaller cities in the RMS and the south of the State of São Paulo and who end up offering their workforce to macro-metropolitan arrangements. From the perspective of economic dynamics in the territorial context between the Metropolitan Regions of Sorocaba, São Paulo and Campinas, in addition to proximity, there is an openness to new investments and the functional subordination of the RMS in relation to the other metropolitan regions. It is pointed out that the demographic and economic growth of Sorocaba and the region must consider the limitations existing by the political, social and economic agents involved in combating the socio-spatial inequalities produced, with a view to a socially fair expansion (Mauá Filho and Lima, 2023).

In the 2022 Census (Figure 03), Sorocaba is included in the largest population size class, with more than 500,000 inhabitants. Together with the 40 other centers of the same classification, it makes up 0.74% of Brazilian municipalities which, in total, are home to more than half of the total national population (58,876,980 inhabitants). The city was highlighted as the 4th Brazilian municipality with the highest absolute variation in demographic growth. Among the Regional Capitals, Sorocaba obtained the highest percentage of growth, followed by Joinville-SC, Uberlândia-MG (Figures 01 and

02). These data demonstrate the context of regional capitals undergoing accelerated demographic expansion, in notably higher percentages in relation to large metropolises.

Figure 3. Sorocaba and the cities in expansion in Brazil. Prepared by the authors based on IBGE, 2023.

Given this situation, vertical growth and a wide range of residential real estate developments can be observed. In the last 12 years, such growth can be seen in the city's landscape, in surveys by the Union of Property Purchase, Sale and Administration Companies (SECOVI-SP) and in news from local newspapers that highlight the increase in Sorocaba's population preference for housing in apartments (Jornal Cruzeiro do Sul (JCS), 2023a; JCS, 2023b). Even the Covid-19 pandemic did not negatively

impact civil construction production in Sorocaba; on the contrary, the numbers of commercialization and construction of buildings have been increasing (JCS, 2020a; JCS, 2020b; JCS, 2021; JCS, 2022a; JCS, 2022b; JCS, 2022c).

To identify the areas in which such processes have been occurring, data on buildings with more than five floors in the city were systematized according to location and years of implementation. The Municipality's Building Code (1966) establishes the mandatory use of elevators for buildings taller than 10 meters, counting from the access level. In addition, buildings with five or more floors identified by research documenting constructions with three or more floors in Sorocaba until 2018 were selected (Monteiro; Mauá, 2019). This data was complemented by information on the years the buildings were completed and updated with the most recent detections (from 2019 to 2024), through surveys on construction companies' websites, portals with public information on condominium registrations, and on the collection platform available for subscribers of Jornal Cruzeiro do Sul (JCS, 2024) and through field confirmations initiated on August 6th, 2023, updated on March 9th, 2024 and August 28th, 2024.

In this way, mappings were created that identify tall buildings (Figure 04) with urban perimeters established based on the understanding of road connections when reading the street system in the city plan of Sorocaba. The city plan is made up of the complexities of street elements (street systems), parcels (blocks) and buildings (deployment plans) (Conzen, 2022). The historic core of Sorocaba is the second region with the largest number of tall buildings in the city. When considering the period from the 2000s onwards as another centrality, it is noted that Parque Campolim began to absorb the housing demand aimed at the high-income population, which until then occurred in the city center.

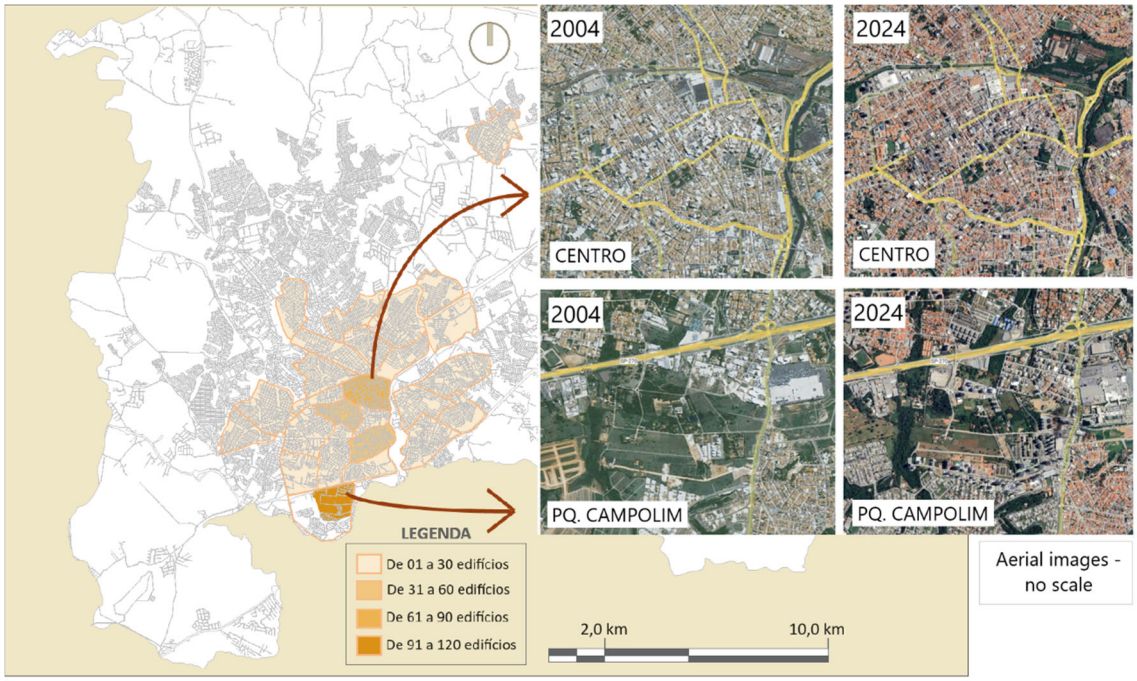

Figure 4. Occurrence of tall buildings in Sorocaba. Prepared by the authors based on Google Earth, 2024.

The occupation process to the south of the perimeter suggests accelerated civil production at the site, given that, while in the 2004 aerial photo the division established by the adjacent condominium of houses is noted, in the 2024 image, the strip that was previously characterized as empty, presents an

emphatic presence of buildings, which are even taller than the first vertical constructions in the region to the northeast. Thus, this street, Antônio Perez Hernandez, concentrates recent tall buildings, with the back of lots sharing walls with the condominium's houses

METHOD

Since this is a late and current verticalization process, it was found that the information about this context in the city of Sorocaba, except for the work by Barreto (2007), is that published in the region's newspapers. Thus, to verify the discourse of the local press, surveys were carried out of reports on the subject, published between 2012 and 2022 (intercensal period), as well as the most recent ones, from 2023 to August 2024, using the keywords “verticalization” and “tall building” in the city's largest circulation newspaper. The news items were organized in a table, with the systematization of the elements: date of publication, headline, subtitle, newspaper section. After verifying the central themes of each one, those that did not relate to the focus of this study were discarded: understanding the discourse of the local press on urban verticalization in Sorocaba. To obtain the delimitation of the objects of analysis, that is, the fabrics of the regions in which recent urban verticalization is observed in Parque Campolim and the Center, the Morphological Regions were identified by checking the street plans, subdivision and buildings of the urban plan (Conzen, 2022). The block arrangements, the connectivity of the street layout and the alternatives for displacement in the urban form of Parque Campolim and the Center were examined. The guidelines organized in the Morphological Dimension of Urban Design (Carmona et al, 2021) discuss block groups and the need for limits and diversity of block sizes in an urban grid that allows accessibility and good mobility conditions for people, through connectivity and permeability (Bentley et al, 1999; Jacobs, 2000 and Carmona et al, 2021), thus ensuring the multiplicity of possible paths (Rapoport, 1978; Jacobs, 2000; Bentley et al, 1999 and Carmona et al, 2021) at comfortable distances for travel (Rapoport, 1978).

To this end, the following were prepared: (1) Urban fabric maps that contrast the designs of the block subdivision layouts and road communications - using the figure and background method, the blocks are emphasized by filling in black; (2) Map of road hierarchy, where arterial connections were marked in red, collectors in yellow and local streets in green; (3) Map with lot divisions, showing the layout inserted in the blocks; (4) Map of block dimensions, where the initial classification (up to 2,500 m²) was based on the hypothesis of the total footage of a short block, with extension on all sides of 50 meters – the other classifications were established with results of footage considering, in relation to the previous one, the doubling of one of the sides; (5) Map of block dimensions, using as a guiding criterion the current local legislation, namely, the Municipal Building Code (1966) – obtaining the establishment of the first classification with blocks of eighty meters in length on both sides, resulting in 6,400 m² of area; and, successively, the others up to the “superblocks” in fabrics with 180,000 m2 of area.

RESULTS AND DISCUSSIONS

The systematization and study of reports on the topic of urban verticalization in the local newspaper of Sorocaba (Figure 05) indicates one report per year until 2016, the gap that occurred in the years preceding the Covid-19 pandemic and the increase in occurrences on the subject in recent years. It is worth noting that advertising materials or those with a bias towards social records of events, such as, for example, the launch of new projects, were discarded.

Figure 5. Systematization of reports on urban verticalization in Sorocaba. Prepared by the authors based on Jornal Cruzeiro do Sul, 2024.

Even so, many reports deal with a specific project or construction company, with an almost advertising tendency, even though, for the most part, they appear in the Economy section, some examples of this are shown in Figure 06. Likewise, most of the news items that address local verticalization are linked to discuss such processes as a result of economic growth and expansion of the city.

Figure 6. Example of reports. Prepared by the authors based on Jornal Cruzeiro do Sul, 2024.

Except for one of the reports from 2024, the news discourse does not address the consequences of construction on the formation of new neighbourhoods or transformations of already consolidated areas, presenting a positive discourse from an economic perspective. The news from February 2024 (Figure 07) stands out, regarding the revision of the Municipal Master Plan, where it is mentioned that "accelerated urban expansion and vertical growth are a concern for the population and city councillors" – it is interesting to note that the photo in the headline is not of a recent vertical condominium, having been completed years before the last revision of the Master Plan, carried out in 2014. Figure 07 also indicates other examples of reports that touch on the subject – such as the interference of cranes and large construction equipment in the city spaces. The analyses of urban form presented here are aimed at clarifying the attributes of connectivity, displacements and the conditions and alternatives in the urban form occupied primarily by vertical housing; The recommendations that aim to create quality urban spaces seek to provide the parameters for analysis to understand public space. The aim is to clarify the levels of accessibility and mobility in the streets, the opportunities for choosing routes and the conditions for movement and social integration.

Figure 7. Example of reports. Prepared by the authors based on Jornal Cruzeiro do Sul, 2024.

In the diagnosis of the road network plan for Campolim Park (Figure 08), the observation of the road hierarchy and the constitution of the urban fabric of the area is unsatisfactory. Figure 08 shows the classifications of the streets, road networks and divisions of lots of the study perimeters, these shown on the same scale. The road hierarchy maps indicate that the predominantly residential area of Campolim Park lacks local streets and is made up of few connections, most of which are made up of collector streets. The contrast between the existence of short and unconnected streets, the scarcity of appropriate local streets and the consolidation of very long streets that play the role of collecting access to the interior of the area from the arterial road axis to the east is striking. The low occurrence of road intersections demonstrates the precariousness of land division and urban permeability in the

area. Furthermore, an analysis of the road network maps shows that, except for the blocks to the northeast (originating from the initial subdivision project for the neighbourhood), the Parque Campolim area consists of huge blocks, without adequate subdivision and road intersections. Reading the maps with the divisions of lots (Figure 08) suggests that the consolidation of the urban network is subject to the insertion movements of vertical developments, starting from the arterial road connection to the east, from the backs of industrial lots to the north and from the walls of condominiums to the south, up to the core of the contour – where urban voids with characteristics of farm lands can still be seen and, to the west, the border with the Permanent Preservation Area can be seen.

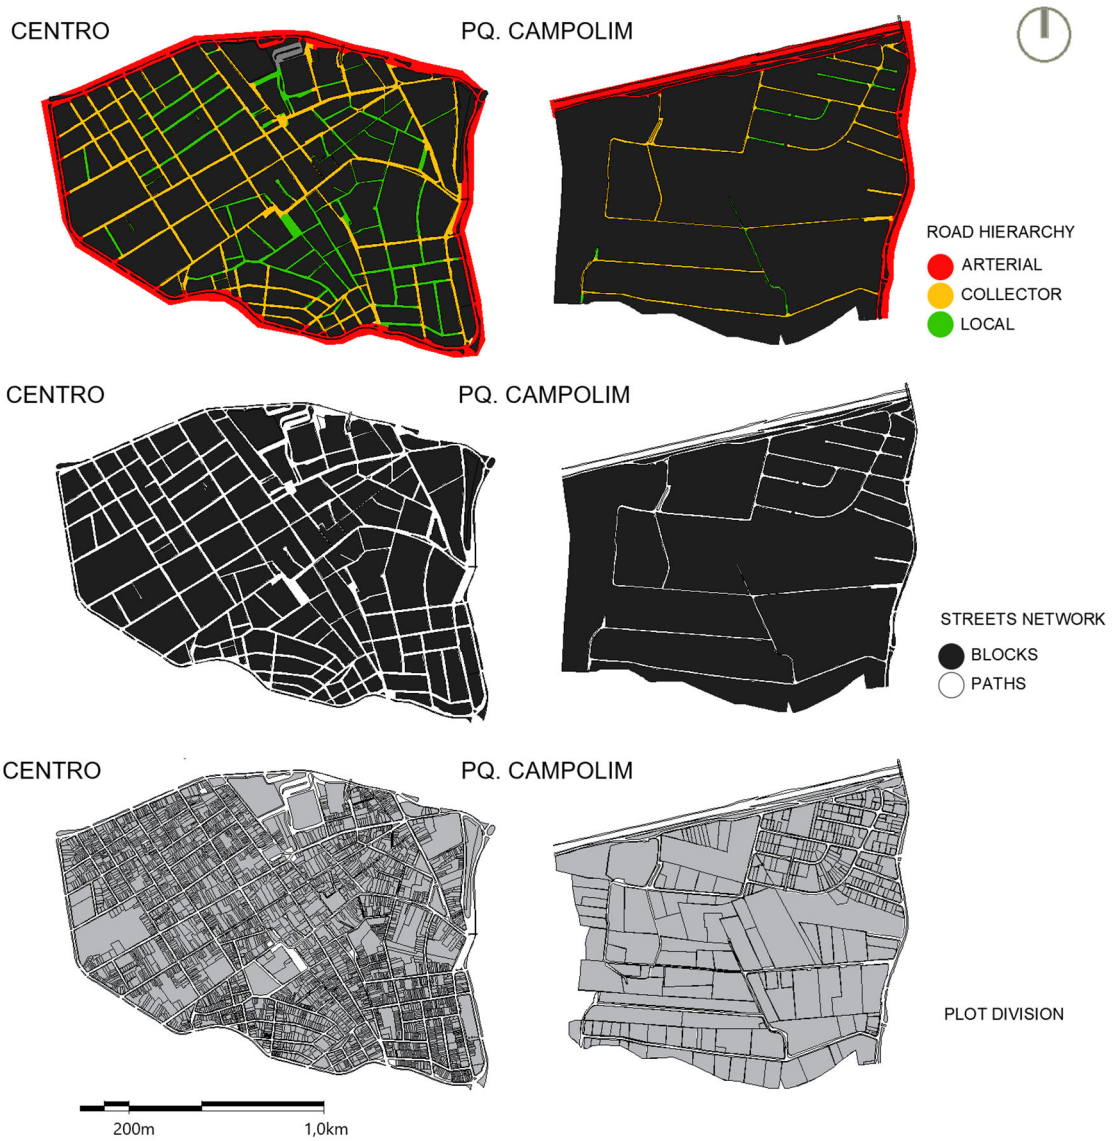

Figure 8. Analysis maps.

Long streets and blocks with high land use constitute oppressive spaces, while a more permeable network can encourage connections with parks and squares, different uses and a variety of housing typologies in the constitution of an adequate density (Jacobs, 2000). The lack of variety in block sizes or arrangements and few road intersections generate low levels of permeability and urban

connectivity, hindering motorized travel and, mainly, walkability. The northeast portion of Campolim Park (Figure 09), because it has smaller block lengths, demonstrates, through the interpretation of its paths, that the arrangements of the fabric indicate a certain oversizing of blocks, since, even so, it consists of blocks larger than those indicated in the literature.

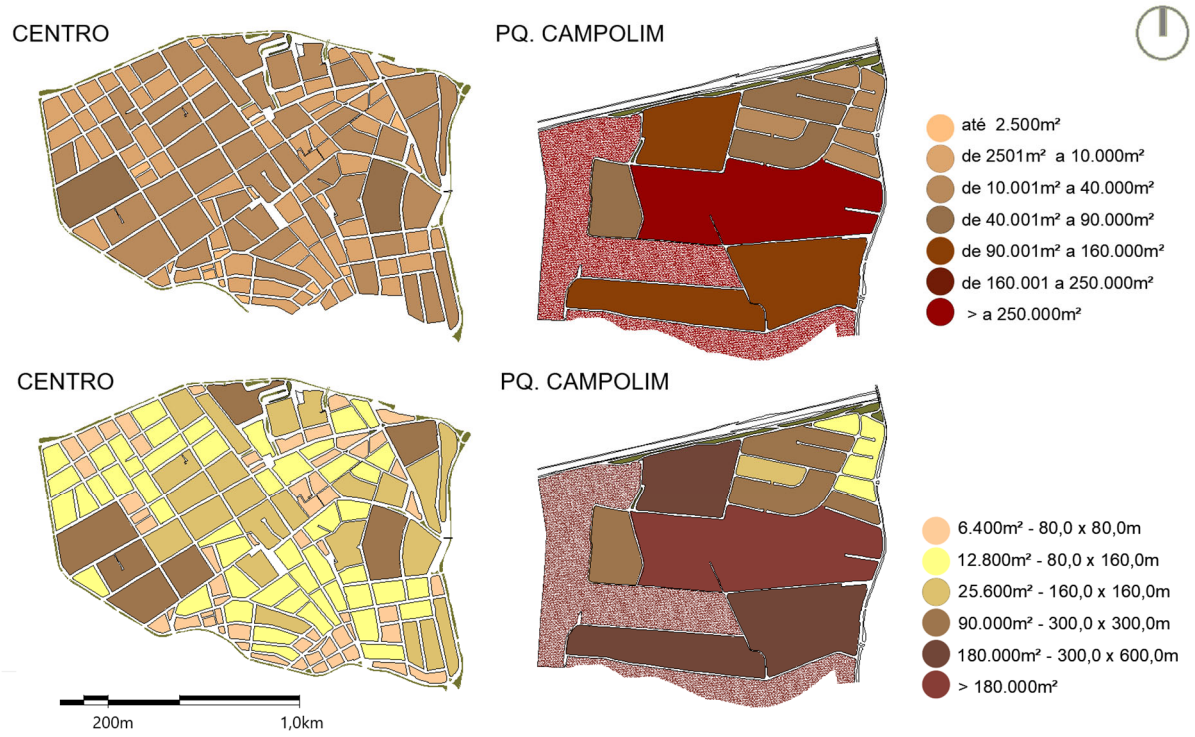

Figure 9. Analysis maps.

The dimensions of the blocks are related to the aspect of road permeability, since the smaller the blocks, the greater the alternative routes (Bentley et al, 1999). The arrangement of blocks can determine the quality of the urban form but does not necessarily define the architectural forms. Street patterns are more resilient in relation to infrastructure and must present measures that allow for transformations, as well as sufficient areas for commercial development, circulation and social space (Carmona et al, 2021)

CONCLUSIONS

It is possible to point, through this examination, that the process of consolidating vertical areas has generated public spaces without urban quality, despite being seen as positive in the absorption of an expanding housing demand by the local press. These spaces are the result from practices that prioritize the real estate market to the detriment of urbanity, in other words, the narrative presented to the population does not serve the collective sphere of the city.

Current patterns of urban verticalization are far from the sustainability needed for the future of cities in terms of mitigating and adapting, for example, to avoid the continued harmful effects of climate change. In the case studied, housing production is evidently disconnected from the urban and humanistic context – unfortunately, there is no assessment by the government or any pressure from the press, given the problematic prognosis for the region, which could imply the precariousness of the

already non-existent environmental quality, as well as requiring high investments from the municipality to, at the very least, solve problems that could have been avoided at practically no cost.

The morphological analysis points to situations that may be irreversible, since much of the occupation of this territory occurs in the absence of a block division project. Verticalized concentration can be a powerful instrument for meeting the population's demands for more compact growth, but this is not what has been done. Marketing strategies aimed at high exchange value define other values for architecture and urban landscape. It also highlights the effectiveness in shaping a narrative that, instead of providing citizens with access to information, resigns itself to being another advertising tool for the real estate market.

ABSTRACT

Over the past two decades, China has maintained a high rate of urbanization, with high levels and rates of urban expansion and the formation of large urban suburbs. China's urban suburbs have an extremely large total amount of residential areas, accommodating a large number of people. The imbalance of jobs-housing has also led to extreme congestion on major arterial roads connecting the city center to the suburbs during peak commuting hours. Metros have become the preferred mode of transport for most people. However, in most Chinese cities, the city expanded first and the metro was built later, resulting in a high degree of disparity in the accessibility and convenience of metro stations, as well as a failure to maximize their public service performance. Thus, many studies have attempted to distinguish their morphological characteristics, accessibility, and convenience. However, most of these studies are directly based on the circular area with a certain radius from the center of the station, ignoring the specificity of the real accessible area due to the road network. In this study, based on the walking navigation function provided by mobile phone apps, the real walking isochronous fields of metro stations are obtained through big data acquisition and analysis. A series of isochronous fields are also mapped to deeply analyze and evaluate the accessibility and service convenience of metro stations. The study selected a set of metro stations in the suburbs of Nanjing, China as the cases for isochronous fields mapping. The quantitative analyses included not only the morphological features and service facilities within different isochronous fields, but also the characteristics of the isochronous field's own shape, such as area, compactness, and directionality. The results presented a more accurate and refined understanding of the accessibility and convenience of these stations, and provided a more targeted strategy for optimizing their public service performance.

Keywords: Isochronous field; Urban morphology; TOD; Walking accessibility; Convenience

INTRODUCTION

Over the past two decades, China has maintained a high rate of urbanization, with high levels and rates of urban expansion and the formation of large urban suburbs. China's urban suburbs have an extremely large total amount of residential areas, accommodating a large number of people. The imbalance of jobs-housing has also led to extreme congestion on major arterial roads connecting the city center to the suburbs during peak commuting hours (Ta et al., 2017). Metros have become the

preferred mode of transport for most people. However, the delayed construction of metro systems in many Chinese cities—following urban expansion—has resulted in disparities in station accessibility and convenience. This misalignment has prevented metro systems from fully optimizing their public service capacity.

Many studies have attempted to distinguish their morphological characteristics, accessibility and convenience (Liao and Scheuer, 2022; Wu and Zhou, 2023; Stojanovski, 2015). However, these studies have often relied on simplified circular zones around stations, failing to account for the specific road networks that influence real-world accessibility (Zhang et al., 2023; Sun et al., 2016). Zacharias and Zhao (2018) used tracking data of metro users to generate walking service areas of the metro stations. Although the results are more accurate, they are time-consuming and difficult to replicate. In contrast, the walking navigation data provided by mobile phone apps offers a more efficient and cost-effective method for delineating real walking isochronous fields (Shen and Tong, 2022).

In this study, a series of isochronous fields are calculated to deeply analyze and evaluate the accessibility and service convenience of metro stations. The study selected a set of metro stations in the suburbs of Nanjing, China as the cases for isochronous fields mapping. The quantitative analyses included not only the morphological features and service facilities within different isochronous fields, but also the characteristics of the isochronous field's own shape, such as area, compactness, and directionality. The results presented a more accurate and refined understanding of the accessibility and convenience of these stations, and also provided a more targeted strategy for optimizing their public service performance.

METHOD TO CALCULATE 15 MINUTES WALKING ISOCHRONOUS FIELD

Existing studies on isochronous field divisions have several limitations, often failing to account for the complexity of the urban road network. To address these issues, Shen and Tong (2022) developed a method based on walking navigation data from mobile phone APP, applying big data to capture real-time walking paths. For the selected start point, a point array is generated around each station (with a 40m interval and a range of 3000m), as in the left image of Figure 1. Then the navigation APP is used to calculate actual walking times from the start point to each destination point in the array. This process visualizes walking times as point attributes (middle image of Figure 1). Using the interpolation algorithm of the GIS platform, the point arrays are rasterized to generate isochronous fields for different time ranges (right image of Figure 1).

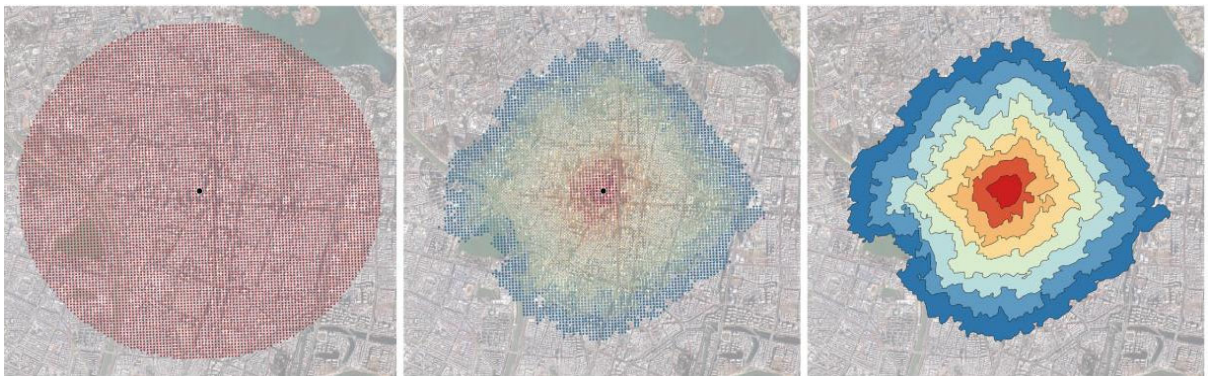

Figure 1. Process to calculate the isochronous field with navigation function of mobile phone APP (Shen and Tong, 2022).

Compared to traditional methods—such as using circular "buffer zones" to delineate living areas—this approach offers a more localized and precise analysis. The Baidu Maps data provides real-time updates of the road network, offering a more comprehensive view of the actual walking paths. This

method is more efficient and cost-effective than other models, such as GPS or cell phone signal-based approaches. Additionally, compared to ArcGIS road network models, which are static and often outdated, Baidu Maps' real-time road data allows for more accurate calculations.

Given that metro stations typically have multiple entrances and exits, and each entrance may be separated by considerable distances, the isochronous field for each entrance is calculated individually. The final isochronous field for each station is obtained by superimposing the results for all entrances, providing a comprehensive overview of the station's accessibility.

CASE STUDIES

Located in the east of China, Nanjing is the capital of Jiangsu Province and is a typical large city. It covers an area of 6,587 km2 and has a population of approximately 9.5 million. The city currently has 13 metro lines and 226 stations, with a total metro line length of about 473 km, in addition to 12 metro lines under construction or extension. The Nanjing metro serves an average of more than 3 million passengers daily, making it the primary mode of transportation for most residents. Based on the population density, this study divides the Nanjing urban area into five zones: the core area, the main urban area, the near-suburban area, the middle-suburban area, and the far-suburban area. As shown in Figure 2, the selected cases are located in the red dashed circle. Figure 3 shows the four station cases selected for this study and the lines they belong to.

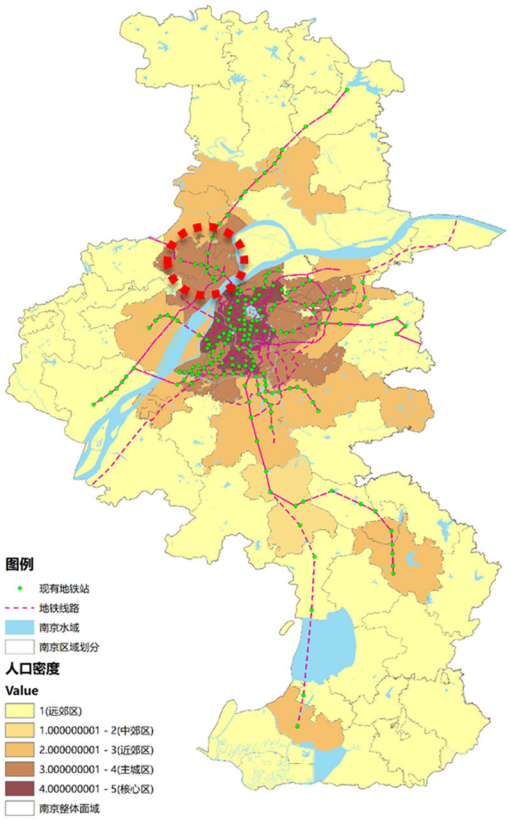

Figure 2. Metro lines and stations of Nanjing. The selected cases are located in the red dashed circle.

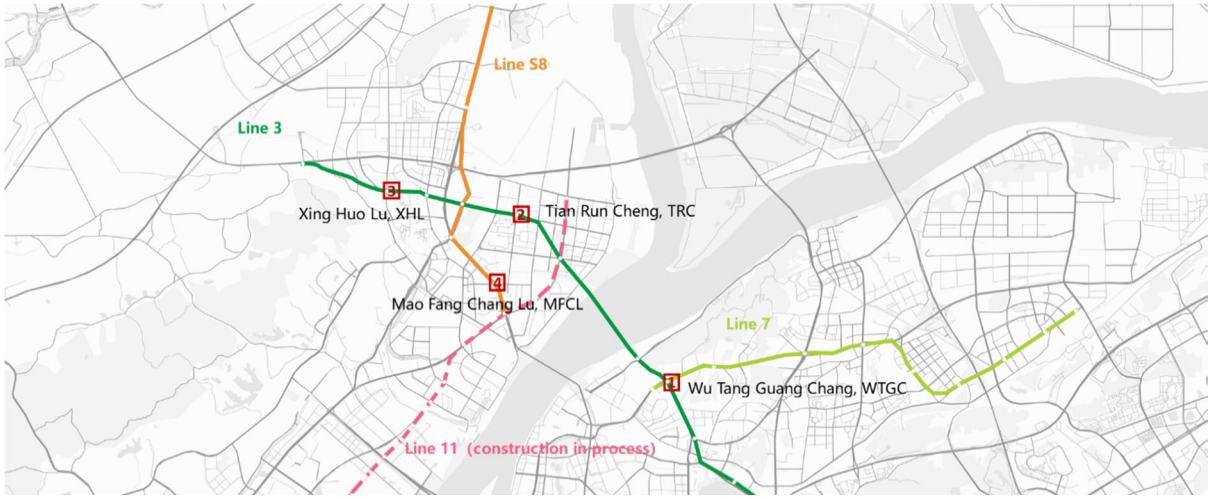

Figure 3. The locations of the selected 4 metro stations and the lines they belong to.

Figure 4 shows the satellite map of these four stations and the actual photographs of the station entrances. From the figure, it can be seen that each of these stations has its own typical characteristics. Wutangguangchang (WTGC) Station is an interchange station with five entrances and is surrounded by mostly old settlements. Tianruncheng (TRC) Station is surrounded by high-density large-scale emerging residential areas and has 3 entrances. Xinghuolu (XHL) Station is surrounded by low-density mixed functional areas and some natural hills, with 4 entrances. In addition to the high-density residential area around the Maofangchanglu (MFCL) station, there are also large commercial complexes, with a total of four entrances. The first three stations are located on Metro Line 3, and the last one is located on Metro Line S8. The urban form around the four stations basically represents the morphological characteristics of urban suburbs: a large number of high-density residential, large commercial complex nodes, some old neighborhoods, and integration of the natural environment. The analysis of these stations can better cognize the characteristics and limitations of urban metro stations and their surrounding urban construction.

Figure 4. Satellite maps and street photos of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

MORPHOLOGICAL ANALYSIS OF 15 MINUTES ISOCHRONOUS FIELD

Applying the isochronous field calculation method, we generate a point array with a spacing of 40m around each of the four stations, and calculate the walking time for different entrances of each station

to reach these point arrays, and then get the 15-minute walking isochronous field ranges of the four study stations by taking the minimum value of each. The resulting 15-minute walking isochronous fields are shown in Figure 5, revealing significant variations in size and shape between the stations. Most stations have an isochronous field area of around 200 ha, but XHL Station has a smaller field, covering only 164 ha.

Figure 5. The isochronous fields of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Correspondingly, the total area of buildings covered by the 15-minute isochronous fields also caries significantly (Figure 6). The XHL station has a lower density of buildings in the surrounding area, and its 15-minute isochronous field area is also small, covering a total building area of only 1.29km2, and the Floor Area Ratio (FAR) calculated by the isochronous field area is only 0.79, of which the residential FAR is only 0.25. The other three stations have similar 15-minute isochronous field areas, but the WTGC Station covers a total building area of 1.97km2, with a FAR of 0.98, of which the FAR of residential is 0.78. The TRC Station covers a total building area of 2.65km2, with a FAR of 1.27, of which the FAR of residential reaches 1.2. And under the influence of the neighboring large-scale commercial complex, the MFCL Station covers a total building area of up to 5.46km2, with a FAR as high as 2.77, of which the FAR of residential is 1.38. Differences in building FAR and function across the isochronous fields reflect the diverse range of people served by each metro station (Table 1).

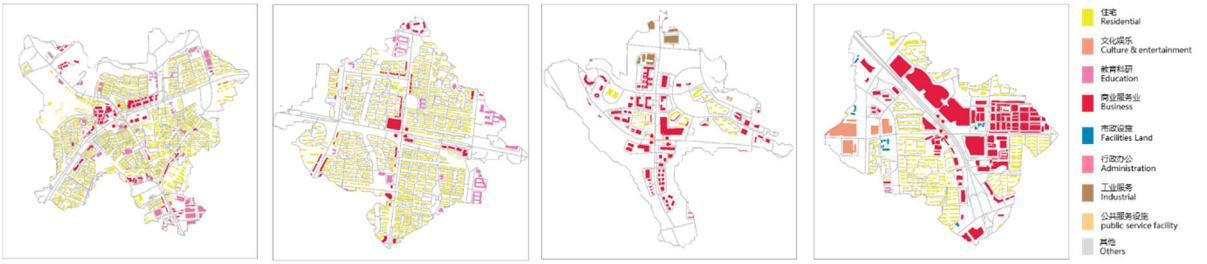

Figure 6. The buildings inside the isochronous fields of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Table 1. The areas of buildings inside the isochronous fields of the 4 metro stations.

Metro stations	Area of 15min isochronous field (ha)	Area of buildings (km^2)	FAR	FAR of residential
WTGC station	200.53	1.97	0.98	0.78
TRC station	208.07	2.65	1.27	1.20
XHL station	164.02	1.29	0.79	0.25
MFCL station	197.36	5.46	2.77	1.38

Similarly, once the isochronous fields were defined, we analyzed the roads, bus stops, points of interest (POIs), and some other elements within each field (Figure 7). These elements illustrate the real-world influence of the metro stations within a 15-minute walking distance. The roads reflect the

accessibility of the area around the metro station. The bus stops and lines reflect the convenience of metro and bus transfer. The number of POI classification reflects the convenience of life around the metro station. As shown in Table 2, the statistics for the WTGC station and TRC station are largely similar, reflecting the residential neighbourhood. However, the number of POIs at the WTGC station is more than that at the TRC station, indicating that the former, as an old neighbourhood with some history, has a greater abundance of amenities than a new neighbourhood such as the latter. The XHL Station has the lowest statistical values for all indicators except for the POIs, which is related to its special topography. However, the office facilities represented by the large number of red dots in its POI indicator also reflect the work attributes of the area. The MFCL station has low values for total road length and density, but has the most bus lines, suggesting that the area has more major roads but few minor streets. In addition, the MFCL station has the highest number of POIs around it, implying the most convenient amenities.

Figure 7. From top to bottom are roads, bus stops, and POIs inside the isochronous fields of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Table 2. The statistical data of roads, bus stops, and POIs inside the isochronous fields of the 4 metro stations.

Metro stations	Total length of roads (km)	Density of roads (km/ha)	Number of bus stops	Number of bus lines	Number of POIs
WTGC station	62.03	0.31	15	13	1496
TRC station	69.34	0.33	17	15	1242
XHL station	23.66	0.14	11	13	1322
MFCL station	39.37	0.20	14	37	3573

ANALYSIS BASED ON MULTIPLE ISOCHRONOUS FIELDS

By employing this new isochronous field calculation method, we can easily determine the walking range for various durations, allowing for a more nuanced analysis of metro station accessibility and convenience. In this study, we subdivided the isochronous fields into 5-minute, 10-minute, and 15-minute intervals for each station, and deepened the analysis of these fields.

Figure 8 presents the isochronous fields for different time intervals at the four stations, while Table 3 shows the change in area for each station across time. These subdivided isochronous fields highlight how the walking range coverage differs from station to station as walking time increases. For instance, although XHL Station has the smallest 15-minute field, it covers the largest area in the 5-minute range. In contrast, TRC Station has the smallest 5-minute isochronous field, covering only half the area of XHL Station. These differences have practical implications. It can imply that there is a significant difference in the accessibility of different stations for different age groups. In the case of the TRC station, for example, it may be more suitable for younger people, while the accessibility of the station is poorer for older people who are not conducive to longer walks. For the WTGC station, it shows a more consistent increase in area coverage across time intervals, suggesting better accessibility for all age groups.

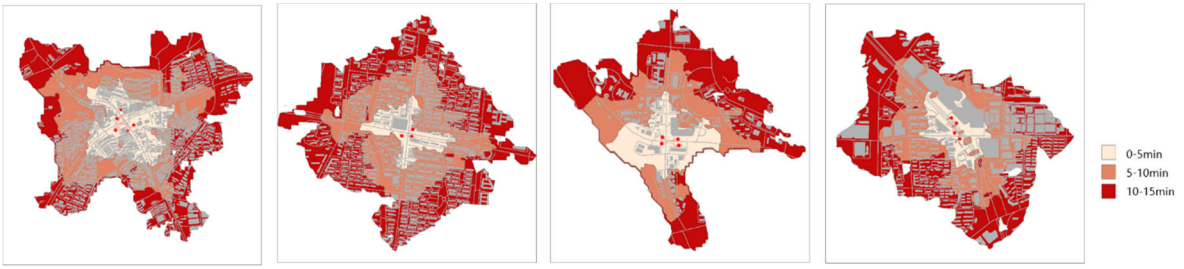

Figure 8. The isochronous fields of different time intervals at the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Table 3. The areas of the isochronous fields of different time intervals at the 4 metro stations. (IF: Isochronous Field)

Metro stations	Area of 0-5min IF (ha)	Area of 5-10min IF (ha)	Area of 10-15min IF (ha)	Area of 15min IF (ha)
WTGC station	32.51	72.97	95.05	200.53
TRC station	17.81	68.99	121.27	208.07
XHL station	32.96	51.75	79.31	164.02
MFCL station	24.09	63.66	109.61	197.36

Figure 9 shows the buildings located within the isochronous fields of different durations, i.e., we can directly identify the walking time for each building to reach the metro station. This analysis offers a detailed perspective on the station's coverage and its convenience for residents. As shown in Table 4, the MFCL stations have the most buildings area in every isochronous field. With the exception of the MFCL station, the data for the other 3 stations were relatively even. Among them, the WTGC station has the most buildings area in 5-minute and 5-10-minute isochronous fields. The TRC station has the least buildings area in 5-minute isochronous field, but has the most buildings area in 10-15-minute isochronous field.

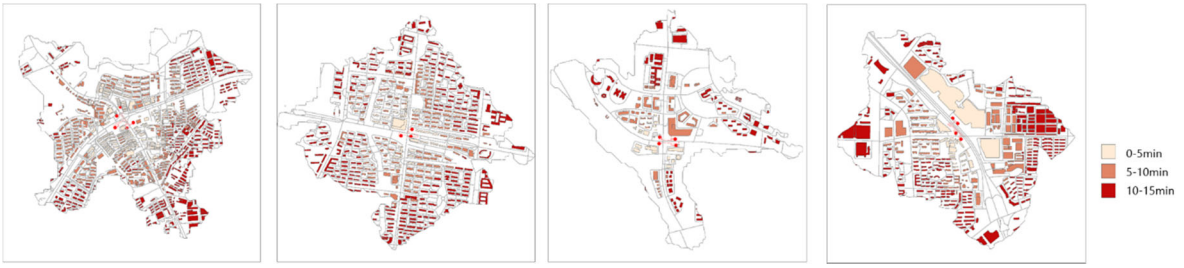

Figure 9. Walking duration of the buildings of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Table 4. The buildings area in the isochronous fields of different time intervals at the 4 metro stations. (IF: Isochronous Field)

Metro stations	Buildings Area in 0-5min IF (10000 m^2)	Buildings Area in 5-10min IF (10000 m^2)	Buildings Area in 10-15min IF (10000 m^2)
WTGC station	43.29	75.19	78.87
TRC station	21.42	66.44	97.60
XHL station	39.89	46.15	49.09
MFCL station	118.57	156.48	274.21

We also examined the relationship between metro stations and bus stops, as the distance between these can significantly affect metro-bus transfers (Figure 10). And Table 5 shows that the WTGC, TRC, and XHL Stations have several bus stops within the 5-minute isochronous field, enhancing the convenience of transfers. However, most of the bus stops near the MFCL Station are located within the 10-15 minute range, making transfers less convenient at this station.

Figure 10. Walking duration of the bus stops of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Table 5. The number of bus stops in the isochronous fields of different time intervals at the 4 metro stations. (IF: Isochronous Field)

Metro stations	Number of bus stops in 0-5min IF	Number of bus stops in 5-10min IF	Number of bus stops in 10-15min IF
WTGC station	3	2	10
TRC station	4	6	7
XHL station	3	2	6
MFCL station	1	3	10

Finally, Figure 11 illustrates the distribution of POIs within different isochronous fields. As shows in Table 6, the WTGC and TRC Stations have a relatively even distribution of POIs, while POIs at the XHL Station are concentrated within the 10-minute walking range, with a sharp drop beyond that. In

contrast, the MFCL Station has more POIs in the 10-15 minute range, indicating better accessibility to amenities further from the station.

Figure 11. Walking duration of the POIs of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Table 6. The number of POIs in the isochronous fields of different time intervals at the 4 metro stations. (IF: Isochronous Field)

Metro stations	Number of POIs in 0-5min IF	Number of POIs in 5-10min IF	Number of POIs in 10-15min IF
WTGC station	406	535	555
TRC station	344	492	406
XHL station	503	629	190
MFCL station	583	1240	1750

Through this detailed analysis of multiple isochronous fields, we can gain a deeper understanding of the accessibility and convenience of metro stations, as well as the significance of the surrounding road network.

ANALYSIS OF ISOCHRONOUS FIELD SHAPE

While most of the previous analysis focuses on area coverage, the shape of the isochronous field itself also provides important insights. In addition, the unconventional shape of the isochronous field reflects its unique characteristics from another dimension after we abandon the traditional circular calculation range (Figure 12). This feature is closely related to the morphology of the road network around the metro station, and thus can express the structural characteristics of the road network. This study further analyzes the shapes of isochronous fields with different time lengths in an attempt to explore the features embedded in them.

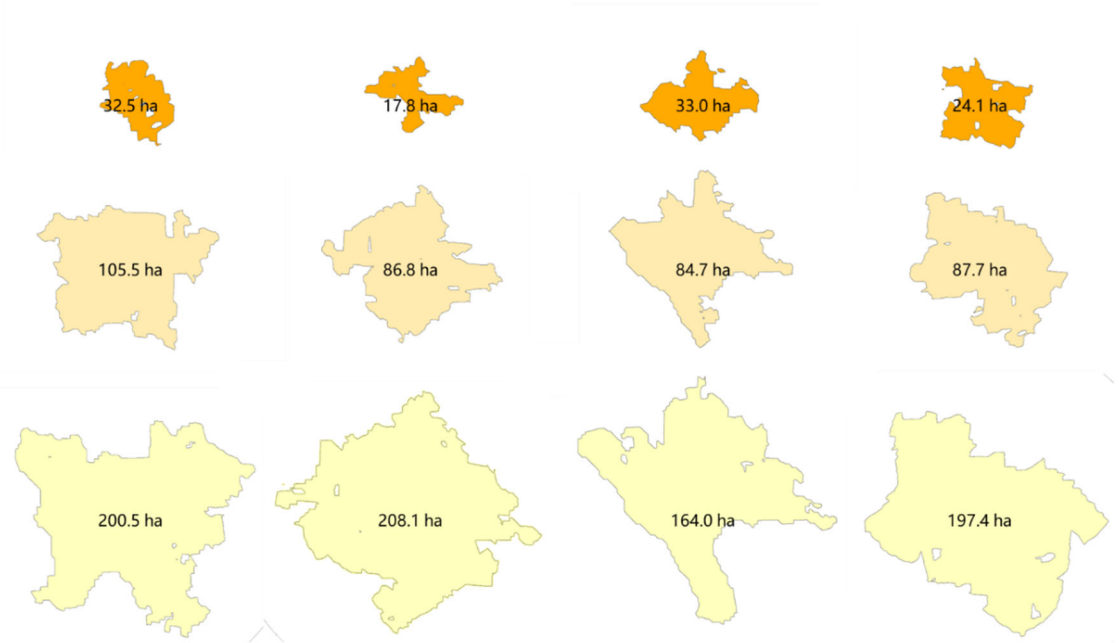

Figure 12. The shape and area of the multiple isochronous fields of the 4 metro stations. (From left to right: WTGC station, TRC station, XHL station, MFCL station.)

Compactness is a commonly used indicator to characterize shapes, and is generally used to express the relationship between the shape and the circle. Among the many public notices for compactness calculation, the formula proposed by Prof. Stephen Marshall can describe the shape from the Elongation, Convolution, and Dispersal, which can better reflect the shape characteristics (Marshall et al., 2019). Therefore, this study adopts this calculation formula to calculate the compactness of the shape of the isochronous field. The calculation formula is:

$$C=4A/DP$$

where C is the compactness, A is the area of the shape, D is the diameter of its outer circle, and P is its perimeter. Based on this formula, the maximum value of C is 1, which corresponds to a perfect circle. A smaller value of C indicates more fragmented, irregular shapes.

Applying this formula, we calculated the compactness of the isochronous fields at the four stations for 5, 10, and 15-minute walking intervals (Table 7). The results reveal that TRC Station has the smallest compactness value for the 5-minute isochronous field, while the MFCL Station has the highest compactness for the 15-minute isochronous field. The highest compactness value observed is less than 0.5, indicating that none of the fields closely resembles a circular shape. It reflects that the overall road network structure has a strong directionality, resulting in the isochronous fields appearing a distinctly finger-like, especially the 5-minute isochronous field at the TRC Station and the 15-minute isochronous field at the XHL Station, which are also the two smallest compactness among all the isochronous fields. Even the most compact ones have shapes that are just close to rectangular.

The table 7 also shows that there is a correlation between the compactness and the area of the isochronous fields. The smaller fields tend to have lower compactness, as seen with the 5-minute field at the TRC Station, the 10-minute and 15-minute fields at the XHL Station. However, the reverse is not always true, as fields with larger compactness do not necessarily have larger areas, such as the 15-

minute field at the MFCL Station, which, despite its high compactness, ranks third in terms of area size.

Table 7. The areas and compactness of the multiple isochronous fields of the 4 metro stations. (IF: Isochronous Field)

Metro stations	5min IF		10min IF		15min IF	
	Area (ha)	Compactness	Area (ha)	Compactness	Area (ha)	Compactness
WTGC station	32.5	0.350	105.5	0.387	200.5	0.336
TRC station	17.8	0.269	86.8	0.338	208.1	0.355
XHL station	33.0	0.353	84.7	0.323	164.0	0.289
MFCL station	24.1	0.336	87.7	0.366	197.4	0.410

Figure 13 plots the compactness trends for the four stations over different walking intervals. The line diagrams show that the four stations do not have the same trend of isochronous field compactness as the walking time increases. The trends of the TRC station and the MFCL station exhibit increasing compactness as walking time increases, indicating that their road networks are more suited for longer walks. On the other hand, the compactness of the XHL Station decreases with walking time increases. Upon our own inspection we found that the perimeter of the station is surrounded by natural hills in the southeast corner and southwest side. Due to its obstruction, the road network has large gaps in both areas, thus creating a significant reduction in compactness. In addition, the WTGC Station shows a more irregular trend, with compactness initially increasing at 10 minutes, then decreasing again at 15 minutes. A close examination of its road network reveals that, due to the large area of old settlements around the station, its road network structure is characterized by an obvious patchwork of different groups. The lack of sufficient connections between different groups results in a compactness that is greater at the 10-minute isochronous field than at the 15-minute field.

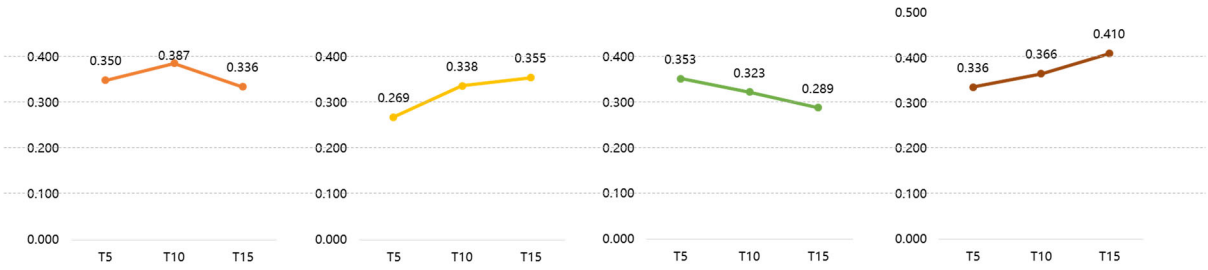

Figure 13. The compactness of the multiple isochronous fields of the 4 metro stations.

This compactness analysis provides insights beyond simple area coverage, highlighting the road network's influence on station accessibility and offering a deeper understanding of the structural characteristics that shape isochronous fields.

CONCLUSIONS AND DISCUSSION

The paper should be completed with your conclusions. Future research directions may also be mentioned. Please note that every reference cited in the text should also be present in the reference

list and vice versa. Citations should follow the Harvard referencing style, which is also used in the Journal of Urban Morphology. References in the reference list section should be arranged first alphabetically and then further sorted chronologically, using the appropriate pre-defined paragraph style.

Rapid urbanization urban form - a theoretical study of chinese megablock urbanism

Yixuan Peng[1], Gerhard Bruyns[2]
[1] Environmental Design, The Faculty of Art and Design, The Guangdong University of Technology, Guangzhou, China, evelyne.peng@connect.polyu.hk

ABSTRACT

As the most extensive urbanization in human history, rapid development in China has led to the proliferation of the megablock urban form—a distinctive approach to managing the spatial dynamics of burgeoning populations and their demands. Existing theories on Chinese urbanization have failed to provide a clear understanding of megablock development, given its exceptional context and spatial characteristics. Understanding and assessing this unique urban phenomenon requires a morphological matrix with a comprehensive framework critically derived from urbanism theories, with Chinese urbanism characteristics. This study investigates the theoretical underpinnings from an international perspective, for instance, the garden city, new town movement, new urbanism, suburbia, urban sprawl, compact city, and communist planning, by studying their context, factors, cases, and urban forms. It further connects and restructures the theoretical framework with the Chinese context and conditions of megablock urbanism, seeking to understand its role in shaping the urban landscape. The aim is to critically assess the spatial characteristics of this urban form with representative factors and variables. Utilizing a qualitative research methodology, the study synthesizes findings from theoretical and historical interpretations, policy reviews, case studies, and factor analyses. The findings reveal that Chinese megablocks differ from existing urbanisms, from their theoretical content to analytical tools. The study concludes that while the megablock urbanism model offers a rapid response to urban expansion, it necessitates careful consideration of its development mechanism. The implications of this research are significant for understanding the Chinese urban form and for future practice that should be consciously aligned with the need for sustainable and inclusive urban environments.

Keywords: Urbanism Theories, Megablock Research Framework, Morphological Metrix

INTRODUCTION

Chinese modern rapid urbanization is unprecedented and exceptional in urban development history. It is characterized by the largest population, the fastest pace, and a publicly owned land system. This unique combination sets China apart from other urbanization processes observed globally.

The sheer scale of urbanization in China is staggering. Over the past few decades, hundreds of millions of people have migrated from rural areas to urban centers, transforming the demographic landscape. This massive influx has resulted in the rapid construction of cities, infrastructure, and housing, often at a pace that far exceeds historical precedents in other countries.

Moreover, the speed of urban development in China is unparalleled. While many countries have experienced gradual urbanization over centuries, China's transformation has occurred in just a few decades. This accelerated growth poses significant challenges and opportunities, influencing economic, social, and environmental dimensions of urban life.

The publicly owned land system in China further complicates the urbanization narrative. Unlike many Western countries where land is privately owned and market-driven, China's land is primarily owned by the state. This system allows for swift decision-making and implementation of large-scale projects but can also lead to issues such as displacement and social inequality.

Given these distinctive features, applying existing Western urban theory to explain Chinese urbanization would be inadequate and potentially misleading. Western theories often rely on assumptions rooted in individual property rights, market dynamics, and incremental growth patterns, which do not fully capture the complexities of China's urban transformation. A more nuanced approach is required, one that recognizes the unique social, political, and economic contexts shaping Chinese cities.

This study explores three pivotal concepts—speed, scale, and form—in relation to contemporary Chinese urbanization. Speed refers to the rapid expansion of urban areas in China, characterized by a swift migration of populations and the quick construction of infrastructure. Scale addresses the massive scope of urban development, with entire cities designed to accommodate millions of residents within a remarkably short timeframe. Form pertains to the physical layout and architectural design of these large-scale urban areas, particularly at the community level.

The research originated from a keen observation of these unique aspects of Chinese urbanization, prompting questions about how speed, scale, and form intersect to shape the morphologies of Chinese mega-block developments. The introductory chapter establishes the research background, underscoring the rapid rate of urbanization in China and the emergence of mega-block developments as a response to this growth.

This introduction contextualizes the genesis of the research questions and theoretical framework, situating them within China's unprecedented urban transformation. By reviewing key concepts and laying the analytical groundwork, the introduction prepares the study for a critical investigation of its research queries and clearly articulates the research objectives and expected outcomes.

Gaubatz (1995) characterized post-reform urbanization in China as a transition from traditional work-unit structures to expansive commodity housing compounds, largely developed by a mix of private and state-owned real estate companies. Despite this shift, the designs of these developments often maintain an enclosed, amenity-rich environment. Guillaume elaborates that many of Beijing’s current gated communities originated as work-unit compounds (danwei dayuan, 单位大院) during the socialist era, which have since been commercialized and commodified following housing reforms.

Some of these extensive compounds feature dozens of towers, capable of housing over 100,000 residents, essentially functioning as self-contained miniature cities.

Huang (2006) details how Chinese commodity housing estates often act as self-sufficient mega-communities. This design approach reflects the communist ideal of self-sufficiency, minimizing the necessity for residents to venture outside their community. From a governance perspective, this model fosters social cohesion and cultivates a sense of collective identity. Features such as unified façades, strategic branding, professional property management, and active homeowner associations work together to dictate the community's operations and aesthetics. At its core, the People's Republic of China (PRC) implements a publicly owned land system, evolving from the traditional communist danwei (单位) model into modern capitalist mega-compounds. Nevertheless, the foundational principles of creating large-scale, collective communities continue to permeate the narrative of China's rapid urbanization.

However, the real estate-driven commodity housing model diverges significantly from both Western urbanism and the Chinese communist work-unit system. Its distinctive characteristics of speed, scale, and form have generated a unique urban model that this study seeks to investigate. By examining relevant urban theories—including their definitions, descriptions, influencing factors, and case studies—the research aims to construct a theoretical framework specifically tailored to the rapid urban forms emerging in China. This framework will facilitate a deeper understanding of the complexities and implications of Chinese urbanization in a global context.

CRITICAL LITERATURE REVIEW FOR THEORETICAL FRAMEWORK

Urbanism encompasses the study of how urban inhabitants interact with their built environment, capturing the essence of urban life, organization, and challenges (CTI Reviews, 2016; Jacobs, 1961). It is characterized by density, diversity, and intricate social structures (Gottdiener et al., 2016; Florida, 2002). One of the most influential definitions comes from Louis Wirth (1938), who outlined four key features of urban experience: population heterogeneity, functional specialization, anonymity, and standardized behavior. His ideas were expanded by scholars like Herbert Gans (1962) and Manuel Castells (1977), who examined the nuances of urban experiences and the significance of space.

Since World War II, urban challenges in the U.S. have been analyzed by scholars such as Thomas Sugrue (1996) and Robert Putnam (2000), while post-war European urban development has often focused on restoring historical identity (Hall, 1998). The boundaries between urbanism and suburbanism have blurred, with subcultures permeating various regions and a high-consumption lifestyle becoming prevalent (Gottdiener et al., 2016; Baudrillard, 1981).

The emergence of urbanism in the early 20th century was tied to centralized manufacturing, mixed-use neighborhoods (Leyden, 2003; Jacobs, 1961), and social networks (Dupuy et al., 2008; Castells, 1989). Savage and Blokland (2008) describe this convergence of political, social, and economic citizenship as a reflection of collective urban life (Park et al., 1925). Dupuy et al. (2008) applied network theory to urbanism, identifying its networked nature as a dominant characteristic that challenges traditional spatial concepts.

Stephen Graham and Simon Marvin (2001) argue we are entering a post-urban environment, where decentralized neighborhoods replace traditional urban spaces, leading to "splintering urbanism." This fragmentation results in enclaves of global connectivity alongside network ghettos (Graham & Marvin, 2001). Dominique Lorrain suggests that this splintering began in the late 20th century with the rise of gigacities, characterized by network density and blurred boundaries (Brenner & Schmid, 2015).

Manuel Castells (2002) posits that premium infrastructure networks selectively connect favored users while bypassing others. Graham and Marvin (2008) argue that attention to infrastructure is often reactive rather than systematic, highlighting a disconnect between urban life and infrastructure networks (Fainstein, 2000).

Additionally, Douglas Kelbaugh (2001) identifies three paradigms within urbanism: New Urbanism, Everyday Urbanism, and Post-Urbanism. Paul L. Knox (2010) discusses the “aestheticization of everyday life” (Zukin, 1995), while Krieger & Saunders (2009) contend that urban design is more a mindset than a technical discipline (Cuthbert, 2006).

For this research on Chinese megablocks, we can consider scale, speed, and form as technologies of urbanization. Urban morphology theory posits that space itself is a form of technology, intricately linked to how spatial elements connect (Hillier, 2007; Rapoport, 1977). Thus, understanding urbanity necessitates examining space and scale (Lefebvre, 1991). Figure 1 illustrates the relevant urbanism theories contributing to the phenomenon of Chinese megablocks.

Figure 1. Framework of relevant urbanism theory that contributes to the phenomenon of Chinese megablock

New Town

The Garden City concept significantly influenced modern urban planning, representing a shift from historical city centers to planned satellite towns. While not directly part of the New Town Movement, early designs like Versailles set a precedent for comprehensive urban planning, and cities like Amsterdam integrated garden city principles into their suburbs (Mumford, 1961). The New Town Movement emerged as a response to urban overcrowding, exemplified by Letchworth, the first Garden City, and developments like Crawley and Toa Payoh aimed at alleviating housing crises (Howard, 1902; Cullingworth, 1997).

Pioneered by Ebenezer Howard in the late 19th century, the Garden City Movement sought alternatives to the chaotic industrial cities of Britain, emphasizing ecological balance and functional land use (Ward, 2002). Patrick Geddes critiqued urban living conditions, while the rise of modernist

thought—spurred by planners from the Soviet Union, the Bauhaus Group, and figures like Le Corbusier—focused on functional land allocation and high-density designs (Choay, 1965). Le Corbusier's "Towers in the Park" concept proposed high-rise structures surrounded by greenery, promoting urban density management and sustainability (Kostof, 1991). Planners influenced by the Athens Charter played crucial roles in orchestrating urban expansion, acquiring peripheral lands in advance to mitigate congestion (Merlin, 1980). The postwar era saw the garden city and neighbourhood unit principles guiding societal cohesion (Wakeman, 2016). The New Town Movement's principles spread to British colonial territories, laying the groundwork for contemporary urban planning (Home, 2013; Hall & Ward, 1998).

Garden City and New Town Movement illustrates a paradigm shift toward ecological balance and managed density in urban planning. Key concepts of scale, functional land use, and community design have evolved from Howard's vision, influencing modernist interventions and fostering a collective vision for sustainable urban growth.

New Urbanism

The New Urbanism movement emerged in the 1990s as a response to regional sprawl, advocating for human-scaled urban environments (Gottdiener et al., 2016). Unlike the holistic concepts of modernist designs like La Ville Radieuse, New Urbanism promotes limitless and open-ended territorial expansion. A defining feature of this movement, especially in American cities, is the prominence of highways, which shape urban planning and contribute to sprawling development.

Key figures, such as Elizabeth Plater-Zyberk and Andres Duany, exemplified New Urbanism through their design of Seaside, Florida, emphasizing grid layouts and identifiable town centers (Grant, 2001). This approach is further illustrated in transit-oriented developments like Chatswood in Sydney and Del Mar Station in Los Angeles, which integrate residential, commercial, and recreational spaces to promote walkability.

The movement draws on Clarence Perry's concept of the Neighborhood Unit, which emphasizes schools as central nodes surrounded by accessible services to foster community and reduce car dependency. Doug Farr's Sustainable Neighborhood Unit updates these principles by incorporating green infrastructure and addressing climate change (Farr, 2010). Peter Calthorpe and William Fulton advocated for a holistic approach to urban planning, where all components interact effectively, as seen in projects like Laguna West in California (Tabb et al., 2013). Andrés Duany's Urban to Rural Transect concept further informs New Urbanism by recognizing the spectrum of environments from dense urban centers to natural landscapes, promoting context-sensitive planning.

New Urbanism counters car-centric planning by emphasizing walkability, connectivity, and diverse land use. Its principles, as articulated by the Congress for the New Urbanism, advocate for sustainable transport, increased density, and a traditional neighborhood structure that fosters community. Collectively, these elements aim to create cohesive, inclusive communities that balance urban growth with environmental sustainability.

Urban Sprawl

Suburbs serve as transitional spaces between urban and rural areas, often contrasting with the compact city movement that advocates for higher urban density. Gottdiener et al. (2015) define suburbs as residential areas outside large central cities, characterized by lower population densities

than urban centers but higher than rural areas. The rise of suburbs was facilitated by the expansion of railway services to cities like London and the development of streetcar lines in North America, which enabled middle-class migration to picturesque residential zones (Ward, 1968; Gilfoyle, 1998).

Rapid suburban growth, exemplified by areas like Milton, Ontario (Bunting & Filion, 2010), and Arden Park, Sacramento (Jividen, 2005), was driven by economic prosperity and infrastructure investments. Suburban areas often cater to diverse needs with retail, recreational, and residential spaces, while zoning laws have shaped their landscapes, typically designating areas for residential use on larger plots (Hirt, 2015). The suburbanization process has also been marked by racial dynamics, with historically white-dominated regions increasingly welcoming minority groups seeking better opportunities (Fichman & Fowler, 2003; Yen, 2010). Cities like Portland, Oregon, have implemented urban growth boundaries to manage suburban expansion (Nelson & Dawkins, 2004), while post-war developments like Panorama City, California, exemplify self-contained suburban communities (Fogelson, 2005). Despite criticisms of suburbanization, including higher maintenance costs and the homogenizing effects of megablocks, suburbs have increasingly become centers of innovation and economic activity, as seen in Silicon Valley (Gottdiener et al., 2015).

Suburbanization trends have also spread globally, with countries like China experiencing rapid suburban development characterized by Western-style residential blocks (Lang, 2012). Scholars like McManus & Ethington (2007) and Mary Corbin Sies (2001) emphasize the need to redefine suburbs by considering geographical and economic contexts, moving beyond traditional stereotypes. In summary, suburbanization has transformed human settlement patterns, creating distinct landscapes that bridge urban and rural areas. Driven by mobility, economic forces, and evolving planning policies, suburbs strive for self-sufficiency while navigating challenges related to identity, autonomy, and integration with urban centers.

Compact City

The compact city model has become essential in sustainable urban planning, tracing its origins to Dantzig and Saaty's work in 1973, which emphasized high-density designs to enhance residents' quality of life while minimizing environmental impacts. Their framework included architectural, geographical, and socio-economic elements.

Following this, the European Commission's 1990 Green Paper on the Urban Environment advocated for denser urban forms and mixed land use, aligning with Burton's (2002) definition of a compact city as one that promotes efficient public transport and encourages walking and cycling. Subsequent scholars, including Jabareen (2006) and Dempsey et al. (2010), expanded the concept by stressing social diversity and the need to avoid urban sprawl through strategies like infill and redevelopment. Practical examples like Melbourne and Ballston in Virginia illustrate successful compact city implementations, focusing on walkable neighborhoods that integrate residential and commercial spaces. In contrast, critics like Breheny (1992) question the model's effectiveness, suggesting that higher densities may not yield the desired outcomes, as supported by studies from Stead and Marshall (2001). The compact city also intersects with the concept of megablocks, which may homogenize urban landscapes and reduce spatial diversity. The lack of a universally accepted definition complicates discussions around compact cities, leading to potential misapplications. Neuman (2005)

identifies key characteristics of compact cities, including high residential densities, mixed land uses, and multimodal transportation systems.

Ultimately, while the compact city model aims for efficient, livable environments, the integration of megablocks necessitates localized and nuanced strategies to ensure social equity and adaptability, reflecting the complexities of individual urban contexts. This evolution underscores the balance between fostering sustainable urban growth and maintaining community diversity and resilience.

Communist Planning

The urbanization of Soviet Bloc countries, particularly Russia, unfolded during the Cold War, characterized by a blend of ideological rigor and practical needs. In Moscow, state-controlled land facilitated large-scale housing and industrial projects, leading to uniform high-rise developments inspired by Modernist architects (Colton, 1995; Wybieralski & Mikulec, 2009). This approach resulted in mass housing on city outskirts, neglecting historical centers (Churakov, 2021). Notable examples include Yaroslavl's compact city complex, which centralized public services in a dense urban core (Ruble, 1995).

China adopted Soviet planning principles from the 1950s, prioritizing rapid industrialization and urban development, often at the expense of historical preservation (Xie & Costa, 1993; Tang, 2000). The establishment of self-contained "danwei" units reflected a collectivist vision under Mao, while post-1978 reforms under Deng Xiaoping catalyzed extensive urban reconstruction, blending socialist ideals with market dynamics (Wu, 2009; Ma, 2002).

Overall, the evolution of urban planning in Soviet Bloc countries and China illustrates a complex interplay of ideological dictates and practical necessities, shaping their urban landscapes and the function of megablocks in contemporary development.

METHODOLOGY

This study employs a systematic approach to develop a theoretical framework for Chinese Modern Urbanization (CMU) through an extensive literature review of urban theories. The initial phase involves a comprehensive examination of existing urban theories, particularly those rooted in Western urbanism, to identify relevant concepts and factors applicable to the study of megablocks in China.

Following the literature review, the methodology incorporates collaborative group discussions and Delphi analysis. These discussions aim to build a consensus among experts in the field, synthesizing insights from their academic work to refine the theoretical frameworks. This iterative process ensures that the revised frameworks are grounded in a broad spectrum of urban theories, reflecting both Western perspectives and the unique characteristics of the Chinese urban landscape.

To further enhance the theoretical framework, factor analysis is utilized to categorize significant variables identified from Western urbanism theories into comprehensive factors. This analytical approach allows for a structured evaluation of how these factors manifest within the Chinese context, ensuring that the framework is both relevant and adaptable to local conditions.

The literature review also leads to the selection of 50 pilot cases from various global regions, each representing distinct categories of urbanism that form the theoretical framework. These international cases are paired with 50 corresponding Chinese cases that exhibit characteristics of megablocks or

show influences from Western urban theories. The compilation of these 100 case studies provides a robust empirical foundation for the subsequent investigation into the urban morphology of megablocks in China, facilitating a comparative analysis that illuminates the intersections of local and global urbanization trends.

The methodology integrates literature review, expert consensus, factor analysis, and case study comparison to construct a comprehensive theoretical framework for understanding megablocks within the CMU context. This multifaceted approach ensures a thorough exploration of urban morphology, enabling the study to contribute valuable insights to the field of urban planning and development.

THEORETICAL FRAMEWORK OF CHINESE MEGABLOCK URBANISM (CMU)

In exploring the concept of Chinese Megablock Urbanism (CMU), a comprehensive theoretical framework has been established through a meticulous literature review and analysis of urban development models. This framework serves as a structured lens through which to examine the unique characteristics and dynamics of megablock developments in China. By identifying and synthesizing key factors and variables that influence these urban forms, the framework aims to illuminate the complexities of CMU. It encompasses various dimensions, including scale, density, accessibility, and livability, allowing for a nuanced understanding of how these elements interact within the broader context of rapid urbanization. This systematic approach not only highlights the significance of these factors in shaping urban experiences but also facilitates a rigorous analysis of megablock configurations in both domestic and international settings.

Development Process

The development of the CMU framework follows a structured methodology:

Variable Extraction: The initial phase involves gathering a diverse range of variables and factors from various urbanism models discussed in the earlier sections of the thesis, particularly focusing on the concepts of Megablock and relevant urban forms. This extraction process is documented in summary figure, which highlight the potential variables pertinent to CMU.

Relevance Filtering: In the second phase, the identified variables are meticulously filtered to ensure they are specifically relevant to the characteristics and nuances of Chinese megablocks. This step guarantees that the variables selected for the framework are contextually applicable to the phenomenon of CMU.

Factor Grouping: The filtered variables are subsequently organized into five core factors, reflecting their interrelations:

Radicalness: This factor includes critical variables such as scale and construction speed, key elements that define the rapid and extensive nature of megablock development in China.

Intensity: This encompasses variables like density, collectivity, and sustainability, which are essential for evaluating the compactness and operational efficiency of megablocks.

Morphology: Variables under this factor, such as urban form quality, architectural design, boundary definition, and public spaces, facilitate the analysis of the physical attributes and spatial organization of the megablocks.

Accessibility: This factor addresses transportation, walkability, and proximity, which are vital for assessing how well the megablocks connect with the surrounding urban environment.

Livability: This includes variables such as mixed-use diversity, quality of life, and self-sufficiency, which help gauge the comfort and convenience provided to residents within the megablocks.

Validation and Refinement

To ensure the robustness of the theoretical framework, the researcher engaged in group discussions and expert interviews, applying a Delphi method for feedback collection. This iterative process allowed for refinement and enhancement of the framework based on expert insights. The selected factors were also chosen for their capacity to be evaluated through morphological measurements, facilitating a more objective and quantifiable analysis of the CMU concept.

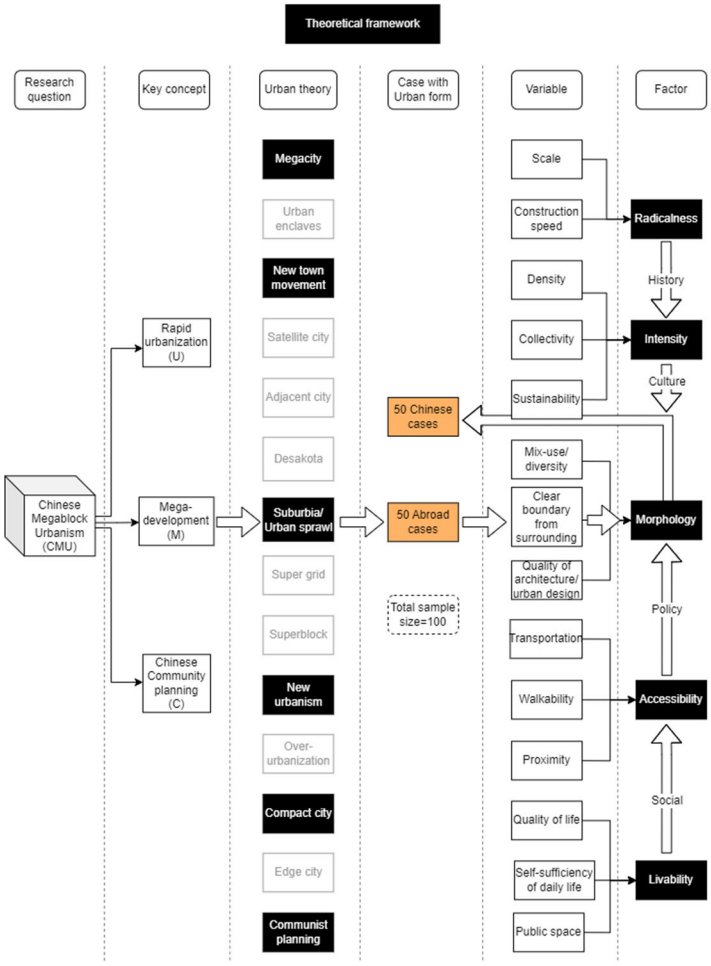

Figure 2 Theoretical Framework

Analytical Structure

The framework is designed to facilitate a hierarchical analysis, wherein broader factors are examined through extensive case studies, while specific variables are scrutinized in detailed case analyses. This

dual approach enables a comprehensive exploration of Chinese Megablock Urbanism (CMU) at both theoretical and analytical levels. The cases utilized in developing the theoretical framework have been assessed using morphological measurements tailored to the research objectives. Figure 3 presents examples of the analytical results. For each case, visualizations depict block scale and form, road density, network connectivity, and proximity in cartographic representations. In total, this study has assessed 100 cases using the same methodology, thereby providing an objective analysis of the morphological characteristics of CMU.

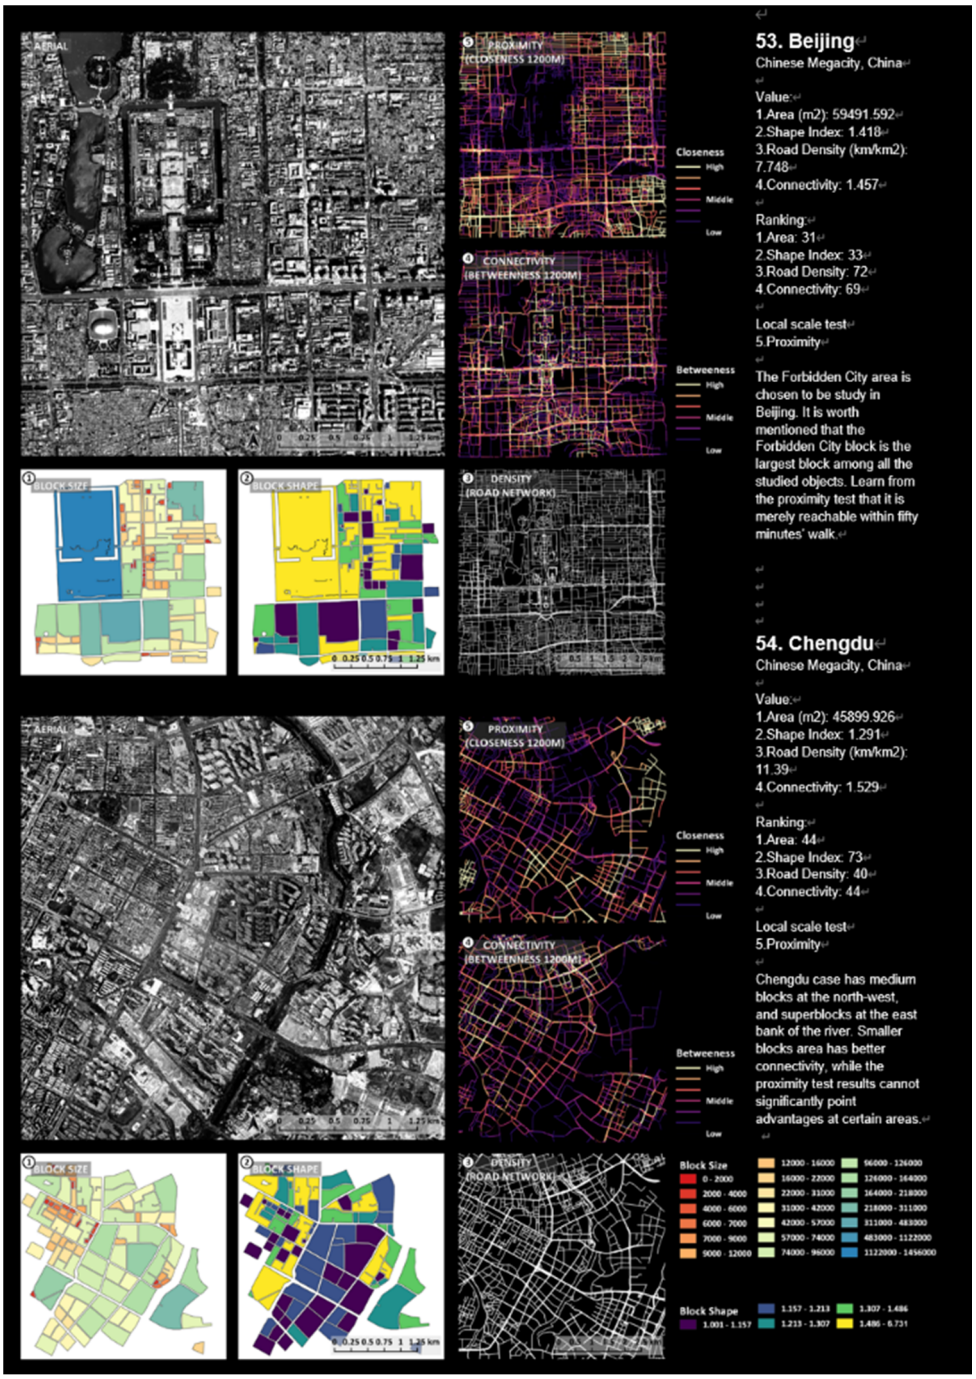

Figure 3. Examples of CMU morphological analysis results.

In conclusion, the theoretical framework established in this research provides a systematic and thorough lens through which to understand the dynamics of Chinese Megablock Urbanism (CMU). The framework facilitates a hierarchical analysis, wherein broader factors are examined through extensive case studies, while specific variables are scrutinized in detailed case analyses. This dual approach enables a comprehensive exploration of CMU at both macro and micro levels. The cases utilized in developing the framework have been assessed using morphological measurements tailored to the research objectives. Figure 3 presents examples of the analytical results, with visualizations depicting block scale and form, road density, network connectivity, and proximity in cartographic representations. In total, this study has assessed 100 cases using the same methodology, providing an objective analysis of the morphological characteristics of CMU. The logical interconnections between the identified factors and variables, as derived from the critical literature review, are visually represented in a diagram (FIG 2), offering a clear overview of the framework's structure and relationships. This comprehensive approach not only elucidates the complexities of CMU but also serves as a robust foundation for further research in this evolving field.

CONCLUSIONS

The rapid urbanization occurring in China represents an unprecedented phenomenon in human history, necessitating a reevaluation of existing Western urban theories. These theories often fail to adequately interpret the complexities and unique characteristics of Chinese urbanization, which is shaped by distinct socio-economic, cultural, and political contexts. As such, it is imperative that urban studies and planning frameworks evolve to better account for these factors, leading to the development of a theoretical model specifically tailored to Chinese conditions.

Chinese megablock urbanism (CMU) should be recognized not only as a case study but as a foundational theory in urban planning that can inform practices in other countries or regions experiencing similar urbanization processes. By examining CMU, planners and policymakers worldwide can gain insights into the dynamics of rapid urban growth, the interplay between urban morphology and social characteristics, and the implications for sustainable development.

The preliminary findings suggest that the analysis of CMU cannot be confined to a singular focus on context or morphology. Instead, it necessitates a hybrid approach that integrates context, morphology, and characteristic descriptions. This multifaceted perspective allows for a more comprehensive understanding of urbanization in China, facilitating the formulation of a robust CMU model that can serve as a reference for other urban contexts facing rapid transformation.

In conclusion, as global urbanization intensifies, the lessons derived from CMU are invaluable. By acknowledging the distinctive elements of Chinese urbanization and developing tailored theoretical frameworks, scholars and practitioners can enhance their understanding of urban dynamics. This approach not only enriches the academic discourse but also provides practical strategies for managing urbanization effectively in diverse global contexts.

DISCUSSION

This study aims to initiate a critical dialogue regarding Chinese modern urbanization (CMU), an area that has not received sufficient scholarly attention from either Western or Chinese academics. Given the context of significant national strategies such as the "Belt and Road Initiative," the "Asian

Infrastructure Investment Bank," and the Greater Bay Area (GBA) development, the implications of CMU extend beyond national borders and warrant a more profound investigation into its potential impacts both domestically and internationally.

Understanding the interplay among scale, density, and morphology within the framework of CMU is crucial for revealing urban spatial characteristics that define this unique urbanization process. These elements not only shape the physical landscape but also influence socio-economic dynamics, necessitating a comprehensive approach to developing an instructional guideline for CMU. By elucidating these relationships, researchers can better understand how urban forms evolve and how they can be optimized for future urban planning initiatives.

Future research should focus on deepening our understanding of CMU through the lens of urban morphology, aiming to direct urban development toward higher quality and sustainability. This perspective emphasizes the need to analyze urban forms and their interactions, which can lead to more effective strategies for managing urban growth and enhancing livability.

Moreover, adapting and refining analytical tools specifically tailored for the study of CMU is essential. Traditional urban analysis methods may not adequately capture the complexities of rapid urbanization in the Chinese context. Thus, there is a pressing need to develop innovative frameworks that can more accurately assess the spatial, social, and economic dimensions of CMU.

As Chinese rapid urbanization approaches a saturation point, we must consider the implications of entering a Post-CMU era. This transition presents an opportunity to explore urban regeneration strategies that can revitalize existing urban areas while addressing challenges such as environmental degradation and social inequity. Investigating how to effectively conduct urban regeneration within the CMU context will be critical for fostering sustainable urban environments that can adapt to evolving socio-economic conditions.

In summary, the study of CMU not only contributes to a richer understanding of urbanization in China but also offers valuable lessons for global urban planning practices. By focusing on scale, density, and morphology, adapting analytical tools, and exploring regeneration strategies, we can better navigate the complexities of urban growth in a rapidly changing world.

ABSTRACT

Rail transit is a pivotal mode of transport in high-density cities, and time sensitivity is of paramount importance, particularly for passengers walking to stations. Prior pedestrian accessibility measuring approaches have concentrated on space-based obstacles, thereby neglecting the temporal challenges encountered by pedestrians. The present study proposes a novel method that incorporates time obstacle parameters, including traffic light waiting time, elevator speed and stair climbing speed, via the use of Spatial Design Network Analysis (sDNA). This method is designed to evaluate 3-dimensional pedestrian accessibility in rail transit station areas utilizing precise time cost, which is reflective of the need for pedestrians to conserve travel time. Using this method, 5 typical rail transit station areas in Shanghai central district are analyzed and compared the 500m radius accessibility, whilst exploring its influencing factors. The results indicate that, multilayer walkways are effective in replacing pedestrian crossings thus save the walking time of rail transit station and improve travel efficiency, while reducing the number of vertical traffic conversion in the path is also necessary; network morphology can influence the distribution of accessibility of station area, the benefit on accessibility descend from circular network, chain network to isolate network.

Keywords: pedestrian accessibility, travel time, rail transit station area, sDNA

INTRODUCTION

As a pivotal mode of transportation in high-density cities, time sensitivity of rail transit is of paramount importance, and its travellers have a significant demand for time efficiency on commuting. Walking is the basic way to travel by rail transit, and it is also connects rail transit to other modes of transportation. The pedestrian accessibility of rail transit station area is of great importance on improving the efficiency of rail transit travel and attract passengers. Therefore, it is necessary to

evaluate the pedestrian accessibility of rail transit station area from the perspective of travel time cost.

The concept of Accessibility originated in the 1920s, which is generally regarded as the convenience in getting from one location to another via a specific transportation mode. In the current urban form studies on rail transit station area, the road network morphology is often regarded as the key influence factor on accessibility (Morris et al., 1978). Evaluation methods include: (1) The global quantitative evaluation based on the overall connectivity of the network; (2) the evaluation of network structure characteristics based on the calculation of indicators for specific paths (Xu et al., 2020). These evaluation methods mainly focus on spatial distance, converting walking time into walking distance by multiplying average walking speed, but neglect the importance of time cost as a fundamental travel characteristic of rail transit, and the walking experience of pedestrians. Moreover, rail transit station areas in Chinese cities are often high-density in construction with multiple layers of walking path, and the complexity of built environment leads to more waiting and speed changes during walking rather than exactly uniform movement. Therefore, the evaluation of pedestrian accessibility based on time and spatial distance perspective differs.

Though there were studies discussing the impact of obstructive factors on walking time in rail transit station area, such as trunk road and viaduct (Gao et al., 2021), waiting at signalized intersection (Jiao et al., 2017), standstill (Ando and Ujihara, 2019; Gehl, 2009), etc., current studies are qualitative analysis, and lack of solid quantitative analysis. Therefore, this study intends to quantify different types of spatial barrier factors into accurate walking time cost index, and use analytical software sDNA to objectively evaluate the pedestrian accessibility of the station area from the perspective of time.

METHOD

Research object

Rail transit station area

The research scope in the rail transit station area is set according to the comfortable walking distance for pedestrians, and 500m is widely used as the radius of analysis in existing studies. Therefore, the research area in this study is set as a buffer zone formed by a radius of 500m centered on the entrance-exits of the rail transit station (Figure 1).

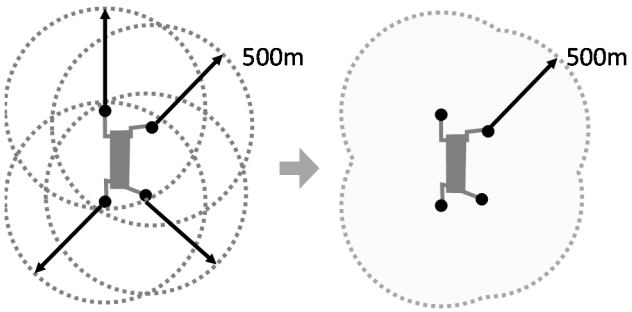

Figure 1. Research scope of rail transit station area.

Research cases

Five rail transit stations in Shanghai, China were selected as research cases: Xujiahui (S1), Wujiaochang- Jiangwan Stadium (S2), Jing'an Temple (S3), Zhongshan Park (S4), and Hongkou Football Stadium (S5). They are all located in the central city within the Outer Ring Road in Shanghai, surrounded by large business districts, as transfer stations of multiple rail transit lines, and have high intensity of construction and development, and their multilayer walking systems provide rich choice of walking paths.

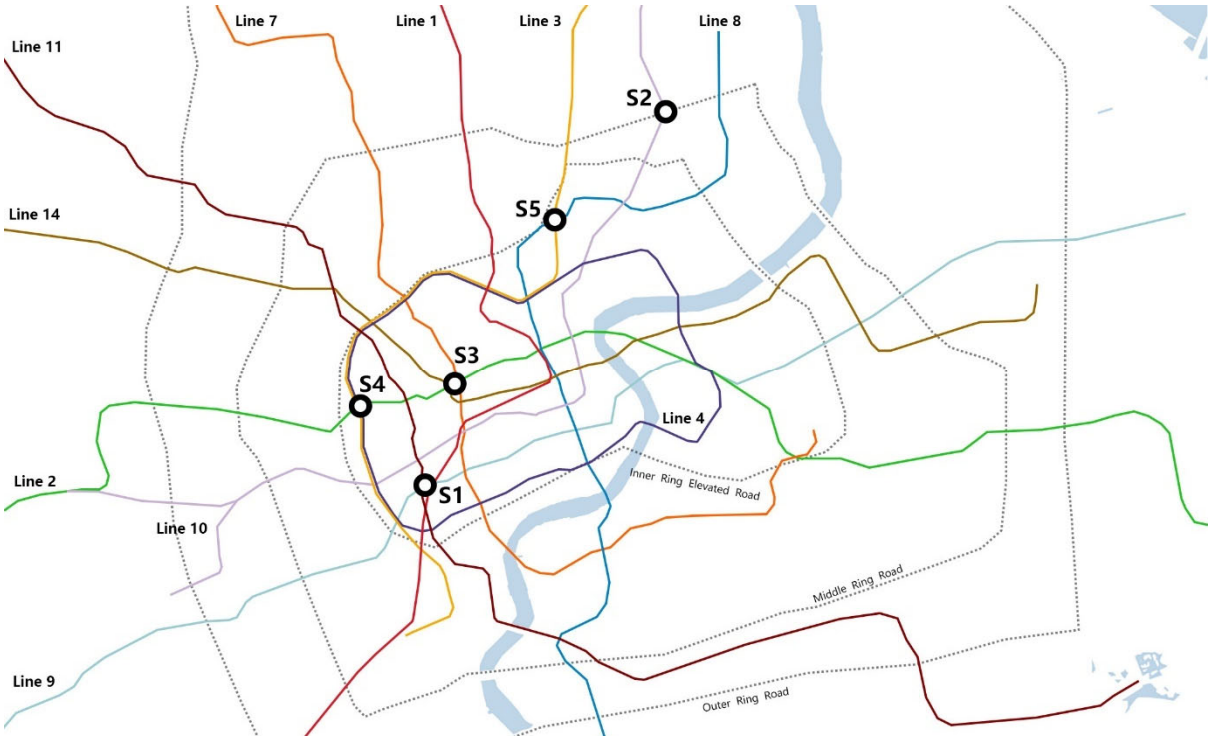

Figure 2. Location of 5 stations.

Figure 3. satellite image and street view photograph of 5 stations.

sDNA and the application

Spatial Design Network Analysis (sDNA) is an analysis tool developed in recent years based on ArcGIS platform and 3-dimensional perspective, which can achieve the goal of computing accessibility and analyzing the rationality of road network structure in a 3-dimensional environment (Cooper and Chiaradia, 2020). Compared with traditional network analysis, sDNA is able to objectively measure the difference of paths in the vertical direction by calculating the changes of distance, Angle or direction

equally on the X, Y and Z axes, and better simulate the path selection in multilayer walking system. In addition, sDNA also provides a custom measurement calculation method to adapt to diverse research scenarios. The application of sDNA has developed rapidly in recent years. Scholars such as Zhang (2019; 2021), Chen (2022) have applied this tool to the analysis and optimization of pedestrian networks in high-density cities, indicating that the tool is effective in analyzing the accessibility of 3-dimensional pedestrian network in high-density cities, and the application is highly flexible. Therefore, sDNA was selected as the calculation tool for the pedestrian accessibility of rail transit station area in this study.

sDNA uses Betweenness and Closeness to measure the "centrality" of a network (Bavelas, 1950; Freeman, 1977). Betweenness can be used to analyse the importance of individuals in a social network (Cooper, 2024). The potential of each street segment x as a through-movement channel is reflected by calculating the number of times each street segment x is crossed by the shortest path between any two other street segments y and z within a particular analytical radius.

$$Betweenness(x) = \sum_{y \in N} \sum_{z \in R_y} W(y)W(z)P(z)OD(y,z,x) \quad (1)$$

Where

N = The set of polylines in the global spatial system,
R_x = The set of polylines in the network radius from link x,
P_y = The proportion of any polyline y within the radius,
$W(y)$ = Weight of a polyline y.

sDNA parameter setting

In existing studies of pedestrian accessibility, Euclidean distance measurement and angular measurement are commonly used, while the composition of metric of angular and Euclidean (hybrid distance) measurement is widely used in sDNA analysis. In this study, the scenarios of standstill (waiting for red lights at the crossroads, waiting for the elevators, etc.) and speed changes (going up and down stairs, using escalators and elevators, etc.) are taken into account. By adjusting the parameters of different types of road sections, the time cost of travelling is accurately calculated by assigning the metric values of each road section based on the Euclidean distance in the sDNA calculation.

The time cost measurement parameter (N_t) denotes time-cost coefficient per unit length in the sDNA calculation, which represents the ratio of the actual walking time-cost of the road section to the time on a common walkway section the same length.

$$N_t = \frac{T}{T_0} = \frac{v_0}{v} = \begin{cases} \frac{L}{v_0 \times T_{cros}} & \text{(pedestrian crossings)} \\ \frac{2 \times v_0}{v_{up} + v_{dn}} & \text{(stairs)} \\ \frac{v_0}{v_{\text{esca}}} & \text{(escalators)} \\ \frac{v_0}{v_{\text{elev}}} & \text{(elevators)} \end{cases} \quad (2)$$

Where

T_{cros} = time span of whole street crossing process (s),
v_0 = walking speed at common walkways (m/s),
L = length of the path (m).

Common walkways

Existing studies have shown that pedestrian walking speed is generally within the range of 0.9 to 1.5m/s. Among them, Henderson's (1971) study in Sydney, Australia found that the average speed of pedestrian was 1.34m/s. Compared with other countries, the pedestrian walking speed in China is relatively low. Dai's (2009) study adopted 4km/h (1.11m/s) as the average pedestrian walking speed, and results of some surveys in Shanghai and Beijing show that the average walking speed of pedestrians is 1.21 to 1.24 m/s. Walking scene and crowd characteristics have a great influence on the walking speed. The walking speed inside rail transit station is higher than that in streets, passages and shopping malls, the walking speed of young and middle-aged people is higher than that of the elderly and children, and men's speed is higher than that of women. Based on the above research, this paper defines the average walking speed of common walkways (v_0) = 1.2m/s in the rail transit station area.

pedestrian crossings

Due to the high volume of motor vehicle traffic on urban arterial roads, vehicle efficiency is a higher priority when organising traffic at the crossroads, which is ensured by the use of a long-period signal control scheme, which interrupts pedestrian walking at intersections and causes an increase in travel time costs.

In this study, pedestrians are considered to be affected by two parts of delay when crossing the street at signalised intersections: the waiting time for the red light and the walking speed for crossing the street. Congestion due to the large number of pedestrians and the interference caused by right-turning vehicles at intersections are ignored.

$$T_{cros} = T_{pass} + T_{wait} \tag{3}$$

Where

T_{cros} = time span of whole street crossing process (s),
T_{pass} = time span of walking crossing the street (s),
T_{wait} = time span of waiting for a red light (s).

According to existing studies on pedestrian crossing walks at signalised intersections, and considering the age ratio of Shanghai's population, a speed of walking crossing the street of 1.4m/s is used in calculation.

When people pass through the intersection according to the signal, the waiting status can be divided into two categories: (1) if the light is green at arrival, and the remaining time of green light is long enough to pass the crossing, there is no need to wait; (2) if the light is red at arrival, or the remaining green light is not long enough to pass the crossing, then pedestrians need to wait until the next green light comes on.

$$\mathrm{F}_{\mathrm{wait}}(t) = \begin{cases} 0, \ 0 \le t \le T_1 - T_{pass} \\ T_2 + T_{pass} - t, \ T_1 - T_{pass} < t < T_1 + T_2 \end{cases} \tag{4}$$

Where

$\mathrm{F}_{\mathrm{wait}}(t)$ = The function of waiting time with respect to t (s),
t = time variable when pedestrian arrive at the crossroad (s),
T_1 = time duration of a green light (s),
T_2 = time duration of a red light (s).

Since the calculation involves the data of traffic light duration at each intersection, we recorded and counted the traffic light duration at 33 intersections in the research area, and calculated the average waiting time to cross the road according to formula (3). The results show that the waiting time to cross the road is significantly correlated with the number of motor vehicle lanes in the road section. After regression analysis of the data, formula (5) is obtained.

$$T_{wait} = 10.03 + 8.66 \times N_{dw} \quad (5)$$

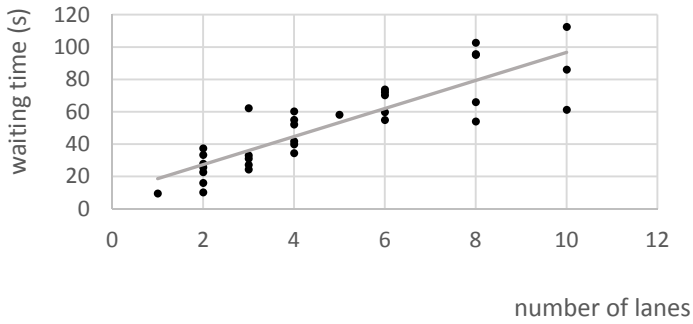

Figure 4. scatter diagram of average waiting time versus the number of lanes.

Therefore, crossing waiting times are estimated according to formula (5) based on the number of lanes in each road section. Then the time cost measurement parameter of pedestrian crossings can be calculated according to formula (6).

$$N_{tCros} = \frac{\frac{L}{1.4}+10.03+8.66\times N_{dw}}{\frac{L}{1.2}} = \frac{6L+18.43+72.744\times N_{dw}}{7L} \quad (6)$$

Where

N_{tCros} = Time index of pedestrian crossings,
L = length of the path (m),
N_{dw} = number of lanes.

Stairs

In the investigation of Beijing's pedestrian 3-dimensional crossing facilities, it is shown that the vertical speed of pedestrians going up the stairs is 0.21m/s, the inclined speed is 0.47m/s. Walking speed in the metro station is faster, and in the investigations of metro stations in Shanghai, Beijing, and Nanjing, the pedestrians go up the stairs at a speed of about 0.69 to 0.79m/s, and go down the stairs at a speed of about 0.81m/s to 0.92m/s. Based on the above investigation data, this paper adopts the

average speed of pedestrians going up the stairs (inclined speed) v_up=0.60m/s, and the average speed of going down the stairs v_dn=0.70m/s, then:

$$N_{tStair} = \frac{2 \times v_0}{v_{up} + v_{dn}} \approx 1.85 \quad (7)$$

Escalators

According to the relevant norms, the rated operating speed of escalator inclination angle α ≤ 30° is not more than 0.75m/s; the rated operating speed of escalator inclination angle α < α < 35° is not more than 0.50m/s. Field research is carried out on the escalators within the scope of this study, and the inclined speed of the escalator operation is calculated by measuring the length of time pedestrians use to pass through the escalator, the number of stair steps with the same height difference and the inclined angle of the escalator. The results show that the running speed of the escalators at the entrances and exits of the rail transit stations and that inside the commercial complexes are all about 0.5m/s, thus obtains:

$$N_{tEsca} = \frac{v_0}{v_{esca}} \approx 2.4 \quad (8)$$

Elevators

The elevators within the scope of this paper are mainly divided into two categories: accessible elevators in public facilities (underground stations, footbridges and underpasses) and passenger elevators in commercial complexes. Field measurement results show that the underground and public facilities configured barrier-free elevator has height of 1 to 2 floors, time of riding the elevator and waiting for the elevator length is roughly equal, the average speed is about 0.45m/s after entering the car, including the operation and operation of the buffer time; for the passenger elevator of the commercial complex, due to the number of floors, waiting time is about two times the time spend of the ride, the speed of about 0.3m/s. Therefore obtaining the following formula:

$$N_{tElev} = \frac{v_{esca}}{v_0} \approx \begin{cases} 8.0 & \text{(public facilities)} \\ 12.0 & \text{(commercial area)} \end{cases} \quad (9)$$

Modelling

The road network data was obtained through the open-source map (OSM), and on its basis, the correctness of the road network information was verified by combining satellite maps, street views and field research, and then the pedestrian network was mapped in Autodesk AutoCAD Map 3D. The pedestrian network included in the study consists of the following three categories: (1) at-grade public pedestrian paths; (2) 3-dimensional public pedestrian walkways; and (3) urban public space accessing the public pedestrian system.

According to range of the 500m research radius plus 500m analytic radius, the road network within 1000m radius of the rail station entrances and exits was modelled (Figure 5).

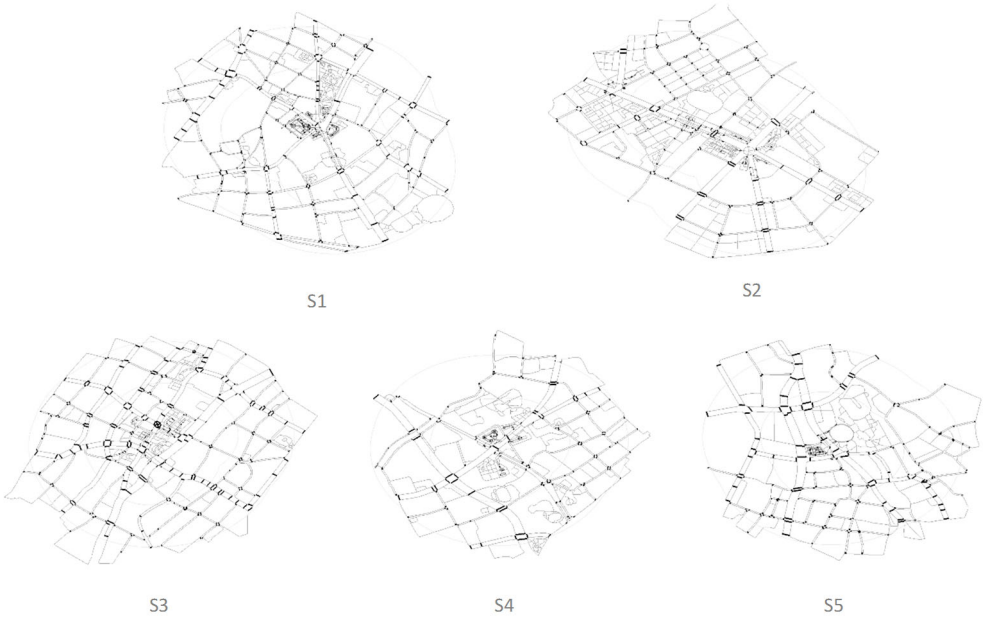

Figure 5. Illustration of pedestrian network modelling and N_t value of each sections.

The 3-dimensional structure of the pedestrian network is shown in Figure 6. The rail transit station hall, shopping malls and public pedestrian walkways in the station areas of S1 and S2 are connected to each other to form circular 3d walkways and extend outward; the network of S3 and S4 are mainly based on the station passage as the skeleton and extend in the form of a chain; and the network of S5 are more introverted, congregated on the interior of the station and the stadium ring road, and less extended and diffused to the outside.

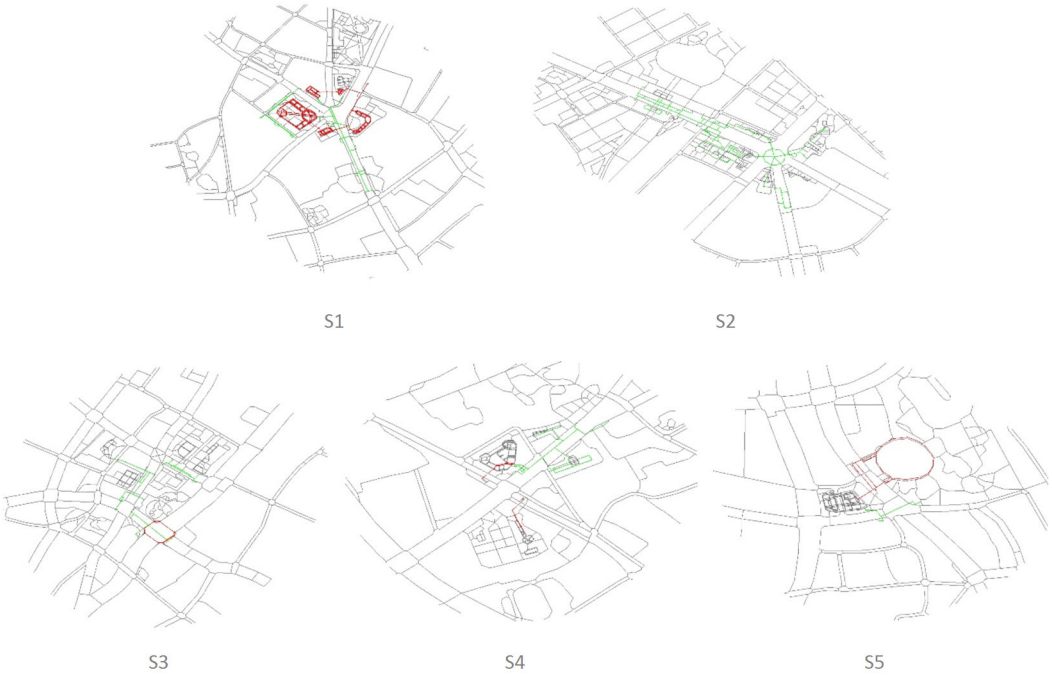

Figure 6. Composition of 3d walkways of each station area.

After the sDNA analysis, the calculation result of Betweenness in 500m analysis radius measured by time cost (BtC500) of each station areas are shown in Figure 7.

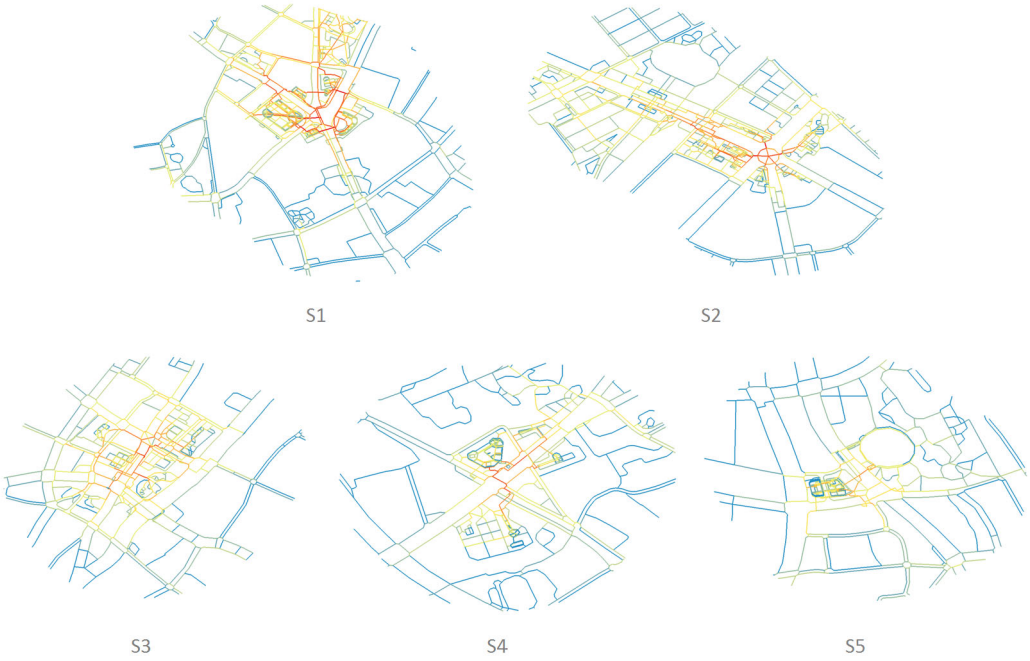

Figure 7. Calculation result of Betweenness in 500m analysis radius measured by time cost (BtC500).

ANALYSIS

Comparison of accessibility from the perspective of distance and time cost

The betweenness of 3-dimensional pedestrian network in each station area is calculated based on traditional measurement of Euclidean distance and the time cost measurement (Table 1). It is found that the sections with the highest betweenness in the former are mostly at-grade walkways and contain many pedestrian crossings, while the sections with the highest betweenness in the latter are mostly aerial and underground paths for crossing streets. This shows that the time cost of vertical traffic and detour through three-dimensional path is shorter than the average time cost of waiting for traffic lights. Therefore, compared with the at-grade pedestrian crossings, the multilayer walkways connecting land blocks can help save the walking time of the rail transit station area and improve the travel efficiency, though it takes a longer spatial distance. At the same time, this also reduces the potential for pedestrian-vehicle conflicts and safety hazards associated with crossing motorways.

Table 1. Comparison of Betweenness measured by Euclidean distance and time cost.

Station	BtE500（Measured by Euclidean distance）	BtC500（Measured by time cost）

S1		 0.00 - 347.06 347.07 - 522.96 522.97 - 870.01 870.02 - 1554.78 1554.79 - 2905.85 2905.86 - 5571.59 5571.60 - 10831.24 10831.25 - 21208.82 21208.83 - 41684.33 41684.34 - 82083.61
S2		S3		
S4		S5		
From time cost perspective: how 3D paths influence accessibility

The above studies show that under the consideration of time efficiency, people are more inclined to choose the 3d walkways in rail transit station area, which is consistent with the pedestrian activities observed on site. Therefore, the following studies all adopt the measurement from the perspective of time cost. In order to further explore the impact of 3d walkways on pedestrian accessibility, accessibility of the basic at-grade pedestrian network of the station area and the network containing 3d walkways (including the public walkways in the commercial complex) were further calculated and compared (Table 2 and Table 3).

Table 2. Comparison on BtC500 of different pedestrian network.

Station	basic network	3d network
S1		
S2		S3		
S4		
S5		
Table 3. Pedestrian network data and accessibility of each station area.

Station	length percentage of 3d walkways	Average equivalent distance of pedestrian crossings (m)	Average BtC500 of station area		
			basic network	3d network	rate of increase
S1	13.18%	62.65	2679.68	5477.19	**104.40%**
S2	12.42%	86.04	1814.43	3825.85	**110.86%**
S3	7.55%	110.32	2491.73	3362.11	**34.93%**
S4	12.91%	95.09	1399.79	2682.07	**91.61%**
S5	14.02%	117.20	836.44	1985.68	**137.40%**

The results show that the pedestrian accessibility of the station area after adding the 3d walkways is substantially improved. This is mainly influenced by the rail transit station construction mode. Constrained by development timing, engineering difficulty and other practical conditions, the layout of rail transit lines and stations in Chinese cities is often combined with the arterial traffic road for motor vehicles, resulting in generally long pedestrian crossing distances in the station area. From the time perspective, the equivalent crossing distance is about 3-4 times of the actual spatial distance on average, resulting in a large amount of time-consuming and negative influence on the station area pedestrian accessibility. Setting of 3d walkways can effectively reduce the negative impacts of the excessive time spent on crossing the street.

From time cost perspective: how 3D path morphology influences accessibility

According the above analysis, it is clear that the 3d walkways has a significant effect on increasing pedestrian accessibility from time cost perspective, but the effect varies from station to station, which is presumed to be related not only to the length of the 3d walkways, but also to the morphology of the network (Figure 8). Most of the 3d walkways in the rail transit station area are closely integrated with the station entrances, which enhances the accessibility of the rail transit station to the urban road network, so the effect of the 3d walkways on the accessibility of the station entrances and exits is included in the analysis. (Table 4).

Table 4. Comparison on Betweenness of station areas and entrance-exits.

Station	Average BtC500 of entrance-exits			Average BtC500 of station area		
	basic network	3d network	rate of increase	basic network	3d network	rate of increase
S1	3756.86	6719.32	78.85%	2679.68	5477.19	104.40%

S2	883.20	4229.43	378.88%	1814.43	3825.85	110.86%
S3	4201.82	6639.22	58.01%	2491.73	3362.11	34.93%
S4	1975.31	5090.77	157.72%	1399.79	2682.07	91.61%
S5	1021.35	4183.82	309.64%	836.44	1985.68	137.40%

The 3d walkways of S1 and S2 appear to be circular structure with outward extension, which closely connects multiple land blocks cut by the motorway, so that the rail transit station and the surrounding land blocks form a good connection, and the high-accessibility area radiates outward with the circular 3d walkways as the centre, so that the overall accessibility of the station area is increased exponentially. In addition, the circular 3d walkways are highly coupled with commercial complexes, and the high-accessibility areas of the station area are concentrated between commercial complexes, thus bringing in more consumer crowds. At the same time, 3d walkway of these two stations are set at the same level with the entrance-exits of station or commercial complex, avoiding the increase of walking time cost brought by complicated conversion in vertical circulation. For example, corridors on the first floor of S1 connects five shopping malls together, improving the accessibility of the commercial area; north side of the S2 station hall is closely combined with underground commercial street, which brings a very large increase on accessibility of entrance-exits of station.

In contrast, the morphology of the 3d walkways in S3 and S4 are in the form of catenate structure, and their high-accessibility area concentrate in the catenate space connected by the metro passage, which extends outward in the form of fishbone through the entrances and exits. Although these extension passages make sense in connecting the land blocks, their ability to radiate outward is relatively weak. The addition of the catenate 3d walkways to pedestrian network enhances the accessibility of the station entrances-exits more than that of the whole station area, so the scope of influence is relatively limited. In addition, the high-accessibility area of the rail transit station area is concentrated in the metro passage itself, and the connection between the neighbouring land blocks relies on the rail transit station hall to a large extent, which fails to better enhance the accessibility of the surrounding urban public space, and is prone to cause congestion in the metro station.

It should be noted that the pedestrian network structure of 3d walkway in S5 is an isolated one, with the worst degree of road network connectivity in general, and the 3d walkway is weakly connected to the surrounding urban space. The two rail transit station halls are located on the second floor and the basement floor, which leads to a complicated vertical circulation transfer and add to the walking time cost to a large extent, and it is also difficult to replace the at-grade walkway for quick connection among the land blocks. Although the interchange between the two station halls is spatially via the interior of the shopping mall, it is managed independently of the mall and cannot attract more consumers; on the other hand, the aerial walkway connecting the football stadium on the east side is also relatively isolated and does not have a good connection with the surrounding commercial and urban public spaces, resulting in a low efficiency of the 3d walkway and poor accessibility to the station area in general.

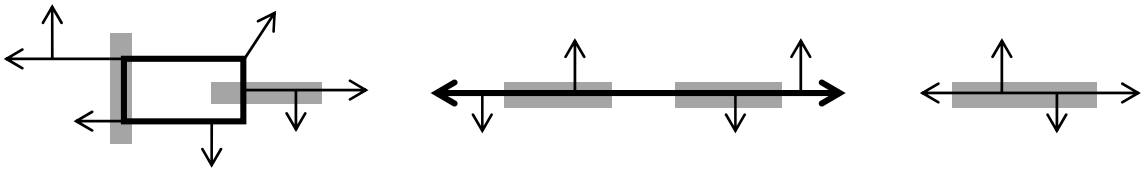

Figure 8. Different structure of 3d walkway in rail transit station area.

CONCLUSIONS

In this paper, the sDNA method is innovatively applied through the calculation of pedestrian accessibility in rail transit station areas. According to the actual situation of urban pedestrian network, the road section characteristics are quantified as time cost measurement parameters, making the sDNA accessibility calculation result more relevant to the travel efficiency needs of rail transit passengers and surrounding residents.

Through the case study of Shanghai rail transit station area, the following conclusions are drawn: (1) compared with the at-grade crossing pedestrian path, 3d walkways, although longer in spatial distance, is more conducive to saving the walking time of the rail transit station area to improve the efficiency of travelling; (2) the existence of 3d walkway in the rail transit station area can improve the pedestrian accessibility of the station area under the time cost perspective to a large extent; (3) circular 3d walkways, catenate 3d walkways and isolated 3d walkways, plays a descending role of improving pedestrian accessibility and consumption potential in the order, so future planning of pedestrian network in rail transit station area should give priority to the morphological consideration and reduce the complexity of vertical traffic transitions.

ABSTRACT

The combination of urban rail transit and walking has been widely used to solve different transportation problems as well as being catalyst for sustainable urban development. However, most previous studies and practices have focused on residential areas, neglecting that the characteristics of the built environment around subway stations in different functional zones may be different. This paper aims to explore the influence of pedestrian environment details around different functional types of stations on pedestrian walking psychology and satisfaction.

In this study, 11 evaluation indexes were extracted from five dimensions which include walking convenience, traffic safety, indication guidance, sidewalk quality and environmental facilities, and the framework of pedestrian environment assessment in station area was established. In addition, 15 typical subway station areas in Shanghai were selected and categorized into three functional types: residential area, commercial service area and business office area. At each survey station, the investigators were asked to collect 30 questionnaires, a total of 446 questionnaires were collected and the response rate was 99.1% (446 /450).

The results show that: (1) the interviewees are generally but not excessively satisfied with the pedestrian environments around three types of stations; (2) the convenience of crossing the street intersection has a major impact on pedestrian overall satisfaction, and the smooth and clean sidewalk, less vehicle traffic interference are also highly correlated with pedestrian overall satisfaction; (3) the influence factors of pedestrian satisfaction evaluation are different among the three types of station areas, among which, the pedestrian satisfaction of business office area is higher than that of other types of station area, but it has higher requirements for bus transfer, street commercial facilities and climate shelter facilities, while the pedestrian satisfaction in residential station areas is generally low, especially in terms of traffic safety and sidewalk quality.

Keywords: subway station area, pedestrian environment, satisfaction evaluation, functional zone

BACKGROUND

With the popularization of green travel and low-carbon development, the construction of pedestrian-friendly environments around metro stations has become a common concern in urban transportation planning and urban design fields (Xu, Liu and Lu, 2015; Jiao, Chen and He, 2017; Houston et al., 2015). A high-quality pedestrian environment in station areas is crucial for attracting citizens to choose public transportation and fostering diverse public activities such as social interactions and leisure (Freeman et al., 2013). Previous studies have mostly focused on the environmental walkability of specific functional types of station areas (Shen et al., 2020; Zhang et al., 2020; Guo, 2009), lacking analysis of the pedestrian environment needs of different functional types of station areas. However, the functional types of metro stations are influenced by the types of urban land use and urban forms around the stations (Duan and Zhang, 2020). For example, land use dominated by commercial services, residential living, and office employment will have different planning layouts, resulting in different built environments (Lu et al., 2023). Additionally, passengers traveling to and from different functional types of station areas may have varying requirements for the performance of the pedestrian environment in these areas due to different travel purposes.

Shanghai, China, is experiencing a rapid development period in its rail construction. Currently, there are 20 operational lines with a total of 508 stations and an operating mileage of 831 kilometres, ranking first in the world. The fast and convenient urban rail transit construction has attracted nearly half of Shanghai's citizens, with an average daily passenger flow exceeding 10 million, presenting new opportunities and challenges for the pedestrian-friendly environment in station areas. Taking the central urban area of Shanghai as an example, this paper evaluates the pedestrian-friendly environment of 15 station areas, analyses the differences in pedestrian environment needs of station areas with three dominant functions: commercial services, residential living, and office employment, and explores corresponding environmental improvement and optimization design strategies. The aim is to provide ideas and references for the planning and design of pedestrian environments around metro stations, promoting green travel and low-carbon development in the city.

RESEARCH DESIGN

Evaluation Indicators

Referring to Maslow's hierarchy of needs theory and the TOD (Transit-Oriented Development) walkability evaluation system (Jiao, Chen and He, 2017), the evaluation of pedestrian-friendly environment performance in station areas is summarized into five major performance indicators: convenience and continuity, pedestrian and vehicle safety, signage and guidance, sidewalk quality, and environmental facilities. These are further subdivided into 11 specific individual indicators (Table 1).

Among them, convenience and continuity refer to the accessibility of rail transit stations perceived by walkers, involving the street network, bus stops, and street crossing facilities around the station area. Pedestrian and vehicle safety refers to the interference of pedestrians by motor vehicles when walking, which is related to mixed traffic, disorderly parking, and occupying lanes. Signage and guidance refer to the signage and guidance of the site, mainly related to the signage guidance system of the surrounding streets. Sidewalk quality refers to the quality and width of the pavement foundation, including flatness, cleanliness, footpath width, etc. Environmental facilities are designed to meet the daily basic needs of walkers, including sufficient commercial facilities along the street, recreational facilities for public communication, shelter facilities for bad climates, and so on.

Table 1: Pedestrian environment indicators for metro station areas

Performance Dimension	Element Code	Element Indicator
Convenience and Continuity	A1	Convenient and direct walking paths
	A2	Easy access to bus stops
	A3	Convenient pedestrian crossings
Pedestrian and Vehicle Safety	B1	Low interference from motor vehicle traffic
	B2	Sidewalks free from vehicles or obstructions
Signage and Guidance	C1	Clear signage for the metro station
Sidewalk Quality	D1	Smooth and clean sidewalks
	D2	Spacious sidewalks
Environmental Facilities	E1	Numerous commercial facilities along the road
	E2	Enough green spaces and plazas along the road
	E3	Ample shaded areas along the road

Case Selection

The jobs-housing ratio is a key indicator for evaluating the balance between employment and housing, revealing the land use patterns around the station area (Woo, 2021). The definition of this ratio involves specific factors depending on local demands, economic structure, and commuting patterns (Wu, Zhang and Yang, 2015). Considering Shanghai's large urban scale and high-density built environment, along with the measure of walkability, this study defines the service coverage area of each station by taking the station exit as the centre and a radius of 500 meters. The jobs-housing ratio within this defined area is calculated to categorize metro stations into three dominant functional types: commercial, residential, and office (Table 2).

Table 2: Indicators of dominant functional types in metro station areas

Type	Index
Commercial Type（I）	0.6 < jobs-housing ratio (building area) < 1.5
Residential Type（II）	jobs-housing ratio (building area) < 0.6
Office Type（III）	jobs-housing ratio (building area) > 1.5

Based on the above three main function types, 5 typical rail interchange site areas are selected (Figure 1, Table 3). The above 15 stations are transfer stations, with an average daily passenger flow ranging from 56,000 to 154,000, and their large number of people can ensure the diverse social attributes of passengers, and have the urgency of improving the walking environment.

Figure 1: Location distribution of railway interchange stations

Table 3: The selected rail transit station number

Type	Code	Station Name	Metro Line	Passenger Amount
Commercial Type（I）	I-1	Caobao Rd	1+12	63157
	I-2	Dongan Rd	4+7	57519
	I-3	Jiangwan Stadium	4+8+10	80314
	I-4	Nanjing Rd.(W)	2+12+13	153760
	I-5	Yishan Rd	3+4+9	90065
Residential Type（II）	II-1	Caoyang Rd	3+4+11	64432
	II-2	Changshu Rd	1+7	61358

Office Type（III）	III-1	Hanzhong Rd	1+12+13	73512
	III-2	Hongkou Football Stadium	3+8	73584
	III-3	Jinke Rd	2	66934
	III-4	Lujiazui	2	153701
	III-5	Zhaojiabang Rd	7+9	58098

Data Source

Information about the pedestrian environment in the three types of functionally dominant station areas was collected through questionnaires. The questionnaire comprised three main sections: the first part collected the respondents' basic social attributes, the second part ranked the importance of different pedestrian environment performance indicators according to the respondents, and the third part evaluated the respondents' satisfaction with the pedestrian environment. In the second part, the importance ranking of each indicator by the respondents was assigned corresponding scores: 3, 2, and

1, and the importance scores of each single indicator were weighted and normalized to obtain the demand degree of the corresponding indicators. The third part evaluated the respondents' satisfaction with the environment using a Likert scale, with five levels: "Very Satisfied," "Satisfied," "Neutral," "Dissatisfied," and "Very Dissatisfied," corresponding to scores of 5, 4, 3, 2, and 1. The data were then statistically analysed using Excel and SPSS software.

Data collection was conducted from May 2023 to April 2024. Thirty questionnaires were distributed to pedestrians using the metro at each survey station, with a total of 446 valid questionnaires collected, resulting in a response rate of 99.1%. According to statistics, the overall situation of the respondents is as follows: males accounted for 44.62%, less than females; the age range was mainly concentrated between 18 and 60 years, accounting for 81.61%; more than half of the respondents used the metro at least three days a week, ensuring the validity of the questionnaire information. During the survey, additional methods such as spatial environment annotation analysis, semi-structured interviews, and behavioural activity observations were also used for cross-verification of the survey results.

DATA ANALYSIS

Demand degree of Pedestrian Environment

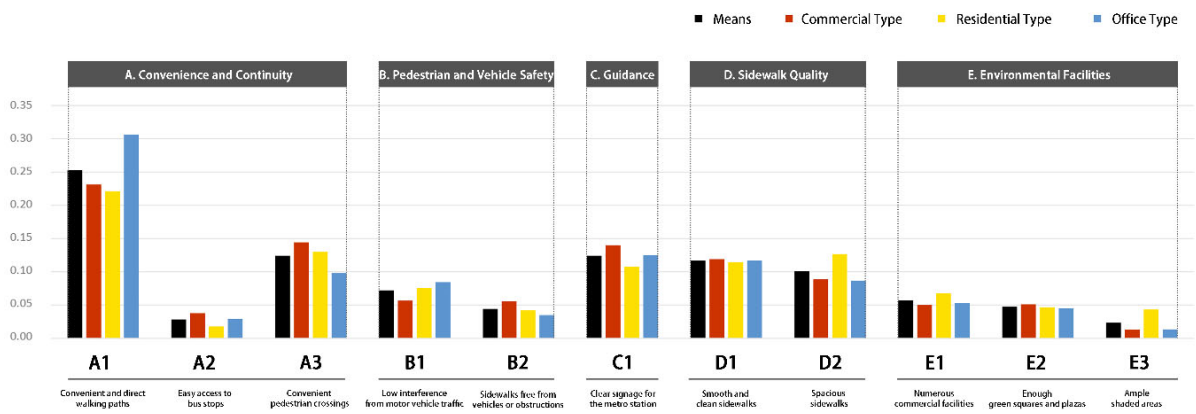

Figure 2: The demand degree of pedestrian environment dominated by different functions

From the performance indicators of respondents' demands for the pedestrian environment in station areas (Figure 2), "A: Convenience and continuity", "C: Signage and guidance", and "D: Sidewalk quality" have generally higher demand levels, indicating significant concern from pedestrians. Among the individual indicators, "A1: Convenient and direct walking paths" has the highest demand level (25.26), followed by "A3: Convenient pedestrian crossings" (12.43), suggesting that the convenience of reaching the station should be a primary consideration in design.

As for the dominant functional types of the station areas, there are significant differences in pedestrian demands. Residential dominant stations have a significantly higher demand for "D2: spacious sidewalks", "E1: Numerous commercial facilities", and "E3: Ample shaded areas" compared to the average. Office dominant stations have a significantly higher demand for "A1: Convenient and direct walking paths" and "B1: Low interference from motor vehicle traffic" compared to the average. Commercial dominant stations have a significantly higher demand for "A3: Convenient pedestrian crossings", "A2: Easy access to bus stops", "B2: Sidewalks free from vehicles or obstructions", and "C1:

Clear signage for the metro station" compared to the average. Overall, residential areas focus more on the comfort and convenience of the pedestrian environment, office areas emphasize the efficiency and safety of pedestrian access, while commercial areas prioritize the convenience and continuity of walking paths. These differences in demand can provide a basis for targeted optimization of the pedestrian environment around metro stations.

Satisfaction Evaluation of Pedestrian Environment

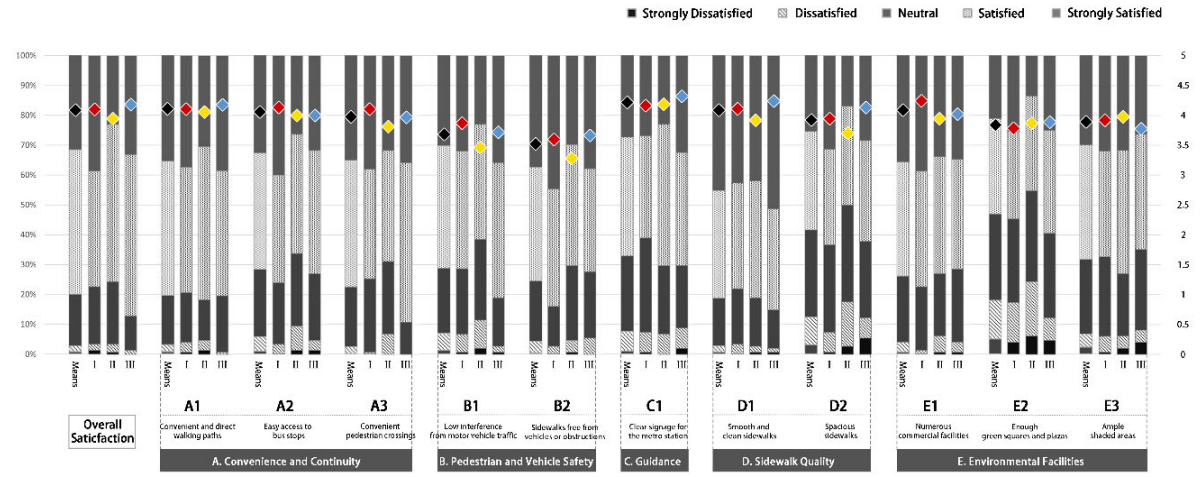

Figure 3: The satisfaction evaluation of pedestrian environment dominated by different functions

Based on respondents' overall satisfaction with the pedestrian environment around station areas (Figure 3), the average score is 4.08, indicating a generally high level of satisfaction with the pedestrian environment around the case study stations. From the perspective of the performance dimensions of the pedestrian environment, the rank is that "C: Signage and guidance" (4.24) > "A: Convenience and continuity" (4.05) > "D: Sidewalk quality" (4.02) > "E: Environmental facilities" (3.94) > "B: Pedestrian safety" (3.60). Among the individual indicators, "C1: Clear metro station signage" has the highest satisfaction score (4.24), while "B2: Sidewalks free from vehicles or obstructions" has the lowest satisfaction score (3.51), indicating that illegal occupation of sidewalks by non-motorized vehicles, motor vehicles, and other facilities affects the smooth passage of pedestrians around the stations.

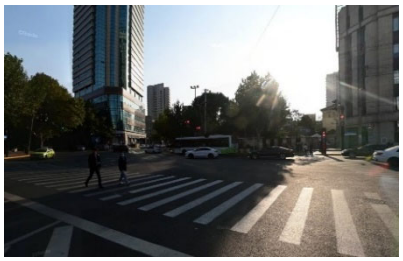

Figure 4:
Problem of intersection crossing (A2) around residential type (Station Code ：II-2)

Figure 5:
Problem of walking path width (D2) around residential type (Station Code ：II-1)

Figure 6:
Problem of vehicle interference (B1) around residential type (Station Code ：II-3)

Further comparison of the satisfaction indicators for the pedestrian environment in station areas with different functional types reveals that residential stations have the lowest overall satisfaction (3.94) and generally lower satisfaction across various performance dimensions. Pedestrians rate "A:

Convenience and continuity", "B: Pedestrian safety", and "D: Sidewalk quality" relatively low (Figures 4-6). However, some individual indicators, such as "E2: Numerous green spaces along the road" and "E3: Ample shaded areas" are rated higher than average, indicating that the construction of recreational facilities in the pedestrian environment around residential dominant stations is relatively complete. Office stations have the highest overall satisfaction (4.19), with generally high individual satisfaction scores, although "A2: Easy access to bus stops", "E1: Numerous commercial facilities along the road", and "E3: Ample shaded areas" are below average (Figures 7-8). Commercial stations have slightly above-average overall satisfaction (4.11), with individual satisfaction scores fluctuating around the average, and all elements are rated well.

Figure 7:
Lack of commercial facilities (E1) around office type (Station Code ：III-3)

Figure 8:
Lack of shade space (E3) around office type (Station Code ：III-2)

Differences in Satisfaction of Stations with Different Functional Types

Table 4: One-way Anova Analysis of Different Functional Station

Dimension	Code	Element	F
	—	Overall Satisfaction	3.792*
Convenience and Continuity	A1	Convenient and direct walking paths	
	A2	Easy access to bus stops	
	A3	Convenient pedestrian crossings	4.526*
Pedestrian and Vehicle Safety	B1	Low interference from motor vehicle traffic	5.483**
	B2	Sidewalks free from vehicles or obstructions	5.067**
Signage and Guidance	C1	Clear signage for the metro station	
Sidewalk Quality	D1	Smooth and clean sidewalks	5.814**
	D2	Spacious sidewalks	7.944**
Environmental Facilities	E1	Numerous commercial facilities along the road	5.341**
	E2	Enough green spaces and plazas along the road	
	E3	Ample shaded areas along the road	

Note: The significance test value of ** is less than 0.01, and the significance test value of * is less than 0.05.

Using the One-way ANOVA method, the between-group and within-group variances of each influencing factor for the three types of functional stations were calculated. This quantified whether the differences in observed variables (satisfaction with various indicators) were due to random errors or controlled variables (station functional types), thereby identifying the influencing factors of pedestrian environment satisfaction (Table 4). The results indicate that under the null hypothesis of

no difference in overall pedestrian environment satisfaction among the functional types of stations, the significance level P-value is less than 0.05, meaning there are significant differences in overall pedestrian environment satisfaction among pedestrians at different functional types of stations.

Among the individual indicators, at the significance level of $P < 0.01$, there are significant differences in pedestrian satisfaction among different functional types of stations regarding "B1: Low interference from motor vehicle traffic", "B2: Sidewalks free from vehicles or obstructions", "D1: Sidewalks smooth and clean", "D2: Spacious Sidewalks", and "E1: Numerous commercial facilities along the road." Among these, "D2: Spacious sidewalks" has the highest F-value (7.944). Combined with the demand analysis in Figure 2 and the satisfaction evaluation in Figure 3, it is found that there is a correlation between demand and satisfaction of this indicator. Specifically, elements with high demand have relatively low satisfaction scores, indicating that the improvement of "D2: Spacious sidewalks" should be prioritized in the pedestrian environment around residential stations. For the remaining four indicators, the satisfaction scores for residential types are lower than those for other dominant functional types, indicating that these are the primary reasons for the lowest overall satisfaction in residential types and are important factors affecting overall pedestrian environment satisfaction.

Additionally, "A1: Convenient and direct walking paths" has the smallest F-value (0.670). In Figure 2, it is shown that the demand for this indicator is very high in the areas surrounding office-dominant functional stations, while in Figure 3, the satisfaction is higher than that of other types of stations. This indicates that the construction of the pedestrian environment in terms of "A1: Convenient and direct walking paths" performs well in Shanghai, with little room for optimization, and can be considered for slower improvement.

CONCLUSIONS AND DISCUSSIONS

Based on the empirical research of pedestrian demand and satisfaction in 15 metro station areas in downtown Shanghai, this study finds that the overall evaluation of the pedestrian environment around metro stations results from the aggregation and reorganization of different aspects of pedestrian environment perception, but it is more closely related to the functional types of the stations. Key factors influencing overall satisfaction include low motor vehicle traffic interference (B1), sidewalks free from vehicle or facility obstructions (B2), clean and smooth sidewalks (D1), spacious sidewalks (D2), and numerous commercial facilities along the road (E1). This suggests that a safe and continuous pedestrian environment, spacious and smooth sidewalks, and a variety of street-level commercial establishments all contribute to enhancing the overall pedestrian environment of metro stations.

From the survey results, it is evident that residential dominant stations face significant pedestrian environment issues that need to be prioritized by the government and relevant departments in urban planning and management. On one hand, the road rights distribution around residential stations often prioritizes vehicles, leading to problems such as insufficient sidewalk width and pedestrian-vehicle traffic accidents. On the other hand, the residential population around these stations has diverse characteristics in terms of age, health, and occupation, which may result in different needs for the pedestrian environment. It should be noted that commercial and office-dominant station areas also have their own pedestrian environment issues to varying degrees, which need to be addressed by

considering the pedestrian environment needs specific to different functional types, and adopting a multi-faceted and multi-level approach to achieve overall environmental quality improvements.

Advice for stations dominated by residential function

Typically located in densely populated areas, these stations have a high demand for pedestrian space. It is necessary to rationally adjust the distribution of road rights to ensure a safe and spacious pedestrian environment and reduce vehicle interference. Additionally, the diverse characteristics of the residential population—reflected in age, occupation, and family structure—mean that inclusive design for the pedestrian environment is also important. Accessibility features should be improved, unnecessary steps or height differences should be minimized, and road surfaces should be kept smooth. Furthermore, a safe and well-equipped activity space and various service facilities should be provided, particularly considering amenities for the elderly, such as fitness and rest facilities, and children's play areas, to enhance the walking experience for different users.

Advice for stations dominated by office function

The population around these stations primarily consists of working professionals in their young and middle years, who have a fixed walking pattern during weekdays, with peak times in the morning and evening. Due to high work pressure and time constraints, they require a convenient and accessible pedestrian environment. Based on this survey's conclusions, there are common issues in such areas related to convenient access to bus stops (A2), commercial facilities along the route (E1), and shaded areas along the route (E3). These issues need to be addressed by considering convenient transfers between various transportation modes and providing a more comfortable walking environment through appropriate urban greening, architectural design, and road layout.

Advice for stations dominated by commercial function

These stations are typically well-connected and emphasize the convenience and diversity of commercial facilities, attracting a large number of shoppers and tourists. The characteristics of the crowd are dense and varied, including local residents and visitors. As the population is not fixed and may include many first-time visitors, improving the signage system (C) should be a primary focus to assist pedestrians who are unfamiliar with the area. Additionally, the surrounding areas of comprehensive stations should be designed with a focus on commercial characteristics, incorporating commercial facilities, cultural facilities, and recreational spaces into the pedestrian environment, such as cafes, small shops, and public art spaces. Adding artistic elements and distinctive pavings can enhance the artistic effect of the station area, boost the attractiveness and vitality of commercial activities, and promote the prosperity of the commercial district

ABSTRACT

In the past decade, large railway stations have emerged in urban areas with the rapid development of high-speed railways in China, significantly impacting urban form and transportation patterns of surrounding areas due to their scale and functions. The construction of large railway stations, in particular, alters the block scale of the surrounding areas and introduces substantial traffic flows, often leading to these areas becoming traffic bottlenecks within urban regions. Consequently, the in-depth analysis of traffic problem in the hub-type railway station areas has become a crucial issue, including their types, causes, and the strategies of improvement. This study focused on 84 hub-type railway station areas in China, investigating the characteristics of station-area traffic through spatial organization and traffic flow configuration. This paper proposed a classification method for the traffic organization around hub-type railway station areas. Then, the study analyzed traffic performance indicators at three scales: within the station, station area, and the urban context. By quantitative analysis, the research summarized the traffic performance characteristics of station areas with different types of organization. The results of this study revealed that block morphology and scale significantly influence the traffic performance within the station area. In conclusion, this research identified the causes of traffic problems, and suggested traffic improvement strategies tailored to different organization types.

Keywords: Railway station area; traffic organization; traffic performance

INTRODUCTION

As railways have developed as a medium- to long-distance transportation mode, research on the planning and construction of railway stations began to emerge at the end of the last century, with a marked increase in studies after 2000. Foundational theories on the urban spatial development of station areas have also continuously emerged, including Urban Catalysts, Smart Growth, Transit-Oriented Development (TOD), and Holistic Design on Urban Architecture (Gui, 2018). Under the guidance of these foundational theories, scholars from various countries, in light of their national contexts, have conducted extensive research on the urban development of station areas.

Since the beginning of the 21st century, Chinese scholars have also, based on the country's specific circumstances, conducted numerous studies on the urban development of railway station areas. During the early stages of the development of China's high-speed rail network, researchers proposed the "Node-Place" model and used it to study the development of railway station areas in China. The studies suggested that these hubs will become new key nodes in national spatial policy, and the transportation node value and urban functional value of these hubs should be considered together. Both values have marginal effects and require balanced development (Zheng and Du, 2007). Following the rapid expansion of the railway network after 2008, issues surrounding the urban development of station areas have drawn more attention from scholars. During this period, station areas have increasingly been regarded as integrated entities, with spatial issues dissected into three interconnected levels: surfaces, lines, and points, all of which must function together (Gui, 2018). The mechanism by which station-city integration promotes urban development has also become a major focus of research, encompassing areas such as passenger flow forecasting models, optimization techniques for connecting transport systems, commercial development models, and collaborative management mechanisms under the station-city synergy framework. These studies have contributed to forming a comprehensive set of organizational methods for station area of high-speed railways (Zhou, 2021).

In response to the challenges facing the urban development of railway station areas in China, relevant studies have also reflected on the station-city synergy development and compared domestic and international development models, offering recommendations for domestic station-city synergy. These studies have put forward views such as "diversified travel purposes and demands," "significant differences in time and cost sensitivity among different passenger groups," and "station-city synergy is not synonymous with TOD." They argued that the current main issue facing station-city synergy was the relatively weak demand for "the station as a destination." (Li, 2022).

Traffic issues in station areas primarily involve the disciplines of traffic engineering and urban planning. Both disciplines have conducted research on topics such as traffic demand, characteristics, configuration, and efficiency within station areas, though their research methods and objectives vary.

Traffic engineering research on internal station area traffic can be divided into studies on traffic demand and traffic characteristics. The former includes various types of traffic flows such as pedestrians and vehicles, while the latter focuses on the organizational characteristics of different traffic elements within the station area. Studies on traffic demand start with analyzing passenger flow and activity characteristics, proposing optimization strategies for spatial organization in station areas that meet the needs of travelers (Kang, et al., 2019; Sun, et al., 2012). Research on traffic characteristics, on the other hand, aims to study layout and capacity calculation methods for station area components such as station forecourts, bus terminals, and taxi stands. Some scholars also use analysis tools like VISSIM and space syntax to model and simulate station area traffic spaces, with the simulation results providing quantitative reflections of existing problems in the station area traffic space.(Li, 2018; Fu, et al., 2009)

Since the traffic organization within station areas often impacts the traffic pattern of an entire district or even a metropolitan area, in addition to the internal traffic issues, the connectivity of station area traffic has become a key research topic. In the early stages of China's high-speed rail development, some scholars attempted to establish predictive models for passenger transfer demand and focused

on evaluating the connection between railways and urban transit systems (Zhang, 2006). As China's high-speed rail network matured, the research became more segmented and in-depth, and the ring-layer model began to be widely accepted as a spatial model in railway station research (Niu and Wang, 2016).

Research in the field of urban planning, on the other hand, has focused more on the spatial ontology of station area traffic organization, particularly on the characteristics of spatial ontology and how to organize station areas within the context of rapid high-speed rail development. In the early stages, scholars in the field of urban planning were concerned with clarifying the relationships between the complex functional spaces within high-speed rail hubs and designing station spaces that would be sustainable for China's long-term railway planning. As China's high-speed rail network and station development matured, there was an increase in case studies and analyses of station areas. Scholars have classified China's high-speed rail stations according to spatial form and scale, with a consensus emerging on dividing the development of these stations into four eras. (Sheng, 2019)

Evaluation studies on station and station areas have focused more on quantitative evaluation methods, establishing indicator models to evaluate space performance, vitality, and sustainability. Depending on the research direction and objectives, scholars have used different methods to build evaluation models. Based on existing research results, we can summarize several primary objectives of station area space evaluation: space performance, space vitality, and transportation connectivity. The "Node-Place" model, a significant model in this research area, suggests that the node and place characteristics of station areas should be adjusted according to factors such as the geographic location and traffic characteristics of the cities where they are located. Achieving a balanced state among these factors represents an ideal development model for railway station areas (Yang and Zhuang, 2023).

This study attempts to address railway station traffic issues from a "configuration" perspective. First, it quantitatively analyzes the current traffic configuration types in station areas across China to clarify spatial characteristics. Then, using open online map traffic data, the study analyzes station area traffic performance. The research seeks to answer the question: "What types of configurations can achieve better vehicular traffic performance in station areas?" and proposes strategies for future station area traffic design and optimization.

RESEARCH OBJECT AND DATA SOURCE

Research Objects

This study classified railway stations in Chinese cities into four categories based on traffic and functional characteristics: traffic node type, traffic hub type, specific function area type, and public activity area type. The focus of this study is on the traffic organization and efficiency of traffic hub type railway stations. These stations serve as important nodes for urban and intercity traffic conversion, often at the intersections of two or more main railway lines, and frequently handle multiple other transportation modes such as highway, air, and water transport. These station areas feature complex functions and traffic characteristics. In selecting research objects, this study first filtered out cities by grade, selecting 41 provincial capitals and major non-provincial capital cities. For each city, data on railway line configurations and public transport facilities were collected and filtered, ultimately identifying 84 traffic hub-type railway passenger stations as the research objects.

Table 1. List of Stations selected in this research

Data Sources

To conduct a study on the spatial morphology and traffic performance of railway stations, we acquired relevant data for each station area from open data platforms. The study area was defined as a core study area with rectangular regions measuring 2 kilometers diagonally . Building outlines and road network information within the study area were obtained from the OpenStreetMap website. Due to potential data delays on this platform, the latest satellite imagery of the station areas was also sourced from Google Maps, alongside road network information, to serve as the foundational geographic data for this research.

In addition to examining the urban morphology and spatial organization of station areas, this study also focuses on the efficiency of motor traffic under different spatial configurations. Accordingly, we collected real-time traffic data for the station areas and their surrounding areas at different times. This data was sourced from the Area Traffic Query Application Programming Interface (API) provided by the Baidu Maps Open Platform. The API service offers real-time traffic information for areas with a maximum diagonal length of 2 km, including overall traffic conditions, names of congested segments, lengths of congested segments, and average vehicle speeds on these segments. This information enables us to calculate congestion index.

The core study area was defined as a rectangular zone with a diagonal length of 2 km centered on each station. Additionally, the extended study area was expanded to a rectangular zone with a diagonal length of 6 km centered on the station. This supplementary area includes eight 1-square-kilometer grid zones surrounding the primary study area. By obtaining time-based traffic condition data for the nine grid zones of each station, we can assess and analyze the traffic efficiency of the station areas.

ORGANIZATION OF MOTOR TRAFFIC

The spatial organization of station-area motor traffic represents the tangible structural configuration that accommodates transportation, while the urban motor traffic mix serves as the functional element

configuration that engages with the traffic system. In this study, these two components collectively form the framework of motor traffic configuration.

Organization of Space

The history of station area (generation of China railway stations)

The development of China's railways can be traced back to the early 20th century. In the early stages, railway stations did not distinguish clearly between passenger and freight services, often providing a single railway transport function and typically adopting a side platform layout (where the railway lines and waiting areas are on the same level). The early Dalian Railway Station is a typical example of this. Since the 1980s, China has gradually implemented a separation of passenger and freight services, leading to the specialized definition of "railway passenger station." From this stage onward, the design of railway stations began to focus on passenger experience and needs.

The Shanghai Railway Station, completed in 1987, represents a new type of railway passenger station. It was the first to adopt a "north-south entry, elevated waiting" format and constructed dual-level motor vehicle circulation routes, both on the ground and underground, enhancing the efficiency of passenger flow at the station as an urban transportation hub. Since 2008, with China entering the "high-speed railway era," the organization of motor traffic at railway passenger stations has become increasingly complex and more focused on circulation efficiency. The main factors driving these changes include the following:

Rapid Increase in Passenger Volume: China's railway passenger volume increased from 1.46 billion in 2008 to 3.66 billion in 2019, a 2.5-fold increase. The passenger volume growth at central stations in first-tier cities has been even more rapid. For example, Beijing West Railway Station saw its passenger volume in 2016 reach 3.7 times that of ten years earlier. Station areas have increasingly borne the heavy burden of passenger circulation.

Diversification of Urban Transfer Demands: Over the past two decades, the development of urban public transportation in China has accelerated continuously. By 2018, the operating mileage of subway in China had reached 5581.6 kilometers. Subway, as a transition between urban and intercity transportation, has played a crucial role in connecting cities and railway hubs. However, with the construction of subway, many railway stations have undergone expansion and renovation of their underground spaces. The emergence of new transportation modes such as trams, ride-hailing services, and maglev trains has also made the organization of motor traffic at railway stations increasingly complex.

Emergence of Station-City Integration Demands: On one hand, the development of urban planning theories has emphasized the connection between transportation spaces and surrounding urban functions. On the other hand, with the rapid expansion of Chinese cities, railway stations originally located in suburban areas have gradually become surrounded by urban built-up areas. The combination of urban traffic and access traffic for passenger pick-up and drop-off in station areas has pushed the hierarchy of motor traffic networks in these areas to continuously increase.

In summary, the diversity of transfer modes, emphasis on circulation efficiency, and the diversification of traffic demands have become important characteristics of the motor traffic organization at contemporary traffic hub-type railway stations.

The influence to nearby the "giga-scale" railway stations

Over the past few years, the construction of large railway stations in China has significantly altered the regional dynamics of their surrounding areas, leading to changes in urban form, urban functions, and traffic organization. In many cases, a previously open urban block has been transformed into a closed precinct, often served by urban expressways, fundamentally changing the existing urban fabric. The roads within these station precincts are typically designed to cater exclusively to the traffic demands of the station, often neglecting the transportation needs of local residents. This can result in increased traffic pressure, and in cases where traffic organization is poorly managed, the station area may become an "isolated entity" within the urban context.

By comparing satellite images and urban data of several typical railway stations before and after their construction, we have identified the following impacts on the surrounding urban areas:

Significant Changes in Block Scale and Increased Difficulty in Block Permeability: On one hand, railway platforms, stations, and forecourts need to accommodate passenger flow and allow for future expansion. On the other hand, domestic railway stations in China are subject to strict security measures, including dual-ticket checks, which prevent the possibility of “walk-through” access. Consequently, stations are often equipped with large-scale waiting halls. These factors combine to create urban blocks that are significantly larger than the surrounding areas, with many facilities being enclosed, thereby limiting pedestrian and vehicular permeability across the block.

Complex Traffic Networks and Increased Traffic Pressure: A comparison of urban traffic networks before and after the construction of railway stations reveals an overlap of arrival/departure traffic and through-traffic, as well as a mix of private cars, taxis and buses. This overlapping of traffic flows not only complicates the traffic network but also necessitates the allocation of more space within the station precinct to accommodate the various types of vehicles, thereby increasing overall traffic pressure.

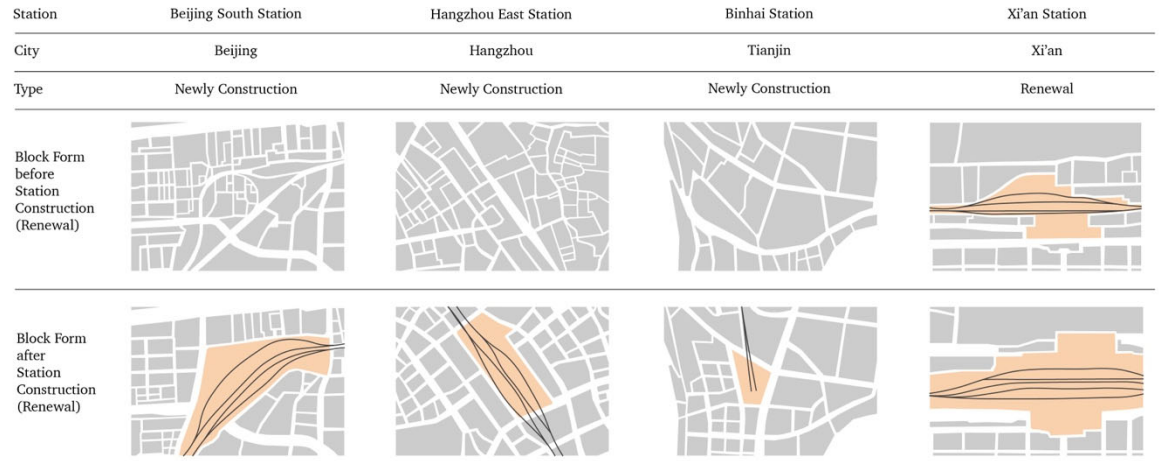

Figure 1. A comparison of the urban morphology in the areas surrounding four typical stations before and after the construction of the station

The spatial organization of motor traffic in the station areas

First, we define the concept of station-area motor traffic organization configuration. This refers to the spatial organization pattern of motor traffic roads within a specific area surrounding a railway station. The configuration of station-area motor traffic reflects the unique urban spatial morphology of the station area. The primary function of motor traffic in the station area is to facilitate passenger arrivals, departures, and transfers, while also accommodating the city's through traffic. Through observation, it has been found that most stations separate station-bound traffic from city through-traffic on urban roads at a certain distance from the drop-off platform. This separation occurs within a designated block area, forming dedicated roads within the station area. In this study, we refer to such block areas as "station-area motor traffic units." City through-traffic is typically routed onto urban expressways, passing through the periphery of the station area without overlapping with the internal station-area traffic.

The internal organization and scale of station-area motor traffic units are key factors in our configuration research. The internal organization reflects the different urban morphologies of station areas. Typological research on organization methods aids in understanding the spatial forms of station-area traffic. We categorize the motor traffic organization methods in station areas into four types:

Adjacent Type (Surface/Elevated): The adjacent type refers to a configuration where the drop-off platform and the station entrance/exit are seamlessly connected. The station square and entrance/exit are located on either side of the drop-off platform, with parking lots and taxi stands located adjacent to the station building. A typical example is Wuhan Station.

Remote Type (Surface/Elevated): The remote type describes a configuration where the drop-off platform and station entrance/exit are separated by a certain distance. This often results from a restricted area in the station plaza located between the drop-off zone and the station entrance, preventing seamless connection between the station hall and the drop-off zone. A typical example is Hankou Station.

Interleaved Type: The interleaved type is a traffic organization method adopted by many newly constructed large railway stations. In traditional railway stations, the access roads and drop-off areas are aligned parallel to the tracks, with no roads crossing the tracks. However, in the interleaved type, the drop-off platform is arranged perpendicular to the tracks, and the access roads cross the tracks. A typical example is Beijing South Station.

Hybrid Type: The hybrid type often includes two or more of the above-mentioned organization methods. Some stations employ different strategies on either side of the station for organizing ingress and egress traffic, resulting in a hybrid traffic configuration. A typical example is Shanghai Station.

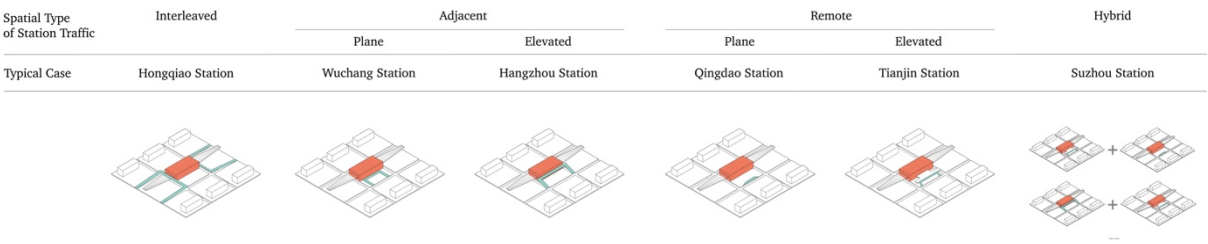

Figure 2. Four types of station-area traffic configuration

Traffic share

The spatial configuration of motor traffic in the station area serves as the physical structure that accommodates traffic flow. Another factor influencing the traffic performance in the station area is the share of motor traffic among all traffic modes. Before conducting data analysis, we hypothesize that cities with a higher motor traffic share will have more railway passengers choosing to travel to or from the railway station by car, which in turn increases the traffic pressure within the station area.

In this study, we use the modal share of public transport, non-motor transport, and private cars as our research data to represent the motor traffic share configuration in the cities where the stations are located.

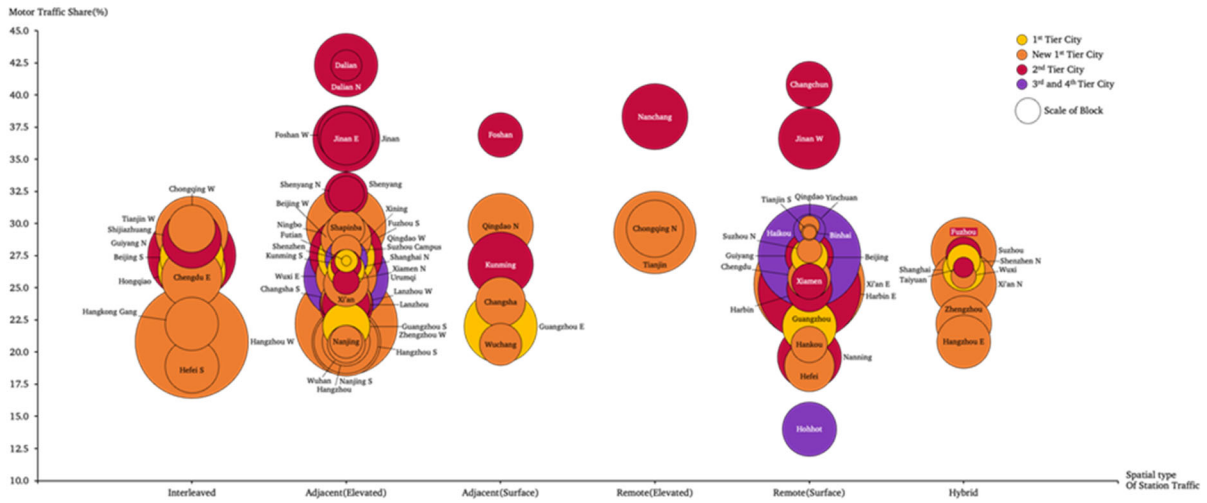

Figure 3. Spatial organization, Traffic share and Scale of block of 84 selected stations

From a spatial organization perspective, among the stations we studied, the Adjacent Type (Elevated) configuration is the most prevalent, accounting for 39.3% of the cases. This mode, where elevated roads lead directly to the station platforms, has become the most mainstream organization model for

station-area motor traffic. The next most common configuration is the Remote Type (Surface), representing 26.2% of the cases. This type is often found in railway hubs built before the high-speed rail era, where large station squares were designed between the station roadways and the station halls to accommodate crowd dispersal needs. Consequently, the roadways are located at a distance from the station entrances and exits.

The scale of the station-area motor traffic units represents the urban area influenced by station-area vehicle flows and the distance from the station to the traffic diversion point between station and city flows. In our study of 84 cases, the average scale of the station-area motor traffic units is 1.43 square kilometers. The smallest is Futian Station, with its unit covering only 0.04 square kilometers, while the largest is Hangzhou West Station, with a unit covering 5.78 square kilometers. First-tier cities, due to land constraints and early station-area developments that have often undergone multiple redevelopment cycles, generally have the smallest average unit scales. In contrast, new first-tier cities, driven by high-speed rail development, have established large railway hubs in suburban areas, resulting in larger traffic unit scales for these hubs.

From the perspective of traffic share configuration, across the 40 cities encompassing the 84 stations, the average motor traffic share is 27.2%. First-tier cities have the lowest average motor traffic share, primarily due to their extensive public transportation networks and higher public transit shares. On the other hand, second-tier cities have the highest average motor traffic share.

PERFORMANCE OF MOTOR TRAFFIC

Ideally, the motor traffic within the station area should efficiently accommodate the inflow and outflow of vehicles related to the station area. We define the capacity of the station area's motor traffic system to handle traffic volume as its performance. When the performance of the station area’s traffic system is inadequate to manage the traffic volume, congestion occurs, indicating that the design performance does not meet the actual demand. To analyze and compare the motor traffic performance of station areas, we gathered real-time traffic data from the Baidu Maps Open Platform across multiple time periods.

To ensure comprehensive and reliable data, we selected several weekdays and weekends, collecting real-time traffic data for the core station area every hour from 8:00 AM to 11:00 PM. The analysis revealed that peak motor traffic periods in station areas differ from the typical "urban rush hour." For many station areas, the peak traffic period occurs between 1:00 PM and 4:00 PM. This is because the traffic volume in these areas is primarily driven by train arrivals and departures. By examining the timetables of various stations, it becomes apparent that the afternoon often marks the peak period for train activity, leading to the highest motor traffic volume of the day.

At certain stations located at the terminal points of the rail network, such as Harbin Station and Guangzhou Station, train arrivals and departures are concentrated during early morning and late evening hours, causing congestion around 11:00 AM and 7:00–8:00 PM. However, the traffic pressure during these times is generally lower compared to the afternoon peak.

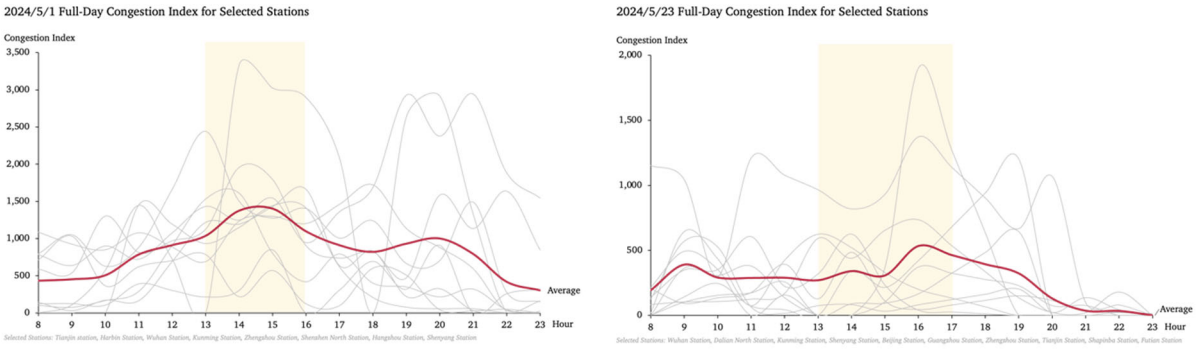

Figure 4. Full-day Congestion Index of selected stations

From a city tier perspective, second-tier city are more prone to experiencing congestion in station areas compared to first-tier and new first-tier cities. In contrast, lower-tier cities (third-tier and below) generally do not experience congestion in station areas.

When comparing the average congestion index between core areas and expanded areas, it is evident that in both first-tier and second-tier cities, the reduction in congestion from the core to the expanded area is minimal, with little difference in average congestion index between these areas. However, in new first-tier cities, congestion decreases more significantly as one moves outward from the core area. This suggests that the impact of station-related congestion in new first-tier cities is relatively limited in scope, exerting less influence on the surrounding urban traffic.

DISCUSSION OF CONGESTION PHENOMENON

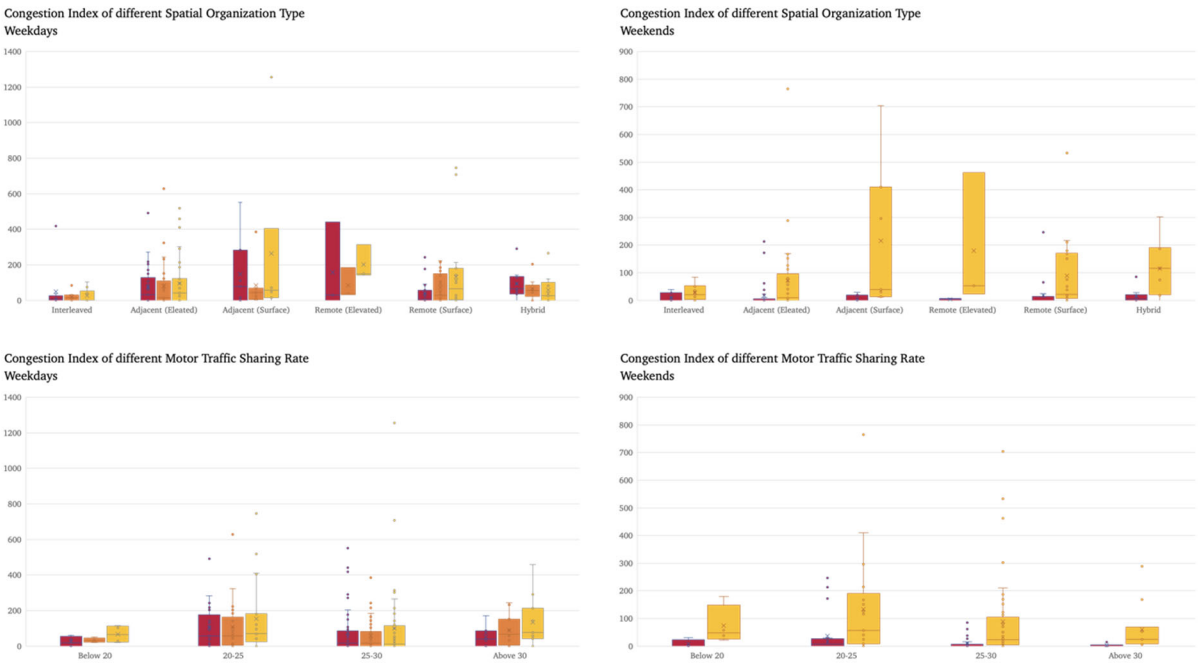

Figure 5. Motor traffic performance under different configurations and different motor traffic share

Performance and Configuration of Station-Area Motor Traffic

In our study, we first divided the congestion data for station-area motor traffic into two groups: weekdays and weekends, to represent the traffic flow characteristics of different time periods. Next, we classified each station into one of the four spatial configuration types identified earlier in the study. By comparing the congestion index of station areas with different spatial configurations, we found

that stations with an Adjacent Type (Surface) configuration exhibited poorer motor traffic performance and were more prone to severe and widespread traffic congestion.

Detailed observation of the traffic conditions in these specific stations revealed that such stations typically organize their forecourt spaces sequentially as square, drop-off platform, and station hall. This layout causes large numbers of pedestrians entering the station from the square to cross the roads in the drop-off platform, reducing the efficiency of motor vehicle passage. Additionally, vehicles dropping off passengers also need to pause in the drop-off platform, further compounding the congestion. The combination of these factors makes stations with this configuration more susceptible to traffic jams. Furthermore, the surface configuration is less effective than the elevated configuration at separating station-area traffic from urban traffic, making it easier for increased station traffic volumes to spread congestion into surrounding areas, leading to more extensive traffic issues.

Among the six types of station-area motor traffic configurations, stations with the Interleaved type configuration showed the best motor traffic performance, with the least likelihood of congestion in the surrounding areas. Observation of real-time traffic conditions in these stations suggests that their superior motor traffic performance can be attributed to two main factors. First, this configuration has been implemented more recently, with some stations only recently completed and operational, meaning they were planned with sufficient capacity reserves. Second, unlike traditional configurations where roadways run parallel to the railway tracks and are located on both sides of the station building, the Interleaved type configuration allows roadways to cross the railway, with drop-off platforms situated above the tracks. This design avoids the isolation effect caused by the railway dividing urban traffic on either side, resulting in smoother traffic dispersal in all directions.

When attempting to analyze the correlation between urban motor traffic share and station-area congestion, we found that the overall correlation was weak. In some cities with a higher motor traffic share, congestion was actually less severe. Upon reviewing the data, we speculate that this result may not be entirely due to motor traffic share alone. Cities with a higher motor traffic share are often lower-tier cities, where overall travel demand and railway passenger volumes are lower, meaning that station areas do not frequently experience high motor traffic pressures.

Distribution characteristics of Station-Area Congestion

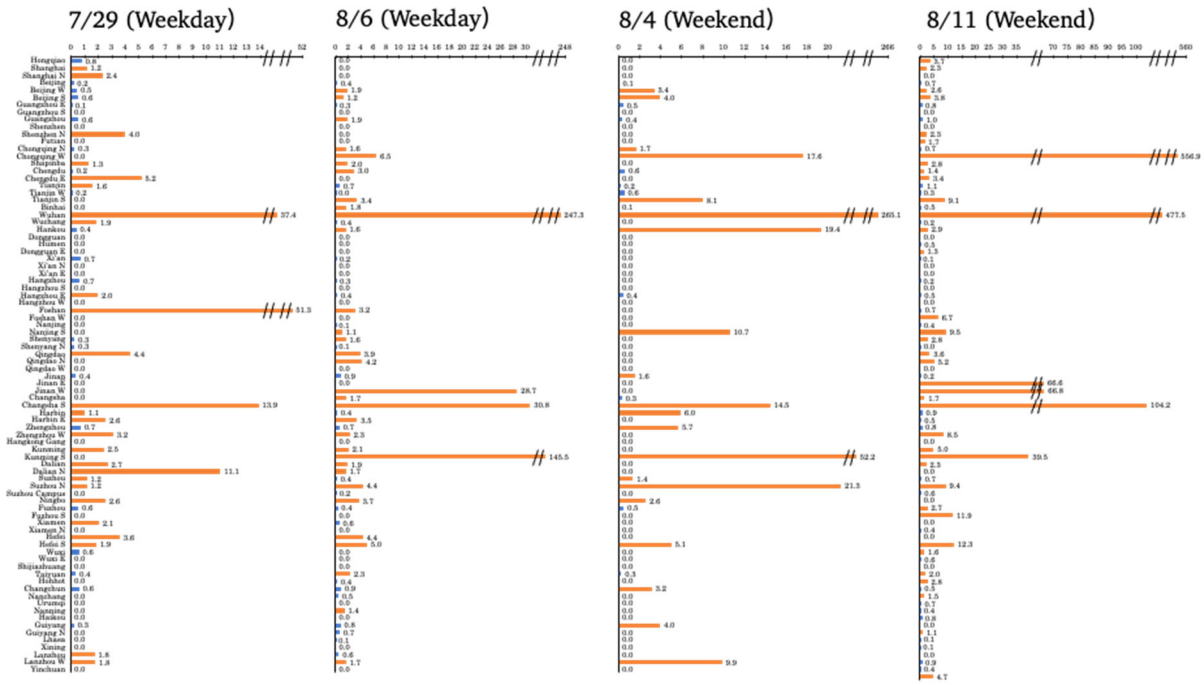

Figure 6. Ratio of congestion Index between core study area and extended study area

In our research, we delineated a core study area (a rectangular region with a 2 km diagonal centered on the station) and an extended study area (a rectangular region with a 6 km diagonal centered on the station). We compared congestion Index between the station's core area and its surrounding area. This comparison helps us further understand whether congestion in the station-area space is primarily due to the station's own low traffic performance or if it originates from the inherent congestion-prone nature of the surrounding urban area. For these two scenarios, we should propose different strategies in future traffic improvement plans.

For stations where congestion in the core area is significantly higher than in the surrounding region, we hypothesize that this congestion is mostly attributable to the station itself. Typical examples include Wuhan Station, Changsha South Station, and Kunming South Station. Improving the motor traffic performance of these stations will require optimizing their internal traffic systems.

Conversely, for stations where congestion levels in the core area are similar to or even lower than those in the surrounding area, it indicates that the broader urban area is already under high traffic pressure. Examples of this include Guangzhou Station, Xi'an Station, and Hangzhou Station. For these stations, enhancing passenger dispersal capacity in the future will likely be constrained by the limited potential to improve the station's motor traffic performance. Therefore, the focus should shift toward developing high-capacity public transit options (such as subways and BRT systems) to reduce the demand for motor vehicles entering and exiting the station area.

CONCLUSIONS

Based on urban traffic big data platforms and open map platforms, this study conducted a comparative analysis of the motor traffic configurations and motor traffic efficiency across 84 railway stations in 41 cities. In the study of motor traffic configurations, we conducted a typological analysis of the spatial organization models of station-area motor traffic and analyzed quantitative information

such as the block scale of the station areas and the motor traffic share of the cities where these stations are located. This allowed us to derive a dataset that encapsulates the characteristics of each station.

In the study of motor traffic performance, we collected and processed real-time traffic data for the 84 stations at different time intervals. By analyzing congestion index, we assessed the gap between the motor traffic performance of the station areas and the actual demand. From this data, we conducted an overall analysis of congestion patterns for stations with different spatial configurations. The findings indicate that interleaved type can enhance traffic performance in station areas and mitigate the barrier effect of railways on the adjacent urban areas. By delineating different study areas, we analyzed the distribution of congestion in station areas and proposed various traffic optimization strategies for different types of stations. For stations that predominantly experience endogenous congestion, improving their performance will require optimizing their internal traffic organization and management models. In contrast, for stations where exogenous congestion is more prevalent, a more developed public transport network will be necessary to alleviate the pressure on motor traffic.

However, this study also has some limitations. First, due to time and data resource constraints, we only obtained real-time traffic congestion data for a limited period. While this data provides a general overview of the traffic conditions in the station areas, more comprehensive real-time traffic data will be needed for more precise research and analysis in future studies. Secondly, the "congestion index" calculated in this study was based on two parameters: the length of congested road segments and the average vehicle speed on these segments. In subsequent research, incorporating additional parameters could yield more accurate results. Finally, there is room for further exploration in improving the traffic performance of station areas. Future work will involve utilizing traffic simulation tools to evaluate the effectiveness of proposed traffic improvement plans.

Through this research on the traffic configurations and performance of station areas, we aim to provide data support and basic conclusions that can inform urban design for station-city synergy, ultimately contributing to the development of high-performance station-area traffic systems that meet the needs of Chinese cities. This research will continue, with two key directions for further deepening in the next phase. First, there will be an effort to obtain a broader range of real-time traffic data to provide stronger data support for the conclusions drawn in the traffic performance section. Second, after completing the analysis of traffic configurations and performance in station areas, the research plans to propose optimized traffic configurations for specific station areas. These optimized designs will be evaluated through traffic simulations to compare their impact on traffic performance. This approach will allow the qualitative and quantitative conclusions derived from this study to be translated into concrete urban design strategies.

Resilient neighbourhood transformation in Cape Town, South Africa

Kathryn Ewing[1]
[1] Urban Design, School of Architecture Planning and Geomatics, Faculty of Engineering and the Built Environment, University of Cape Town, South Africa, kathryn.ewing@uct.ac.za

ABSTRACT

Urban morphology in Southern African cities reveals expanding, incremental, auto-constructed, and resilient neighbourhood transformation. The study aims to demonstrate peripheral patterns in the changing urban form in Cape Town, South Africa. Local meanings and urban processes are interpreted through a succession of deliberate, engaged and change-orientated design teaching studios, called Studio Hope, and ongoing research in the neighbourhood of Gugulethu. The design research methodology is multi-scalar, practical, affordable, participatory, and relevant to the context. 'Off-grid' data is collected using multiple, innovative ways of discovery and exchange through real and virtual urban walks and urban talks with local agents and youth. Findings plot three patterns of interrelated, underrepresented, yet emerging urban morphology in a local neighbourhood: 1) Incremental expansion and peripheral transformation occurring within and beyond unrecognised, self-built settlements, post-apartheid (neighbourhood/block); 2) Informal urban infill and dynamic change within an established apartheid-built 'township' neighbourhood (block/street); and 3) Urgent, everyday occupation and the flux of urban space (street/plot), including micro urban forms or social infrastructure, such as spaza shops, taverns, hair salons, community gardens, informal markets, public walkways, and waterways. The translation of expanding 'township transformation' enables a deeper understanding of spatial co-production, socio-economic practice, and everyday culture that influence Gugulethu's changing plot, street, block, and neighbourhood. Meaningful interpretation of diverse urban forms guides a working concept of a resilience framework. Design strategies and planning scenarios reveal an approach to urban morphology with purpose, value, and local agency, but also consciously rupture the methods of understanding unhealthy patterns of fragmented and deeply divided spaces inherited from colonial, modernist and apartheid spatial planning.

Keywords: urban transformation, peripheral neighbourhoods, South Africa, emerging network.

INTRODUCTION

Urban morphology in the urban Global South reveals interrelated processes and diverse practices of expanding, incremental, auto-constructed and informal neighbourhood transformation (Arefi, 2011; Caldeira, 2017; Roy, 2011). The rate of urbanisation and rapid, dynamic urban change expose the various spatial patterns and typologies of adaptive and informal built form in African territories. However, the fine-grain and fragile nature of the built urban fabric influenced by socio-cultural practice and the increasing informal density, mix, micro adaptation and rapid increments of change

remain underrepresented and largely undocumented in Southern African cities (Ewing, 2023; Mottelson and Venerandi, 2020).

There is a need to consider the study of the form of settlements over time (Scheer, 2016). Dovey (2012) argues informal morphologies or the forms of informality remain "…under-researched and under-theorised at micro-spatial scales" (p.351). The intention here is to grapple with the complexity of emerging informal neighbourhoods, across sizes, scales, densities and heritages (Larkham, 2022). However, there is an urgency to interpret urban transformation to provide guides to urban upgrading versus the 'slow' and singular approach to measuring the city. We, therefore, require new ways of understanding urban morphology in Southern Africa that are relevant, practical and usable beyond the spatial disciplines. The study aims to explore alternate methods and emerging patterns of peripheral urban form in a township territory, Gugulethu, in Cape Town, South Africa.

Outcomes from ongoing design research and the University of Cape Town's (UCT) Master of Urban Design (MUD) programme's teaching studio, Studio Hope, are translated into lessons on urban morphology to design relevant urban design frameworks and interventions.

Three key findings are gathered from five years of teaching and fifteen years of action research in Gugulethu. First, peripheral transformation within settled auto-constructed informal settlements illustrates the expanding neighbourhood beyond boundaries and town transformation in processes of peripheral urbanisation. Second, incremental, urban infill and dynamic change inserted within formal housing are presented. Third, spontaneous, socio-economic occupation of urban space reveals a fine-grain, adaptable, underestimated, and attached micro-urban form. The micro-morphology shows a distinctive form of local agency where spaces are incomplete or constantly in the process of evolution.

Although not within the scope of this paper, the findings ignite a meaningful interpretation of diverse urban forms that surface a resilience framework. Further, student-led design strategies and planning scenarios show an approach to urban morphology with purpose, value and local agency. A guiding principle is to "rupture" (Scheer, 2013) and deliberately break the unhealthy pattern of apartheid and modernist spatial planning thinking in the South East Cape Metro territory.

The paper is part of a working journal article on urban design pedagogy in the Global South. It presents four interrelated sections. First, the methodology, approach and intentions are briefly described. Second, three key findings on peripheral urban form are presented and interpreted in the context of Gugulethu. This forms the key focus of the paper. Third, reflections on creative student work and ongoing research facilitate an emerging resilience framework to understand urban morphology in the global south. Last, recommendations for further research are discussed in the conclusion. Theoretical perspectives on urban morphology and peripheral urbanisation in the Global South are interwoven throughout the paper.

STUDIO HOPE, GUGLETHU: APPROACH AND METHODOLOGY

Although this paper will not detail a teaching and learning pedagogy per se, nor an overarching research methodology, the focus is on urban form (Scheer, 2016). However, the research and teaching methodology is action-based, multi-scalar, practical, affordable, participatory, and relevant to the emergent southern territory.

In our South African context, a decolonised design studio course curriculum intentionally prepares students to deal with socio-spatial inequality caused by apartheid spatial planning (Dewar, 2019). The research actively engages a transdisciplinary approach through practice, research and teaching.

Studio Hope is a situated pedagogy, grounded in design research. The studio course takes a transformative and collaborative learning framework including urban design and landscape architecture students. The studio is taught over a 12-week series of four progressions from site analysis (to explore), co-design workshops (to disrupt) to design interventions (to transform) and concludes in a summative oral presentation (to represent). A blended approach has been developed that seeks experiential learning, utilising digital tools and active learning activities in the field and the studio.

Deliberate and engaged scholarship (Longo, 2013) forms the foundation for the work. This gives rise to the inclusion of local agents to support a flexible methodology to study urban morphology in a "critical neighbourhood" (McFarlane, 2011; Moreira, 2022) or critical urban form in Cape Town. This has been constant over 5 years of teaching. One of the local agents, Xolile Ndzoyi, has been involved in research since 2015 with the author in practice with the Violence Prevention through Urban Upgrading (VPUU) programme and as a fieldworker on research projects with UCT from 2020. Opening the studio and research to different disciplines, local agents and design practitioners allows multiple voices to be heard and translated. Participants in our studio are encouraged to take authentic responsibility for the co-production of knowledge as an active community of practice (CoP).

Data collection through walks and talks

Spatial data collection is considered a basic form of knowledge to interpret urban form (Scheer, 2016). Basic GIS and aerial photography are gathered from the local municipality. However, conventional methods make 'off-grid' urban data difficult to access. We, therefore, acquire unrecognised, informal or undocumented data using multiple, innovative ways of seeing, being, and knowing. Alongside Google Earth time-lapse maps, historical analysis, and the layering of information, real-time and virtual urban talks and urban walks are conducted. The urban talks include youth exchange co-design workshops and focus group discussions on campus and in the field, with online conversations and digital stories via What's App diaries. Guided urban walks involve strategic and engaged fieldwork combined with virtual site visits via Zoom online and WhatsApp App live and recorded videography, photo stories and context discoveries of place-making in Gugulethu (Ewing, 2022b). A large-scale neighbourhood working model (1:1000) is used yearly to situate Gugulethu as a neighbourhood. Rough, mobile, urban block models (1:500) are developed to allow for quick, participatory approaches for data collection with local agents and rapid interpretation, rather than long and expensive fieldwork. Section models (1:25) investigate streets and public space.

Pattern recognition and local agency

A local archive and e-library of 'otherwise invisible' maps have been co-produced over the years which guide pattern recognition. Digital GIS information has been used on open-source QGIS and geo-located AutoCAD drawings for group sharing. Services, streets, housing and urban economic space typologies are labelled as specific layers. Each year students add to the 'base layers' and find emerging patterns dependent on the areas of investigation or theoretical application.

Figure 3. Creative mapping of cultural practice and everyday practice in Gugulethu, image credit: Lizelle Jackson, MUD, 2024

Photo stories of ordinary places from local agents and author research since 2010 are themed and stored under blue-green infrastructure (waterways and community gardens), informality, including block (urban infill) and street transformation (dwelling interface), social infrastructure (communal taps, toilets, walkways, public space and facilities), and fixed and temporal spaces of exchange (jazz venues, meat markets, hair salons, furniture repair, fruit stalls and so on).

The outcomes from pattern recognition are further 'plotted' onto exploratory social, emotional and memory maps. The drawings reveal the ordinary and everyday urban spaces across the scales (neighbourhood, block, street, plot) in Gugulethu. The processes surface hidden socio-cultural and economic and spatial practices, gendered identities in place-making and spatial transformation.

Towards a theory of change

Current urban scholars note the rising interest in peri-urban spaces in the African context (Buire, 2014; Chirisa and Matamanda, 2019; Mabin et al., 2013; Meth et al., 2021). Buire (2014) notes, "…accelerated urbanisation in Africa has led to an unprecedented variety of urban forms that reach beyond and reconfigure these centre-periphery dualities… and South Africa… shows rapid reconfigurations of their local and regional urban patterns."

The design research and teaching approach purposely infiltrate Southern theory, expanding the conventional vocabulary of urban morphology to deal with the urgent, changing nature of the African urban fabric. The process of the production of space (Lefebvre and Nicholson-Smith, 1991) is reframed through the concept of *peripheral urbanisation* (Caldeira, 2017), combined with concepts from *subaltern* (Roy, 2011), *critical* (McFarlane, 2011) and *incremental urbanisms* where "urban informality produces a range of different morphologies" (Kamalipour and Dovey, 2018).

FINDINGS ON PATTERNS OF PERIPHERAL URBAN FORM: THE CASE OF GUGULETHU

Aligned with Scheer's (2013) viewpoint on the death of the master plan in an era of limited resources and the need for sustainability, the developing design solutions are "utterly dependent on urban morphology" (p.170) as an essential lens to unravel the inner workings of deeply troubled and peripheral cities. However, the combination of working with local agents in plotting critical urban forms, and working through exploratory, co-designed activities and multi-dimensional approaches to informal urban morphologies become more attractive and relatable to younger, 'woke' students engaged in transformation and spatial justice (Soja, 2010). The implications of including themes on social and blue-green infrastructure, informality, everyday culture, safety, and temporality add extra dimensions, upsetting a more scientific measured approach to urban form.

'Expanding': situating the Southern territory of Gugulethu

In the past 30 years, urban neighbourhoods have transformed in South Africa due to mainly, increasing urbanisation, poverty, migration and informality (du Plessis et al., 2015). Extreme territorial violence and inequality continue to impact the quality of life in many low-income areas. At a city scale, the fragmented regions remain embedded in outdated regulations and stubborn, separated urban form inherited from colonial and modernist, apartheid spatial planning (Dewar, 2016). Policy, albeit well-meaning, struggles to shift or implement an appropriate urban form. Informality continues and post-apartheid formal development follows established patterns of socio-economic division. Further, the delivery of basic infrastructure and state housing appears sluggish, restless, and unsuitable to the needs and practice of urban residents.

However, resilient connections and social networks are prevalent, albeit ambiguous at a local neighbourhood, street and micro scale. Dynamic spatial occupation, socio-economic activities and everyday culture are constantly disrupting the landscape through a "silent encroachment" (Bayat, 1997) of urban space, allowing cities to adapt and persist over time (du Plessis et al., 2015). Further, giving local meanings and the ability for urban citizens to participate in a form of peripheral or fractional urbanism (Ewing, 2021) by expanding the city horizontally (sometimes vertically) and filling the gaps in open space.

Gugulethu is a contraction of *igugu lethu*, meaning 'our pride'. Although Gugulethu is centrally located 20 km from the Cape Town central business district, access to resources, infrastructure and services remains economically peripheral. Historically, it was established in 1958 as a black residential area or 'township' on the Cape Flats under apartheid spatial planning through the Group Areas Act of 1950.

The original township or 'suburban' peripheral settlement remains racially divided from the coloured neighbourhood of Manenburg to the west by the Central railway line. To the east, Gugulethu merges seamlessly with Nyanga township, displaying the connection with the original name of Nyanga West. The rapidly evolving Philippi East area, including Siyahlala, Sweet Home and other informal settlements in Browns Farms, lies across Govan Mbeki Road to the south. The N2 national highway separates the Cape Town International Airport and the north of Gugulethu. The peripheral informal settlements of Lotus Park, Waterfront, and Phola Park are situated in the southern portion of Gugulethu with the informal settlements of Barcelona, Kanana, KTC and Europe edging the northern portion of the township.

However, throughout Gugulethu, formal and informal systems are inextricably entangled. Building on the concept of incremental adaptive processes (Kamalipour and Dovey, 2018) and King and Dovey's (2011) typology of informal settlements, the following three findings on expanded patterns of urban form are presented as *settling, inserting* and *attaching (action words)*. In some cases, overlaps are seen as a hybrid mix of many processes and spatial outcomes and are difficult to define as one pattern.

'Settling': urban informality and township transformation (neighbourhood/block)

Auto-constructed or informal settlements illustrate the expanding neighbourhood within and beyond the territory of Gugulethu. The focus of the pattern is on the urban morphologies of spatial evolution, and within informal settlements, "Spatial boundaries are inscribed and erased…" where "Territorialisation is a synthetic process wherein wholes form from parts, identities form differences" (Dovey, 2012, 353). Informality is considered as a site of critical analysis (Banks et al., 2020).

Using aerial photography over 20 years shows a process of 'settling' on underutilised land in the southern portion of Gugulethu including Lotus Park, Waterfront, and Pholla Park Informal Settlements and the more formal housing environment of KwaKhikhi and southwards to Philippi East. The analysis transcends the boundaries of paths and plots and questions the scales of recognition at the neighbourhood scale, including housing typologies, forms of tenure and land occupation.

Settlements are sometimes built on unclaimed land. This results in contested and confusing ownership debates within governance structures, communities and the local municipality and further influences the basic delivery of services and future upgrading possibilities.

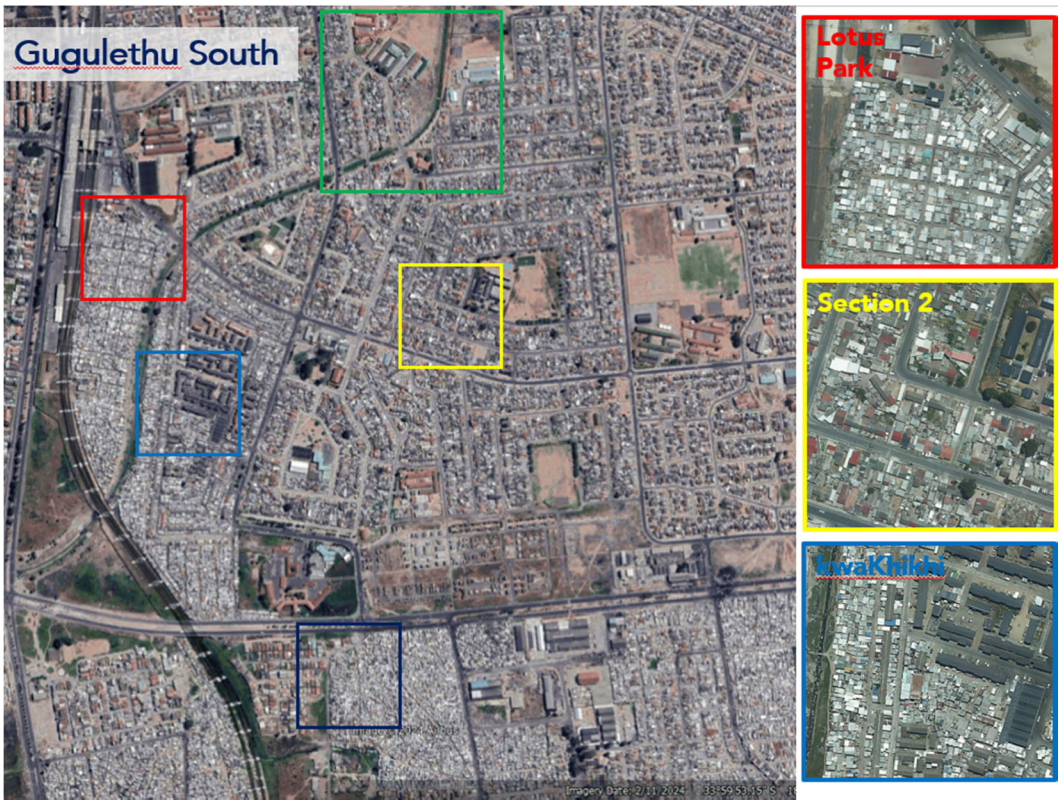

Figure 4. Southern Gugulethu, illustrating the focus areas of Lotus Park (red), Kwakhikhi (bright blue) and Section 2 (yellow) in 2024. The area in green represents a central sports and education precinct adjacent to the Lotus River. The area in dark blue is Siyahlala Informal Settlement in Browns Farm, which is outside of Gugulethu.

The study area zooms in on the informal settlement of Lotus Park. The spatial informal patterns of Lotus Park include detailed data collection of basic services and enumeration of informal dwellings since 2010, as part of the Violence Prevention through Urban Upgrading (VPUU) programme. The Lotus Park case reveals no formalised, individual plots, rather illustrated as a series of urban blocks, defined by shared streets and social and basic infrastructure (sanitation, water and waste collection points). The informal structures are never considered fixed to a plot or completed, sometimes extending into the public street or urban space as an attachment or extension into common space for household gain. The internal space of Lotus Park remains largely constant or settled. Yet, the informal edges have expanded, occupying unclaimed land south and west along the railway line. Physical barriers, such as the railway line and the Lotus River, limit further growth. The ability of the settlement to change and remain settled, yet still unrecognised in the municipality, speaks of adaptive resilience.

Student fieldwork in 2015, 2016 and 2022, mapped and re-mapped the local economic built form (containers, stand-alone structures, markets) and social infrastructure. The data and spatial pattern of land occupation and economic activity have guided the urban design of a spatial reconfiguration plan for incrementally upgrading an informal settlement through a live participatory approach through the VPUU programme. Further mapping of the urban transformation between 2010 and 2020 of a shared public space and community facilities of the VPUU Lotus Park Neighbourhood Centre (NHC) and Oliver Kahn Safe Hub© have developed a public investment framework and design approach to precinct development (Ewing, 2021). Urban imaginations by students build on practice-based work.

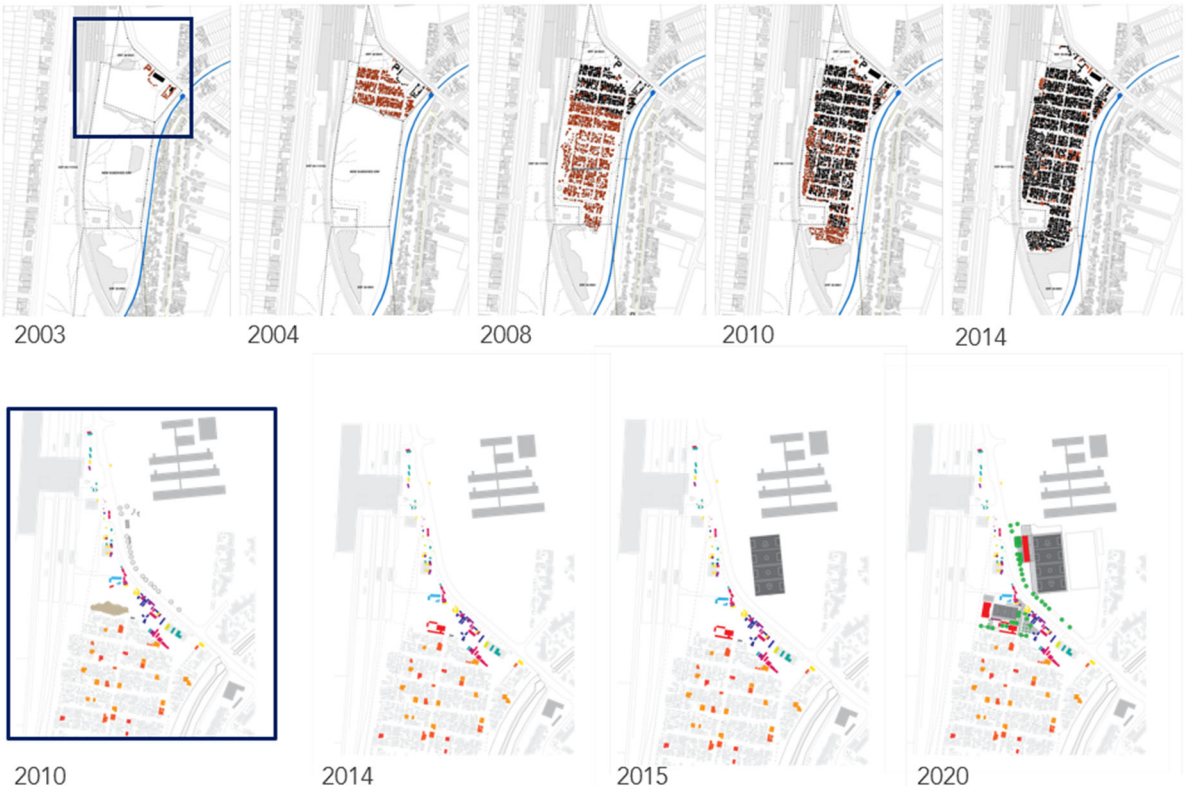

Figure 5. Lotus Park (LP) informal settlement historical expansion from 2003; and the mapping of an urban precinct over 10 years of the LP Neighbourhood Centre and Oliver Khan Safe Hub urban township transformation.

‘Inserting’: Urban infill and plot or housing transformation (block/plot)

Incremental, urban infill and dynamic change inserted within formal housing plots are illustrated within an established apartheid-built township neighbourhood in an area known as Section 2 (the original name given to the Sections in the inception of the township) in the south of Gugulethu. The block-to-street interface and the changing layout of the urban form on the individual recognised formal plot, including undocumented back-yard informal rental housing and front-yard extensions, illustrate a changing urban form to the original brick government semi-detached housing (4 and 2 row-housing typology, each with two rooms and total area of about 50m²).

It is well known that self-constructed, secondary dwellings on formal plots are common in South African townships from previous research and current investigation (Harris et al., 2023). However, there is minimal recorded spatial documentation of plot transformation in internal residential blocks of former black townships such as Gugulethu. The pattern reveals block and plot-by-plot transformation that can inform alternative and recognised forms of suitable mixed-use housing and active street typologies through auto-constructed township transformation.

Backyard spaces are often used for rental accommodation in secondary dwellings, commonly referred to as ‘back-yard shacks’ and more recently, ‘back-yard flats’. These dwellings are rarely inspected for health and safety, nor do they comply with building regulations or have approved building plans. The secondary dwellings may consist of a series of rooms, approximately 25m², built from informal materials. The flats are more stable, masonry double-storey apartment blocks divided into multiple rental flats, some with ablutions adjacent to the room and some with communal shared services in the back yard. They are generally inserted onto the edge and back of the 250m² plot.

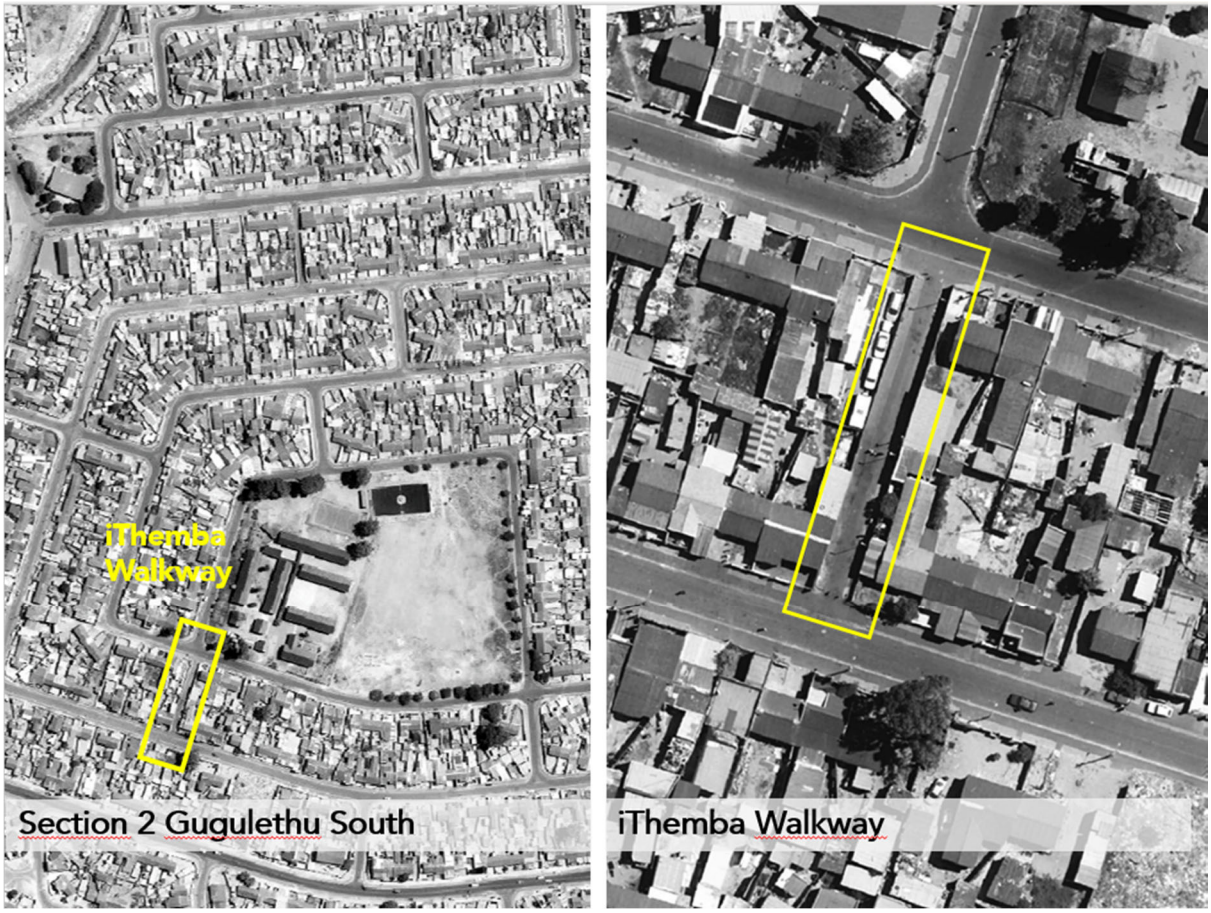

Figure 6. Section 2, Gugulethu South and urban block formation shown on the left and the image on the right shows the path through the urban block showing incremental plot transformation in inserted urban form.

Informal and formal extensions to the front yard generally reveal a pattern of economic urban form as an extension of the dwelling and access to the street. These include spaza shops, beer halls and so on. The adaptations from the original home provide additional income or expanded space through incremental architecture. They illustrate blurred boundaries of public and private use. Further, they display a range of densities and functional mixes of the plots with changing street access networks. Section 2 in Gugulethu is also undergoing a more recent and unfortunate phenomenon around the street transformation and the emergence of patterns of solid high walls, ornate gates and concrete columns, signifying a sense of permanence and an emerging identity of the adapting Gugulethu street interface. This requires further investigation to understand the social and cultural meaning. Stories from local agents suggest the interface conditions are a sign of wealth, but so a demand for safety.

Figure 7. Section 2, Gugulethu South (from left to right): 1) Back-yard flat above and local shop below; 2) front yard spaza shop on NY89; 3) ornate street interface on NY3; and 4) original two-room, 50m² 'township' house.

‘Attaching’: Micro-urban form as soft infrastructure (street)

Spontaneous, socio-economic occupation or use of urban space reveals a fine-grain, adaptable and informal micro-urban form, that co-develops with the buildings and attaches to the formal city structure. This is a vastly unrepresented pattern of urban form, mostly as it changes so quickly or is merely invisible to state regulations, design frameworks and municipal budgets.

The micro-urban form focuses on the everyday practices of the ordinary citizen. It can be temporal or permanent or may only be occupied at certain times of the day, week or month. Complex connections and diverse functions are understood through the evolution (and eradication) of small-scale built elements across scales and systems (du Plessis et al., 2015).

Patterns of adaptable micro-morphologies in Gugulethu include stand-alone spaza shops, tuckshops, taverns or shabeens (drinking bar), hair salons, barber shops, community gardens, self-made street furniture, informal meat markets, transitory street spaces, bridges, crossings and urban walkways.

Three specific examples that reveal the micro-urban form are, first, spaces of exchange (Ewing, 2022a, 2021), including the smiley (raw and cooked sheep heads) corner, located by the Lotus Park entrance along the street of NY3 (native yard from the original township naming). The space was largely unused in 2010. With the development of the VPUU Lotus Park NHC and surrounding public space, the area has attracted small-scale meat traders in the mid to late afternoon. Mobile ‘braais’ (BBQs), umbrellas, and fold-up tables allow traders to actively occupy the space, almost like shadows of urban form.

Second, blue-green infrastructure (BGI) is often neglected as a pattern of urban form. Self-constructed bridges, communal water taps and engineered formally implemented infrastructure are scattered along the Lotus River that runs 3,5km through the centre of Gugulethu. The edges to the river are cut off from the rest of the neighbourhood, making the space unsafe and vulnerable. The BGI forms an important element that has resulted in students developing a kit of parts and using components towards design toolkit for upgrading spaces along the river.

Third, a small-scale project called iThemba Walkway illustrates the impact of social infrastructure and public space transformation. The walkway is located within Section 2 of Gugulethu and is a 50m long and 6m wide passageway. Locally, it is called iRhanga, a space where people are connected. Since 2021, the space has been incrementally upgraded through strategic interventions along the edges through a timeline, tree planting and mural painting. Students are involved in a design-build process.

Figure 8. Gugulethu micro-morphologies (from left to right): 1) LP entrance ‘smiley corner’; 2) children play on an infrastructure pipe as a temporary bridge across the Lotus River; and 3) iThemba Walkway in 2024

REFLECTIONS TOWARDS A RESILIENCE FRAMEWORK

Through Studio Hope and constant research in Gugulethu over the years, it was clear that an expanded vocabulary and typology are required in the southern context to interpret urban form, particularly the intricacies of micro-urban morphologies. The translation of 'township transformation' enables a deeper understanding of spatial co-production, socio-economic practice, and everyday culture that influence and adapt Gugulethu's changing plot, street, block, and neighbourhood evolution. The spatial arrangements and patterns of urban form were investigated through the typology of *expanding* informality and further concepts adapted from Kamalipor and Dovey (2018) of *settling, inserting* and *attaching*.

Although not discussed in detail within the scope of this paper, meaningful interpretation of diverse urban forms guides a working concept of a *resilience framework as a humanising approach*. This sets up a potential framework concurrent with a more inclusive and compassionate perspective to direct appropriate and affordable urban design interventions, both real (practice and design-build implementation) and imaginary (student learning), including concepts of *justice, participation,* and *care* (Gachago et al., 2022).

Spatial justice as the desired goal: The scales of recognition and access acknowledge the role of the urban designer and the influence of the historical context, including power, politics, positionality and place (4 P's) forward-thinking and backwards-looking. History analysis of urban form is critical in understand the goal of justice.

Participation as a process: There is a desire to understand and develop alternative forms of cooperation and social agency, involving critical engagement *with* multiple stakeholders to uncover hidden meanings in the urban form, past, present and for the future.

Care as a key principle: Democratic access to information, critical deep analysis and interpretation of urban patterns enable an inclusive design towards transformative action, within the studio and the context. This allows participants to have a say in both the translation and the decision-making processes of urban design and trauma healing in critical neighbourhood transformation.

By reviewing the urban form of Gugulethu, students make informed decisions towards design interventions using different methods and understandings. Design strategies and planning scenarios further reveal an approach to urban morphology with purpose, value, and local agency, but also consciously rupture the methods of understanding unhealthy patterns of fragmented and deeply divided spaces inherited from colonial, modernist and apartheid spatial planning.

In 2022 the spatial outcomes of Studio Hope were co-presented by students, local agents and academics to the Mayor of the City of Cape Town as part of a project called The Walkway Project. Further, researchers and local agents co-presented their research at an Innovation Indaba in 2023 hosted by the City of Cape Town. A representative from the municipality attended the student's summative assessment exam in 2024, showing a commitment to the outcomes of the studio.

The intention is to add to an ongoing toolkit of urban elements for BGI implementation and urban design intervention projects. Interpretation and translation of student work is continuing. The student design-build and the relationship of academia and community through the iThemba Walkway project are important creative works towards rethinking urban form as the intersection between the ordinary and the extraordinary complex patterning of change post-apartheid (Harrison and Zack, 2014).

CONCLUSION

The paper focused on an approach and method to understand patterns of urban form in a township territory. There are concerns about the growing informality, rapid transformation and peripheral urbanism in South Africa (Kovacic and Giampietro, 2017). As the neighbourhood of Gugulethu expands, local agents argue that it remains economically marginal in Cape Town, entangled in insecurity, extreme violence and social inequality with little hope of integrating into the city. However, the patterns described reveal a certain level of resistance and resilient township transformation that transcends multiple scales, dimensions and critical sites.

In conclusion, data collection, pattern recognition, design approaches and Southern theory are used as clues to disrupt and 'plot' spatial design scenarios with local agents to reframe a theory of change for peripheral urban morphology in Cape Town.

Du Plessis, Landman, Nel and Peres (2015) note that "Urban form aids (and hinders) urban resilience in several ways." (p.183). Adaptive strategies in certain focus areas of Gugulethu are most prevalent at the complex, yet successful and robust micro-scale, albeit almost invisible at the network, policy and municipal level. Micro-urban morphologies are perhaps the most unrepresented type of urban form in Gugulethu with the most potential towards resilient *township transformation*. Further research is underway on micro-urban forms aligned with a research project on social infrastructure and underground networks (Gehl, 2024), entitled *Spaces of Exchange,* aligned with *The Walkway Project* on the urban upgrading of public space in Gugulethu.

Acknowledgements

Acknowledgement is given to the local agents in Gugulethu, Xolile Ndzoyi, Wawa Siyengo and Nontsika Mnotoza and to the students and teaching staff within the Master of Urban Design programme at the University of Cape Town. The teaching studio was partially funded through the UCT Social Responsiveness Curriculum Development Grant in 2019 and the UCT Teaching and Innovation Grant in 2021. iThemba Walkway was further complimented by funding via a UCT URC Project Grant and the Association of Commonwealth Universities Climate Resilience Challenge Grant from 2022 to 2023. The spatial practice work produced within the Violence Prevention through Urban Upgrading (VPUU) Non-profit Company (NPC) between 2010 and 2018 is acknowledged and appreciated.

ABSTRACT

As the Transit-Oriented Development (TOD) model matures, rail transit stations have evolved beyond their original function as transportation nodes to become key nodes of urban public life. Sunken plazas, as important types of connecting spaces between transit stations and urban environments, have advantages such as improving pedestrian experience, increasing property value, and promoting effective integration of stations with urban spaces, and their construction and development are receiving increasing attention. This paper reviews the spatial form indicators and evaluation framework of sunken plazas at transit stations in Shanghai's central urban area, using the entropy method to quantify the relative importance of various evaluation indicators and establishes a corresponding quality assessment model. It evaluates the sunken plazas of transit stations in Shanghai's central urban area in three dimensions: path walkability, transfer convenience, and activity comfort, and analyses the reasons for these evaluations. The results indicate that evaluating the spatial quality of sunken plazas is a multi-dimensional, multi-path process influenced by the three dimensions, with the complete configuration of accessibility facilities, the number and layout of entrances, and the density of facilities in sunken plazas being representative indicators of these dimensions. The development of most sunken plazas in Shanghai is inconsistent, indicating significant room for improvement.

Keywords: sunken plaza, rail transit station area, spatial quality, Entropy Value Method

INTRODUCTION

As the Transit Oriented Development (TOD) model matures, compact development centred around rail transit stations has become an important type of construction in high-density large cities. Consequently, rail transit stations are no longer confined to their original function as transportation nodes but are gradually becoming key nodes of urban public life, possessing the dual attributes of "node" and "place." In large cities in China, an increasing number of rail transit stations are integrating their entrances and exits with the open space of sunken plazas, making them intermediary spaces that

connect urban surface space with surrounding commercial spaces. This integration helps improve pedestrian experience, increase property value, and promote the effective integration of stations with urban spaces.

Currently, there is limited research related to the spatial form and usage conditions of sunken plazas within rail transit station areas. Among the few existing studies, some analyse the important role of sunken plazas in improving the pedestrian environment, enhancing the land use value around stations, and creating urban public spaces (Wu Jun, 2020); others explore the coordination relationship between sunken plazas, urban construction, and the behavioural activities of users based on the current usage of existing sunken plazas (Cooper Marcus, 2001). These studies have relatively narrow perspectives and lack comprehensiveness, failing to propose a systematic framework and methodology for evaluating the spatial quality of sunken plazas. This paper reviews the spatial form indicators and evaluation framework of sunken plazas in rail transit station areas, utilizing the Entropy Value Method to quantitatively analyse the relative importance of various evaluation indicators, and establishes a corresponding quality assessment model, aiming to provide objective evidence and theoretical reference for the planning and design of sunken plazas in future rail transit station areas.

Research Design

Evaluation Indicators

Based on relevant studies such as the Node-Place (N-P) model of transit stations (Bertolini 1996), the Five Levels of Walking Needs model (Alfonzo 2005), and the Public Space Design Evaluation Table (Cooper Marcus 2017), this paper analyzes the spatial quality and form indicators of sunken plazas from three dimensions: path walkability, transfer convenience, and activity comfort (Table 1).

Path Walkability

Path walkability refers to the degree of accessibility of sunken plazas as basic infrastructure at the entrances and exits of transit stations for different groups of people. It mainly includes evaluating the condition of the plaza's surface and the completeness of accessibility facilities. Good surface conditions are characterized by flatness, slope, walkable area, and the ability to remain dry and non-slip in adverse weather (Han et al. 2022). In this paper, Walkability of the site is used as a measure; the completeness of accessibility facilities reflects the service conditions of the sunken plaza for people with mobility difficulties (including the elderly, children, parents with strollers, and people with disabilities) (Purnamasari et al. 2022). This is measured by the coverage rate of accessible elevators and escalators at the entrances and exits of the plaza.

Transfer Convenience Dimension

Transfer convenience refers to the ease with which users switch between different functional spaces within the sunken plaza. This includes the evaluation of the convenience of transport transfers and the optimization of walking paths. The convenience of transportation transfers is mainly reflected in the scale and number of transfer facilities, measured by the density of staircases and entrance and exit facilities used for transportation transfers in the sunken plaza. The optimization of walking paths is mainly reflected in the convenience of walking from station entrances to various travel destinations, measured by three indicators: walking distance from the sunken plaza to nearby residential, office, and commercial facilities, detour factor, and the Betweenness Centrality (BtH) of the sunken plaza path in the neighbourhood walking path. In calculating the average value of multiple paths, the building scale of destination facilities is used as the weight in calculating the average value of walking distance and detour factor.

Activity Comfort Dimension

Activity comfort refers to the degree of humanized convenience and aesthetic pleasure users experience in the sunken plaza, primarily including the evaluation of spatial attributes and facility operations. In terms of spatial attributes, this is mainly reflected in the scale, shape, enclosure, and proportion of grey space of the sunken plaza. Regarding facility operations, it is mainly reflected in the attraction and support for diverse walking activities, with relevant evaluation indicators including the proportion of commercial interface, the proportion of service facility area, and the diversity of operations.

Table 1. Calculation methods for each indicator.

Dimension	Indicator	Code	Formula	Description
Path Walkability	Accessibility Completeness of Facilities [-]	ACF	$\frac{N_{acc}}{N_t} \times a$	Where N_{acc} is the number of accessible facilities and N_t is the number of total entries. When an accessible direct elevator is present,$a = 2$; otherwise,$a = 1$.
	Walkability of the Site [-]	WS	$\frac{A_w}{A_t} \times \mu$	Where A_w is the walkable area of the square, μ is the friction coefficient of the ground material, and A_t is the total area of the square.
Transfer Convenience	Entrance and Exit Density [X/m²]	EED	$\frac{N_t}{A_t}$	Where N_t is the number of entries and A_t is the total area of the square.
	Escalators and Stairs Density [-]	ESD	$\frac{\sum_{i=1}^{n} A_i}{A_t}$	Where A_i is the area of elevators and escalators in the square and A_t is the total area of the square.
	Betweenness (R=400) [-]	BtE400	$\sum_{s \neq v \neq t} \frac{\sigma_{st}(v)}{\sigma_{st}}$	The *s* and *t* are any two distinct nodes in the network. Where σ_{st} represents the total number of shortest paths from node s to node t.
	Walking Distance to Amenities [m]	WDA	$\sum_{i=1}^{n} L_i \times \frac{S_i}{S_t}$	Where L_i is the walking distance to each facility, S_i is the building area of that facility, and S_t is the total building area of all facilities within the station area.
	Detour Coefficient of Amenities [-]	DCA	$\sum_{i=1}^{n} \frac{L_i}{D_i} \times \frac{S_i}{S_t}$	Where L_i is the walking distance to each facility and D_i is the straight-line distance to each facility.
Activity Comfort	Scale[m²]	SCA	A_t	Where A_t is the total area of the square.
	Shape[-]	SHP	$\frac{4\pi A_t}{{P_t}^2}$	Where P_t is the total perimeter of the square.
	Enclosure[-]	ECL	$\frac{H}{median(D)}$	Where H is the depth of the sunken area and $median(D)$ is the median width of the square.
	Commercial Interface Rate [-]	CIR	$\frac{\sum_{i=1}^{n} L_i}{P_t}$	Where L_i is the length of commercial interfaces and P_t is the perimeter of the square.
	Grey Space Ratio [-]	TSR	$\frac{\sum_{i=1}^{n} A_i}{A_t}$	Where $A_i$is the area of grey space and A_t is the total area of the square.
	Rest Facility Area Ratio [-]	RFAR	$\frac{\sum_{i=1}^{n} A_i}{A_t}$	Where A_i is the area occupied by rest facilities and A_t is the total area of the square.
	Diversity of Facilities in the Square [-]	DFS	$-\sum_{i=1}^{n} \frac{n_i}{N} \log_2(\frac{n_i}{N})$	Where n_i is the number of individuals in the *i*-th category, and *N* is the total number of individuals across all categories.
	Diversity of Facilities in the Station Area [-]	DFA	$-\sum_{i=1}^{n} \frac{n_i}{N} \log_2(\frac{n_i}{N})$	Where n_i is the number of individuals in the *i*-th category, and *N* is the total number of individuals across all categories.

Case Selection and Data Sources

Shanghai now holds the top spot in the world for rail transit operation mileage, which is distinguished by a dense network, heavy passenger volume, and a wide range of traveller uses. This paper selects 16 sunken plazas across 13 rail transit stations in Shanghai's central urban area as the research objects (Table 2, Figure 1), noting that some transit stations have multiple sunken plazas connected to them. These plazas feature diverse spatial forms, functional types, and current usage conditions, providing reliable case support for studying the spatial quality of rail transit station area sunken plazas. Data collection for the research samples is conducted at two spatial levels: the internal environment of the sunken plazas and the surrounding neighbourhood environment. The internal plaza environment's characteristics are derived from field measurements, surveys, and building drawings. Open Street Map is the original source of the data on the features of the neighbourhood environment, and a GIS platform is used to integrate and calculate the raw data to create the indicators. (Figure 2).

Research Methodology

The evaluation process of the spatial quality of sunken plazas in rail transit station areas is complex, with various built environment elements interacting in a complex manner to collectively influence the final spatial quality of the sunken plazas. The entropy method, as an objective weighting method (Zhang et al., 2023), determines the weights of indicators based on the amount of information provided by the observed values of each indicator, thereby avoiding errors caused by human factors. This paper uses an improved entropy method for evaluation, with the following steps: Firstly, the collected data of 15 indicators from 16 sunken plazas are used to construct the original data matrix x_ij, indicating the observed value of the sample i on the indicator j. To eliminate the impact of the original indicator dimensions and absolute value size, the raw data are standardized after

distinguishing between positive and negative indicators. Based on this standardization, the proportion p_ij of each sample on each indicator is calculated, reflecting the importance of the sample's performance on this indicator relative to other indicators. Subsequently, the entropy value e_j for each indicator is calculated based on this proportion to assess the degree of dispersion of the indicator. If all sample values for an indicator are very close, it indicates low uncertainty of the indicator, meaning it contributes less to the overall evaluation. Finally, the weights of each indicator are allocated according to the entropy value, ensuring that indicators with higher variability have a greater weight in the evaluation, while those with less variability have a correspondingly smaller weight.

RESULTS AND DISCUSSIONS [Heading 1]

Indicator Weight Analysis Using the Entropy Method

Using the entropy method, the 15 morphological feature indicators of 16 plaza samples are ranked by weight(Figure 3). The results show that the spatial scale indicator of sunken plazas has the highest weight, indicating significant differences in spatial scale among the case samples. The size of a plaza largely influences the number of service facilities and the types of public activities it can support; larger sunken plazas can accommodate more diverse service facilities and activities. The weight of accessibility facilities is second, indicating that some sunken plazas still lack adequate accessibility facilities. The ability of people with disabilities, the elderly, and children to use transit and other facilities within the station area safely and conveniently is directly impacted by the presence of accessibility facilities, including accessible elevators, which is still a critical factor in evaluating the spatial quality of sunken plazas. The weights of entrance density and elevator density under the dimension of transfer convenience rank third and fourth, indicating that the number of entrances connecting urban spaces and commercial areas, as well as the number of vertical pathways, play important roles in the efficient organization of pedestrian flow at stations. The weights of plaza spatial shape and ratio of facility area under the dimension of activity comfort rank fifth and sixth, respectively, indicating that the spatial form and recreational facilities play important roles in increasing the use rate, comfort, and attractiveness of sunken plazas. The increase in the number of people lingering not only enhances the vitality of the plaza but also promotes the development of surrounding businesses, fostering a positive cycle.

Additionally, other characteristic indicators also have varying degrees of impact on the spatial quality evaluation of sunken plazas. However, because the differences in these indicators among samples are small, they do not show a significant role in distinguishing the spatial quality of sunken plazas. Nevertheless, this does not negate the value of these evaluation indicators. For example, the degree of enclosure of a sunken plaza is also important for creating the atmosphere of a spatial place. A highly enclosed sunken plaza helps create a private and quiet rest environment in a high-density neighbourhood and aids in shaping a commercial atmosphere. A design with low enclosure is suitable for sunken plazas that frequently host performances, exhibitions, and other public activities, as it helps provide larger open spaces for crowd gatherings and activities.

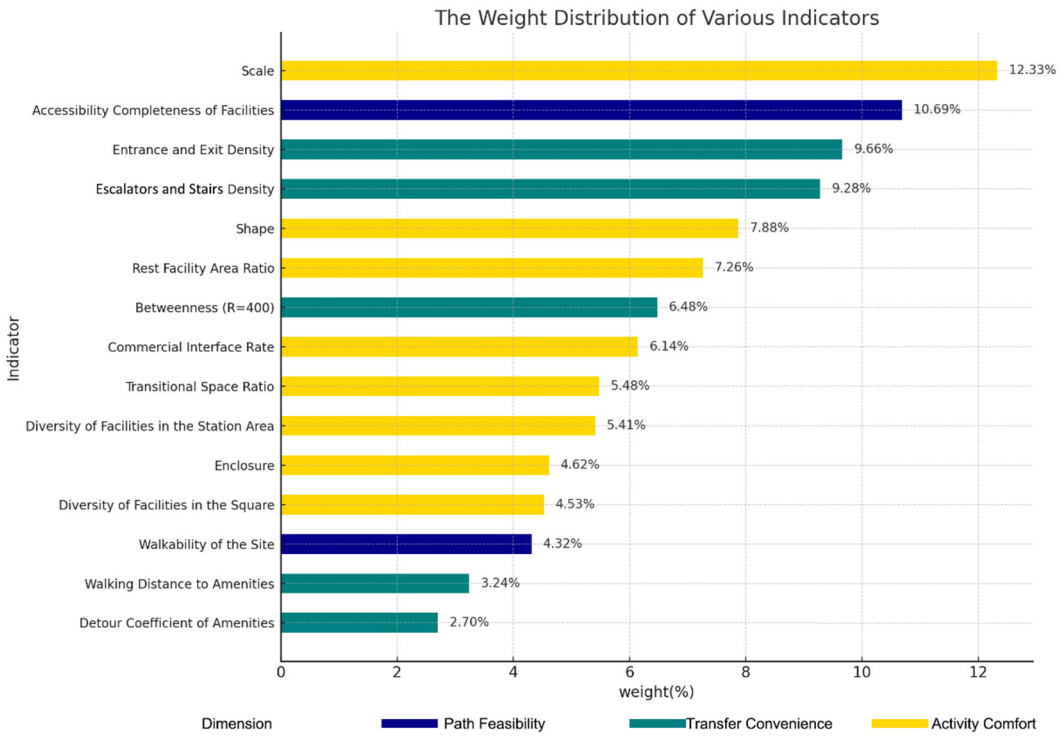

Figure 3. Weights of Indicators

Spatial Quality Characteristics of Sunken Plazas

The comprehensive spatial quality scores for the 16 plazas were calculated using the entropy method model. Additionally, individual scores in the three research dimensions—path walkability, transfer convenience, and activity comfort—were acquired. (Figure 4, Figure 5). In terms of comprehensive scores, plazas F, B, and K ranked in the top three. Analysing the site conditions of these three plazas, both plaza F and plaza K are sunken plazas integrated with commercial complexes above transit stations within the plots, while plaza B is a sunken plaza located below a major intersection. The urban morphology of the station areas for plazas F and K is different.

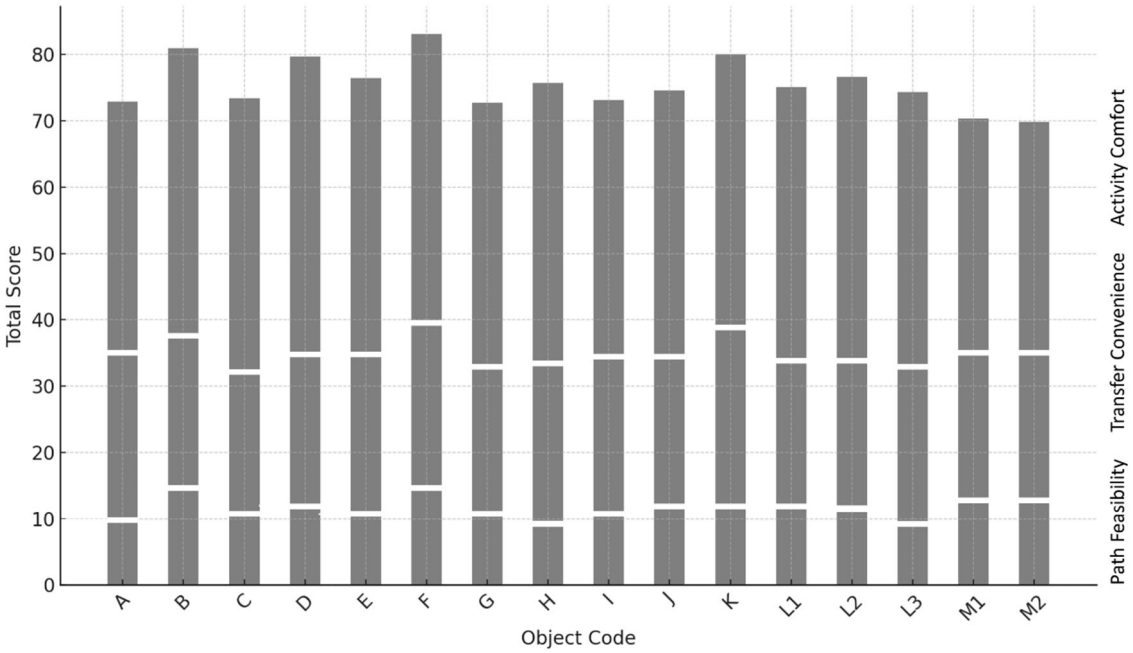

Figure 4. Scores of Spatial Quality for Plazas

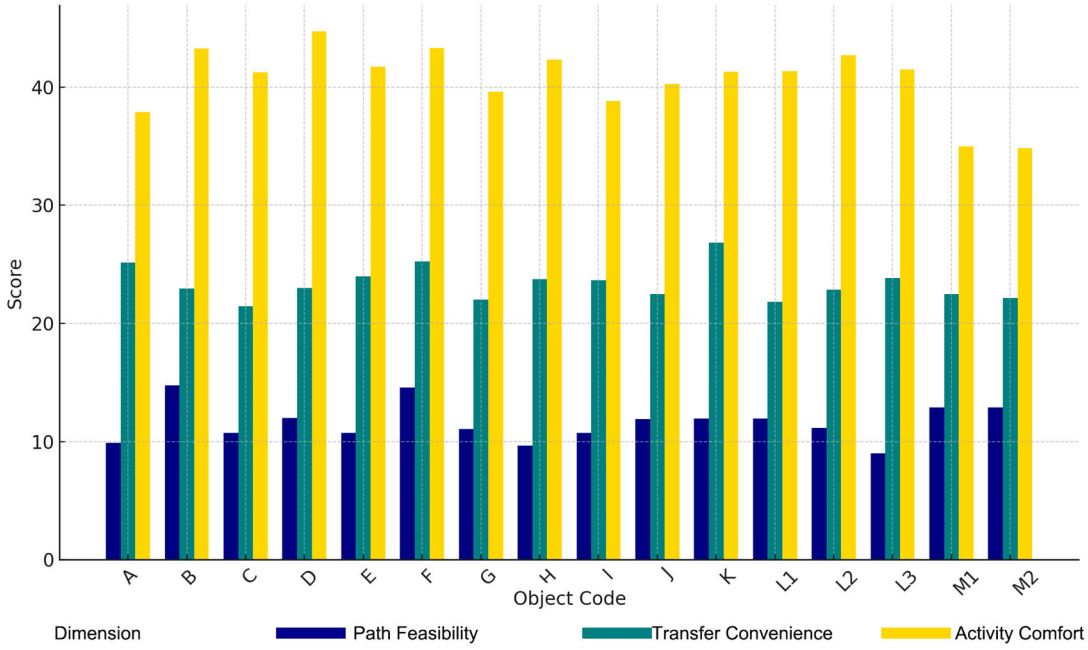

Figure 5. Scores on Three Dimensions for Plazas

Plaza K is in Shanghai's ancient city center, where the extensive road network and compact urban layout facilitate easy transport transfer and good access to business, residential, and office spaces. However, the size of the sunken plaza is tiny, lacking accessible elevators and having unidirectional escalators due to early construction and the requirement to keep existing buildings on the site. This leads to less notable assessments for path walkability and activity comfort. Plaza F is in a new urban area of Shanghai, with the notable advantage of tightly integrated planning and design of the sunken plaza with the transit station area, fully equipped with accessible elevators and bidirectional escalators. Additionally, the sunken plaza is closely linked to a large commercial complex, allowing

commercial activities to effectively extend into the plaza. The 500m² space scale supports coffee, fast food businesses, and brand pop-up events within the sunken plaza. However, due to the influence of wide vehicular lanes and low road network density within the station area, it shows relative weakness in the accessibility of surrounding facilities. The original design intention of plaza B is to serve as a hub for the underground transportation system, alleviating conflicts between pedestrians and vehicles at the intersection of major roads and enhancing public transportation and walking accessibility to commercial facilities adjacent to the main roads. The surface of plaza B uses flat, non-slip permeable stone paving, with accessible elevators set up at each entrance, demonstrating good inclusivity for all user groups, achieving the highest score in path walkability. By setting up multiple entrances directly connecting to surrounding facilities and ground entrances leading to various roads, effective reductions in walking distance and detour factors within the station area facilities are achieved. Plaza B has the largest land area, providing efficient paths for pedestrians traveling to and from the transit station. At the same time, open spaces, sitting landscapes, and temporary commercial facilities are integrated into the site edges, enriching its function as a hub of underground space within the station area. Ultimately, as a multifunctional public activity space that integrates commerce, sports, and leisure, it is well-received by the public(Table 3, Figure 6).

Table 3. Key Indicators of Plazas K F B.

Object Code	ACF[-]	BtE400[-]	DCA[-]	SCA[m²]	RFAR[-]
K	1.00	18702.79	1.23	380.23	0.08
F	2.00	22637.84	1.35	522	0.30
B	2.00	44443.00	1.38	5942	0.13

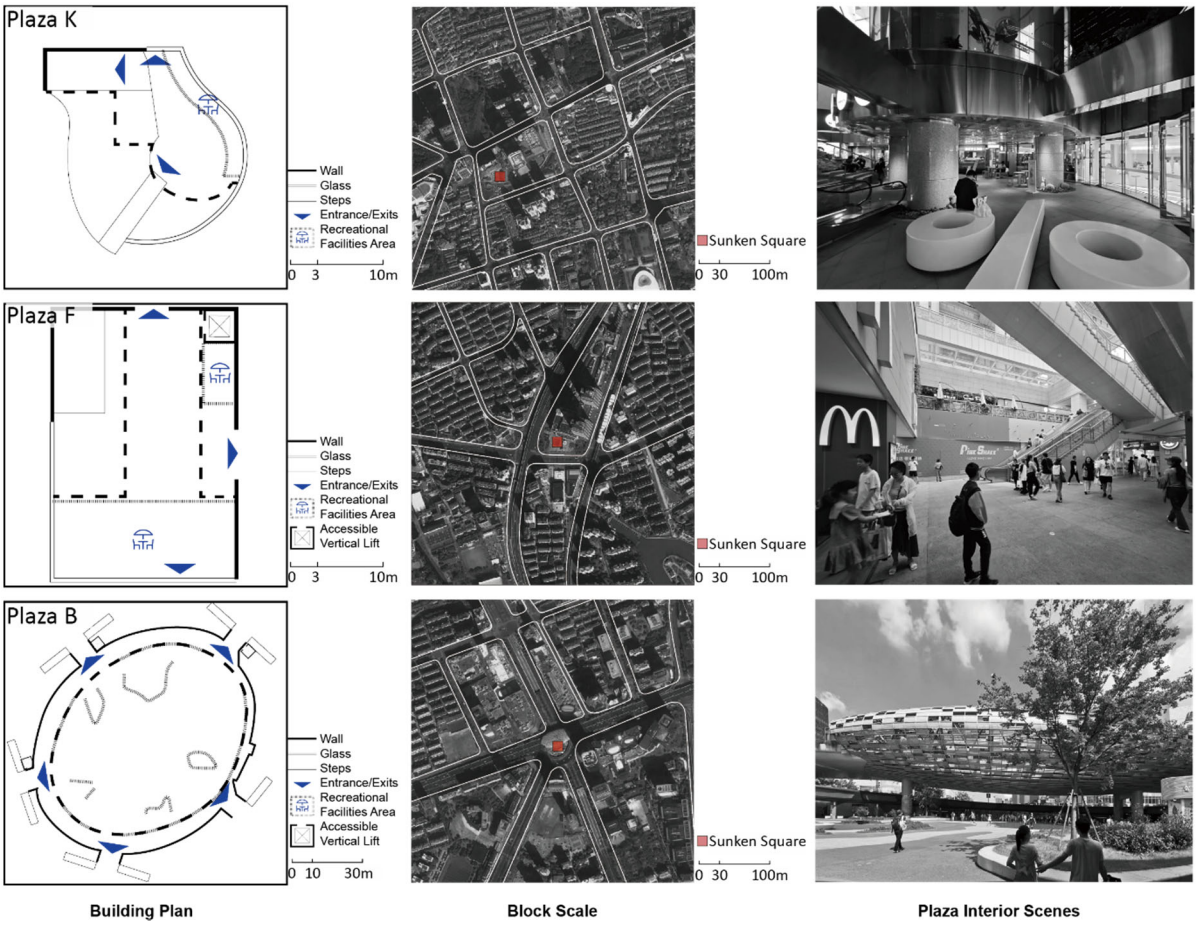

Figure 6.Diagram of Key Indicators of Plazas K F B.

In terms of path walkability, the presence of accessible elevators significantly affects the score differences among the samples. Only plazas B and F have accessible elevators installed, resulting in these two samples having outstanding scores in path walkability. The score differences among other samples are mainly influenced by the configuration rate of escalators and the walkability of the site. Accessible elevators serve people sensitive to walking distance and detours. For sunken plazas, which have unique visual appeal and can effectively function as pedestrian thoroughfares, the installation of accessible elevators should be more widespread.

In terms of transfer convenience, the score differences among the samples are mainly influenced by entrance density and elevator density. Plazas C and D are both large, elongated sunken plazas adjacent to large commercial complexes, yet they show significant differences in transfer convenience scores. Plaza C has entrances to the complex only at the ends, with staircases and escalators sparsely arranged along the long side. In contrast, plaza D has multiple entrances connecting to the complex on one side of the plaza and two additional passages on the other side connecting to the rail transit station. Therefore, in terms of accessibility to surrounding facilities, plaza D has a significant advantage and scores higher in transfer convenience. However, from the perspective of block layout, both samples are arranged along the long side of the complex, aligning with the pedestrian paths of the surface streets, without leveraging the unique advantages of underground pedestrian paths. As a result, both have relatively low scores in BtH within a 400m range(Table 4, Figure 7).

Table 4. Key Indicators of Plazas C D.

Object Code	EED[X/m²]	ESD[-]	BtE400[-]	SCA[m²]	SHP[-]
C	2.15	0.15	29196.26	2326.48	0.24
D	3.26	0.21	21334.65	3005.83	0.23

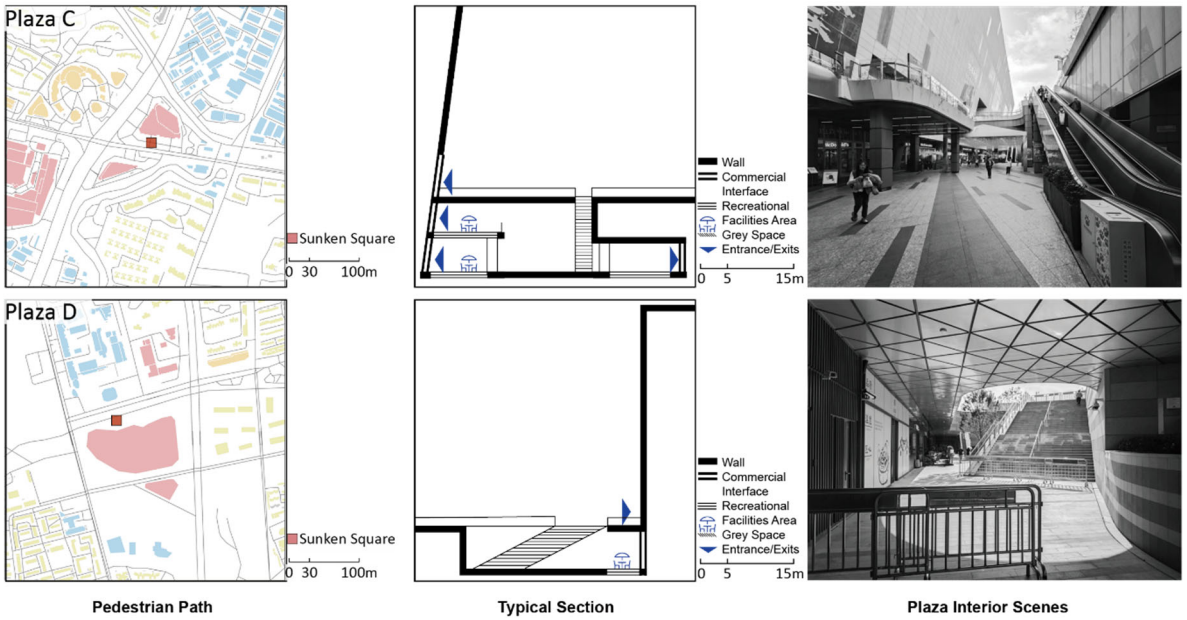

Figure 7.Diagram of Key Indicators of Plazas K F B.

In terms of activity comfort, plazas M1 and M2 score low and show significant gaps compared to other samples, primarily due to the lack of service facilities on site. These two sunken plazas are located in newly developed urban areas, with large areas connected to commercial districts and sports parks, offering good environmental resources that have not been fully utilized. M1 does not extend the business patterns of the adjacent mature commercial district, and M2 does not tap into the potential commercial vitality of the sports park's clientele. The interfaces within both plazas are monotonous and enclosed, lacking seating and commercial facilities, which diminishes their appeal as places for people to linger. As a result, instead of developing into lively urban public areas, they only function as transit buffer spaces for reaching rail transit stations. (Figure 9).

Figure 9 Interior Scenes of Plazas K F B.

Spatial Quality Evaluation Model for Sunken Plazas

The overall spatial quality of sunken plazas in rail transit station areas is calculated by multiplying the scores of various research factors by their respective weights. Based on the natural breaks method, all indicators are classified into two categories by weight, with the more important category including six indicators, leading to the following spatial quality evaluation model for sunken plazas in transit station areas.

$$Y=0.123\times X1+0.107\times X2+0.097\times X3+0.093\times X4+0.079\times X5+0.07\times X6+0.072\times X7$$

Where Y is the spatial quality score of a particular sunken plaza, and X1,X2,X3,X4,X5,X6,X7 are the standardized values of spatial scale, accessibility facilities completeness, entrance density, elevator density, spatial shape, and ratio of recreational facilities area, respectively.

CONCLUSIONS

This study applies the entropy method to empirically analyze the spatial quality of sunken plazas in rail transit station areas in Shanghai's central urban area. It concludes that sunken plazas, as elements of urban public space, are important for boosting the overall coherence of urban space, making the area around rail transportation stations more walkable, and boosting the area's commercial activity above the stations. Through indicator analysis of the spatial quality evaluation model, it is shown that evaluating the spatial quality of sunken plazas is a multidimensional and multi-path process, influenced by dimensions such as path walkability, transfer convenience, and activity comfort. The complete configuration of accessibility facilities, the layout of entrances and exits, and the density of facilities in sunken plazas are representative indicators of these dimensions.

To improve the spatial quality of sunken plazas in rail transit station areas in Shanghai's central urban area, the following recommendations are proposed: (1) Fully configure accessibility facilities to promote inclusive design in the vertical spatial direction of the city, ensuring the basic transit needs

of users with mobility difficulties; (2) Increase the multi-path and multi-directional pedestrian connections of the sunken base surface, using underground passages to mend urban spaces fragmented by vehicular traffic, thus stimulating commercial vitality in the entire area; (3) Diversify the functional types and recreational facilities as much as possible to create a comfortable and pleasant public space environment that meets the needs of different groups.

The paper has limitations such as a relatively singular analysis method and indicator selection mainly derived from literature without perception surveys of sunken plaza users. To provide more thorough and scientific theoretical support as well as useful guidance for the construction of urban transit-oriented development (TOD), future research can broaden the sample range to include more cities, perform comparative analyses of various types of sunken plazas, and delve deeper into the study of the spatial quality of sunken plazas in areas surrounding rail transit stations.

The urban form of peripheral springs: the case of the Lageado watershed, São Paulo/ SP

Luciano Silva[1], Ana Paula Koury[2]

[1] Luciano Abbamonte da Silva (Itaim Paulista Laboratory, Faculty of Architecture and Urbanism, São Judas Tadeu University), Brasil, lucianoalbamonte@gmail.com

ABSTRACT

This study aims to analyze the twenty springs that make up the Ribeirão Lageado watershed, in the Itaim Paulista region, East Zone of the Municipality of São Paulo, and to analyze the characteristics of their amphitheaters, which should be Permanent Preservation Areas with a minimum Non Aedificandi distance of fifteen meters, but which, in practice, are occupied by disadvantaged segments of the population, which generally constitute a framework of socio-environmental vulnerability and socio-spatial segregation. Thus, it is understood that a clearer definition of what constitutes the set of urban elements of these springs in peripheral regions can help in the implementation of future urban plans that aim to mitigate environmental problems and adapt these areas in terms of a minimally adequate supply of infrastructure, mainly basic sanitation, but also combined – green, blue and gray (GBGI). Furthermore, this study revisits the theme of neighborhood units, precisely from an environmental perspective, where each sub-basin of the system can be understood and qualified as a minimum unit of urban planning. As methodological procedures, a specific theoretical framework was established to support the analysis of local tissues, which was carried out by recording in-person and virtual routes. As a result, twenty springs were named, based on prominent elements of the road tracing, and categorized according to the environmental requalification potential of each one, whether high, medium or low. Thus, this research proves to be relevant in light of the Sustainable Development Goals, especially SDG 11, to make cities inclusive, safe, resilient and sustainable, and contributes to the characterization carried out, since these smaller watercourses are embryonic, so to speak, of the water structure of São Paulo as a whole.

Keywords: environmental requalification, rhizome, green blue and gray infrastructures, urban resilience, SDG 11

INTRODUCTION

This paper aims to analyze the twenty springs that make up the Ribeirão Lageado watershed, in the Itaim Paulista region, East Zone of the city of São Paulo (Figure 1). More specifically, it aims to characterize these springs based on the urban elements that make up their surrounding areas, namely, buildings, open areas, lots, blocks and road layout. The aim of this preliminary characterization is to categorize them according to a greater or lesser possibility of future requalification.

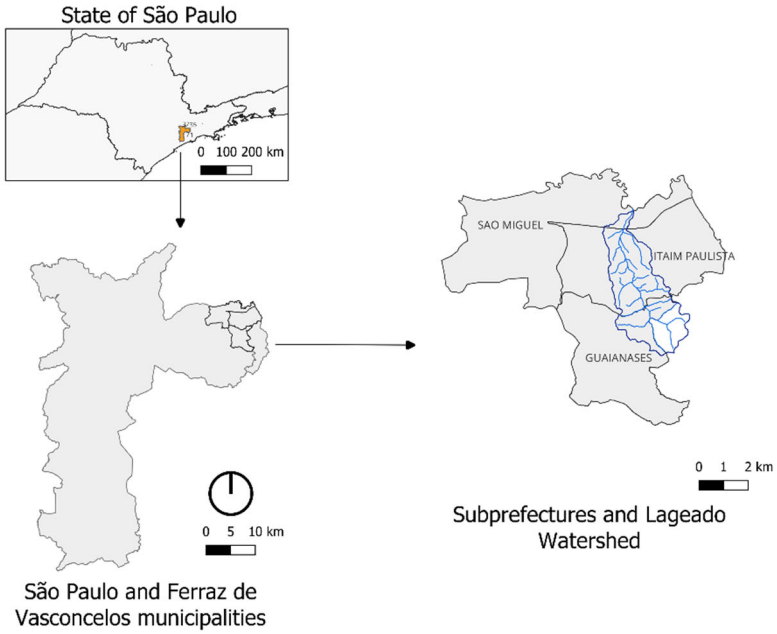

Figure 1 – Urban insertion of the Lageado Watershed. Source: prepared by the authors, 2024.

The typological study that will be carried out is based on the theoretical assumptions of three schools: English (CONZEN, 2022), Italian (MURATORI, 1959) and Portuguese (DIAS COELHO, 2013), which establish distinct methods, but which can be understood as complementary, especially with regard to the characterization of European cities. In contrast, this study proves to be relevant because it seeks to analyze peripheral landscapes, whose spring amphitheaters should be Permanent Preservation Areas with a minimum Non Aedificandi distance of fifteen meters, but which, in practice, are occupied by disadvantaged strata of the population.

Therefore, in general, this is a dual scenario of socio-spatial segregation (VILLAÇA, 2012) and socio-environmental vulnerability (ALVES, 2006; CANIL, LAMPIS and SANTOS, 2020), which can be observed in the insufficiency of the domestic sewage quota network, which implies that it is discharged directly into these same sources. Added to this is a symptom of quite severe underdevelopment, which is the cartographic lag that such urban fabrics present, since areas delimited as favelas, for example, are simply not designed by the Government. This issue was the subject of a previous stage of this research (FIRMINO, KOURY and SILVA, 2023), and demonstrated the importance, for future urban planning actions, of addressing this gap.

Thus, it is understood that a clearer definition of what constitutes the set of urban elements of these springs in peripheral regions can help in the development of future urban plans that aim to mitigate environmental problems and adapt such areas in terms of a minimally adequate supply of infrastructure. Furthermore, this study revisits the theme of neighborhood units, which was also previously addressed from a historical perspective (CESARINO and SILVA, 2015). Therefore, an environmental lens will now be applied, where each sub-basin of the system can be understood and qualified as a minimum unit of urban planning.

It is important to highlight a technical report that was recently published, on August 1, 2024, by the City of São Paulo, organized by the Hydraulics Technological Center Foundation (FCTH) and the Secretariat of Urban Infrastructure and Public Works (SIURB), in this case the Wartershed Notebook:

basins of the Água Vermelha, Lajeado and the São Martinho streams. A previous study of this research is directly cited in this Notebook, related to a hydrological modeling of the Lageado watershed (SILVA and KOURY, 2023), with compensatory drainage devices distributed throughout the basin, in this case small parallel reservoirs with potential for public use for leisure, sports and recreation. From now on, it will be necessary to carry out another future study to discuss the contents of this Notebook in relation to the research that has been carried out. In any case, one of its maps was used as a reference base for the analysis of the springs (Figure 2), even though there is a considerable difference – and insufficiency – in the number of springs identified in the Notebook and the thalwegs traced in this research, as can be seen by comparing them with the GeoSampa base (Figure 3).

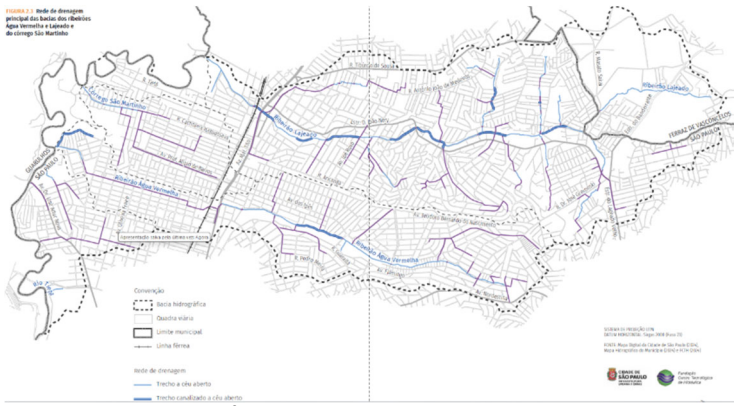

Figure 2 – Main drainage network of the Água Vermelha, Lajeado and the São Martinho streams watersheds. Source: SÃO PAULO (MUNICIPALITY), 2024, p. 30-31.

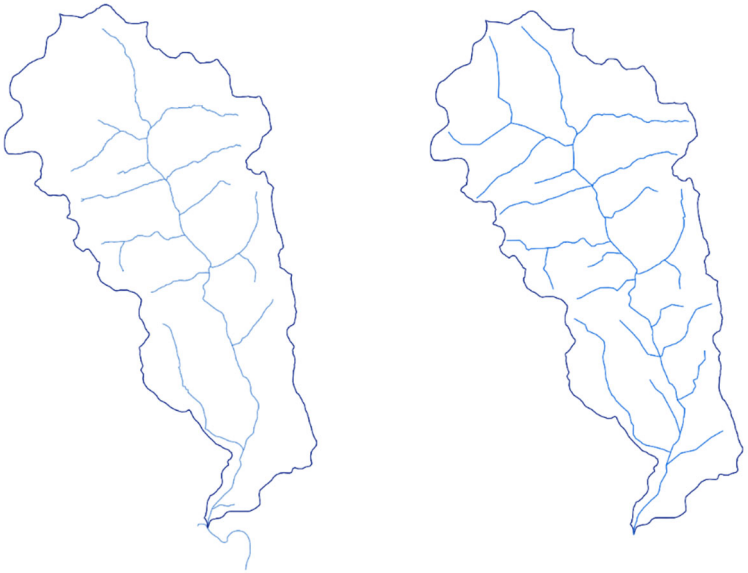

Figure 3 – Comparison between hydrography according to GeoSampa (left) and thalwegs as produced in this research (right). Source: prepared by the authors, 2024.

Henceforth, it is understood here that the set of sub-basins of Ribeirão Lageado can and should be the object of future interventions, mainly in the provision of environmental sanitation infrastructures. Therefore, these interventions can and should be articulated with combined urban projects, which combine functionality with the enhancement of the landscape and environments. In particular, the combined typologies of green, blue and grey infrastructures constitute important instruments of

urban resilience and climate adaptation (KUMAR et al., 2024), since they can contribute to the mitigation of heat waves by creating islands of coolness.

In short, this research is relevant to the Sustainable Development Goals, especially SDG 11, which aims to make cities inclusive, safe, resilient and sustainable, due to the characterization it proposes, since these smaller watercourses are embryonic, so to speak, of the water network as a whole. This network, which in the case of São Paulo consists of a myriad of springs (Figure 4), is, in most cases, apparently banal and invisible. However, as observed in this study, they present many peculiarities and a very complex formal variation.

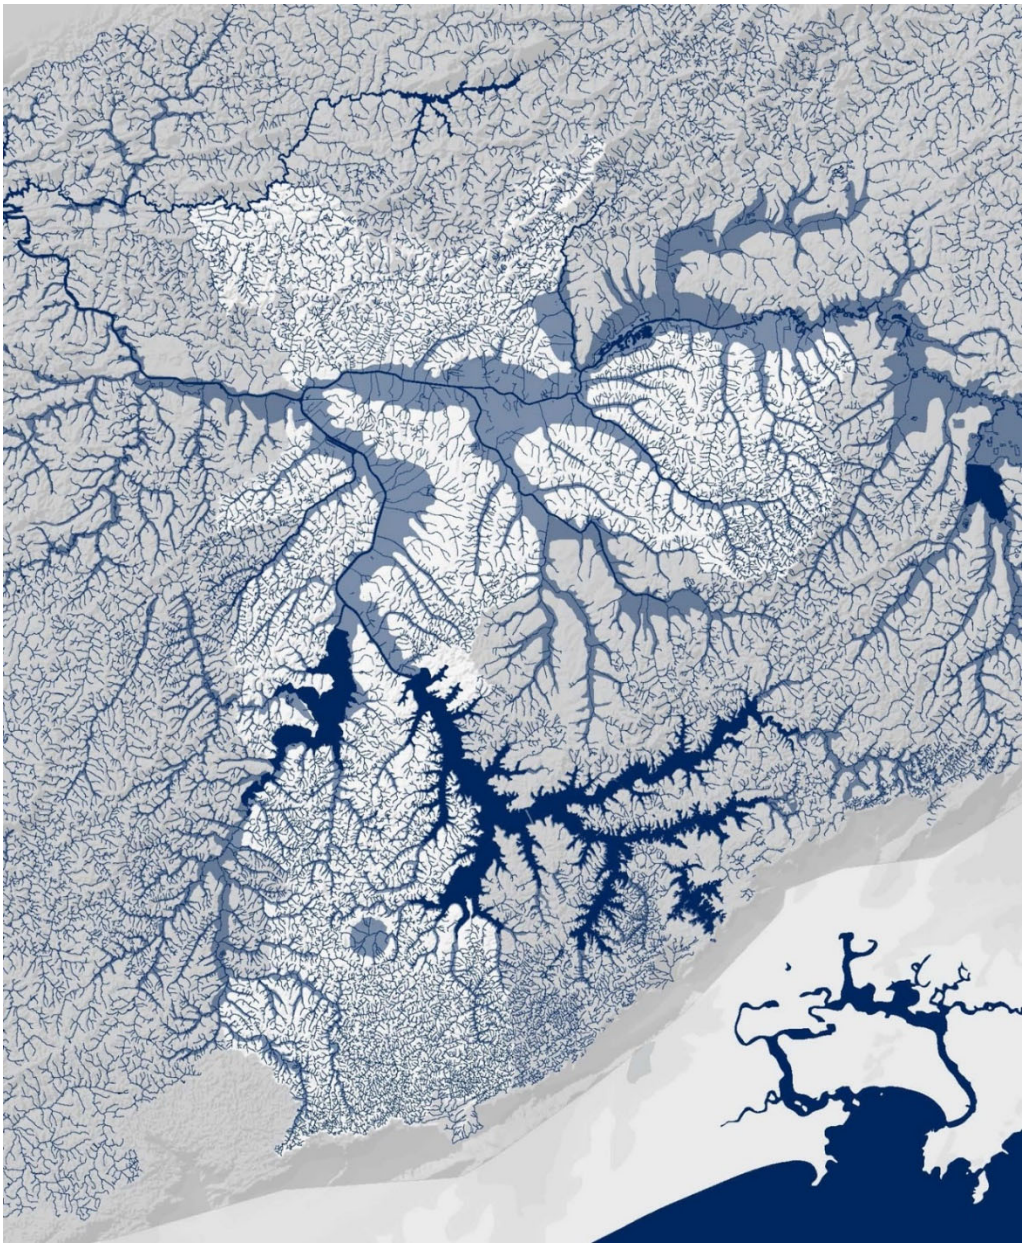

Figure 4 – Hydrography of São Paulo. Source: São Paulo (Municipality), 2016, p. 41.

OBJECTIVES

From a broader perspective, the objective of this study is to deepen the understanding of what constitutes, in terms of urban form, the set of springs that make up the Ribeirão Lageado watershed, making its constitution clearer. The aim is to define a quick but effective methodology – a how-to – that will enable more detailed guidelines for future urban projects. More specifically, the study seeks to:

List a theoretical framework that supports an understanding of the complexity of the set of "frameworks" that make up the object of study, in order to enable its characterization;

Characterize each spring based on environmental variations – or constancy – along its axis, from upstream to downstream;

Appoint, then, each spring based on an element of the surrounding road layout, be it a street, lane or avenue, so that such names are significant of local characteristics, for example, a word of indigenous origin possibly designates some previous characteristic of the natural site;

Identify, based on the characterization carried out, in which springs it is possible to prioritize an urban requalification project, environmental recovery and landscape enhancement;

Complement, in terms of a dialogue and a technical proposal, the Watershed Notebook of the Água Vermelha, Lajeado and São Martinho streams;

Demonstrate, therefore, that it is necessary to advance not only in terms of a more detailed formal understanding of the object of study, in order to increase the resolution of the scale of analysis of the water network, but, above all, of a cultural appreciation of peripheral landscapes, in addition to the criticism that can – and should – be made of the framework of socio-spatial segregation and socio-environmental vulnerability.

METHOD

This study combines different methodological procedures, constituting an empirical process that intersperses diverse and complementary activities, mainly in-person and virtual field visits. These procedures have constituted a platform for sequential and uninterrupted actions, constituting step-by-step advances in the process of a research that focuses on a trans-scale plan, from the river basin to various local situations.

Theoretical framework

Some works were listed as strategic to support the analysis that was carried out. In both, the similarity in the way in which the territory is unveiled stands out, mainly due to a continuous movement. A "fleet in being" – as proposed by the philosopher Paul Virilio, who discusses the place of fluidity in a completely scrutinized territory, where, according to Deleuze and Guattari: "one no longer goes from one point to another, but dominates the entire space from any point: instead of striating the space, it is occupied with a vector of deterritorialization in perpetual movement" (1980, vol. 5, p. 161).

It is no coincidence that Deleuze and Guattari are the main references for "Aesthetics of ginga: the architecture of favelas through the work of Hélio Oiticica", by Paola Bereinstein Jacques (2003). In this work, the author proposes three conceptual figures to explain the urban fabric of favelas – fragment, labyrinth and rhizome. These are distinct and complementary scales of approach, which draw a parallel with the artistic projects developed by Hélio Oiticica, which, according to his biography, incorporated themes originating from the culture of these places, especially the Favela da Mangueira.

Another work that provides a timely approach to urban form is the books “A Rua da Estrada” (2009) and “A Vida no Campo” (2011), by Álvaro Domingues, whose analyses of rural and peri-urban landscapes in Portugal are conducted through absolutely economic aphorisms. Using simply photographs, the author defines the main themes of the landscapes observed, as well as typologies, which are evident, mainly, in the character of a dispersed economy, be it agricultural, commercial or industrial. In this way, he outlines a panorama of what the urban form of these parts of Portuguese territory would be.

Finally, another work deserves to be highlighted, which was not conceived to be organized as such. It is a collection of letters from the writer Anton Chekhov to his publisher, on the occasion of his reconnaissance trip to what would become the penitentiary colony of Sakhalin, located on the coast of Russian territory. In “A Good Pair of Shoes and a Notebook: How to Write a Report” (2008), Thekhov makes an on-site observation of the territory, seeking to understand the way of life of the population there, a place that was the object of an “official discourse” by the Russian government, but which had its own rules, as he himself observed.

Thus, this set of works allows us to consider an integrated but, above all, rapid approach, so that planning actions can be carried out in parts of the territory that are largely unassisted, whether in terms of cartography or in terms of available infrastructure, especially basic sanitation. This agility in diagnosis is nothing new, and already appeared as a prerogative in 1969, as discussed by Jorge Wilheim in “Urbanism in underdevelopment”. However, there would be a shortage not only of technical teams, but, rather, of portions of territory that are produced, yes, by an arrangement of absolutely marginal and relatively anonymous techniques.

From field visits to Google's database

The in-person visit to the territory makes it possible to observe details that cannot be perceived in any other way, whether through cartography or other data formats. Several visits have been made in the context of this research, driven by different, albeit complementary, motivations. However, a river basin such as the one studied here makes it impossible, due to its size, to undertake long walks. Therefore, the conceptual figures of the fragment and the labyrinth become palpable and understandable, since such routes necessarily need to be undertaken by motorized transport, whose speed is incompatible with any consideration of the landscape.

Conversely, when using the virtual route tool provided by the Google platform, in this case Google Street, this same motorized transport now assumes the time of “slow pace”. It then becomes feasible to make a detailed observation of the areas surrounding the road layout, moving frame by frame, with the possibility of 360° rotation. This is a formidable database that makes it possible to fill many of the gaps between the fragments observed in the maze of field visits.

One of the uses of this tool is the direct comparison between an aerial photo and a ground-level perspective, as if the observer were parachuting into the desired location. In the case of Spring 11, for example, what in the aerial photo appeared as a large vacant lot (Figure 5) turned out to be a large housing development in perspective, even allowing the identification of very detailed information through the construction sign (Figure 6). This example demonstrates how much progress is needed in terms of cartographic updating for accelerated urbanization processes such as those occurring in the outskirts of São Paulo. It also demonstrates that it is necessary to take advantage of alternative procedures to those considered more traditional in the scope of urban form studies, which should not simply be dispensed with, but rather contextualized in terms of the relevance of their application.

The "notebook"

In order to characterize the springs analyzed here, this study opted to create a mosaic of images for each case, constituting the notebook where the rhizomatic route itself is recorded, through the way in which the movement between points in the territory is conducted. In an earlier stage of this research, the special nature of the creation of a route was already discussed, as well as the trajectories and tracking intrinsic to field visits, which can be observed, for example, in the paths taken by cats at night, recorded by Global Positioning System – GPS (Figure 7). In this way, the design of the form is carried out through the collage of images, and the notebook, with a card for each of the twenty springs, is created as a set of assemblages (Figures 8 and 9).

Figure 7 – Nighttime path of a cat recorded by GPS. Source: Central Tablelands LLS.

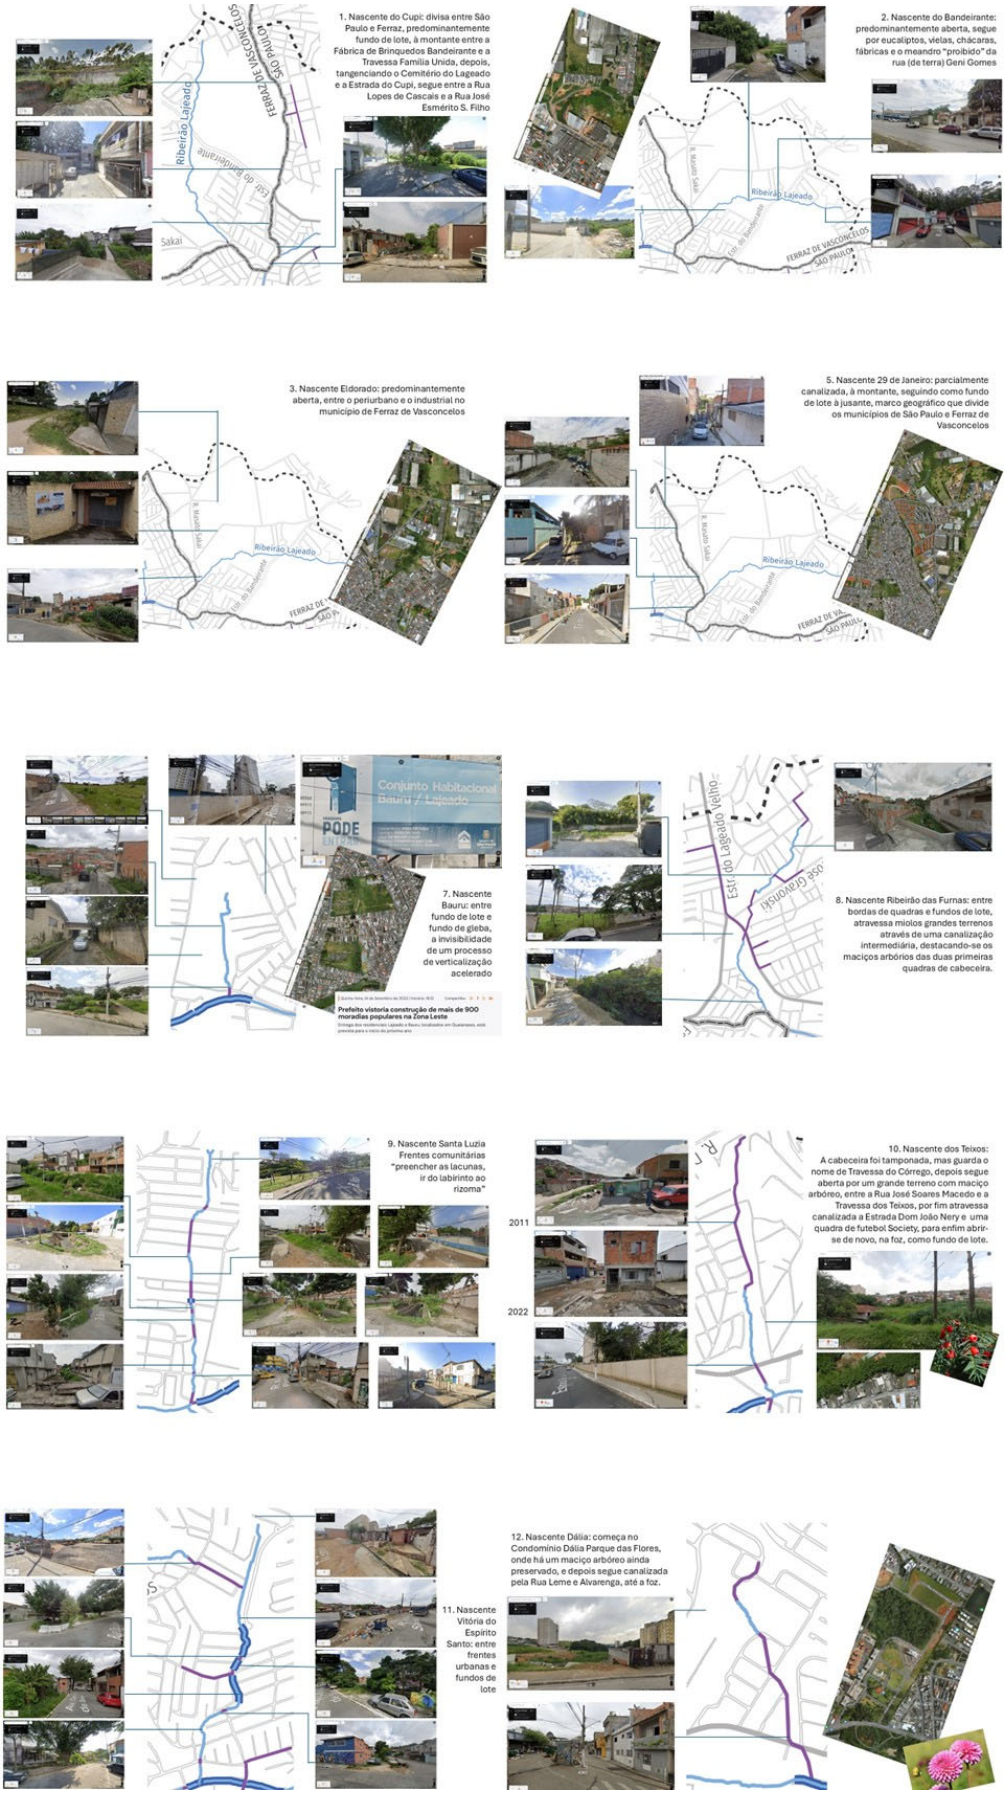

Figure 8 – Analysis sheets for Springs 1 to 11. Source: prepared by the authors, 2024.

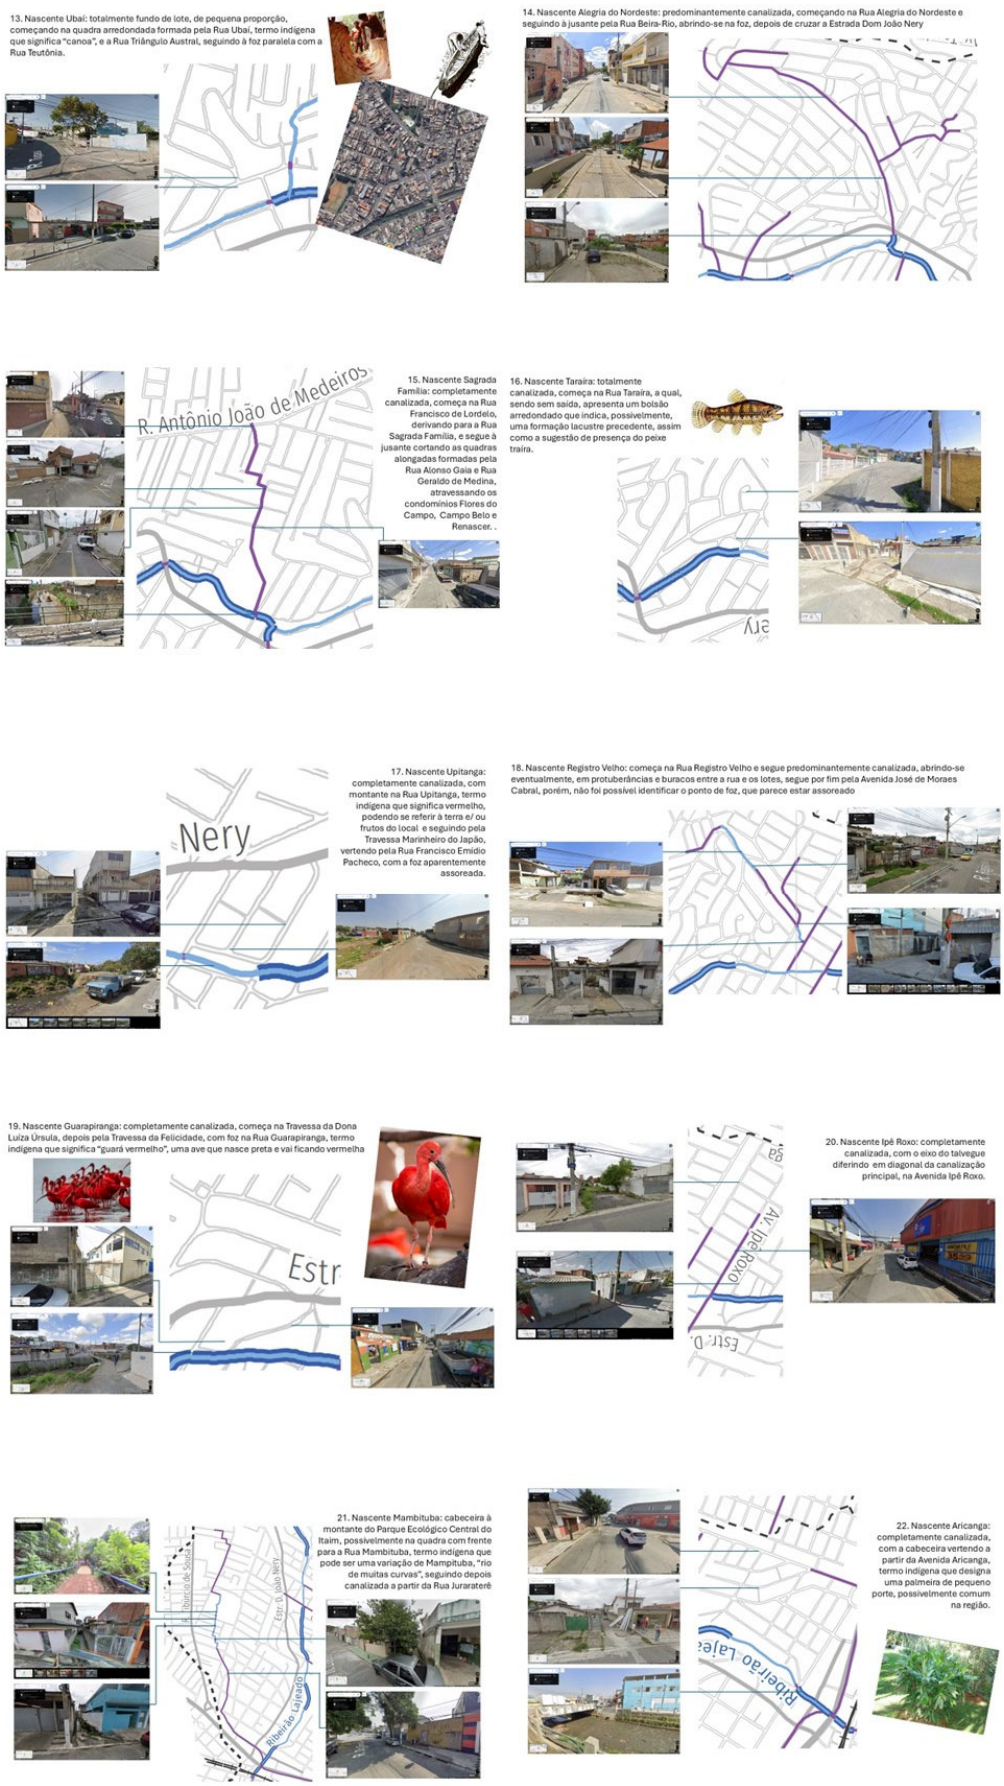

Figure 9 – Analysis sheets for Springs 12 to 22. Source: prepared by the authors, 2024.

Each of the sheets has its own proportions, but in all of them, a stratum of the cartography of the Notebook was used to frame the spring under analysis, directing all of them vertically, with upstream above and downstream below, except for Spring 2. In this way, the collage of images would also follow a pattern in terms of organizing the analytical path. As these strata were explored, we sought to identify a prominent name in one of the elements of the road layout, be it a street, an alley or an avenue, in order to give the name to the spring under analysis. Some of these names stand out as indigenous expressions – such as Spring 13 – Ubaí (Figure 10), and others as names of trees and flowers – such as Spring 20 – Ipê Roxo (Figure 11), revealing a potential to support environmental education actions and the valorization of local culture.

Figure 10 – Sheet of Spring 13 – Ubaí. Source: prepared by the authors, 2024.

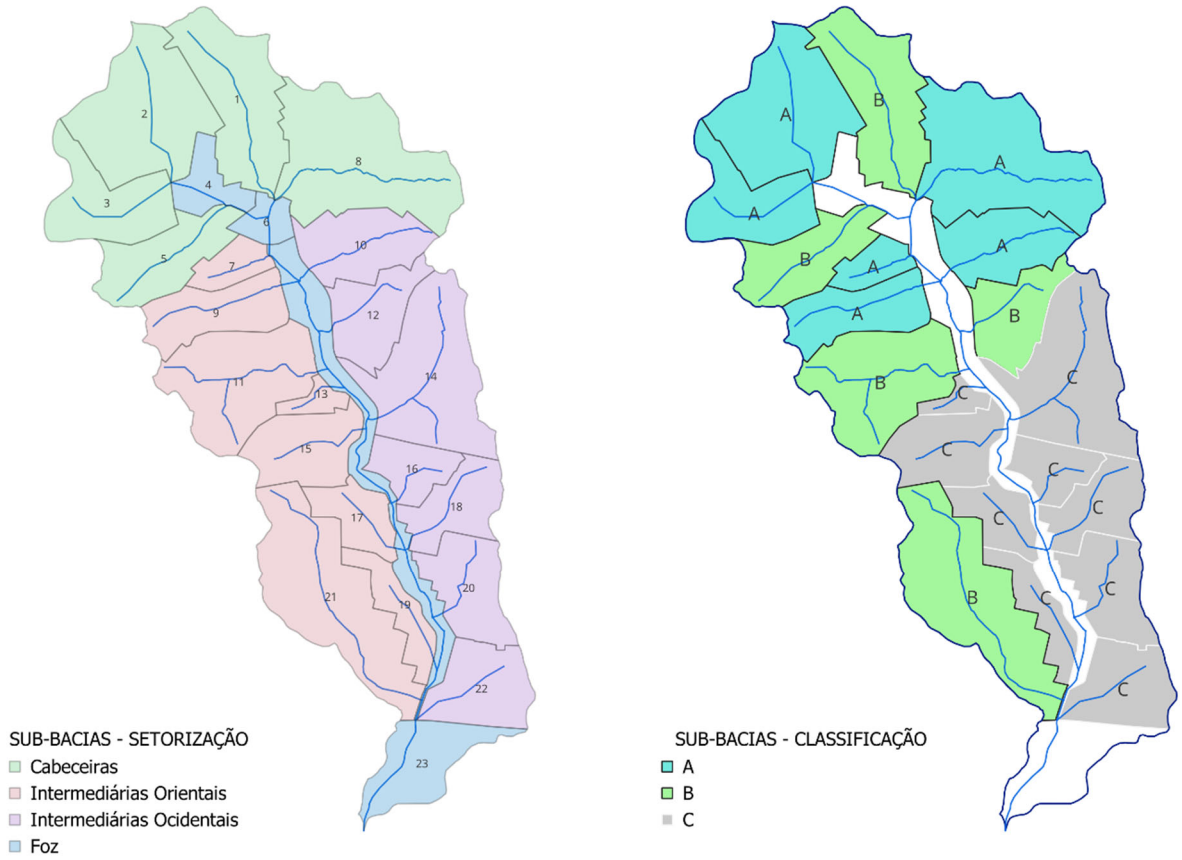
Figure 11 – Sheet of Spring 20 – Ipê-roxo. Source: prepared by the authors, 2024.

RESULTS AND DISCUSSIONS

This study resulted in two distinct but complementary products: one was the naming of the springs, creating a link between the observed landscapes – "fragments" – and the characteristic "labyrinthine" complex of the peripheral layout analyzed that constitutes each amphitheater of springs (Table 1). The other product consists of the categorization of each spring according to its potential for environmental requalification – high, medium and low. The research then progressed from a generic topological sectorization – headboards, eastern and western springs (Figure 12), to a specific classification according to their potential for environmental requalification (Figure 13).

Table 1. Naming and classification of the twenty springs of Ribeirão Lageado. Source: prepared by the authors, 2024.

Number	Name	Classification
1	Cupi Spring	B
2	Bandeirante Spring	A
3	Eldorado Spring	A
5	29 de Janeiro Spring	B
7	Bauru Spring	A
8	Ribeirão das Furnas Spring	A
9	Santa Luzia Spring	A
10	Teixos Spring	A
11	Vitória do Espírito Santo Spring	B
12	Dália Spring	B
13	Ubaí Spring	C
14	Alegria do Nordeste Spring	C
15	Sagrada Família Spring	C
16	Taraíra Spring	C
17	Upitanga Spring	C
18	Registro Velho Spring	C
19	Guarapiranga Spring	C
20	Ipê-Roxo Spring	C
21	Mambituba Spring	B
22	Aricanga Spring	C



Figures 12 and 13 – Sectorization and classification of the Ribeirão Lageado sub-basins. Source: prepared by the authors, 2024.

Regarding categorization, those springs that are predominantly open, such as more or less preserved shores, and that cross land with significant vegetation, even if they are partially channeled or cross the back of lots, were considered to have high potential for requalification. Those springs that are predominantly open, but cross the back of lots, were considered to have medium potential for requalification, which implies both a land limitation and a health problem, due to the discharge of domestic sewage directly into the watercourse, as can be seen at the mouth of the Spring 29 de Janeiro (Figure 14). However, in these springs with medium potential, significant masses of vegetation were observed, as is the case of the Spring Mambituba, which crosses the Itaim Central Ecological Park. The springs defined as having low potential for environmental requalification are those that are predominantly plugged, thus becoming alleys, streets and avenues.

Figure 14 – Discharge of domestic sewage directly into the mouth of Nascente 29 de Janeiro. Source: Google Street, 2024.

CONCLUSIONS

This study presents important advances in the field of urban studies applied to its construction form in contact with environmental aspects, such as the more or less "hollowed" sites of the amphitheaters or the more or less sinuous design of the watercourses. In addition, it allowed the collection of a series of evidence that demonstrates how an accelerated urbanization process is taking place in the outskirts of São Paulo, whose interventions, in their rapid advancement, seem to escape official records. In a comprehensive manner, it allowed an understanding of the main problem identified in this portion of the territory, in addition to the variations in form: the lack of basic sanitation infrastructure, and in all the open springs it was possible to identify the discharge of domestic sewage directly into the watercourses.

Urban expansion on the edge of Avenida Brasil highway, Rio de Janeiro

Mateus Rodrigues[1], Rodrigo d'Avila[2]
[1] LEC - Laboratório de Estudos e Pesquisas em Cidades, PROURB, FAU, UFRJ, Brazil, mateussfr@gmail.com

ABSTRACT

Avenida Brasil is a major highway in Rio de Janeiro, Brazil, which serves as a vital artery for the traffic flow of the metropolitan region. Crossing the city from east to west and intersecting 29 neighborhoods, its 58 kilometers have had a huge impact on urban mobility and form, and have been a vector of urban expansion since its construction in the 1940s. This article seeks to investigate how Avenida Brasil has structured the adjacent urban tissue, and to understand how the urban growth on its border has developed and expanded the city, creating new peripheral districts until today. Using historical morphological cartography, the research examines the evolution of urban forms and segregation patterns around the highway. It adopts a comparative historical approach, analyzing maps and satellite images to show how urbanization has evolved in response to the highway. The findings suggest that while Avenida Brasil facilitated urban expansion, it also contributed to spatial fragmentation and segregation. The study identifies three distinct categories of urban tissue: plot subdivisions, self-built settlements, and large residential or industrial complexes, each reflecting different phases of urban development and contributing to the morphological segregation of the city. This analysis highlights the complex relationship between urban mobility infrastructure and urban form, and provides insights into the spatial dynamics and segregation patterns influenced by major mobility vectors on the peripheries of metropolitan regions in the Global South. Such phenomena can generate and perpetuate higher levels of dependency and urban segregation, particularly in economically disadvantaged areas.

Keywords: Avenida Brasil, Highway, Urban expansion, Urban Mobility Infrastructure, Urban form

INTRODUCTION

This article is part of the development of the thesis on the segregation of urban form, following the work of the Master's thesis entitled "The dimension of segregation of mobility infrastructures: the case of Avenida Brasil", presented by the author in 2020. Exploring the intersection between infrastructure and urbanization, the research focuses on the influence of major roads on the organization of urban space. This particular investigation focuses on the urban expansion along the Avenida Brasil highway, a study that presents the issues through historical morphological cartography. Located in the city of Rio de Janeiro, Avenida Brasil is approximately 58 kilometers long and crosses 29 neighborhoods, and is one of Rio's most important urban mobility infrastructures. Avenida Brasil

is an icon in the history of Rio de Janeiro's urban expansion. Crossing the city from east to west, it links the central area with metropolitan peripheral regions, playing a crucial role as a structuring axis in the growth of the urban fabric and the occupation of the Western Zone. As part of the urban section of the BR-101 in the city, Avenida Brasil is responsible for the largest traffic flow in Rio de Janeiro, with more than 300 thousand vehicles a day, according to estimates by the City Hall.

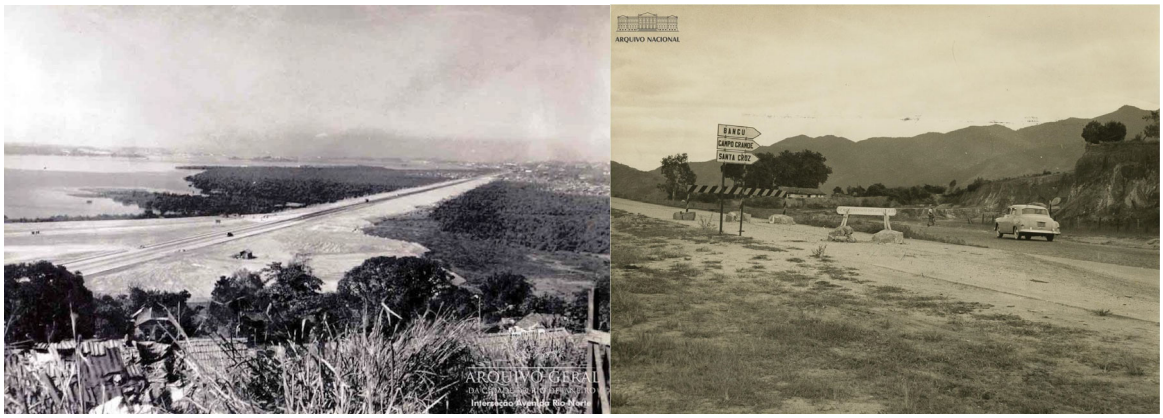

Figure 1. Historical photos of the construction of Avenida Brasil, respectively, between 1940 and 1957. Sources: General Archive and National Archive.

Built in the 1940s, it became a visible landmark in the urban transformations resulting from the emergence of the automobile as the main modern urban transport of the time. The highway project aimed to expand the Brazilian industrial field, thus becoming an axis for urban expansion. The images provide a glimpse of the initial conditions around Avenida Brasil in the 1940s and 1950s. The first image, from 1940, shows Avenida Brasil at the height of the Maré region. The absence of buildings and the large green areas indicate that the road was in a very early stage of development, serving as a transport axis through an area that was still sparsely populated. The second image, taken in 1957, shows the current Avenida Brasil (formerly Avenida das Bandeiras) in the area of Realengo. It is still partly rural, with vegetation and uninhabited land. Due to its importance, Avenida Brasil has been a recurrent object of study for the scientific community in the fields of urbanism, history and other social sciences. The importance of the highway for the development of the city and its role as a highway, as an expressway or even as a "street" (GAMA-ROSA, 2006), as well as its role as one of the main vectors of urban expansion in the metropolitan periphery (TORRES, 2017). More specifically, in the field of morphological urban studies, the important work of Pedro Barreto de Moraes stands out, which deepens the discussion on "urban spaces defined by large road infrastructure works" (MORAES, 2021) and uses Avenida Brasil as a case study, proposing the concept of "metropolitan highway".

Mobility Infrastructure and segregation

Urban mobility infrastructures are often considered as vectors of urban growth, enabling urban expansion and constituting an interface between urban mobility systems and landscape landmarks. Cases of highways in the urban realm are significant as they can represent forms of interpretation of urban phenomena at different scales. David Harvey (2008), in his concept of 'space-time compression', argues that technological innovations, particularly in transport and communication, have changed perceptions of space and time over the centuries. This process illustrates how changes in transport have not only reduced distances, but also radically changed the organization and shape of urban spaces over time. In the twentieth century, innovation in transport focused on urban mobility

infrastructure, and the reduction in travel time was accompanied by an expansion of urban space. Cities began to be adapted, shaped and planned to respond to the increase in the distances that could be traveled. This led to the emergence of suburbs, settlements outside central areas and dispersed urbanization, which has been criticized for its dependence on motorways. This research argues that the current Avenida Brasil, despite being a link between the western periphery and other regions of the city, shows patterns of urban fragmentation and dispersion at a local scale. In its extension, there are different morphological patterns of occupation: continuous and discontinuous settlements; associated and fragmented; concentrated and dispersed, of different scales and urban tissues.

In addition to transport innovation, the study of urban segregation took on particular contours during the 20th century, reflecting the complex social, economic and spatial dynamics of Brazilian cities. Among the major contributions to the understanding of this phenomenon, Roberto Lobato Corrêa, Flávio Villaça and Maurício de Abreu stand out for their analysis and interpretation of the configuration of urban space and the segregation processes that occur within it. Corrêa (1989) offers a detailed analysis of the formation of urban spaces, highlighting the dichotomy between self-segregation and imposed segregation. Villaça (2001) works on the issue of urban segregation, defining it as any form of exclusion that is spatially manifested in the city. Abreu (1987) is a major contributor to studies on the history of urbanism in Rio de Janeiro and the transformations of its urban landscape. In his work "Urban Evolution of Rio de Janeiro", he points out that the difficulty of importing manufactured goods led the municipal government to allow the indiscriminate location of industries on the outskirts of the city. The project that characterized the industrial growth of the city at that time was the effective occupation of a new axis of industrial expansion recently implemented by the State: Avenida Brasil.

New nuances, layers, faces or distinct dimensions of urban segregation are currently emerging in urban studies. Albert Pope (2014) identifies significant changes in the way cities are structured and experienced, particularly through the process of suburbanization, and introduces the concept of 'ladders'. These represent discontinuous and hierarchical connections that contrast with the traditional continuous grid, reflecting a shift towards a less integrated and more focused urban organization. This phenomenon is described as 'network erosion', where the introduction of vehicular circulation systems and the priority given to the convenience of travel ultimately undermines the integrity and quality of the network. In his studies, Pope (2014) points to a direct correlation between socio-spatial residential segregation and morphological or physical or purely spatial segregation. Morphological segregation can therefore reflect processes of fragmentation, dispersion, discontinuity and isolation in the urban form by dividing spaces and, consequently, populations. This phenomenon occurs when groups are separated by large distances and physical barriers. The result is a fragmented city, where the continuity of the urban network is interrupted and whole areas are cut off from each other. This spatial dispersal makes social and economic integration more difficult and is characterized by islands and urban enclaves, creating greater isolation, reinforcing inequalities and limiting access to resources.

Hipotesis and article structure

This article seeks to understand how urban growth around Avenida Brasil has developed and expanded the city, creating new peripheral neighborhoods and structuring the adjacent urban tissue. When mobility infrastructures enable urban expansion, does it result in a more integrated or segregated city? In order to answer this question, this introduction is followed by a cartographic

methodology that focuses on the immediate surroundings of the urban tissue at the edge of the highway. Historical maps at both metropolitan and local scale are used, covering almost 40 of the 58 km of highway built. In addition to the description of the historical material used, the methods of analysis are presented, which include the temporal and morphological classification of the urban tissue at the local scale. Next, we present the results of our mapping and classification methodology. These results include two main aspects: firstly, a metropolitan scale analysis that illustrates the process of urban occupation along the edges of Avenida Brasil over several decades; and secondly, an analysis based on 15 aerial photogrammetric maps from Rio City Hall at a scale of 1:2000. These maps provide a detailed view of urban growth and the development of the urban fabric along the highway. By comparing these maps with historical data, we show changes in the urban landscape before and after the construction of the highway. Finally, we deepen the discussion of these results through the comparison and analysis of the tissues classified along the highway in the 15 maps and discuss the organization of this analysis by sections of the highway, which, in the end, leads us to final considerations based on this morphological analysis in relation to spatial segregation on the edges of Avenida Brasil.

METHOD

Using a comparative historical approach, we have analyzed documents and maps from different periods, comparing maps from the beginning of the highway in the 1940s with contemporary satellite images. This analysis aims to reveal different characteristics along the areas of Avenida Brasil: where the urban tissue is continuous or fragmented, where there is a morphological difference between the left and right sides of the road, and where there are variations in the scale of urban elements. The tools used to analyze urban development have become increasingly sophisticated, allowing a deeper understanding of spatial transformations over time. Geographic Information Systems (GIS) allow historical and contemporary data to be overlaid, facilitating detailed temporal analysis. In addition, the digitalization and georeferencing of old maps improves the accuracy of comparisons with current data, providing a clearer picture of the changes that have occurred in cities over the years.

Firstly, in order to analyze the occupation around Avenida Brasil at a metropolitan scale, the existence of "urban tissue" (PANERAI, 1983), illustrated by old maps on the edges of the highway over the decades, is identified, using the ImagineRio application as a basis. The elements represented on the website have approximate locations, which corresponds to the proposed objective, since the development of this stage takes place on a large scale. As a result, it is possible to map, decade by decade, which parts of the edges of the highways, divided into right and left sides (always taking into account the movement away from the city center), were urbanized at each time.

Secondly, in order to analyze the expansion on the edges at a local scale that allows us to classify the urban tissue into categories, a comparative approach has been used on documents and maps from different periods, comparing historical images from the beginning of the highway in the 1950s with contemporary satellite images. It is possible to observe the existing buildings, plots and streets on the historical maps as well as on the contemporary cadastral plans. The satellite images allow us to analyze other layers of information, such as the materiality of the ground (green, sandy or asphalt areas) and the roofs. The selected maps refer to the documents available at the IPP (Pereira Passos Institute) from the 1950s and 1960s, as a result of an aerial photogrammetric survey carried out by the

Municipality of the Federal District of Rio de Janeiro at that time. Among the cadastral maps found in the survey, all those that were in good condition and that framed the location relative to the current position of the highway were selected. In some cases, for example, a projection of the construction of the highway can be seen with dashed lines, while in others contour lines indicate the earthworks prior to construction. It was not possible to include all the regions of Avenida Brasil, due to the lack of maps available under these conditions, as in the case of the Santa Cruz neighborhood, but in general, with the 15 maps studied, it is possible to have a good illustration of the urban condition of the city at times prior to the construction of Avenida Brasil.

Historical cartography is the study and creation of maps that represent geographical space in different historical periods. These maps are used to analyze how cities have grown, changed shape and adapted to different circumstances. The development of transport infrastructure over time has a direct impact on the form and functionality of cities. Analyzing a specific case study such as Avenida Brasil in different historical periods can show how local and global factors influence its development. By using time as a category of analysis, we can observe changes over the years, understand urbanization processes and visualize the impact of historical events. The analysis of urban morphology from a historical-geographical perspective is based on the work of Conzen, who seeks to understand the character and structure of cities over time through a systematic evaluation of their constituent elements. In this approach, structures are analyzed according to the time intervals that define morphological periods. When analyzing urban evolution, it is important to define time in significant periods, developed by synthesizing historical periods with evolutionary periods. As a result of these analyses, we have the process of evolution of the urban landscape. (CONZEN, 2004 apud NETO et al. 2014)

This analysis allows us to visualize the occupation of the different sections of Avenida Brasil that occurred over time, compared to what was maintained, erased and added after its implementation. In addition to the historical record of the urban tissue over time, we used a method to classify the tissues based on their morphological characteristics. In this way, we crossed two axes of information for each category of tissue: the historical period (prior or post construction of Avenida Brasil) and the morphological classification (Fig. 2). Considering the study of urban form as the study of the processes that define the city and its unique physical characteristics, distinguishing it from the concept of "form" (AURELLI, 2011), this morphological analysis aimed to deepen the understanding of these processes in order to systematically organize the urban tissues into different categories. Based on three fundamental elements: the building, the plot and the urbanization (SOLÀ-MORALES, 1973), how they relate to the processes (what comes before and what comes after) and their physical dimensions, it was possible to group them into unique conditions that define a specific category of urban tissue.

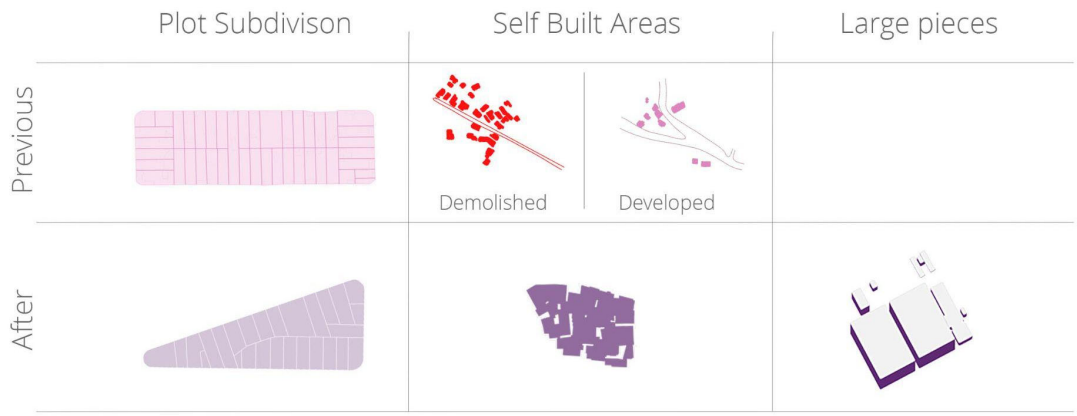

Figure 2. Scheme for categorisation of urban tissues according to historical period and morphological characteristics. Developed by the authors.

We have identified three categories of urban tissues that we consider significant in the structuring of the city of Rio de Janeiro, especially along the Avenida Brasil: plot subdivisions, self-built occupation areas, and large residential or industrial pieces. It is worth noting that these categories may evolve, subdivide or be replaced in the course of ongoing research, as new relationships and processes of construction and expansion of the city are analyzed. The peripheral expansion of Rio de Janeiro was initially marked by the subdivision of land, both private and public, promoted by companies that transformed large areas into urbanized lots for the sale of single-family homes. In these cases, the urbanization of the roads and the legalization of the subdivisions are carried out simultaneously, while the construction of the buildings takes place later. The plots have typical dimensions of between 300 and 600 m², and the blocks are generally rectangular, long and narrow, with a width equivalent to two plots, placed back to back. Although these areas become denser over time, with many changes in building and land use, the street structure and plot configuration remain relatively constant. However, as a result of isolated and independent initiatives, the design of these subdivisions usually does not create continuity in the road network between them, despite maintaining orthogonality and a certain standard of lot and block sizes.

From the 1970s and 1980s, self-constructed settlements became more widespread, characterized by the construction of buildings without prior demarcation of plots or implementation of roads and infrastructure (urbanization). These settlements emerged in undervalued areas, such as hills and riverbeds, and over time developed an irregular road network that followed the curves of the local topography, resulting in a homogeneous density, albeit detached from urban formality. The large residential or industrial buildings typical of contemporary expansion are characterized by complexes built in isolated blocks with specific functions, where the building, the plot and the urbanization occur simultaneously. In contrast to self-constructed settlements, polygons are often self-segregating, surrounded by walls that clearly demarcate public and private space and do not contribute to the continuity of the urban tissue. The plots are generally large, occupying the entire block (with dimensions ranging from 20 to 100 thousand m2), and the buildings are centralized, with a considerable distance from the street and higher heights than in other categories. Examples include classic mass construction initiatives such as the “Banco Nacional de Habitação” (BNH), the industrial parks and the “Minha Casa Minha Vida” (MCMV) programme.

RESULTS AND DISCUSSIONS

Since the analysis was carried out first on a broader scale, covering the entire length of the highway, we seek to understand its role as a metropolitan axis and a structuring factor in the urban expansion of Rio de Janeiro in recent decades. This approach has generated insights that relate the occupation of the margins of Avenida Brasil to the history of the city, offering a deeper understanding of the impact of the construction of the highway, especially through a "before and after" classification that underpins the subsequent categorization of urban tissues. This view of the highway as a unique structuring element of the city serves as the basis and starting point for the detailed analysis of the maps of each section of the study that follows.

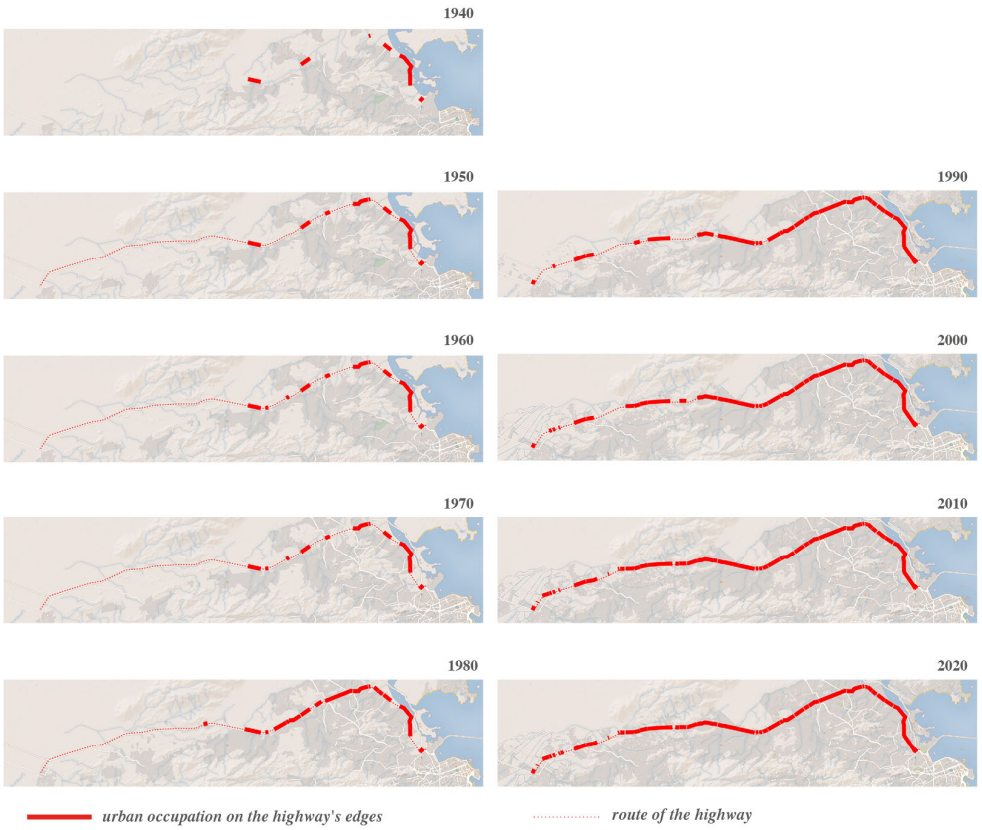

Figure 3. Maps showing the occupation of the "edges" since the implementation of Avenida Brasil, based on the Imagine Rio app. From 1940 - 2020. Source: Adapted, by the authors, 2020.

In the 1940s, when the Avenida Brasil was in its initial phase of construction, urban occupation along the highway's edges was sparse and limited, reflecting the initial nature of the road's development and its function of connecting existing and growing areas (Fig. 3). Between the 1950s and 1970s, with the completion of the highway, urban occupation along its banks began to increase, driven by the development of new infrastructure and the national migration of workers to Rio de Janeiro. The 1980s saw a consolidation of urbanization, with the area around Avenida Brasil being largely occupied. This increase in urban occupation can be linked to economic growth and the intensification of land use for commercial and industrial activities. Occupation in the 1990s followed the occupation trend of previous years, leaving little space for new urban development. Occupation along Avenida Brasil became more dispersed, especially due to the significant expansion of occupation in the part corresponding to the western zone.

Between 1990 and 2000, this movement towards the periphery illustrates the significant urban 'diffusion' that took place in the city of Rio de Janeiro. During this period, the population density fell from 15,000 inhabitants/km2 to 10,000 inhabitants/km2. Although the city's population almost doubled (from 3 million to 5.8 million), the occupied urban area tripled. The dynamics of urban expansion and its correlation with density show a change in urban models in the mid-20th century, based on road construction (MAGALHÃES et al., 2012). At the beginning of the 2000s, urbanization along Avenida Brasil was practically complete, leaving little space for new development. In the 2010s, urban development continued, with a focus on the modernization and restructuring of previously integrated areas. There has also been investment in infrastructure to support the high levels of traffic and demand for urban services in the region. In 2020, urban occupation along Avenida Brasil is characterized by extensive occupation. The thick red line on the map indicates consolidated occupation, although it shows some empty spaces at the western end.

In recent years, from 2000 to the present, diffusion has continued in the city of Rio de Janeiro: land occupation increased by 44.5%, while the population grew by 24%. (MAGALHÃES et al., 2012). The phenomenon of expansion with a decrease in population density observed in Rio de Janeiro, especially along Avenida Brasil, reflects a trend towards dispersed urbanization, where new areas are occupied without a corresponding increase in population density. This phenomenon results in dependence on urban mobility infrastructure, socio-spatial fragmentation and areas with few services and economic opportunities for the population living in their vicinity. The transformation of Avenida Brasil from a sparsely populated peripheral road into a vital urban corridor is an example of the profound impact of mobility infrastructure on urban development. As can be seen in both the historical images and the maps (Figure 3), this highway facilitated the physical expansion of Rio de Janeiro. In order to examine the spatial morphology resulting from this urbanization process, we carried out an analysis of the impact of this highway on the expansion of the urban area, by collecting before and after urban patterns on some historical maps, geographically indicated in the following figure:

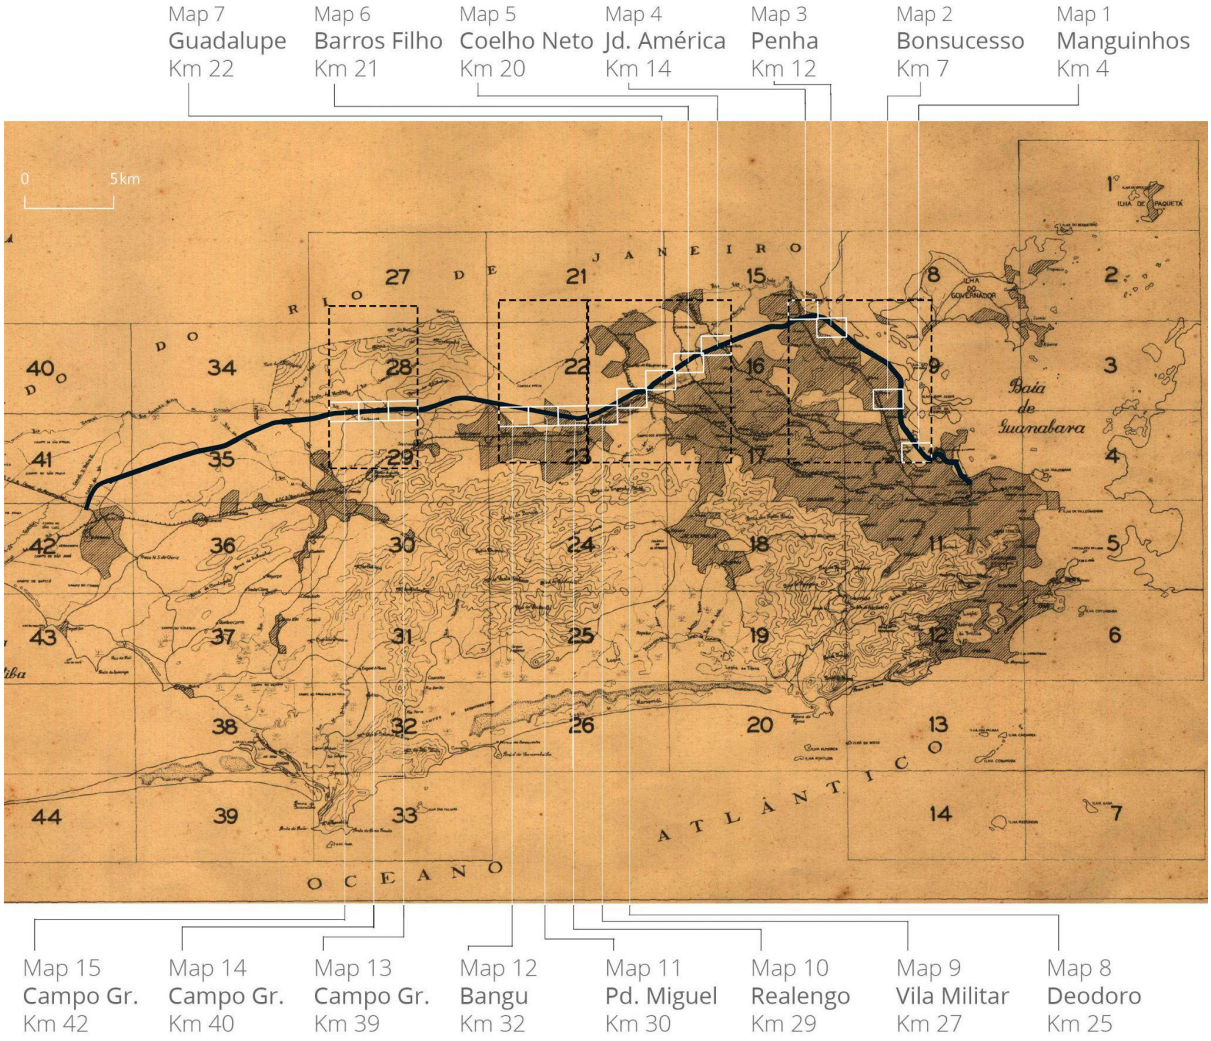

Figure 4. Location of the studied aerial photogrammetric maps in relation to the 1942 Federal District Charter. Source: IPP Imagine Rio

The superimposition of the location of the aerial photogrammetric survey maps studied in this article with the current layout of Avenida Brasil and the 1942 urban area of the city allows a deeper understanding of the relationship between the period before and after the construction of the highway and its impact on the urban expansion of the city (Figure 4). Firstly, a section (maps 1 to 4) is considered where the highway runs along the bay of Guanabara, crossing a previously inhabited area, such as Manguinhos, Ramos and Bonsucesso, until it reaches Penha, where it changes course to the west. In a second section (maps 5 to 9), the highway crosses the main railway branches to the north, passing through areas that are not yet inhabited but have great potential for public transport connections (maps 5 to 7). Deodoro and Vila Militar (maps 8 and 9), neighborhoods with large military installations, represent an important landmark in the city's urban structure and act as an important divider in the expansion area.

The third section (maps 10 to 12) is notable for crossing the still rural areas of important neighborhoods in the western zone, such as Realengo and Bangu. Finally, the fourth section (maps 13 to 15) marks the end of the section studied in this article and represents the occupation of rural areas isolated from the consolidated urban area of the city before the construction of the highway.

Compared study cases: Penha and Campo Grande

Figure 5. Case study maps and comparisons between historical maps, current satellite imagery and morphological classification of urban tissues. Sources: IPP Data Rio, City Hall, Google Earth.

This in-depth study of the urban fabric and the dimensions of blocks, plots and buildings allowed for a differentiated understanding of the characteristics of each category. The categorisation of the maps according to the previously presented legend allowed a deeper understanding of each case and facilitated their comparison. Of particular note are maps 4 and 14, which show parts of the Penha and Campo Grande neighborhoods, respectively (Fig. 5). In Map 4, the presence of the three classified types of urban tissue can be observed: subdivisions, self-constructed settlements and polygons. After the construction of the highway, there was no additional development of subdivisions; only large pieces (whether industrial or residential) and self-built occupations occupied the edges of Avenida Brasil. These filled "gaps" represent the spaces between the new infrastructure and the old urban fabric of the early 20th century. The fact that they were not occupied by a continuous expansion of the existing may indicate the catalytic potential of a mobility infrastructure such as Avenida Brasil, which stimulates the expansion of the network created by specific initiatives that generate new forms. Another relevant point is the demolition of a small self-built settlement to create a ring road for the highway, highlighting the impact and strength of a metropolitan scale infrastructure such as Avenida Brasil. In contrast, Map 14, which shows part of the Campo Grande neighborhood, illustrates a situation that is the opposite of Penha's. At the time the highway was built, this was a rural area, not yet integrated into the urban area of Rio de Janeiro.

In the years that followed, urban expansion, driven by easy access to the highway, took place in a catalyzed and radiocentric manner from the old center of the Campo Grande district towards the new highway, gradually occupying the rural areas of the region. The result of this expansion is a mosaic of disconnected and independent pieces, with little diversity. Self-built settlements predominate, with some isolated subdivisions. The road network is based on the old rural roads of the region, resulting in main axes that connect each of these isolated areas to the main road.

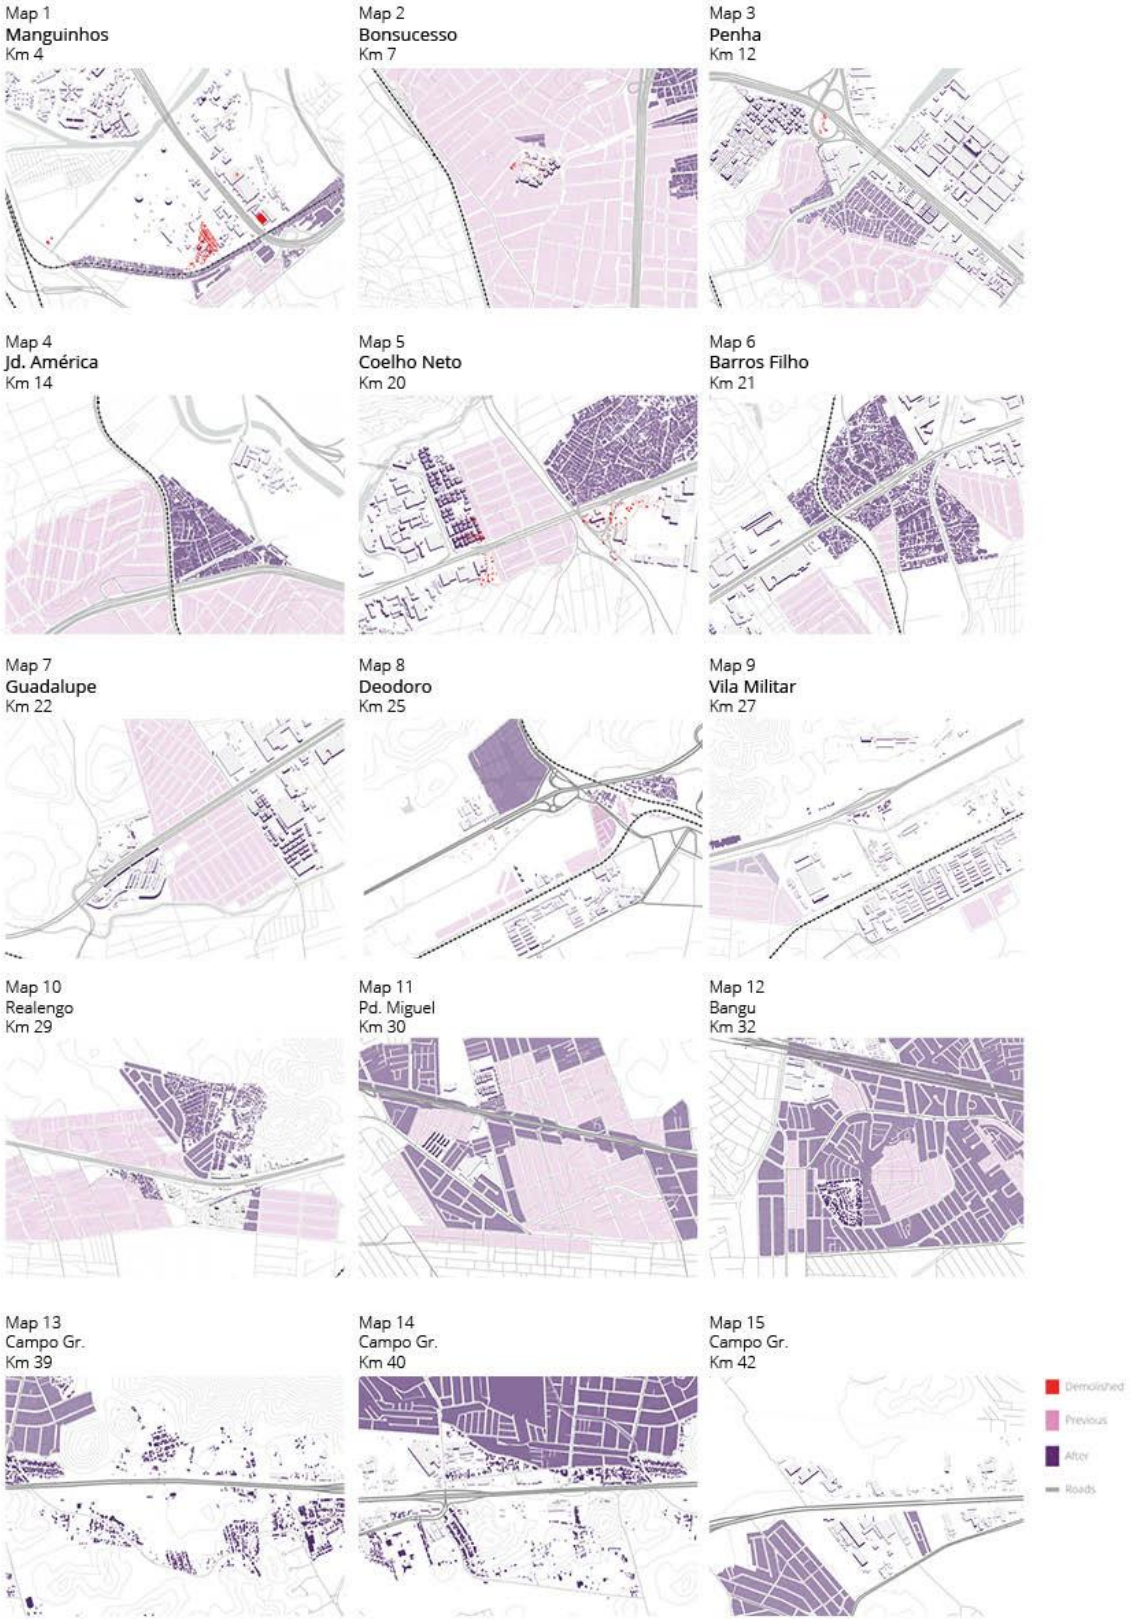

Figure 6. General Analysis of the 15 maps and the urban tissue categories. Sources: IPP Data Rio, City Hall, Google Earth.

Putting all 15 maps into perspective, we can see some convergence. Maps 1 to 7 show that the new settlements created after the construction of the highway are mainly characterized by

industrial/residential complexes and self-built settlements. Maps 5 and 7 in particular show the continuity of the road structure in the subdivisions, rare cases where the subdivisions were approved and sold at the same time as the construction of Avenida Brasil. Maps 8 and 9 show specific cases where the low density is due to the presence of the large military complex in Deodoro, which creates very specific conditions that are difficult to compare with other areas. From map 10 onwards, there are cases of subdivisions built after the construction of the highway. Some of these are configured as urban enclaves, such as gated communities, while others are extensions of subdivisions that predate the construction of the highway.

Maps 10, 11 and 12 show the greater presence of subdivisions along the edges of the road, highlighting settlements that emerged after the construction of the highway, with the exception of map 10. These maps, belonging to the Realengo neighborhood, are the best examples of the continuity of the urban form between the two sides of the highway and between themselves. A strong presence of the alignment of the road network crossing the highway can be observed, with few empty spaces occupied by informal constructions. Finally, maps 13, 14 and 15, which also represent the Campo Grande neighborhood, show a lack of continuity in the urban fabric, characterized by low population density, low road connectivity and the predominant presence of isolated pieces of urban fabric. There is a typical spread of rural and self-built settlements, linked to structuring roads, as well as a mosaic of disconnected subdivisions and the scattered presence of industrial areas along the highway.

CONCLUSIONS

This case study explores the implications of new morphologies that emerge with the implementation of urban mobility infrastructures in the peripheries of metropolitan regions in the Global South. These phenomena can reinforce urban dependency and segregation, especially in economically disadvantaged areas. The analysis of the current maps reveals different characteristics along different areas of the Avenida Brasil, noting where the urban fabric is continuous or fragmented, where there are morphological differences between the sides of the highway, and where there are variations in the scale of urban elements. Based on this methodological principle of classifying urban tissues, and using the concept of segregation as an interruption of the continuity of the street network or urban form, it is possible to identify four distinct stretches in the relationship between the construction of Avenida Brasil and its proximity to previously consolidated urban areas:

In the first section, the highway crosses previously inhabited areas, replacing the old Avenida dos Bandeirantes. Here, new settlements concentrate on filling empty spaces with industrial/residential polygons and self-constructed settlements. The second section is characterized by the "bundling" of the highway with large housing estates and polygons, such as Fazenda Botafogo, attracting new residents, including in large favela complexes, such as Acari. In the third section, the highway crosses rural areas in expanding neighborhoods, such as Bangu and Realengo, where it acts as a catalyst for an ongoing process (the concentric radio expansion of neighborhood centers), being the least segregated section in relation to the urban fabric along its edges. Finally, in the fourth section, the highway crosses rural areas very far from the urban area or any connective structure. In this case, the occupation driven by the highway is more segregating, generating autonomous forms of isolated subdivisions, scattered self-built occupations and little continuity in the road structure between the edges. The spatial segregation in the urban fabric of the edges of the highway depends on their

proximity to other connective elements of the consolidated city. When the Avenida Brasil crosses previously urbanized areas, there is some continuity in the urban fabric, with the highway itself acting as a catalyst for ongoing expansion. However, when it crosses rural and isolated areas, the highway stimulates the development of a new urban tissue, which does not present continuity, creating a difference between the sides of the highway and creating urban fragments separated from each other. In short, the further the construction of the highway is from any urban infrastructure or previous occupation, the more disconnected and segregated the urban tissue should be.

ABSTRACT

Geographical urban morphology provides a systematic framework for urban form research. In particular, it has been applied in planning, architecture, and urban design towards seeking economically efficient, environmentally sustainable, and socially inclusive future built environments. Despite growing interest in transforming the intellectual ideas of urban morphology into operational tools, practical bases are yet to be fully achieved. In connection with an investigation in Auckland, New Zealand, where transit-oriented development (TOD) has been promoted as a planning response to excessive automobile travel and associated urban problems, this paper reports the use of urban morphology to reveal the development process of Auckland's railway station catchment areas. Clarifying the developmental or evolutionary process provides a foundation for future development to build upon, enhancing place identity and meeting future needs. Alongside global morphological and TOD studies, this research contributes to innovative sustainable development in New Zealand and enhances the practicality of morphological methods.

Keywords: urban morphology, sustainable urban form, transit-oriented development, New Zealand.

INTRODUCTION

First established in central Europe in the late 19th century, geographical urban morphology (Conzen, 1960; Gauthiez, 2004; Whitehand, 1981) was later consolidated as an approach for studying urban form in research conducted by M.R.G. Conzen. Beginning in the 1950s, Conzen used town-plan analysis to clarify the geographical arrangement and distinctiveness of towns by systematically examining their constituent elements and tracing their evolution over time (Kropf, 2009). The framework not only enables a critical analysis of buildings and urban fabrics but also informs and shapes the design process (Strappa, 2023). Not surprisingly, it has since been applied in planning, architecture and urban design (Whitehand, 1981).

Despite the increasing interest in transforming the intellectual ideas of geographical urban morphology into operational tools (Gu *et al*., 2019; Whitehand, 2009), its full potential is yet to be realised. In particular, traditional morphological data collection and analysis require greater clarity. There is a need to improve urban morphology to enable reproducibility and methodological

compatibility across disciplines (Zhang *et al*., 2023) and establish a dependable methodology for measuring and classifying urban forms (Dibble *et al*., 2019), thus widening its applicability.

The morphological approach strives to disclose the 'genesis' or 'engendering process' of landscape forms as a developmental or evolutionary process. Alexander (2004) claims that in order for people to create a sustainable world and maintain its uniqueness, they need to recognise that the living environment transforms in a holistic and sequential unfolding process, inheriting and strengthening the good qualities of systems and rectifying their flaws. This 'structure-preserving (and enhancing) transformation' maintains and improves a place's existing structure or essence, the streets, squares, or urban neighbourhoods, even as they evolve and develop (Alexander, 2002). The morphological process uncovers what will emerge and is always informed by the form at the moment just before (Tan *et al*., 2024). City planning thus seldom begins with a blank canvas and existing land uses play a crucial role in shaping future development (Atkinson-Palombo and Kuby, 2011).

It is argued that the challenges facing urban morphology frequently relate to ignorance of the dynamics of spatial-temporal processes. Seeking to address this gap, this paper explores the challenges facing urban morphology through the exploration of transit-oriented development (TOD). TOD offers a promising approach to achieving carbon neutrality, which remains an important priority for both local and central government. However, practical strategies and methods for TOD implementation are underdeveloped in New Zealand. Based on the 50% benchmark (Hale, 2014), many of the railway station catchment areas in Auckland show low usage of sustainable modes of transport (public transport, walking and cycling). Furthermore, according to analysis of data from the 2018 New Zealand Census, 28 of the city's 39 railway station catchment areas score below 30% in terms of travel by sustainable modes (Li, 2024). This underutilisation of rail transport is an obvious problem, and there has been no investigation of the causes from a morphological perspective. Geographical urban morphology provides a systematic approach to revealing the complex process of TOD development and redevelopment. Specifically, the morphological approach is used in this study to analyse the relationship between the urban development process and current underutilisation of railway stations in Auckland, and thereby provide suggestions for future TOD development.

Morphological periods, fixation lines and plan units are Conzenian terminology (Larkham and Jones, 1991). Urban development can be conceptualised as a series of morphological periods (Conzen, 1960). Each morphological period represents a portion of history that has distinctive forms based on socio-economic conditions. These forms leave varying degrees of residue in the urban landscape depending on the requirements of the societies that follow (Conzen, 1988). The idea of fixation lines has been applied in various planning and design research. For example, the city walls of Pingyao are a fixation line that can be traced from historical maps as well as on the ground now, reflecting the influence of historical structure on built form (Conzen *et al*., 2012). While city walls and mountain ranges have been explored as fixation lines, there has been no research into railways as fixation lines in TOD.

The railway line has a significant influence on urban form and urban development, dividing the land into parts and forming a frame or barrier for development. The ever-changing relationship between the railway and urban form is therefore worth investigating to ensure new development can be continuous and respond to problems left historically by prior development. The plan unit, or areas with similar development qualities, can be recognised from a town plan in terms of distinctive

combinations of streets, plots and buildings formed in the development process (Conzen, 1960). It takes on various sizes, ranging from a single plot to a large portion of a town (Gu, 2014).

This paper therefore addresses the following questions: 1) In what way and to what extent can morphological concepts support explanations of the development process of railway station catchment areas?; and 2) Given the available qualitative and quantitative data for historical development, how can urban morphology be applied to help reveal the changing morphological process of TOD? Answers to these questions are provided by means of a critical examination of urban development and other changes in the area around the Panmure railway station in Auckland. The case study area has a rich history and has been deeply influenced by Auckland's complex transportation evolution and urban development. This paper reports an in-depth study of its 15-minute walkable catchment area. The transition to mobility in urban environments can start with these railway station catchment areas, which are still in operation and have greater potential for TOD than other areas of the city.

The paper is organised into two parts. First, the morphological periods of the study area are described in connection with the concept of fixations lines. This complex layering of the spatial-temporal landscape then forms the basis for urban landscape assessment using historical maps and documents. The second part reports the morphological units based on data collected for each morphological period. The resulting plan units will support the continuity of future development.

METHOD

The methods used to explore the evolving relationship between the Panmure railway station and its surrounding area mainly derive from town-plan analysis, notably reconstruction of the urban development process through analyses of historical series of ground plans and documentary records. The systematic survey conducted for this study used multiple sources including historical maps, property data, Auckland Council Geomap, and field surveys to explore patterns of development (Gu, 2014). Plans and maps of Panmure are widely available, beginning with cadastral maps from 1860 (Auckland Libraries Heritage Collections, 1860a, 1860b). These historical maps play a crucial role in reconstructing the development history of the urban landscape (Gu, 2014). Additionally, Property Guru offers a comprehensive collection of New Zealand property-related information. This dataset includes details such as the names of occupants and owners and the ages of most buildings. A plot-by-plot field survey allows land uses to be identified.

The use of geospatial technology, particularly an integrated GIS system, is increasingly important for analysing and synthesising morphological data. It enables multi-source data to be assembled into a single database for analysis. More importantly, it can spatially relate data from different sources and produce new or missing variables in separate datasets. In this research, the plans and maps of the study area were georeferenced in GIS (Tümtürk *et al*., 2024), and the ground plan information then digitised in ArcGIS Pro.

Panmure and its morphological periods

With 170 years of European history, Auckland is the largest urban area in New Zealand (Gu, 2010). The evolution of society since early colonial days has affected the building types and ground plan,

influencing the development and transformation of building forms, which often leave marks on the ground. About 18 per cent of Auckland's total urban land area lies within the 15-minute walkable zones around its 39 railway stations. The railway station area in Panmure provides an ideal case study, with its historical development and current form representative of many urban railway station areas. The study area was delineated as the surface included within a 15-minute walkable distance of the railway station.

Located in East Auckland, the Panmure station is close to the Auckland CBD and Manukau central business districts. The suburb of Panmure lies between Mount Wellington and Panmure Basin, offering a mountain view and water connections to the Hauraki Gulf and Waitematā Harbour. Throughout the years, key changes in planning, infrastructure, and policies have greatly shaped the development of Panmure and its adjacent urban areas (Beharrell, 2024).

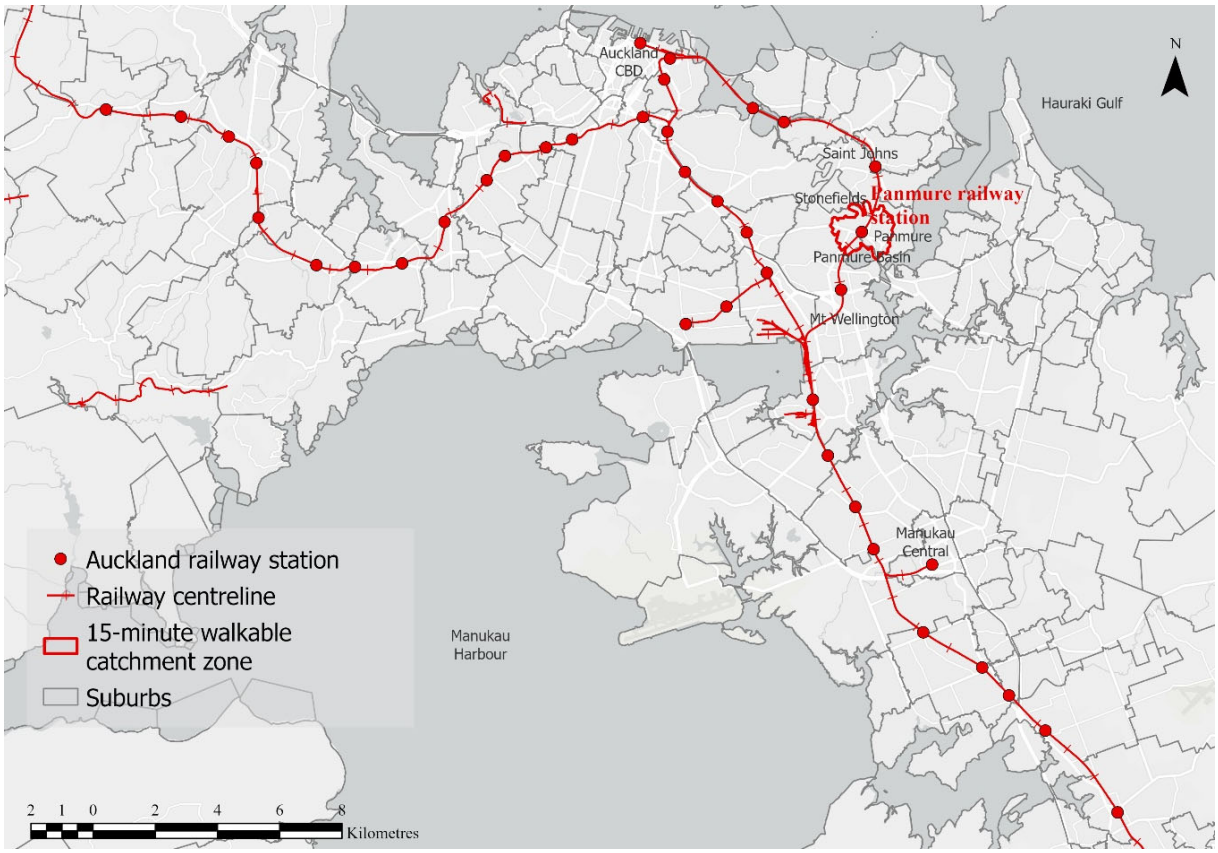

Figure 1. Railway stations in Auckland and Panmure railway station's 15min walkable zone.

Based on a review of the historical records of Panmure, its development can be categorised into four morphological periods of growth and change: pre-urban development (1840s–1880s), railway colonisation and expansion (1890s–1930s), segregation and fragmentation (1940s–1990s), and urban redevelopment and revitalisation (2000s–now).

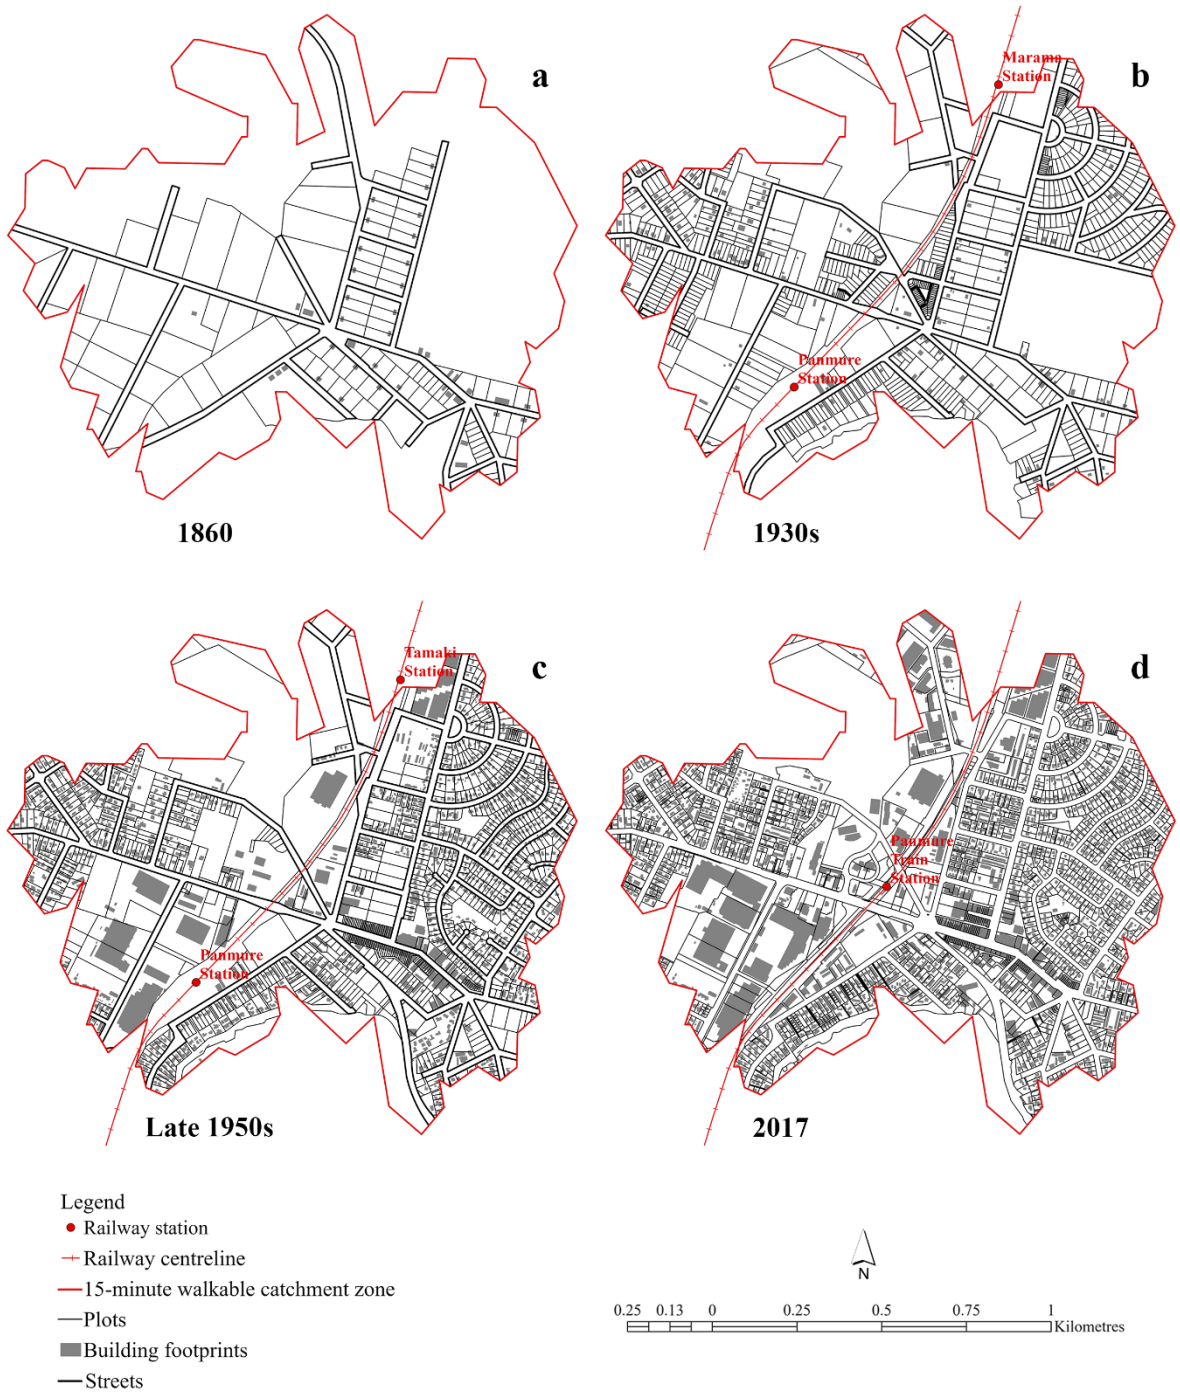

Figure 2. Streets, plots and buildings in the 15min walkable catchment area of Panmure in (a) 1860, (b) 1931–1940, (c) late 1950s and (d) 2017 (based on Auckland Council, 1958, 1959, 2024; Auckland Libraries Heritage Collections, 1860b; Auckland Libraries Heritage Collections Map 71, 1931).

Pre-urban development (1840s–1880s)

Panmure started as a defence post in the 1840s, when it was established as one of Auckland's fencible settlements (Hoffman, 2019) on divided farmlands. Situated along feared potential Maori invasion routes to Auckland after the outbreak of hostilities between Maori and the Crown in the north, Howick, Panmure, Otahuhu and Onehunga were the locations chosen to provide places for 2,500 Fencibles and their family members (almost double the population of Auckland at that time), who

travelled from the UK to New Zealand between 1847 and 1952 (Howick Historical Village, n.d.). The word Fencible comes from ‘defencible’, meaning ‘capable of defence’. The Fencibles had served as soldiers in the wars of Britain in the 1830s and 1840s. To emigrate to New Zealand under the Fencible scheme, retired soldiers were required to be under 48 years of age and of ‘good character and industrious habits’ (Howick Historical Village, n.d.). These retired soldiers were enlisted to serve for seven years in exchange for a cottage and one acre of land (Howick Historical Village, n.d.).

Panmure became a busy place in the mid 19th century, partly because of its location near the narrowest part of the isthmus, on the route between Auckland and the largest fencible settlement of Howick. People and goods were transported across the water by ferry at the narrow point below Mokoia Pa (Auckland Transport, 2018).

Figure 3. Fencible cottage and Panmure ferry in the 1860s (Auckland Libraries Heritage Collections 1031-P619-06, 589-0426)

Railway colonisation and expansion (1890s–1940s)

Railway construction in Auckland dates back to 1863, with the railway system starting to take definite shape in the 1870s (Davidson, 1931). Upon the arrival of railway to Auckland to carry not only goods but also passengers (Lowe, 1973), Panmure became a busy transport hub (NZ Herald, 2010). Steamers from Auckland stopped there on their way to the goldfields in the Coromandel and Firth of Thames. New developments and plans for land around the railway line also started during this period. The original Panmure Station opened on 16 November 1930, shown in Figure 2 (b), on a site to the south of the current station.

After World War I (1914–1918), the newly established profession of town planning and its advocates aimed to provide solutions for the challenges of postwar resettlement in both urban and rural areas, and showcase the effectiveness of town planning (Miller and Roche, 2003). Town planners in New Zealand adopted town planning concepts from Britain, and were especially influenced by the Garden Suburb model when accommodating soldier settlements (Miller and Roche, 2003).

Starting from the beginning of the 20th century, the garden suburb movement gained popularity, with the Tamaki Heights Garden Suburb designed by E. V. Blake (see Figure 4) showing marked garden suburb appeal. The subdivision shown in Figure 4 was marketed by brochures and newspaper advertisements from 1926 to 1928 (Miller, 2004). However, the garden suburb experienced slow development and was eventually incorporated into the State Housing programme, which led to changes in its layout (Miller, 2004).

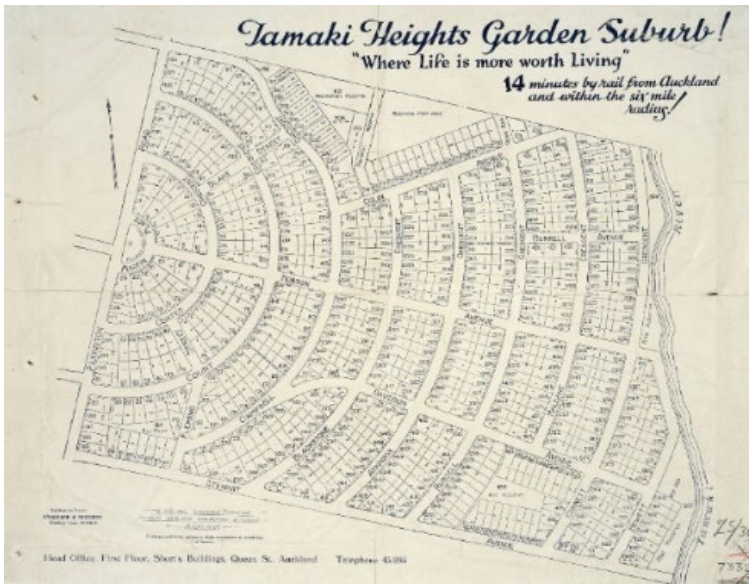

Figure 4. Panmure store and sales advertisement of Tamaki Heights Garden Suburb development allotments (Auckland Libraries Heritage Collections, 1920).

Segregation and fragmentation (1950s–1990s)

Up until the mid-20th century, Panmure remained a prosperous but predominantly pastoral area (NZ Herald, 2010). It was only after the explosive suburban development that occurred around Panmure following World War II (1939−1945) and the construction of better bridges to Pakuranga (NZ Herald, 2010) that the suburb grew significantly and transformed into a commercial centre. During the period 1950−1955, Panmure grew from a small village with a few shops and a hotel into a busy suburban shopping hub with the development of the West Tamaki housing estate (Hoffman, 2019).

Figure 5. State houses on Pilkington Road and Main road (Queens Road) in the 1960s (Auckland Libraries Heritage Collections 895-A62539, Auckland Libraries Heritage Collections 786-A18-03).

In 1948, there was initial discussion about an eastern motorway to cater for Auckland's future growth (Cayford, 2011). In 1955 as part of a Master Transportation Plan, a South Eastern Motorway was proposed to link the central business area to eastern areas of Auckland, Mt Wellington Highway and the existing SH1 Motorway at Mt Wellington via Tamaki (Cayford, 2011). In the 1960s, the Eastern Corridor was part of the regional highway plan (1965 Report on a Comprehensive Transportation Plan for the Auckland Regional Authority), with land designated for a motorway. The intended motorway was changed to a limited access (arterial) road in 1967 (Cayford, 2011). In 1974, the Eastern Corridor was incorporated into the Auckland Regional Planning Scheme, with the Auckland Regional Authority

revisiting the idea of a four-lane arterial road in 1975 (Cayford, 2011). In 1993, the Auckland City Council designated the corridor route under the title Proposed Limited Access Road – Eastern Highway. Effective until 2004, the designation was then extended in August 2004 for ten years to 2014 (Cayford, 2011). The development of highways has meant urban development in the area no longer centres on the railway. As a result, superblock types have formed with through roads for private cars and more cul-de-sacs (Figure 2 (c)).

The creation of the Auckland Regional Planning Scheme in 1988 established a framework for managing coordinated growth in the Auckland region, setting rules to manage expansion and development (Hoffman, 2019). It helped address the previous segmentation and fragmentation.

Urban redevelopment and revitalisation (2000s-now)

Since the beginning of the 2000s, there have been efforts to seek collaborative solutions for urban development and infrastructure improvements around railways. In 2004, the Hobson Bay, Purewa Creek, Glen Innes/Panmure, SH1 and Tamaki River corridors were recommended as the preferred routes between Auckland's CBD and the Tamaki River (Cayford, 2011). Local elections in October 2004 led to a reconsideration of the project by the Auckland City and Manukau City Councils and Transit New Zealand, with more emphasis on passenger transport and improving roads to carry passenger transport. Auckland City subsequently resolved there would be no highway component for the project north of Glen Innes. The Auckland-Manukau Eastern Transport Initiative (AMETI), which originated from the Eastern Highway project, is a package of transport improvements along the Glen Innes – Panmure – Pakuranga –Botany corridor. The project aims to provide a high-quality strategic transport link between Auckland City and Manukau City via the eastern suburbs. Requiring major public investment, AMETI includes land use zoning changes and an urban design approach, providing bus lanes and other bus priority measures, an improved road network, improved walking and cycling facilities, and travel demand measures (Cayford, 2011). Still ongoing, the Auckland Manukau Eastern Transport Initiative (AMETI) involves major public investment (Cayford, 2011). The area's transport infrastructure developments highlight its important role as a transport node and crucial interchange.

Panmure is also the focus of large public investment as part of the Tāmaki urban transformation led by the Tamaki Regeneration Company, a government-council joint venture. The project was set up with the aim of building 7,500 new homes and community facilities over the next 15−20 years. The area has seen a high level of local board planning, with strong political and community backing for change. Launched in 2012, the Tamaki Transformation Programme is the country's first urban regeneration programme. As described in the project plan for Panmure, many of Panmure's facilities and natural assets are underutilised due to poor local connections. The town centre needs to maximise the benefit of transport investments, including through AMETI, greenways, and improvements in walking and cycling. The area offers a wide range of local services, leisure and recreational facilities, including council amenities, that can be enhanced to support future growth (Panuku Development Auckland, 2018). Panmure's town centre is strategically located, featuring infrastructure and access to public transport. The area has the potential to meet the pressing need for sustainable and quality urban development.

The town centre regeneration plan by Panuku Development was approved by Auckland Council's Planning Committee in 2018. It seeks to strengthen links between Panmure Station and the town centre (Panuku Development Auckland, 2018). The Unlock Panmure Project includes planning for new

precincts and new projects within the precincts to create a thriving town centre, upgraded public spaces and more (Eke Panuku Development Auckland, 2023).

The Panmure railway station was relocated to its current site in 2007. Since the opening of the upgraded station in 2014, there has been significant growth in train boardings in Panmure. Based on 2018−2019 data, Panmure station has become the third busiest station, following Britomart and New Market station (Greater Auckland, 2019).

The morphological structure of the Panmure railway station area

Panmure in 1860 was characterised by large plots and empty land as shown in Figure 2 (a), which the railway line later cut through creating a divide (Figure 2 (b)). Large plots were subdivided, resulting in many smaller plots. The two sides of the divide subsequently experienced different types of development, in part related to the location of the train station. The original garden suburb development is still evident on the northeast side of the study area. Seeking to reverse this trend, efforts are now being made to recover a coherent urban form through reconnecting the separate developments.

The plan units

Examination of change in the ground plan has been an important basis for the identification of six plan units in the 15-minute walkable catchment area of Panmure railway station (Figure 6 and Table 1). The area with the longest development history is identified as the first plan unit. Subsequent development occurred as the Garden Suburb unit. The railway station unit, suburban expansion unit and residential unit developed over similar periods. Notably, the railway station unit is completely different from the other two residential units in terms of form and uses; the fixation line of the railway has had a major influence on the result.

Fixation lines in the form of natural and artificial features, such as city walls, rivers, mountain ranges and railways, are often seen as a barrier to development (Conzen, 1960). They have a major influence on the formation and changing direction of urban development and expansion. The spaces around fixation lines have many things in common. For example, these areas often act as corridors and they are low density, exerting less pressure on land. A trend can be identified whereby socio-economic factors influence fixation lines, in this case the railway line. On one hand, the railway station site brings new development and commercial opportunities for the area, and it prospers. On the other hand, the railway track attracts freight yards, industry and housing nearby (Bertolini, 1996). It is important to recognise the long-standing influence of the railway line on the surrounding development as part of the history and identity of the place.

Under certain conditions, urban development can continue beyond the barrier created by a fixation line (Gu *et al*., 2022). In the case of the railway line, the resulting divided environment has been an obstacle in station redevelopment projects. Methods of dealing with this constraint include vertical crossings or having the railway line below or above the ground (Bertolini, 1996). Even once the physical barrier is removed, the characteristics of the developed area brought about by the fixation line will remain unique features on the ground (Gu *et al*., 2022).

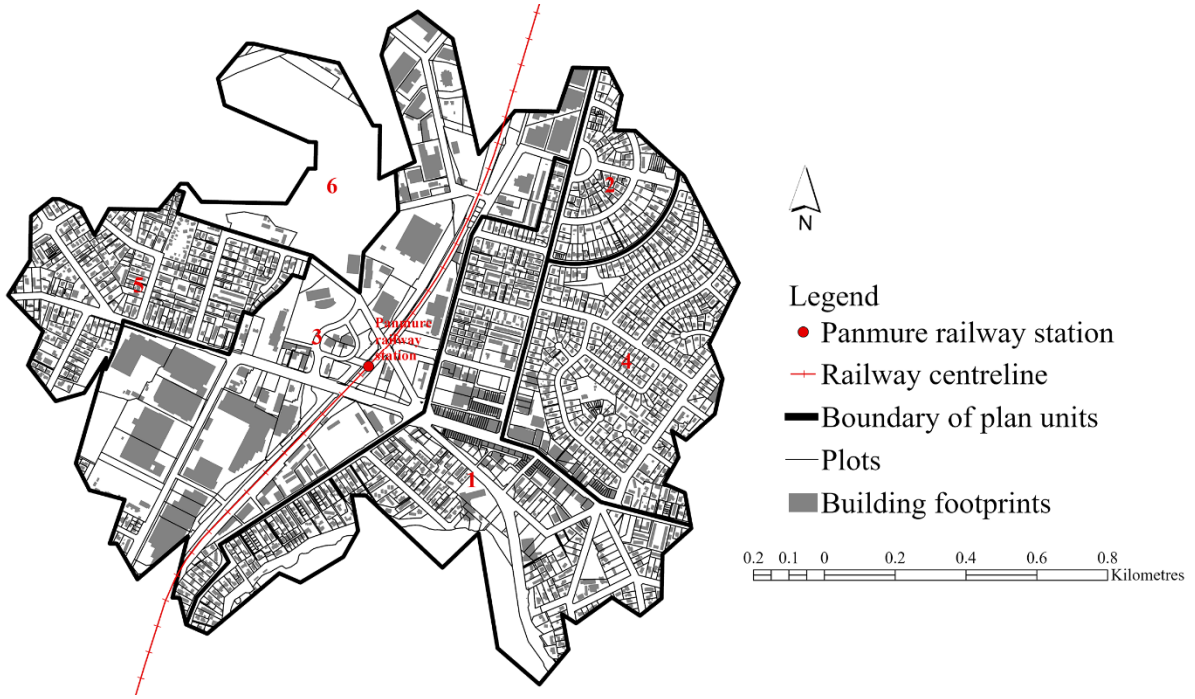

Figure 6. Plan units in the 15min walkable catchment area of Panmure railway station. (1) Historical development, (2) Garden suburb unit, (3) Railway line unit, (4) Suburban expansion unit, (5) Western residential unit, (6) Mt Wellington Domain unit

Table 1. Plots and their metamorphosis and buildings and their block plan in the plan units (Authors own photo 2024).

Plan units	Plot	Building	Image
1.Historical development unit	Mainly small- and medium-sized plots mostly in the form of 1950s	Mixture of commercial, residential and recreational buildings	
2.Garden suburb unit	Planned layout with regular plots	Residential buildings and local commercial stores	
3.Railway line unit	Mainly large plots for industrial purposes resulting from plot subdivision and amalgamation	Industrial, public transport and commercial buildings	
4.Suburban expansion unit	Mainly small plots	Mainly residential buildings, with small portion of commercial and institutional buildings	

5.Western residential unit	Mainly small plots	Mainly residential buildings	
6.Mt Wellington Domain unit	Single large plot	Natural landscape, horticulture yard and recreational buildings	
TOD planning and design

Auckland Council's Plan Change 78 regarding intensification is underway and expected to be finalised by 2025. Prioritising rapid transit, it recognises that strategic planning and development around train station areas are urgently needed (Auckland Council, 2023). The provisions of the plan change have the potential to impact the Panmure station area. There is provision for six-storey buildings within the 800-metre walking catchments of rapid transit network stations (RTNs) through rezoning residential land to Residential – Terrace Housing and Apartment Building, and rezoning all other existing urban residential land to the revised Residential – Mixed Housing Urban category, unless there are valid reasons not to (Auckland Council, 2022). The provisions of Plan Change 78 will likely increase the speed and scale of development in Panmure as the market responds to the new planning regime. As a result, residential intensification and population growth in Panmure will probably be faster and higher than projected in the Auckland Plan 2050 (Auckland Council, 2024b). The spatial distribution of future populations will change as a result.

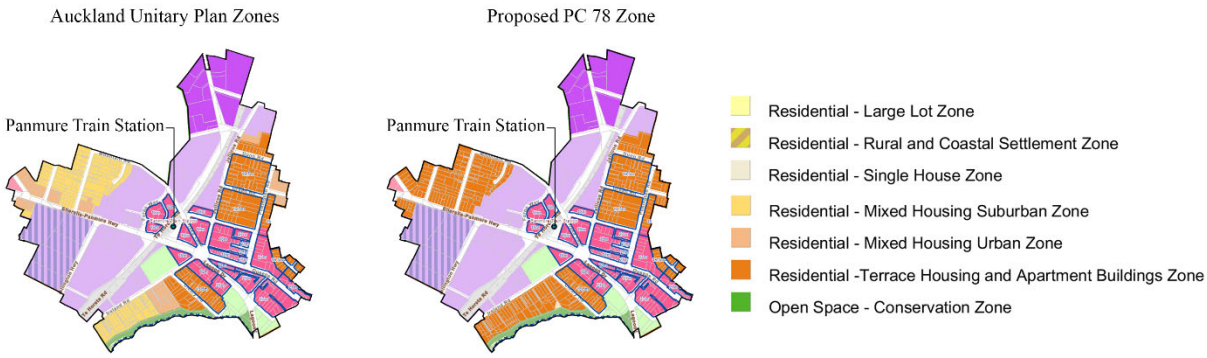

Figure 7. Auckland Unitary Plan Zones and Proposed PC 78 Zones – propose changing residential-mixed housing suburban zone and residential-mixed housing urban zone to residential-terrace housing and apartment buildings zone (Auckland Council, 2022).

However, the PC 78 zones fail to consider the spatial-temporal processes of the areas and acknowledge little of the differing characteristics relating to their development process (Gu, 2014). This will potentially lead to a fragmented landscape. To create a coherant landscape, unit-specific (Gu, 2014) and place and form-based design is recommended. In this way, 'pull factors' including improved

accessibility, walkability, and proximity to public facilities (Gehrke *et al*., 2019; Zondag and Pieters, 2005) will be integrated in the different units.

For the historical development unit, the town centre, the emphasis should be on the historical connection with the railway line, improving public space and roads for easy access, and ensuring a pedestrian-friendly environment. In the Garden suburb unit, which has a historical connection with the previous Tamaki station, work could be done to enhance pedestrian-friendly travel to the railway station. Finally, the western residential and suburban expansion units should be the focus of intensification.

Based on the PC78, there are changes proposed to the railway line unit. However, this area could become the focus for denser mixed-use development around the railway station as there is a lot of publicly owned land available, much of which is currently used for open-air parking. As a result, homes, employment, and supporting retail as well as other services would develop immediately adjacent to, if not directly above the railway station. The roads need to be improved for easy pedestrian and cycle use to connect to the other units in this walkable catchment area, thereby creating a highly connected spatial layout to supplement TOD. This would minimise the negative effect of the rail tracks and maximise the development of TOD neighbourhoods to accommodate the desire of people of various socioeconomic status to live in a TOD neighbourhood (Olaru *et al*., 2011).

CONCLUSIONS

Applying a morphological perspective to TOD study is important, as the physical form of TOD greatly influences its success. Through this approach, continuity can be retained and enhanced, and local characteristics preserved, leading to more successful development around railway stations. This paper has examined the evolutionary process of Panmure railway station's 15-minute walkable catchment area. The distinct characteristics of each morphological period were identified by reconstructing the historical ground plan and analysing how the past influences the present. By tracking the continuous transformation of form from one period to another, factors that should be considered in future planning can be determined.

The identification of morphological units can therefore support future planning and design decisions, ensuring that the development process incorporates morphological research as a planning and design guide (Gu, 2014). The findings and recommended strategies for each unit type identified in this study contribute to research and planning practices aimed at recovering a sustainable urban form in the railway station catchment area.

ABSTRACT

Evaluating the perceptual quality of urban street spaces has always been a significant goal in morphological analysis. Among these methods, analyzing street view photos is particularly important. This analysis primarily focuses on the feature analysis of physical elements in the photos, such as fractal calculations of street view images and the proportion of street view area occupied by elements like the sky and vegetation based on semantic segmentation. It examines their correlation with human perceptual experiences, such as pleasantness and cleanliness. However, the "depth perception" information in visual perception has not yet received attention in street view photo analysis. Depth perception refers to the perception of the distance between the perceived object and oneself, as well as the distance and positional relationship between perceived objects. It significantly impacts people's experience of the richness of urban street spaces. This study first classifies streets based on morphological elements such as street width, intersection distance, the number of along-street building interfaces, their lengths and heights, and the number of along-street plots to establish an ideal analysis model. Then, through the three dimensions of forward level, lateral level, and perspective vanishing point, an evaluation index system is established to distinguish the differences in "depth perception" among different types of street models. Finally, through a perceptual evaluation scale study, the most critical indicators and characteristic thresholds of street morphological elements affecting depth perception are identified.

Keywords: street space, depth perception, morphological analysis, street view photos

INTRODUCTION

Urban street spaces are one of the most important types of public spaces in cities, and their perceptual quality evaluation has long been a significant focus in urban morphology analysis (Chen, ST & Biljecki, F, 2023; Li, XJ, Zhang, CR, et al., 2015). One approach is to directly analyze the spatial elements within two-dimensional street view scenes. Street view images have become widely used data types (Fang-Ying Gong et al., 2018; Tang Jingxian et al., 2016). For example, fractal calculations of street view images and the proportion of street view area occupied by elements such as the sky and vegetation based on semantic segmentation are analyzed to examine their correlation with human perceptual experiences, such as pleasantness and cleanliness (Xu Lei-qing et al., 2017; Jon Cooper & Reza Oskrochi, 2008; C.S.B. Grimmond et al., 2001).

Another approach is to analyze perceptual quality using three-dimensional spatial elements and their indicators of streets. Commonly mentioned morphological characteristics of street three-dimensional space in relevant studies include street width, length, height, aspect ratio (height-to-width ratio), street wall continuity, number of buildings along the street, standard deviation of building heights on both sides, proportion of building intrusions into the street view, and street curvature. These indicators can affect the visual complexity of the street view and may imply perceptions of content and order (Harvey et al., 2015). For example, high-rise buildings can create a sense of "oppression" for citizens, with a critical height for this oppressive feeling being 45 meters. Changing the aspect ratio from 3 to 4 is less effective in reducing or increasing oppression compared to changing the aspect ratio from 2 to 3, depending on whether the width or height is fixed (Esmaeil Zarghami et al., 2019).

In addition to affecting the subjective emotions emphasized in the aforementioned studies, the geometric characteristics of street space have a more direct impact on people, namely depth perception. Depth perception is the ability of humans and other sighted animals to perceive objects as having volume (rather than seeing only planar outlines) and to recognize the relative positions of objects in a three-dimensional environment (rather than in a two-dimensional image). The main influencing factors can be divided into binocular cues and monocular cues. Binocular cues include binocular disparity and binocular convergence, while monocular depth cues include relative position, relative height, relative size, texture gradient, aerial perspective, linear perspective, motion parallax, and shadows (Lebreton, P. et al., 2014).

In a study on the process of human scene perception, researchers have demonstrated that the space-centered theory, which posits that spatial depth perception plays a dominant role in human judgments of scene attributes, holds true (Matt D. Anderson, 2022). In the book Exploring the Visual Landscape, Steffen Nijhuis et al. review past research on the objective existence of spatial depth and depth cues. They argue that the most significant depth cue is occlusion and discuss the effects of height, shadows, focal points, relative object size, atmospheric conditions, and visual illusions on depth perception, emphasizing the importance of these factors in landscape space design. Additionally, depth or distance judgments can be influenced by various factors. When the actual spacing remains constant, a smaller visual angle between two objects and the observation point results in a lower distance estimation (Levin, Charles & Haber, Ralph, 1993). Besides aiding in distance and direction judgments, depth perception is also related to judgments of object size (Inna Tsirlin, 2016; Jiehui Qian, 2016).

Some studies have pointed out that the continuity and integrity of vertical street interfaces are crucial for the clarity of street space morphology cognition (Wowo Ding, 2011), but the relationship between street wall continuity and depth perception remains unclear. Additionally, some research has used three-dimensional point cloud models to measure landscape spaces and has proposed concepts such as hierarchical permeability and spatial overall depth for spatial depth evaluation (Zhang Xiaohan.et al., 2022; Mei Liu & Steffen Nijhuis, 2020).

However, in the aforementioned research on street space perception, the "depth perception" information in visual perception has not been sufficiently emphasized. This paper aims to develop a method for evaluating street space depth perception and to analyze the mechanisms by which specific street space morphological elements or combinations of elements affect street space depth perception.

METHOD

Construction of the "Street 3D Model-Visual Scene"

Previous studies have used street view photos with too many morphological elements, making it difficult to analyze the relationship between morphological elements and visual perception individually. Therefore, this study mainly investigates the impact of the geometric characteristics of street space on depth perception. The study first constructed a baseline street space model. Using street view photos of Nanjing's wider roads with fewer obstructions(Figure 1) as an example, we consider the distance for recognizing the contours of buildings on both sides of the street to be approximately 840 meters, and we use this length as the basic length for the 3D model. Additionally, taking into account relevant provisions in Chinese urban planning and architectural design codes, we selected a street model with a width of 24 meters and building interface heights of 24 meters on both sides as the baseline model. The building interfaces consist of units with a width of 24 meters and a floor height of 4 meters, simulating the perspective changes brought by texture gradients in real scenarios (Figure 2). Since distant objects can significantly disrupt local depth perception, the model does not include blocks simulating tall buildings in the distance (Tribhawan Kumar, Donald A. Glaser, 1991).

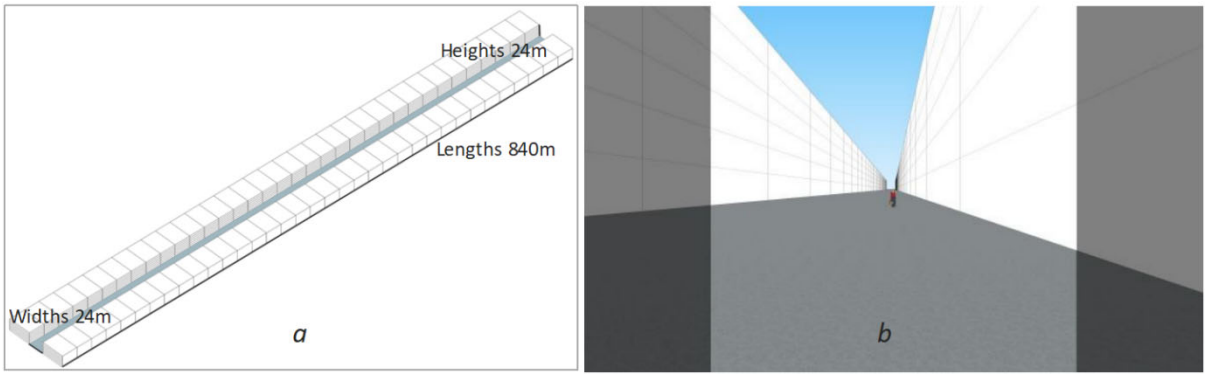

Figure 2.Baseline Street Model .axonometric view (a) ,Human view (b). Photo credit: Author's own drawing

Building on this, the study constructed three groups of street models with different geometric variables. The first group of models consists of streets with continuous vertical interfaces of varying heights and widths (Figure 3). These models are used to analyze the impact of street width, the height

of vertical interfaces on both sides, and the height-to-width ratio on depth perception. The street width and the height of the buildings on both sides were set to four different values: 12m, 24m, 36m, and 48m, resulting in 16 combinations, which form 11 different height-to-width ratio combinations.

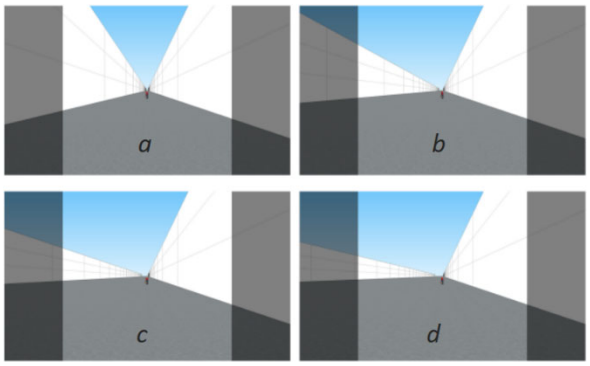

Figure 3 .Models with different widths(a.12m, b.24m, c.36m, d.48m). Photo credit: Author's own drawing

The second group of models studied the presence of openings in the vertical interfaces (Figure 4). In everyday life, streets often do not have continuous vertical interfaces on both sides; instead, there are many intersections and other openings. To simulate the impact of street openings on the perception of street depth, several models with different types of street openings were set up:A single opening with four different widths: 48m, 96m, 192m, and 384m； Two openings, with each opening having three different widths: 48m, 96m, and 192m； Four and eight openings, each with a width of 48m.

These models total nine different scenarios. The starting point of the openings in these scenarios is set at 120m from the street breakpoint, and the openings are distributed as uniformly as possible. Additionally, to explore the potential impact of the opening position, three scenarios were set with an opening width of 384m and the starting points at 120m, 240m, and 384m from the street breakpoint, respectively.

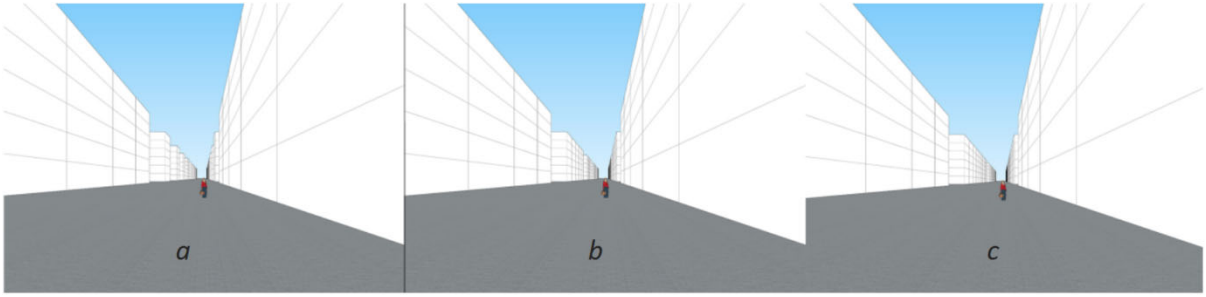

Figure 4. Models with different breakpoints(a.8breakpoints, b.4breakpoints, c.2breakpoints,). Photo credit: Author's own drawing

The third group of models was set up with buildings on both sides of the street having approximately the same average height. These models were arranged in two configurations: one with buildings arranged from low to high and the other from high to low. This setup was designed to explore the relationship between the form of the skyline profile and street depth perception (Figure 5).

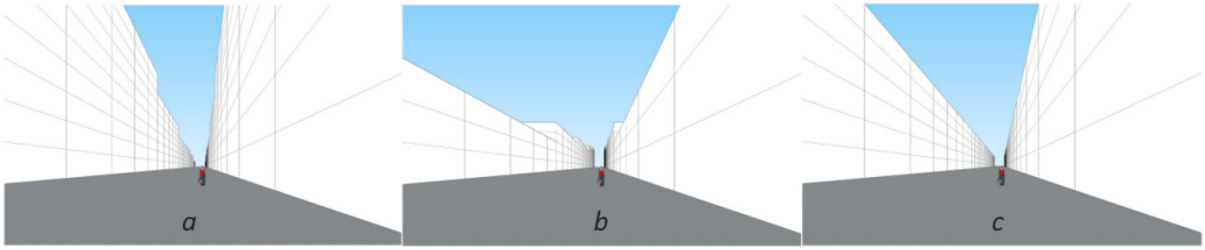

Figure5 .Models with different skyline profile(a.from high to low, b. from low to high , c.Baseline Street Model). Photo credit: Author's own drawing

Based on the street 3D geometric feature models, 30 street view images of the 3D street models were generated for perceptual evaluation. The simulated camera field of view was 60 degrees, with a downward view range of approximately 10-30 degrees when looking forward (Higuchi, 1988). Although the horizontal visual perception range of a person walking or jogging is 124 degrees (Panero & Zelnik, 1979), the clear and main focus range is about 60 degrees, and images simulated with a 124-degree field of view do not match the characteristics of human vision. Objects outside the 60-degree horizontal range but within 124 degrees are perceivable but not sensitive, so they are omitted from discussion.

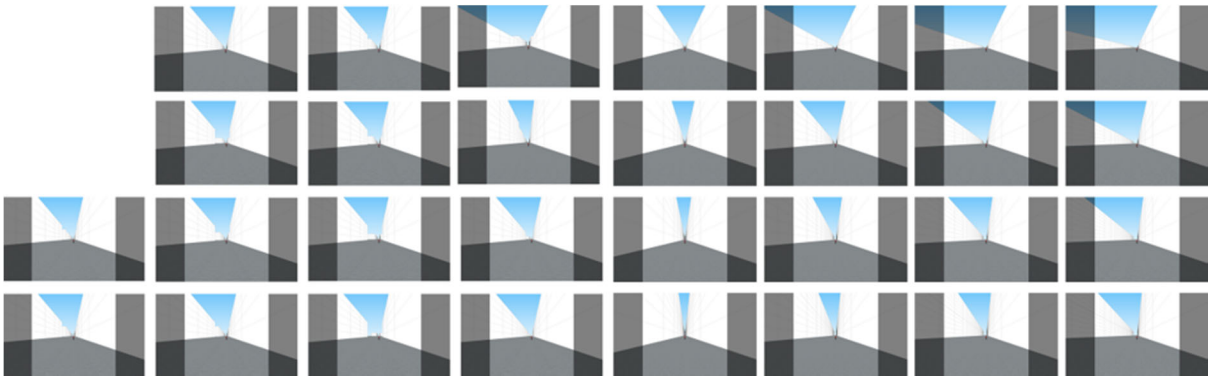

Figure6 . All 30 model pictures. Photo credit: Author's own drawing

Since changes in observation angles can affect depth perception (Charles A. Levin & R. Haber, 1993), the camera observation position also needs to be controlled. To simulate the perspective of a pedestrian, a uniform observation point was chosen at a distance of 5 meters from the right side of the building.

"Visual Scene-Perception Evaluation" Study

In the subjective evaluation of street space, researchers commonly use methods such as the Likert scale and Semantic Differential (SD) method to assess people's subjective impressions of street spaces (Xu Leiqing, 2006). In a study on cyclists' safety perceptions, the research team conducted an online survey where participants were provided with several images and asked to rate them (Rul von Stülpnagel, Nora Binnig, 2022).

In this study, an online questionnaire was used to have respondents rate their perceptions of the depth and spatial intensity of 30 street view images on a scale of 1 to 10. To eliminate the effects of comparison, the street view images in each respondent's questionnaire were randomly arranged.

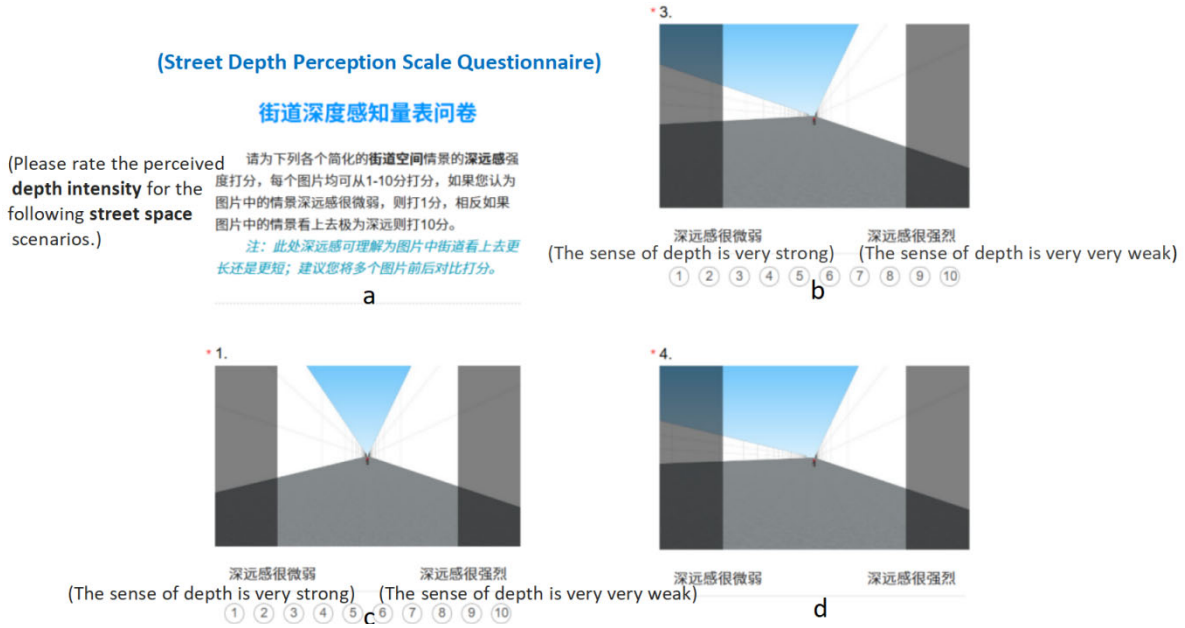

Figure7 .Screenshots of the questionnaire (partial).introduction(a).questions(b,c,d). Photo credit: Author's own drawing

The questionnaire results were analyzed using SPSS. First, the reliability and validity of the overall data were evaluated using Cronbach's alpha coefficient, KMO value, and significance tests. Then, the scale data from the questionnaire were reorganized and classified according to the street width, height, height-to-width ratio, opening types, and skyline profiles corresponding to each image. This included average scores for each scenario and individual data for each questionnaire.

The depth perception scale scores were used as the dependent variable, while street width, height, height-to-width ratio, opening types, and skyline profiles were treated as independent variables. Linear regression analysis was performed using SPSS to determine the significance of the regression relationships by observing the R-squared values and conducting F-tests, resulting in the corresponding regression equations.

Pilot Study and Hypotheses

Before conducting the main experiment, a pilot study was carried out to assess the feasibility of the experiment. Specifically, seven scenario images with different height-to-width ratios, street widths, and building interface heights were selected for a small-scale survey. A total of 15 questionnaires were collected, all of which were valid. Linear regression analysis was performed on the data, revealing that a model could be constructed with height-to-width ratio, height, and width as independent variables and scores as the dependent variable, with the formula:Score=2.554+0.346x+0.008m+0.003n,where x represents the height-to-width ratio, m represents the height, and n represents the width. The R-squared value of the model was 0.966, indicating that height-to-width ratio, height, and width can explain 96.6% of the variance in the scores. The model passed the F-test ($F = 28.225$, $p = 0.011 < 0.05$), which means that at least one of these variables (height-to-width ratio, height, or width) significantly affects the scores. Although the limited number of scenarios prevents us from identifying the specific variables influencing street depth perception, the pilot study has confirmed the feasibility of the experiment.

Based on the pilot study and existing theoretical research, several hypotheses can be proposed. For instance, given the same opening type, streets with a larger height-to-width ratio are expected to induce stronger depth perception. When the basic scale of the street is the same, more openings result in a richer texture gradient and more complex occlusion relationships, leading to stronger depth perception. In cases where the basic scale and opening width are the same, a closer starting position of the opening to the observation point will result in greater disruption of the building interfaces on both sides, leading to weaker depth perception.

RESULTS AND DISCUSSIONS

Basic Data and Analysis Methods

A total of 71 questionnaires were distributed in the formal experiment, with 67 returned. After excluding 2 invalid questionnaires, 65 valid questionnaires were obtained.

SPSS was used for data analysis. The overall Cronbach's alpha coefficient for the data was 0.941, indicating good reliability. The KMO value was 0.794, with a significance level of <0.001, indicating good validity.

Height, Width, and Height-to-Width Ratio

General Analysis:

Height:No significant correlation was found between height and scores, whether analyzing the average scores or all items. The significance level in the ANOVA analysis was 0.065, which is greater than 0.05.

Width:For all items, a linear regression analysis between width and scores resulted in the equation:$y = 8.746 - 0.071x$,where y represents the score and x represents the street width (in meters). The adjusted R-squared value was 0.214, and the model passed the F-test ($F = 298.2$, $p < 0.05$) (Figure 8).

Height-to-Width Ratio:A regression analysis between the height-to-width ratio and scores resulted in the equation:$y = 5.598 + 0.78x$,where y represents the score and x represents the height-to-width ratio. The adjusted R-squared value was 0.139, and the model passed the F-test ($F = 168.3$, $p < 0.05$) (Figure 9).

Combined Analysis of Height, Width, and Height-to-Width Ratio:When height, width, and height-to-width ratio were used as independent variables, the regression equation was:$y = 8.086 + 0.263x - 0.058z$,where y represents the score, x represents the height-to-width ratio, and z represents the width. The adjusted R-squared value was 0.218, and the model passed the F-test ($F = 97.5$, $p < 0.05$). However, the significance value for height was >0.05 in the t-tests, so the coefficient for height was excluded from the equation.

It is worth noting that despite the adjusted R-squared value being slightly above 0.2, this should be considered in the context of a large sample size and the absence of standard reference items in the questionnaire to avoid leading responses. For individual item analysis, the adjusted R-squared value for width was 0.930.

Regression Analysis of Average Scores:For average scores, linear regression analysis yielded:

Width: The equation was:$y = 8.746 - 0.071x$,where y represents the score and x represents the width. The model passed the F-test ($p < 0.001$) with an adjusted R-squared value of 0.930.

Height-to-Width Ratio: The equation was:$y = 5.598 + 0.780x$,where y represents the score and x represents the height-to-width ratio. The model passed the F-test ($p < 0.001$) with an adjusted R-squared value of 0.581.

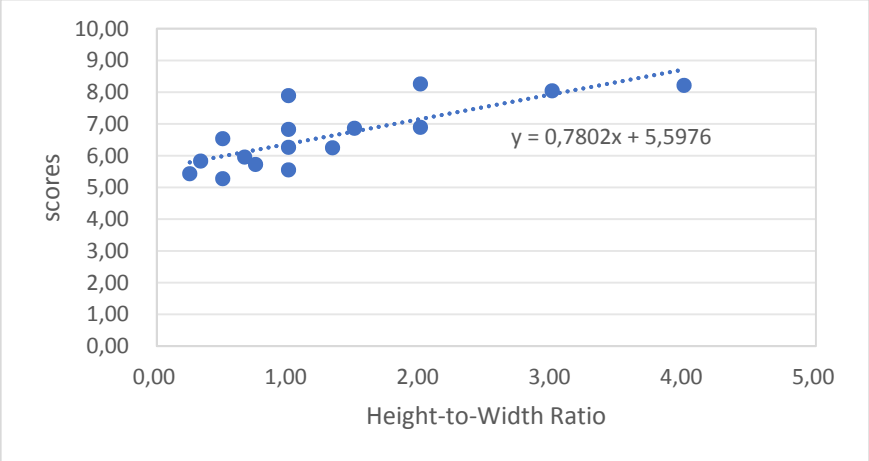

Figure 9: Regression Equation and Data for Height-to-Width Ratio, where y represents the score and x represents the Height-to-Width Ratio. Photo credit: Author's own drawing

Group Analysis:

In the experiment, the heights of the buildings on both sides were set at four different levels: 12m, 24m, 36m, and 48m. The data were grouped based on these different building heights.

It was found that in all four groups, there was a significant linear regression relationship between width and scores. The coefficients for width in the regression equations were -0.067, -0.082, -0.063, and -0.072, respectively, with no apparent pattern of change.

Additionally, in all four groups, there was a significant linear regression relationship between the height-to-width ratio and scores. The coefficients for the height-to-width ratio in the regression equations were 3.194, 1.877, 0.973, and 0.825, respectively. It was observed that as the building height increased, the influence coefficient of the height-to-width ratio decreased（Figure10）.

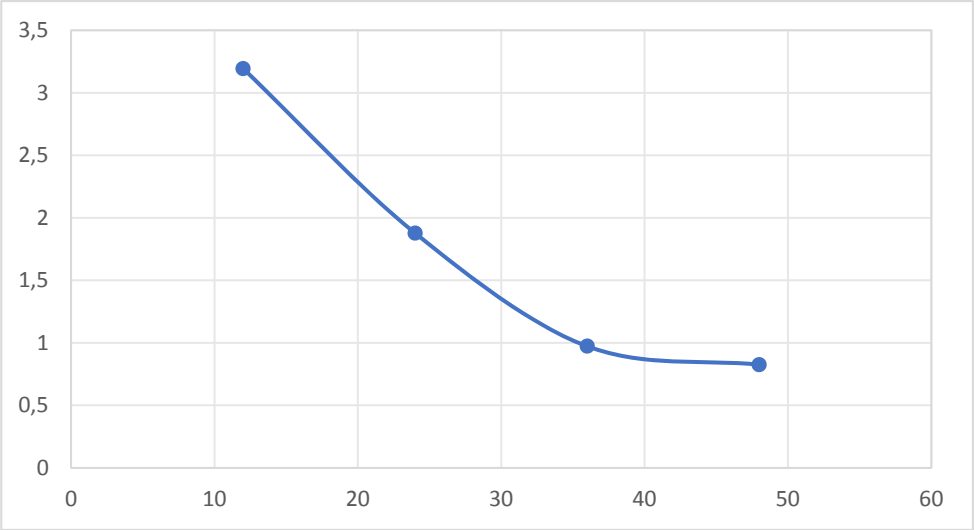

Figure 10：Regression Coefficients of Height-to-Width Ratio at Different Heights（The x-axis represents height, and the y-axis represents the regression coefficients of the height-to-width ratio.）. Photo credit: Author's own drawing

In the experiment, the street widths were set at four different levels: 12m, 24m, 36m, and 48m. The data were grouped based on these different street widths. It was found that in all four groups, height was not significantly correlated with scores. Similarly, controlling for width, height-to-width ratio, and height would be redundant, so the analysis was omitted.

There were 11 different height-to-width ratio situations in the experiment, but only the ratios of 0.5, 1, and 2 had more than one corresponding height (width). Grouping the data based on these height-to-width ratios revealed that in all three groups, there was a significant correlation between width and scores. The coefficients for width (height) in the regression equations for width (height) and scores were -0.105, -0.063, and -0.057, respectively.

The depth perception scores of streets are significantly negatively correlated with street width. This phenomenon can be explained by the fact that when the street width is larger, the visual angle between the start of one side of the building façade and the end of the street becomes smaller, resulting in an underestimation of the distance between these two points, which weakens the intensity of depth perception.

Among the variables, street width has the greatest impact on depth perception, followed by the height-to-width ratio. Although the impact of height is less pronounced, the data suggests that width and height-to-width ratio should not be considered synonymous variables.

In subsequent group experiments, the impact of width did not show regular changes across different height scenarios. This is likely because, with building height unchanged, width as a simple and clear

factor remains easy to perceive across various height scenarios, resulting in no significant variation in its impact on depth perception.

The coefficient for the height-to-width ratio decreases as height increases, suggesting that as the height of buildings on either side of the street grows, the perception of depth becomes less dependent on the height-to-width ratio and more on straightforward width judgment. This change is particularly noticeable when street height is less than 36 meters; beyond this height, the coefficient for the height-to-width ratio shows a clear marginal effect（Figure11）.

A possible explanation is that, influenced by factors such as the visual angle, as street height reaches a certain level, sensitivity to changes in height diminishes. Consequently, the cognitive factor of the height-to-width ratio, which integrates height and width, is disrupted, thereby reducing its impact.

In different height-to-width ratio scenarios, the influence of height (width) diminishes progressively. This may be because a strong canyon-like perception overshadows the single-factor perception of height or width, leading to a reduced impact coefficient. Moreover, in all height-to-width ratio scenarios, the impact of height (width) is negative, meaning that increasing the absolute scale of the street reduces depth perception. This can be interpreted as an excessively large absolute scale causing the street to appear more like a flat plaza rather than a long, narrow street extending in one direction. Fundamentally, this phenomenon might also be related to changes in the sense of volume (SOV), but this has not been confirmed with relevant experiments and data.

Opening Types

The average scores for each scenario were analyzed. Using the number of openings as the independent variable and the scores as the dependent variable, a linear regression analysis was conducted. The resulting regression equation is:$y = 4.943 + 0.200x$, where y represents the scores and x represents the number of openings. The R-squared value of the model is 0.428. The F-test for the model showed that the model passed the F-test ($F = 6.987$, $P = 0.033 < 0.05$) (Figure12).

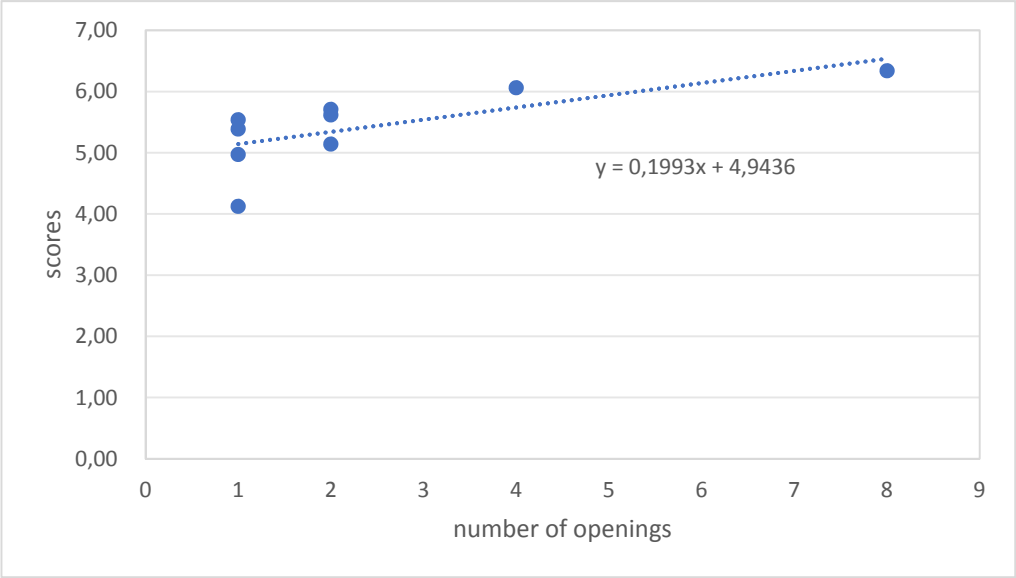

Figure12 ：Regression Equation Graph for Scores and Number of Openings， Photo credit: Author's own drawing

Using the width of a single opening as the independent variable and the scores as the dependent variable, a linear regression analysis was conducted. The resulting regression equation is:y = 6.110 - 0.005x， where y represents the scores and x represents the width of the opening. The adjusted R-squared value of the model is 0.826. The model passed the F-test (F = 39.055, p = 0.000 < 0.05).

When using the number of openings and the width of a single opening as independent variables and the scores as the dependent variable, the regression equation is:y = 5.717 + 0.112x - 0.004z， where y represents the scores, x represents the number of openings, and z represents the width of a single opening. The adjusted R-squared value of the model is 0.971. The model passed the F-test (F = 135.638, p = 0.000 < 0.05).

For scenarios with a total opening width of 384（figure 13）, the analysis was conducted using the number of openings as the independent variable and the scores as the dependent variable. The resulting equation is:y = 4.189 + 0.276x， where x represents the number of openings. The model passed the F-test (F = 25.352, p < 0.001), and the adjusted R-squared value is 0.112.

In the three scenarios where the starting points of openings were 120m, 240m, and 384m from the endpoint, the average depth perception scores were 4.12, 5.38, and 4.91, respectively.

The data indicates that the more openings there are, the higher the depth perception scores, even when the total width of the openings remains constant. This is consistent with expectations. However, contrary to expectations, even in scenarios with the most openings, the scores are still lower than those in scenarios without any openings.

The data indicates that the more openings there are, the higher the depth perception scores, even when the total width of the openings remains constant. This is consistent with expectations. However, contrary to expectations, even in scenarios with the most openings, the scores are still lower than those in scenarios without any openings.

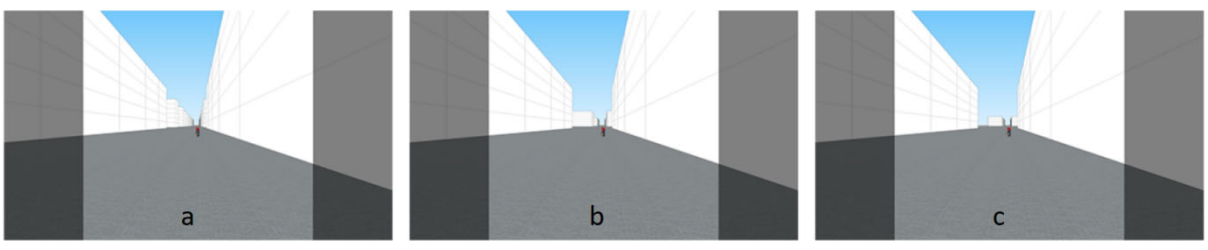

Figure13 ：Three cases with the same total opening width but different numbers of openings 8(a), 2(b), and 1(c). Photo credit: Author's own drawing

Skyline Profiles

The average depth perception scores for the scenarios with gradually lowering and gradually rising skyline profiles are 7.15 and 6.08, respectively. The average depth perception score for the initial model (with a flat skyline profile) is 6.32.

The expectation regarding the distance of openings from the observation point was that when the width of the openings is the same, the further the opening is from the observation point, the stronger the depth perception. However, experimental results show that the depth perception is strongest when the opening is located in the middle of the field of view. This could be because when the opening is too close or too far, it fails to form a clear sense of layering. When the opening is centered, it does not disrupt the gestalt perception of the street interface and adds some level of layering to the street space, resulting in the strongest depth perception, although still less than that of a complete street without openings.

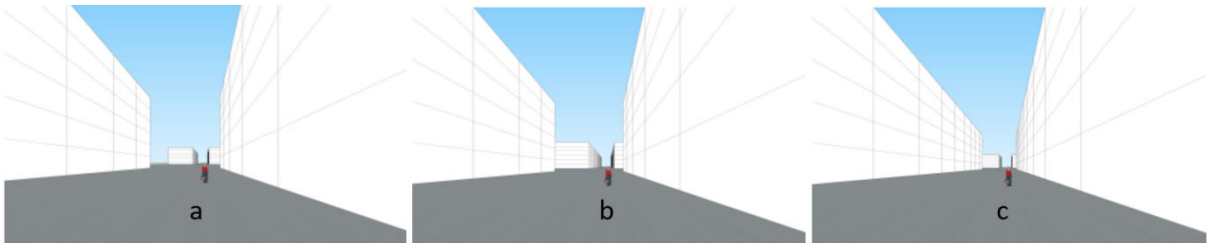

Figure14 ：Street view images corresponding to aperture distances of 120m(a), 240m(b), and 360m(c) from the observation point， Photo credit: Author's own drawing

Scenarios where the buildings on both sides gradually increase in height have lower scores, indicating that a gradually rising skyline weakens the depth perception of the street, and vice versa. It is reasonable to believe that this is caused by a perspective illusion. A gradually rising skyline makes the perspective lines flatter, and perspective lines are very important in monocular cues. The upward slant of perspective lines makes distance judgments tend to be underestimated, thereby weakening the depth perception.

Some Prospects

In the preliminary analysis, it was observed that the impact of street width-to-height ratio on depth perception changes systematically with different street widths. It was roughly estimated that this effect diminishes linearly with increasing width and appears to stabilize around a width of 36 meters. Future studies could explore this pattern in more detail by conducting experiments with a wider range of street widths and width-to-height ratios to identify more precise variation curves.

In the experimental phase related to street profile shapes, only three simple scenarios were tested: lowering, raising, and flat profiles. However, there are many other scenarios with different standard deviations in building heights and varying proportions of building protrusions into the street view that were not explored. The experiment also did not investigate how different opening types might interact with various width-to-height ratio scenarios.

Additionally, due to technological limitations, the study did not examine the effects of binocular cues such as binocular disparity and convergence on depth perception. Utilizing VR technology could potentially allow for the exploration of depth perception patterns under binocular conditions.

CONCLUSIONS

Height, Width, and Height-to-Width Ratio

Wider streets are perceived to be shorter, leading to weaker depth perception. A smaller height-to-width ratio also results in reduced depth perception. In subsequent grouped experiments, the coefficient of the height-to-width ratio decreases as the height increases. This suggests that as the height of buildings on both sides of the street increases, the dependence of depth perception on the height-to-width ratio gradually decreases, leading to a greater reliance on the simple judgment of width.Furthermore, an increase in the absolute scale of the street results in a decrease in depth perception.

We can utilize the changing patterns of height, width, and height-to-width ratio's impact on depth perception. For example, increasing the height-to-width ratio and reducing the street width can enhance the perceived depth of the streetscape, making the street appear longer. When the height of buildings on both sides of the street is below 36 meters, altering the building heights effectively changes people's perception of spatial depth. However, when the building heights exceed 36 meters, priority should be given to changing the street width rather than the height.

Form of Openings

The perception of layering affects the perception of depth. The stronger the layering, the stronger the depth perception, but it will never be higher than a street without openings.

The wider the individual opening, the lower the depth perception score. In design work, when creating large commercial streets with a wide width, simply changing the height of the buildings on both sides to alter the height-to-width ratio has a very limited effect on depth perception. The priority should be to change the number of openings and the width of the openings.

Distance of Openings and Skyline Form

A gradually rising skyline weakens the street's depth perception, while a descending skyline strengthens it.

ABSTRACT

The city of São Paulo, today the most populous in Latin America, has at its roots an urban formation common to other Latin countries: its origins as a colonial city and its development through contemporary exchange between urban analysis methods from southern Europe. Within it, streets play a fundamental role in the urban debate as a public space that structures private space. In this article, Dona Veridiana Street will be used as a case study, a way approximately 500 meters long that belongs to two different districts in São Paulo: Consolação and Santa Cecília. Its way classification is indicated as collector, connecting important streets in Vila Buarque, Higienópolis and Santa Cecília neighbourhoods. Furthermore, it has mixed land use characteristics since, in its extension, it concentrates residential buildings, shops, services and unique institutional buildings such as the Santa Casa de Misericórdia hospital, in addition to connecting Mackenzie University to Largo de Santa Cecília (where the Santa Cecília Parish and the Santa Cecília subway station are located). Considering the diversity of its occupation and the presence of the aforementioned equipment and housing, it is possible to extract – from public georeferenced databases – quantitative and qualitative data that describe not only its characterization, but also evidence of its current morphology that has historical traces that justify their formation. This article seeks, based on georeferenced bases and the characterization of the way, to point out methodologies for analysing urban form and occupation through four main axes: analysis of public and private space; walkability and mobility; typology and characterization of buildings; and urban indexes applied to the territory. At the end of the article, urban propositions that can be carried out through the application of the methodologies presented are presented, as well as notes for future researches.

Keywords: São Paulo, Dona Veridiana Street, methodology, georeferenced data, urban characterization

INTRODUCTION

Dona Veridiana Street is a public street approximately 500 meters in length, located in the center of São Paulo. It has an elongated rectilinear profile that partly demarcates the boundaries of three neighborhoods: Vila Buarque, Higienópolis, and Santa Cecília. Considering the official compartmentalization of the city, which divides it into districts, the street is again divided between two districts as can be observed in figure 1: Consolação (from the intersection with Maria Antônia

Street and Higienópolis Avenue to the crossing with Jaguaribe Street) and Santa Cecília (from Jaguaribe Street to Frederico Abranches Street). The origin of these neighborhoods dates back to the late 19th century, when the Higienópolis region was composed of estates that, after being sold, underwent subdivision processes driven by the urbanization of São Paulo, which began to intensify (Instituto Itaú Cultural, 1996). It is also worth noting that a mansion built on a large plot between Higienópolis and Angélica Avenues played a fundamental role in the neighborhood's expansion: Chácara Vila Maria, which later became Clube São Paulo and is currently named Iate Clube de Santos. This mansion was built as a residence for Veridiana Valéria da Silva Prado, an heir to the São Paulo elite who had recently returned from Europe near the end of the 19th century and who today gives her name to Dona Veridiana Street, the subject of this study. At the time, the mansion became a meeting place for intellectuals of the São Paulo elite who were enthusiasts of the city's urban renewal (Instituto Itaú Cultural, ibid.).

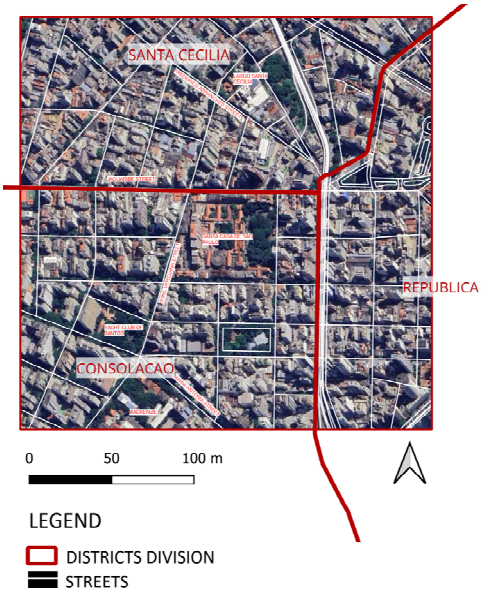

Figure 1: Location. Source: Prepared by the authors based on data from Geosampa, 2024.

This historical account for understanding the formation of streets, neighborhoods, and districts is, according to Moudon (1997), a principle for any study in the field of urban morphology. The theoretical foundations of urban morphological study are as follows: the three fundamental elements are buildings, streets, and public spaces; the scales of understanding are building/plot, street/block, city, and region; and urban form can only be understood through the comprehension of historical elements (Moudon, ibid.). Thus, it is understood that the study of urban morphology focused on an element such as Dona Veridiana Street, an important structuring axis at the neighborhood scale, offers opportunities to approach various aspects, such as the identification of a formative pattern of neighborhoods based on the study of their subdivisions; the occupation pattern of districts in comparison to the overall urbanization process of the city; the formation of plots from mansions and the subsequent verticalization process; and, finally, the identification of urban dynamics in the interaction between public and private spaces in the constitution of neighborhoods.

Buildings, plots, and blocks as elements constituting urban form analysis find synergy through the road system that connects all points. Road axes are vital for the formation of cities and regions as they enable internal and external movement, connecting cities and states and allowing the flow of people

and goods. However, as Magnani (1993) explains, the term "street" refers to a living concept since it can be understood in the simple sense as a public space for flow and transition, but it can also be understood in the complex anthropological sense, which describes it as a place and a medium for sociability among people. Thus, streets are important points in defining the territorial identities of places, and precisely because they are public spaces for multiple and common uses, they can evoke diverse perceptions among individuals, conferring complex singularities when trying to establish a unified logical notion for local description and understanding (Derrosso and Cury, 2019).

The theoretical approach to understanding the term "street" and its intrinsic relationship with daily life is developed through the referenced bibliography, reflecting the applicable concepts in the territory. Moreover, the methodology used in this article involves the use of geoprocessing as a source for data treatment and analysis, drawing on public databases. By downloading the data and processing it through specific geoprocessing software, the data becomes information (Silva, 2009). The information obtained helps contribute to a better understanding of the scales of analysis and the characterization of the elements that constitute urban space, making geoprocessing a key tool for urban morphology studies at any scale.

This article aims to present the application of analytical methods to understand the urban form of a location, using a public road as the central axis. To this end, the study begins with a contextualization of the role of urban morphology as a theoretical discipline and, through its principles and technical foundations, identifies the processes of formation of the neighborhoods and districts of São Paulo related to the street under study. After a brief survey of theoretical references on the municipal urban constitution, the study seeks to contextualize the current form of the street and its importance as a structuring axis for the public space along its length, as well as its importance as a structuring axis for the neighborhoods. These technical foundations support the georeferenced analysis, made possible by the availability of public open-source data provided by the City Hall. By combining the theoretical framework with the applied methodology, the goal is to draw conclusions and insights into what Dona Veridiana Street is and how its urban processes unfold in daily life, pointing to the possibilities of analysis from a study of urban form.

THEORETICAL FRAMEWORK

Currently one of the largest metropolises in the world, the city of São Paulo has undergone recent urbanization. Founded in 1554 by Portuguese Jesuit priests during the Portuguese colonization of Brazilian soil, São Paulo remained for three centuries as a small village with rural characteristics (Rolnik, 2009). At the end of the 19th century, the prolific coffee production established in the municipality attracted immigrants to work in the fields, laying the foundation for the initial processes of forming the city we know today. In the 1870s, the Baron of Mauá, together with the Imperial Government, began studies for the construction of a railway that would connect coffee production in the municipality of Jundiaí to the Port of Santos on the coast of São Paulo, crossing through São Paulo. The ambitious project faced the obstacle of overcoming the natural barrier imposed by the Serra do Mar mountain range, which represents a drop of approximately 800 meters between São Paulo and the coast. Given the difficulties and lack of technology in the country, foreign expertise was sought to carry out the project and build the railway, eventually contracting British engineers along with various

other immigrants to complete the construction. Thus, the São Paulo Railway Company was established, and by enabling movement through the territory, it fostered the formation of several settlement nuclei in the municipalities where there were railway stations (Mazzoco and Santos, 2005). These settlements slowly began to develop into cities, and, together with the arrival of immigrants to meet the increasingly pressing labor needs in Brazil, São Paulo experienced a demographic boom, especially from the mid-1920s onward (Santos, 1996).

The railway cuts through São Paulo longitudinally, starting in the northern region, where today the neighborhood of Perus is located, reaching the central region at the Barra Funda, Brás, and Luz stations, and continuing towards the ABC Paulista region until reaching the top of the mountain range and finally arriving in the city of Santos on the southern coast of São Paulo (Mazzoco and Santos, ibid.). This route through the city's center spurred the development of the region, which had until then been occupied by large mansions and the cultivation of various crops. Still within the central region, a settlement nucleus near the Pacaembu area began to develop in what we now recognize as the Higienópolis neighborhood. Towards the end of the 19th century, educational institutions such as the American School (now Mackenzie Presbyterian University) and Colégio Sion were established, along with imposing mansions built within the subdivision of estates that structured the neighborhood (Instituto Itaú Cultural, ibid.). The first urban estate built in the city was Vila Maria, the residence of Veridiana da Silva Prado, who had recently returned to the city after a period in Europe. These educational institutions, combined with the construction of estates and occupation by the financial elite importing concepts of European urban life, spurred intellectual activity in the region, signaling the area's growth and development as it transitioned from a fully rural to an urban morphology (Macedo, 2012).

This expansionist process quickly transformed the local urban form through the subdivision of large estates, as well as the consolidation of structuring elements of the territory such as the road network and the installation of public spaces, parks, and gardens. The central region of São Paulo covered by this study began precisely with the subdivision of these large estates, and, being a process influenced by the local elite, it underwent a renewal inspired by the architecture and urbanism of European cities (Macedo, ibid.). From a construction standpoint, a homogenization of the typological pattern of buildings constructed during this period is evident, and from an urban perspective, urban guidelines were applied, such as extensive afforestation, the opening of streets and wide sidewalks, and the installation of urban services like public lighting (Toledo, 2004). This local urban form is still partially preserved, as some of the remaining mansions have been converted into cultural and event spaces, while other institutions remain in the same locations, such as Sion, Mackenzie, and Vila Penteado, which has been converted into a school and is now home to the postgraduate architecture and urbanism courses at the University of São Paulo. Many other mansions and initial buildings in the neighborhood later gave way to various buildings as the city began to undergo verticalization (Reis Filho, 2014), while other occasional structures remain standing despite the force of urban transformation, though they do not currently have the same level of conservation as the mansions converted for non-residential use. Understanding the typological patterns of local buildings over various historical periods helps to comprehend the formative processes of neighborhoods and the motivations behind their local characterization (Moudon, ibid.).

Morphological analysis, therefore, involves understanding locations within a complex context, where it is important to analyze their historical influences tied to their current aspects (Costa and Gimmler

Netto, 2015). Considering this premise, focusing on Dona Veridiana Street as the object of study enables two distinct but congruent contexts: situating it as a structuring axis for neighborhood-scale development and its surroundings, and situating it as a structuring axis for the activities currently carried out there, considering the predominantly mixed land use along its length. From one end to the other, the studied street connects Mackenzie University with Largo Santa Cecília, where Santa Cecília Church and the Santa Cecília metro station are located. In addition to the metro nearby, the street is also part of bus routes, as well as experiencing heavy traffic from private vehicles, motorcycles, and taxis. Its importance in terms of mobility is empirically justified by the mixed predominance of occupancy by residences, commerce, services, and institutional activities, bringing together in one street the constitutive elements of the neighborhood's complete landscape.

The understanding of the historical formative elements of the region is based especially on the referenced literature, as well as historical data and photographs relevant to the period between the late 20th century and the early decades of the 21st century. The current analysis, however, benefits from the abundance of available resources, data, and information. One way to analyze the urban and morphological context through precise and unified methodologies is the use of geoprocessing resources, which, through territorial information analysis, generate guidelines, plans, and intervention projects in public spaces (Aguilar, Flain, and Coelho, 2018). This data processing, generating information, allows for a wide range of tabulations and comparisons on the urban scale in a comprehensible and graphically suitable format for territorial analysis, thus making it possible to recognize the urban form of a place in an analytical and exploratory manner, which is absolutely essential for a correct approach to the characterization of contemporary urban space.

METHOD

The theme of this article is based on the application of urban morphology analysis methods on a public road, following the methodology addressed by Borges (2020). However, before starting the digital analyses to obtain cartographies, a theoretical reference base was established, encompassing concepts that clarified the scope of work within the field of urban morphology and that indicated the aspects of analysis capable of relating the concepts of “street” obtained with the precepts of urban form studies. Based on the consolidation of the ideas to be developed, axes were established to define the scope of this article. The chosen structuring axes were three: street, block, and neighborhood. Within each axis, specific studies were proposed to establish a comprehensive morphological view of the chosen region. The survey of possible studies generated 19 potential cartographies to be developed, based on analyses of public and private relationships, walkability and mobility, building characterization, and urban indices, from which the following themes were selected to be produced according to the respective urban scales:

1. Street scale: land use, building height; and building typology;
2. Block scale: block length, average plot utilization coefficient; and average plot occupation rate;
3. Neighborhood scale: analysis of public and private space occupation, analysis of block and road system occupation; and average block area.

The criterion for choosing the street to be studied was based on two interdependent factors: it had to be a street within the city of São Paulo and close to Mackenzie University, which would allow researchers to conduct field visits. Thus, the options were limited to a radius around the university, with the neighborhoods of Higienópolis, Santa Cecília, and Consolação as possibilities. Finally, to select the specific street to be studied, the criterion was based on the diversity of identified uses, allowing morphological analysis of various aspects. This led to the selection of Dona Veridiana Street, considering its proximity to the university and its importance within the neighborhood for concentrating diverse activities and serving as a key mobility axis within and beyond the neighborhoods it passes through. The initial premise of choosing a street within the city of São Paulo was determined by the availability of data from Geosampa, a digital portal maintained by the São Paulo City Hall, which aggregates data and information on a wide range of aspects. These data are available in various formats depending on the topic addressed, with the main format for this research being shapefiles, which allow data processing in specific geoprocessing platforms.

On the Geosampa platform, all data relevant to the topics chosen for analysis in this article were selected and downloaded in the Sirgas2000 version. The main downloaded data included the official base of the municipality's administrative boundaries; the delimitation of districts, blocks, and lots; the shape of buildings; and the axis of streets and roads. All selected data were downloaded in shapefile format and processed in QGis, a free and open-source software used for manipulating georeferenced data. In shapefile format, the data contain what is called an "attribute table" embedded within, in which a series of additional information and parameters are stored. This information was filtered and graphically processed to generate specific thematic maps according to the thematic boundaries mentioned above.

After processing and systematizing all the data and information, the map generation tool within the QGis software was used, allowing for export in both vector and image formats. Once exported, the maps were analyzed in light of the theoretical framework discussed throughout this article, providing an overall view of the street's morphological characterization.

RESULTS AND DISCUSSIONS

Provide For the development of the maps mentioned, the method used was the analysis of a 1 km² buffer zone around the study object, in this case, Dona Veridiana Street. Within this boundary, which corresponds to a pedestrian walkability area, it was possible to observe data related to the street and its reverberations in the region, thus supporting the study of the street's characteristics as an element that reveals urban growth within the city. The four major themes selected for mapping (the relationship between public and private space; walkability and mobility; building characterization; and urban indices) often involve overlapping analyses, as spaces simultaneously create multiple relationships with the urban environment. In the area studied, some particularities should be highlighted: the first is that one of the blocks is entirely occupied by two hospital complexes, one public (Santa Casa de São Paulo) and one private (Hospital Santa Isabel). Another noteworthy particularity at the urban scale is the Yacht Club of Santos, which occupies a large plot with few buildings. A third point of attention is that the street has an elevation difference of approximately 24 meters over a length of 550 meters, beginning and ending at intersections with other important and high-traffic streets in the neighborhood, specifically Higienópolis Avenue and Frederico Abranches Street.

Thus, the first analysis conducted was the relationship between public and private space, which in this study was contrasted using block information (private use) and street information (public use). In the case of Dona Veridiana Street and the neighborhoods it comprises, it is visually evident from Figure 2 how much private use occupies the 1 km² area, with private space predominating over public space, as confirmed by data showing that approximately 30.5% of the area is occupied by the road system. It is worth noting that the block that holds the public hospital was considered private space, as it shares space with the private hospital and has restricted access. Within the studied perimeter, it was found that, apart from the road system, there is only one block occupied by a square, in addition to green areas and the metro station as public spaces:

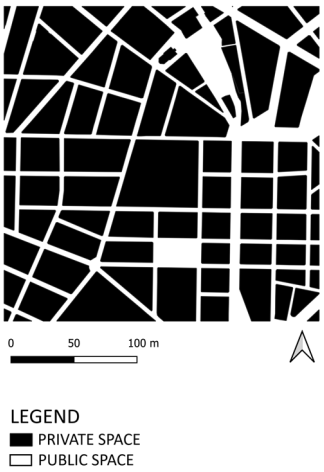

Figure 2: Horizontal permeability and the relationship between public and private space. Source: Prepared by the authors based on data from Geosampa, 2024.

To analyze the mobility characteristics, three maps were produced: the first two (Figures 3 and 4) provide a better analysis at the neighborhood scale, while the last one (Figure 5) focuses on the street scale. As can be observed in Figure 3, the map highlights the previously mentioned elements of the block and the street, but now it also considers the sidewalk, highlighted in red, as well as public-use blocks. It was possible to analyze that there is no public permeability through the blocks, and that the sidewalks do not occupy a significant portion of the urban fabric (only about 13.8% of the demarcated area), except when they gain space due to subdivisions not always aligned with the lot's planning:

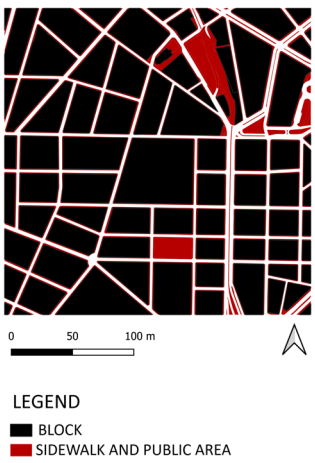

Figure 3: Walkability and mobility. Source: Created by the authors based on data from Geosampa, 2024.

The map shown in Figure 4 clarifies, through gradation, the size of the blocks, with darker tones indicating larger blocks and lighter tones indicating smaller ones. In this sense, it is possible to analyze the diversity of sizes, with a subtle predominance of blocks between 10,000 and 20,000 m²:

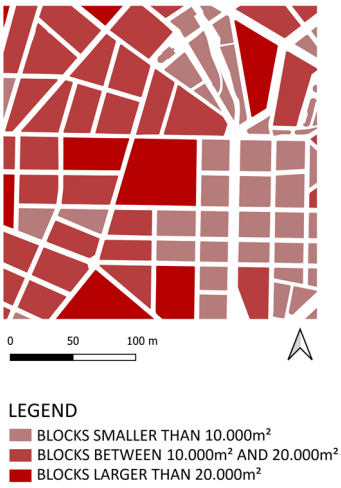

Figure 4: Walkability and mobility. Source: Created by the authors based on data from Geosampa, 2024.

Finally, the map indicated in Figure 5 shows the length of the blocks, a measurement that fosters a closer relationship with the scale of the street. It also reveals the predominance of blocks longer than 250 meters, highlighting how far pedestrians must travel during daily commutes, primarily due to the lack of permeability and enjoyment within the blocks:

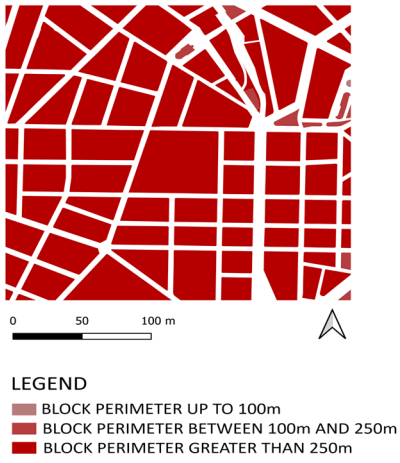

Figure 5: Walkability and mobility. Source: Created by the authors based on data from Geosampa, 2024.

Covering another scale of analysis, resources were gathered to understand the relationship between buildings and the street. The first of these is the block usage map (Figure 6). Created from data from 2021 available on Geosampa, the map shows a predominance of medium-standard vertical residential use, followed by high-standard vertical residential use. Although the map indicates only one block with a predominance of commercial and service establishments, it is noticeable when walking along the street that many residential buildings have commercial spaces on the ground floor. This contributes to a diverse urban dynamic where bars, markets, and convenience stores cater to users of the surrounding facilities:

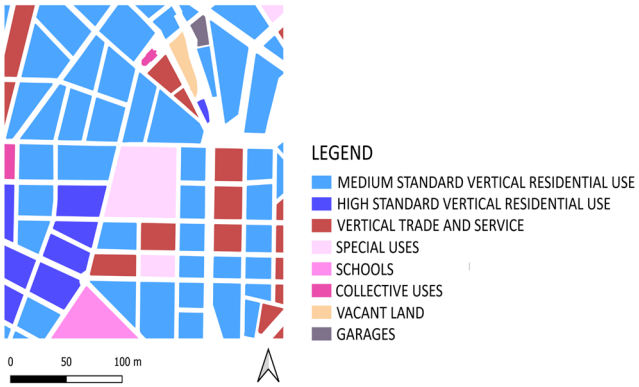

Figure 6: Predominant Use of Blocks. Source: Prepared by the authors based on data from Geosampa, 2024.

Corroborating this data is the building height map (figure 7). It is possible to first notice the diversity of building heights present in the studied area and, subsequently, that the blocks within the Consolação district (mainly those located in the lower left part of the map) are composed of tall buildings with little spacing between them. Meanwhile, in the upper left part of the map, the blocks belonging to the Santa Cecília district feature shorter buildings, with varied heights and closer proximity. Also within the street scale analysis, the aerial photo (figure 8) again confirms the profile of tall buildings:

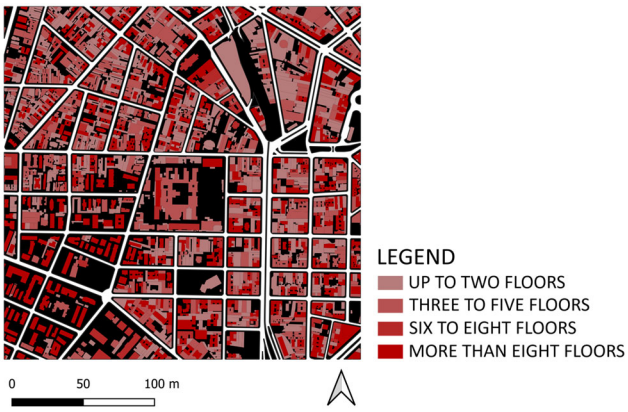

Figure 7: Building Height. Source: Prepared by the authors based on data from Geosampa, 2024.

Figure 8: Aerial Image of the Buildings on the Street. Source: Prepared by the authors based on Google Maps, 2024.

The urban indices involved in this analysis include the lot occupancy rate, the utilization coefficient (that is, how much of what can actually be built has been used), and the natural soil permeability. These values serve as construction parameters determined by the municipal sphere to guide the city's growth. The central area of the city, despite being a consolidated zone, is predominantly classified as an urban transformation zone according to urban legislation, meaning it encourages the promotion of high-density constructions that contribute to the enhancement of the landscape and public spaces.

Through Figure 9, it is possible to identify that the buildings within the study perimeter have a high lot occupancy rate, with a coefficient of buildings over blocks of approximately 0.76; however, this does not necessarily meet the total construction potential of the area, which requires a minimum building size of half the lot area and a maximum size of four times the lot area. This last analysis aligns with Figure 7, as the variety in the heights of the buildings occupying nearly the entire lot area indicates that not all construction potential has been utilized:

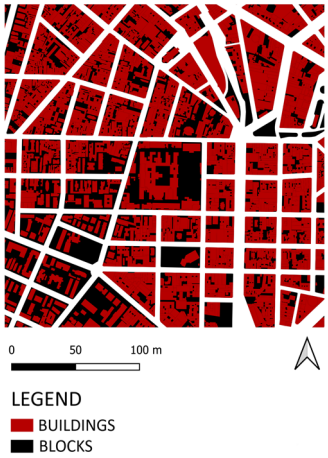

Figure 9: Buildings in the blocks. Source: Prepared by the authors based on data from Geosampa, 2024.

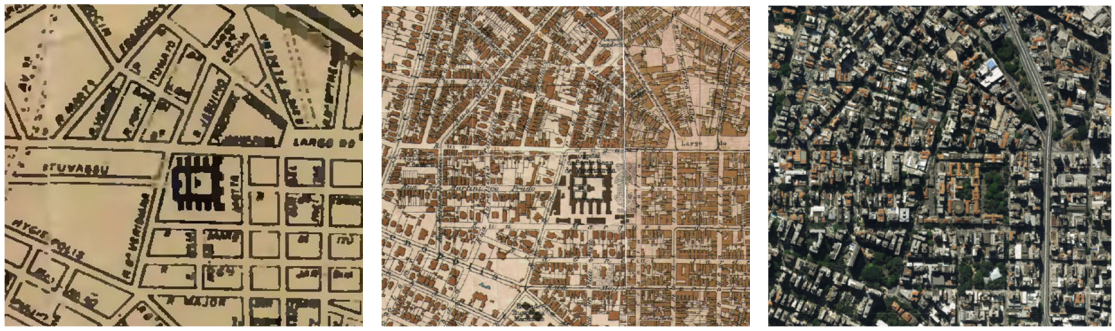
Finally, considering that urban form can only be understood through historical resources, the maps presented below (Figures 10, 11, and 12) allow for an understanding that the subdivision of the street is old and has been maintained since 1890. However, it is noticeable that over the years, the lots, especially in the area of the Consolação district (the lower part of the map), have undergone transformations, as have their buildings when compared to the situation in 1930 with the present day:



Figures 10, 11, and 12: Study area in the years 1897, 1930, and 2020. Source: Geosampa.

The study of the elaborated maps is based on a method that can be replicated when access to mapping tools and public city data is available. It is essential not only to read the georeferenced graphic bases but also to know how to extract specific information from them and transform it into usable data. It

is important to highlight that without the databases provided by Geosampa, the analysis of urban form would be significantly limited, primarily due to the absence of replicable parameters.

CONCLUSIONS

The result of accelerated urbanization due to coffee capital investments in the late 19th century, the city of São Paulo was organized in various ways within a constantly expanding territory, considering the occupation of its edges continually renewed by the city's growth. The analysis of this process from the perspective of urban form begins with an understanding of the occupation that is still evident today and can be recognized through the organization of blocks, streets, and lots. Rua Dona Veridiana was initially occupied by coffee barons and has undergone changes over the years; however, it retains its original structure in historical buildings. Thus, it can be understood as a synthesis of the city's processes, where growth and history coexist with tensions.

In this way, the method used to investigate urban characteristics to understand the formation processes of neighborhoods and districts was made possible by establishing criteria that encompass both current and historical data and materials. Therefore, it was relevant to analyze the public and private areas around the street to verify the regularity of the blocks, the size of the streets, the presence of parks and urban facilities, and thus confirm characteristics of urbanization with planning. The mobility maps related to the public and private area maps confirm this characteristic, as there is space for sidewalks and most blocks do not exceed an area of 20,000 m², demonstrating compliance with pedestrian scale and still providing space for urban infrastructure.

Thus, it is understood that the method used in this article could be replicated for other streets with different characteristics within the city of São Paulo, establishing comparative standards that enable the understanding of the city's transformations, recognizing that there may have been planning in urban characteristics that appear to have occurred by chance. Understanding the historical context and the current characterization is, therefore, a fundamental component from the perspective of urban morphology and allows for comprehension of the territory, a natural and indispensable tool for proposing any interventions in a complex environment such as the city of São Paulo.

ABSTRACT

How to design morphologically appropriate urban layouts and refrain from the usual laissez-faire process noticed in recent urban expansions? New urban areas in Brazilian cities have shown poor sense of place and little adherence to the site conditions. This paper tackles this problem and discusses the process of designing urban layouts along with the coherence between context and urban forms. Based on the idea of 'rendimento' (yield), a concept adapted from the Italian school of type-morphology, and on specific literature review, a set of parameters for the assessment and design of urban layouts was prepared and applied to certain pre-existing anthropic conditions. The resulting layouts depict directives that are discussed. The outcome leads to the conclusion that is possible to design morphologically appropriate, economically viable, and environmentally sustainable urban layouts.

Keywords: rendimento, Caniggia, new towns, urban design, sustainability

INTRODUCTION [Heading 1]

This paper presents the initial findings of an ongoing research into designing morphologically appropriate urban layouts (Costa and Rego, 2019; Costa, 2020; Costa and Rego, 2021; Alves et al., 2023). We will explore the concept of 'rendimento' (yield) from the Italian school of type-morphology, its interpretations, and propose a new application for urban design. The study includes a case analysis of a well-regarded town layout to derive parameters for evaluating 'rendimento.' These parameters are then applied to design new urban layouts, testing their practical use and feasibility. To validate the application of 'rendimento' at the urban scale, we first establish its theoretical foundation and then apply it to Maringá, Paraná, Brazil. This city was selected for its original high-quality layout and its contrasting expansion with a more serial design, providing a basis for comparing different layouts within the same territory. This comparison allowed us to extract the qualities of the original design, relate them to 'rendimento,' and test new layouts to assess their effectiveness. Partial results from the theoretical paper in Portuguese (Costa and Rego, 2019) were applied by Gomes (2024), who used the concept of 'rendimento' to evaluate energy consumption by different types of transportation across various urban layouts. This approach is integrated into the results and discussion of new urban layouts in our research and will influence future stages.

How, what, why, and then?

How to design morphologically appropriate urban layouts and refrain from the usual laissez-faire process noticed in recent urban expansions? In a great number of cities, urban expansion is made with abstract urban layouts, contrasting with context and providing “discontinuous territories” and “contradictory landscapes” (Strappa, 2018: 11). They prioritize financial returns, leading to designs based on minimal effort and cost. These layouts often follow a common practice driven by arbitrariness, rather than context-specific criteria. As a result, many designs are two-dimensional and overlook natural and anthropic contexts, resulting in artificial and serial patterns rather than organic, contextually appropriate shapes.

The Italian school of type-morphology emphasizes the coherence of buildings, towns, and territories with their context, and offers potential solutions to the aforementioned problem. Central to this framework is the concept of ‘rendimento’ (or ‘yield’), initially developed by Gianfranco Caniggia. While this concept has been applied to buildings and territories (Caniggia, 1963; Caniggia and Maffei, 2008; Carlotti, 1995, 2012), it has not yet been adapted to the urban scale, nor does it offer explicit evaluation parameters or guidelines. However, we observed that certain cities with layouts more aligned to their context embody the principles of ‘rendimento.’

Thus, our hypothesis is that it is possible to use the concept of ‘rendimento’ as a guiding principle for the design of new urban areas. This can be done through guidelines and parameters extracted from layouts of new cities that are coherent with the context. In this way, we demonstrate that the ‘rendimento’ is applicable at the urban scale and provide an alternative to the laissez-faire process of design noticed in several urban expansions. Our main objective, then, is to provide a set of directives and strategies for the design of new urban areas based on the concept of ‘rendimento’. This objective aims to refine the process of design urban layouts, driving it away from a laissez-faire way of doing by presenting alternatives rather than proposing a completely new way of design.

METHOD

Our research is conducted as Design Science Research (DSR), aiming to refine the existing process of designing urban layouts (Peffers et al., 2008). This approach parallels the method proposed by McGlynn et al. (2024), where a ‘funnel’ model is used incorporating topography, land structure, legislation, and feasibility. At this stage, our focus is on the relationship between urban layout and topography, using the concept of ‘rendimento’ as a foundational basis.

The first part of this research involves an exploratory literature review based on works by Gianfranco Caniggia and Gian Luiggi Maffei (2008), and Paolo Carlotti (1995). We aim to investigate the application of the concept of ‘rendimento’ across different scales and explore its potential for the urban scale, including any existing evaluation parameters (Costa and Rego, 2019). In the second part, we analyse Maringá’s original urban layout using morphological analysis and literature review. We aim to understand its design in relation to topography and environmental factors, drawing on Raymond Unwin's (1909) manual and works by Caniggia and Maffei (2008), and Carlotti (1995). This helps us identify design variables in Maringá and explore their connection to the Italian concept of ‘rendimento,’ developing evaluation parameters. Finally, in the third part, we systematize the parameters developed from associating Maringá’s original layout with the concept of ‘rendimento’. These parameters are then applied to analyse Maringá's urban expansion and to design two hypothetical layouts. The first layout (Costa, 2020; Costa and Rego, 2021) uses ‘rendimento’

parameters to design a sample from a larger territory, considering only topography and comparing it with the current layout. The second layout (Alves et al., 2023) applies the 'rendimento' parameters incorporating pre-existing elements such as surrounding neighbourhoods, highways, and transmission lines.

RESULTS AND DISCUSSIONS

The term 'rendimento' first appeared in 'Lettura di una Città: Como' (Caniggia, 1963), linking it to concepts of organism and structure. It was further developed in 'Lettura dell'edilizia di base' (Caniggia and Maffei, 2008) and 'Per lo studio del processo di trasformazione del territorio romano' (Carlotti, 1995), generally referring to the efficiency of adaptation between the built environment and its context. Although the term has been associated with building and territory scales (Cataldi, 2015; Carlotti, 2012; De Martin, 2009; Rebecchini, 2008; Dalla Negra, 2015), it has not been explicitly linked to the urban scale and has been applied mainly to historical contexts in Italy. The term derives from the Italian verb 'rendere,' and its Latin root 'reddo,' meaning "to bring from one state to another" (Faria, 1962: 848-849). In type-morphology, it signifies transformation and coherence between the built artifact and its context, an idea introduced by Caniggia in 1963 and further clarified in 1979 by Caniggia and Maffei (2008).

Variants of the 'rendimento'

We can distinguish two understandings of 'rendimento'. First, the 'built rendimento' (Caniggia and Maffei, 2008; De Martin, 2009; Rebecchini, 2008; Cataldi, 2003), implicating the relation between a single building and the built environment in which it is inserted, i. e., the context. And second, the 'territorial rendimento' (Carlotti, 1995), which is associated with the idea of harnessing the territory and natural structures of an area according to their aptitudes and possibilities for human use.

In the context of building, 'rendimento' is "the dialectic between an anthropic action and an environmental reaction, constituted by the lesser or greater effort with which the environment will tend to reabsorb the result of that action" (Caniggia and Maffei, 2008: 52). Thus, 'anthropic action' can be related to 'intervention,' and 'anthropic environment' to 'context.' A higher 'rendimento' signifies that the intervention requires less effort from the environment to be absorbed and integrated, thus making it more "coherent with its context" (Rebecchini, 2008: 107). When building a house (intervention), it must fit seamlessly into its context, the urban block. Greater 'rendimento' is achieved when the new building aligns with the existing architectural 'style' without mere imitation, following the prevalent 'type' of the area (Caniggia and Maffei, 2008: 53; Strappa, 1995: 24). This means adapting to the common characteristics of the environment. 'Built rendimento' reflects the interdependence between new and existing structures. Thus, we can summarize 'rendimento', in general, as the "degree of coherence with the context" (Maffei, 2003: 82).

At the territorial scale, 'rendimento' refers to how suitable an area is for human activities like movement, agriculture, and housing (Carlotti, 1995: 19). It involves 'natural structure' and 'anthropic structure'. These two structures form the 'territory', i. e., the set of anthropic structures–pathways, productive areas, buildings, and urban centres–developed on the geomorphology of a natural area, such as ridges, valley floors, etc., which is bounded by relatively impassable natural limits (Caniggia, 1963: 12-13; Caniggia and Maffei, 2008: 209-216; Strappa, 2012, 1995). Therefore, 'territorial rendimento' refers to the utilization and adaptation of natural structures in the development of

anthropic structures within a territory. The higher the suitability of the terrain's geomorphology for these uses–in terms of slope and altitude, and its 'hierarchy' in geographic position–the greater its 'rendimento' (Carlotti, 1995: 17-18). For example, mountainous areas with steep slopes have lower 'rendimento' compared to gentler terrains like plateaus. While this concept is similar to McHarg's (1971) 'suitability,' Carlotti's idea is more aligned with Caniggia's view of anthropized territories. Thus, 'territorial rendimento' evaluates how well a territory's geomorphology and human structures interact, emphasizing the need to consider natural forms in territorial scale analysis or planning.

Urban rendimento

Cities are composed of pathways, open spaces, and buildings within specific territories that have their own natural hierarchy. Regarding from the conceptions of 'rendimento', we can state that human intervention, especially in urban design and planning, must ensure that the built environment (a comprehensive action) harmonizes with the natural context (the environment which receives it). 'Urban rendimento' recognizes this coherent relationship between the morphological elements of urban form and the characteristics of the site, particularly the relief. Thus, 'urban rendimento' can be defined as the "intrinsic coherence between the layout of the urban form and the natural context" (Costa and Rego, 2019: 7; Costa, 2020: 52). This 'intrinsic coherence' is the alignment of the urban layout with the site's natural relief and hierarchy. And it is achieved through 'organicity', with disparate parts that are well-integrated to perform a common function (Mora, 1962: 341; Strappa, 1995: 24). This can be seen by the aggregation of "elements defined by unique positions and forms," forming a cohesive whole (Caniggia and Maffei, 2008: 77). Therefore, a city demonstrates organicity when its elements—pathways, plots, buildings, and open spaces—are interdependent. This is more evident in spontaneous or informal urban fabrics (Caniggia and Maffei, 2008; Carlotti, 1995, 2012). Organic layouts are shaped by the relief and intersections of pathways, evident in ancient cities with spontaneous formation. The meeting of ridge lines, the confluence of valley floors, and the extension of interfluves structure and define these urban forms (Guerreiro, 2001). The greater the alignment of the urban layout with the site's natural relief and hierarchy, the higher its 'rendimento'.

A new planned town: the case of Maringá

With the concept of *rendimento* theoretically applied to the city scale, we then move on to the case study of Maringá, aiming to relate the requirements of *rendimento* to the qualities of the city's layout and, thereby, develop parameters for 'urban *rendimento*.' The original layout for the city of Maringá was designed between 1945 and 1947 by engineer Jorge de Macedo Vieira, who had previously worked with Barry Parker, a former partner of Raymond Unwin. It is possible to observe how this urban layout exhibits intrinsic coherence both in general and in detail, deriving from the natural morphology of the site (Figure 1).

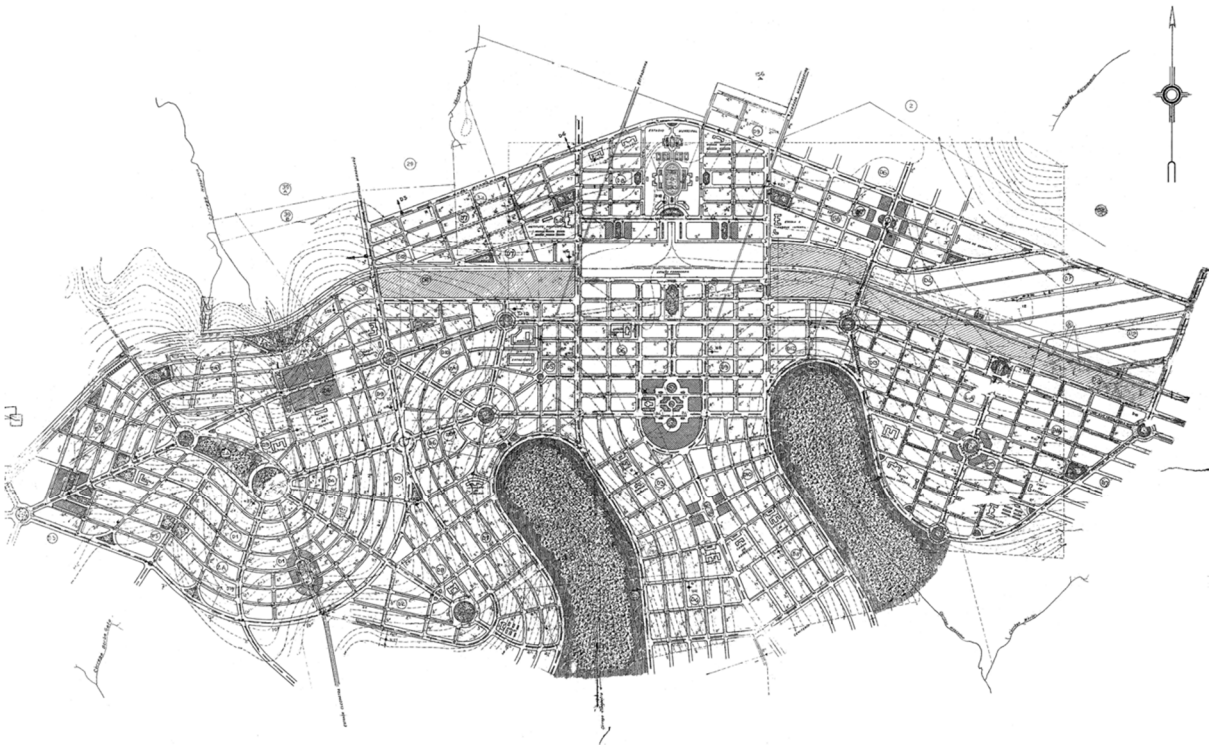

Figure 1. The original layout of Maringá, designed by Jorge de Macedo Vieira. Maringá, photo credit: Museu da Bacia do Paraná (edited by the authors).

Maringá's development began along a ridge that divides two basins to the north and south, creating a territorial crest. Secondary ridges structured the landscape, with small roads and narrow rural plots stretching from the rivers to the waterways (Beloto, 2015: 36; Meneguetti, 2007: 72; Waibel, 1949; Kohlhepp, 2015). A railway branch linked northern Paraná to São Paulo (Rego, 2009), and a train stop was established as part of a regional plan for cities spaced 15 km apart (Rego, 2001). The city was designed with a main civic centre connected to the railway, with secondary centres located on ridges or drainage lines to serve local communities. Neighbourhood layouts followed the terrain, with streets blending straight and curved lines for practicality and aesthetic appeal (Bonfato, 2008, 2003). A hierarchical layout emerged, with main avenues connected by roundabouts framing neighbourhoods and streets, preventing indiscriminate connections between them. Natural features like valley floors were integrated into the infrastructure, and deliberate street mismatches controlled traffic and defined zones. Collectively, these routes and articulations contributed to the city's organic character, reflecting the topography. Interfluves, plains, and valleys were highlighted in Vieira's design, demonstrating a design logic that integrates natural morphology with the layout of local streets in each neighbourhood.

Parameters and tests for rendimento

From the morphological analysis of the Maringá layout, five parameters for evaluating urban *rendimento* can be identified. First, **'coherence'**—the alignment of the urban layout and its elements with the site's relief and natural hierarchy. Second, **'organicity'**—the interdependence between elements of the urban layout. Third, **'hierarchization'**—the arrangement of urban elements and the subordination of some elements to others. Fourth, **'limitation'**—using urban elements to highlight

and integrate natural boundaries into the urban layout. Finally, **'continuity of routes'**—which clarifies the differentiation between neighbourhoods and their hierarchy through connected routes.

'Coherence' involves ensuring routes follow contour lines and avoid unnecessary earthworks. It also examines whether main routes align with ridgelines and whether centres and open spaces are located at key intersections of the relief, on relatively flat or gently sloping terrain, and well-connected to the broader area to support future growth. 'Organicity' refers that urban elements—routes, nodes, and poles—must work together and correspond to the site's pre-existing characteristics, ensuring coherence and mutual support within the layout. Important routes cannot lead nowhere, squares must not be placed randomly, and large facilities must consider their connection to the urban network. Using 'hierarchization' as a result of the coherence and organicity of the layout, we can examine how a central neighbourhood should have predominance over smaller ones. Similarly, routes, nodes, and poles such as avenues, squares, and centres should be emphasized based on their placement in the city, their interconnections, and the location of facilities like churches, theatres, galleries, markets, malls, and other publicly accessible spaces. 'Limitation' involves respecting natural site boundaries, such as steep valley slopes, and using urban elements like streets, avenues, or green spaces to highlight these boundaries. It distinguishes neighbourhoods without isolating them, as these boundaries can later serve as connections between areas or guide future expansions. The urban layout should have clear limits but avoid creating isolation. 'Continuity of routes' helps us understand how routes connect or separate neighbourhoods, showing how limitations and hierarchization are implemented. Interrupted streets meeting avenues prevent flow between neighbourhoods, maintaining separation and defining land use through morphology, not just regulations.

Vieira's layout exhibited both coherence and organicity. The hierarchization of the centres gave uniqueness to the neighbourhoods, while delimiting routes provided individuality and distinction to each one. Moreover, the continuity of the structuring and delimiting routes, as articulated in the Maringá's design, along with the fluidity of passage and the overall cohesion of the layout, reinforced the hierarchization and differentiation of the neighbourhoods. Thus, it is possible to say that the urban *rendimento* can be associated to a new planned town, such as Maringá.

By the other side, the current expansion layout features a complex network of streets and subdivisions that neglects the site's topography, creating steep slopes and lacking cohesive urban design. Potential centres and squares are reduced to planters, failing to occupy the most relevant topographic points. It lacks secondary centres that foster social gathering and connection with the main centre, offering only roundabouts for traffic flow—often at steep intersections where traffic lights would be more effective. Valley bottoms, once prominent in Vieira's design, are now largely occupied by blocks and lots, overshadowing their role as natural boundaries, distorting an orthogonal grid. As a result, this urban expansion exhibits minimal organic coherence and fails to align with the site's topography or the principles of original layout. The area is marked by offset streets, an absence of secondary centres, and poorly defined access points, resulting in a hierarchy focused solely on traffic rather than urban unity. Consequently, the expansion feels like a different city altogether, lacking the efficiency and character of the original layout. To assess the applicability of *rendimento* in evaluating and designing new urban layouts, two proposals for new urban areas are developed as extensions of the original Maringá design following the aforementioned parameters (Figure 2), as alternatives for the actual layout of the urban expansion. Both proposals are connected to avenues that were originally rural paths, more or less aligned with secondary ridges, but designed in a serial manner.

Figure 2. The original layout of Maringá (0), and the city's expansion with areas for the alternative layouts at south (1) and north (2). Maringá, photo credit: Prefeitura do Município de Maringá (edited by the authors).

Test 1

The layout for this area is designed to evaluate the applicability of urban *rendimento* parameters (Costa, 2020). It incorporates three key components: nodes, ridges, and valley bottoms. Routes, centres, and blocks were mapped across the area, and detailed block designs were developed in successive versions from a *tabula rasa* (Figure 3) from natural structure. In this design, the secondary ridge from Vieira's layout is repurposed as a structuring route for the new area, connecting to a primary secondary centre, which functions like a main centre for the interfluve.

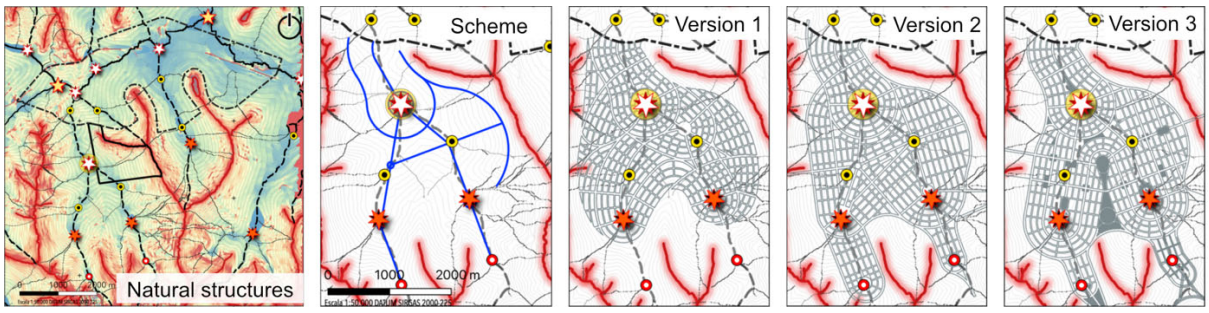

Figure 3. Different stages of design conception: from natural structure (left) to successive versions based on a main backbone of anthropic structures coherent with the site. Maringá, photo credit: Costa, 2020: 88-97.

Two avenues extend toward additional secondary centres, with all nodes interconnected by structuring routes along ridges and other avenues that link centres to the interfluve's outskirts. Streets were aligned with contour lines, keeping slopes under 8% and better stormwater management. By avoiding riverbeds and respecting valley bottom slopes, riparian forests are preserved (Figure 4).

Figure 4. The final version of first alternative layout. Maringá, photo credit: Costa, 2020: 101.

The resulting landscape resembles a terracing surrounded by green wedges, while maintaining the practicality of all neighbourhood streets connected to an inseparable network of avenues. Respect for the terrain and slope also causes the blocks to vary in size depending on their proximity to a centre, another promontory, or a boundary. Thus, the layout of this new urban area appears expandable and well-integrated with the surrounding territory.

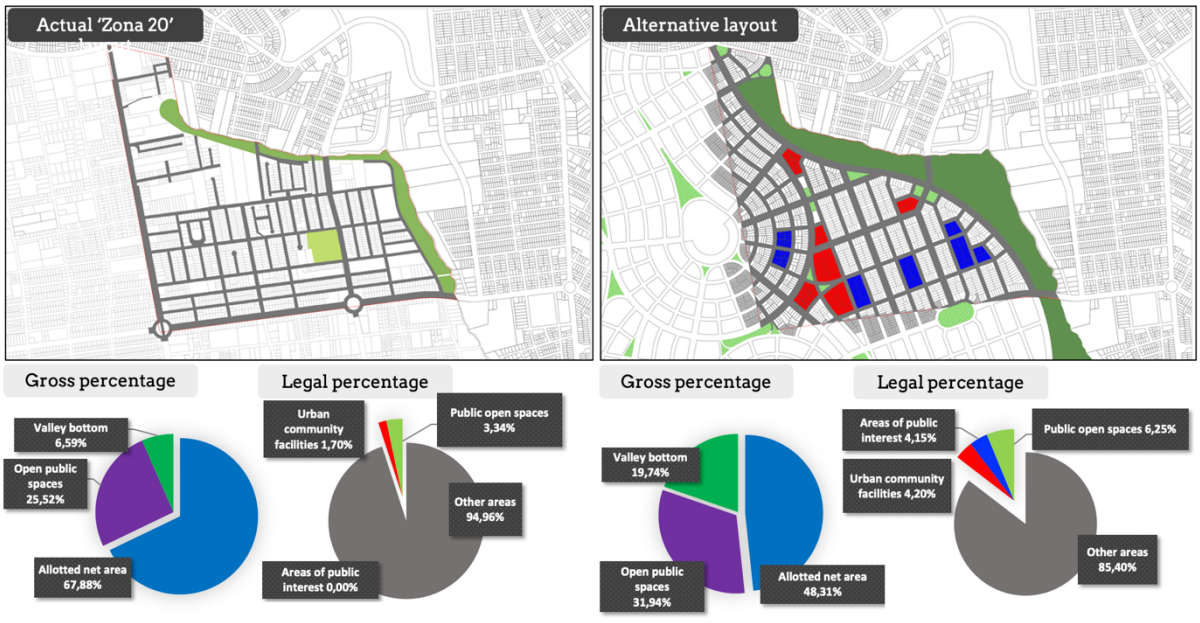

Figure 5. Comparison between layouts and percentages. Maringá, photo credit: Costa, 2020: 111.

Thanks to the forms and arrangement of the layout, the urban quality in the hypothetical design is significantly higher than in the current area. Moreover, these areas do not suffer from isolation due to steep slopes or the distance from open spaces. On the contrary, the configuration of layout elements, based on the parameters of urban *rendimento*, brings these areas closer to meeting legal requirements for higher urban quality (Figure 5).

Test 2

Instead of considering only natural structure, this layout incorporates existing elements such as surrounding neighbourhoods, highways, and transmission lines (Alves *et al.*, 2023). Therefore, pre-existences which defined urban form are considered in this challenge. Nodes, ridges, and valley bottoms were taken into account, and routes, centres, and blocks were mapped across the area with a focus on a walkability to ensure pedestrian accessibility, and sustainability (Figure 6).

Figure 6. Studies of the evolution of layout. Maringá, photo credit: Alves et al., 2023; the authors.

Since the area is surrounded by other neighbourhoods, special attention was given to connections to promote fluidity between different parts of the city. A highway passing through the north bounded the layout, and a green area was created to isolate it from noise and pollution (Figure 7).

Figure 7. Studies of the evolution of layout. Maringá, photo credit: Alves et al., 2023; the authors.

Because of the transmission lines, two of the main avenues go straight into the layout and were taken into consideration. After accounting for anthropic pre-existences, which defined the current area, the natural structure was considered for designing the layout. First, the ridge of interfluve was marked with the nodes of derivation to secondary ridges. Since the designed area lacked a natural node, an intermediary node was established between the two nodes at north and south of the site, creating a central point. Walkability radii of 800m and 400m were established from the pre-existing intersections of avenues, and their convergence near the central point formed the main centre of the area, located along the pre-existing avenue on the main ridge. The overall layout was designed as a web, radiating from the centre and the avenues branching from it, featuring smooth slopes and open spaces within the layout. Additionally, the new design includes slightly more plots than the current situation.

A verdict

The evaluation of these two hypothetical layouts, designed based on the 'urban *rendimento'* concept, suggests that this approach can be effectively adopted in the design of new urban areas. Moreover, urban layouts designed with the '*rendimento'* concept foster better interaction with nature, enhancing the interchange between urban forms and surrounding environment. The application of *rendimento* parameters indicates the potential for better stormwater management within river basins, improved socio-environmental and economic sustainability, and landscape enhancement, as the design aligns with natural site features, resulting in an organic layout. Legal aspects and feasibility are also considered in the design process, including the impact of previous land parceling, and these aspects must now be tested. Additionally, *rendimento* parameters can be applied by professionals and students, leading to accountable and reliable outcomes. In this way, we can design morphologically appropriate urban layouts, moving away from the *laissez-faire* approach often observed in recent urban expansions.

CONCLUSIONS

Presented with the real and hypothetical fabrics of a certain urban area, this work asserts that it is possible to evaluate the rendimento of an urban layout through parameters such as coherence, organicity, hierarchization, limitation, and continuity of urban layout elements. These parameters can serve to assess new urban areas, both as benchmarks for urban design and for evaluating existing areas. As qualitative parameters, all of them are interdependent. Moreover, by using these parameters in the design of new urban layouts, one can structure a series of steps for evaluation, particularly for designing with appropriate urban rendimento.

First, it is necessary to (I) analyse the pre-existing structures, namely, natural structures, anthropogenic structures, and, in addition, the morphological-cultural characteristics of the territory. Next, one can proceed to (II) plan the new urban areas to be developed on that site. This involves defining routes, nodes, and structuring, delimiting, and local elements; selecting possible connecting routes within this network; defining the potential urban nodes of neighbourhoods and local nodes, which will be responsible for the uniqueness of the city's sub-organisms. Finally, one can (III) design the streets, squares, and key buildings.

By using the characteristics of the terrain and the principle of organicity as a starting point in the design, it is possible to reduce costs, mitigate environmental damage, and address socio-economic issues. Furthermore, incorporating rendimento parameters into the design can ensure higher urban

quality, fostering a stronger identification of residents with the city and the territory to which they belong, due to the individuality created by the correspondence between layout and terrain. This creates new possibilities for establishing a more productive relationship between humans and the existing material reality.

ABSTRACT

As urban morphology delves into the form and structure of cities, our study investigates the phenomenon of studentification as a pivotal aspect of Viçosa's (Minas Gerais, Brazil) evolving urban landscape. Over three decades, the city has experienced notable changes, with our focus centred on the central area, where the presence of students significantly impacts urban dynamics. Employing a multidisciplinary approach, we scrutinize shifts in land use patterns, categorize activities, and analyse historical as well as contemporary photographs of streets. Studentification, a concept encompassing the transformation of neighbourhoods due to a surge in student population, manifests prominently in Viçosa. This phenomenon is not only driven by the influx of students but also by the influence of the real estate market and construction industry in producing new apartment buildings catering to this demographic. We observe modifications in building configurations, notably an increase in vertical and mixed-use structures, largely driven by the demand for student accommodation. Moreover, there is a discernible transformation in commercial establishments, marked by the proliferation of restaurants, cafés, bars, bakeries, and real estate agencies catering to the student population; also, the reshape of some street designs can be identified as structural modifications. In Viçosa, studentification is concentrated around the main entrance of the Federal University of Viçosa, characterized by intense commercial and nightlife scenes, alongside a surge in apartment complexes and growth in building heights. Ultimately, our research underscores the profound influence of student presence on urban morphology, shaped not only by demographic shifts but also by market forces driving the construction of student-oriented housing. This dynamic interaction between students, the real estate market, and the construction industry significantly impacts the city's form and function, shaping its form and future trajectory.

Keywords: urban morphology, studentification, university city

INTRODUCTION

By examining the form and structure of cities, urban morphology provides a comprehensive overview of the processes that shape the urban fabric. In this context, the phenomenon of studentification has emerged as a significant and relevant issue, with notable impacts on the urban landscape of numerous cities across the globe. This study aims to analyse the process of studentification in Viçosa (MG), a university city located in the state of Minas Gerais, in the south-eastern region of Brazil (Figure 1), with a particular focus on the impacts of this process on changes in urban form.

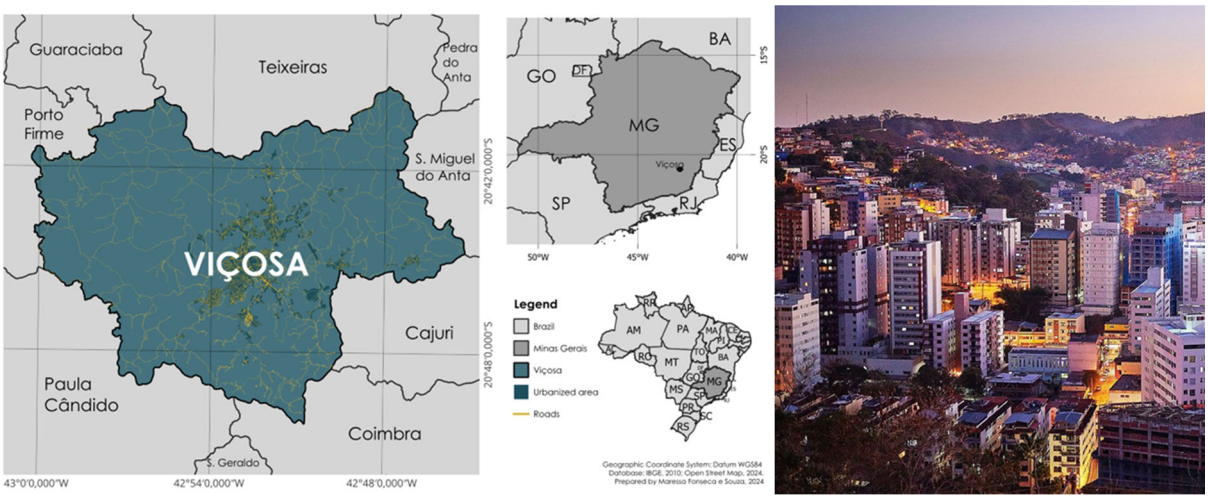

Figure 1. Viçosa'a location in Brazil. Data source: Authors and G1 News Portal, 2024.

Universities significantly impact their host towns in various ways, and morphologically, their extensive landholdings reshape the urban landscape (Larkham, 2000). Previous literature has demonstrated that university campuses and their functional and physical connections to urban environments yield a range of after-effects (Mohammed et al., 2021). Research trends have predominantly concentrated on the social or economic dimensions of this issue. However, the factors influencing the physical relationship between campuses and cities have been only moderately addressed in prior studies. We also located studies congruent to our area and theme of interest, but the literature focuses on historical, economic and political aspects of Viçosa's development, yet lacks spatial analyses.

The research is significant in that the process of studentification, as an urban transformation, has become a topic of increasing academic interest, particularly in countries of the Global North. As Chatterton (2010) notes, neoliberal educational policies, characterised by the outsourcing of activities and the reduction of student benefits, such as on-campus housing, have prompted a search for accommodation in the private sector, intensifying the process of studentification in various cities. The academic literature on studentification in Brazil remains limited, as does the research on this phenomenon in Latin American cities. Nakazawa (2017) highlights the necessity to expand the scope of studies on studentification, encompassing the examination of less investigated contexts, such as university cities in the Global South.

This study aims to address this gap in the literature by investigating the process of studentification in Viçosa (MG) and its impact on the city's urban form. The research focuses on the central area of Viçosa, where the presence of students has a significant influence on urban dynamics. The proximity to the campus of the Federal University of Viçosa (UFV) drives the demand for housing and services, creating a distinctive urban space shaped by the needs and habits of the academic community.

Hence, this study aims to investigate the impact of the evolving phenomenon of studentification in Viçosa (MG) and to contribute to the physical characterization of the phenomenon in city's urban morphology and urban dynamics. In particular, it seeks to elucidate how the demand for housing and specific services associated with the student population has influenced changes in building patterns and configurations of public spaces in the city. The research is based on an analysis of historical and

contemporary data, including maps, aerial photographs, real estate records and field observations, with the objective of providing a comprehensive overview of the urban transformations resulting from studentification.

This article is structured as follows: initially, a review of the literature on studentification is presented, contextualising the topic and highlighting its relevance to the study of urban form. It then describes the methodology used and the research results. Finally, the main findings of the research, their implications for urban planning in Viçosa and the prospects for future research are discussed.

Studentification and urban dynamics

Studentification has often been analysed as a form of gentrification (Smith, 2002), an urban phenomenon that describes the socio-cultural, economic and physical changes resulting from the influx of students into certain neighbourhoods. The link lies in the fact that the concentration of students in certain areas can trigger a process of urban transformation that resembles the patterns observed in gentrification processes. One of the main points of convergence between studentification and gentrification is the impact on the housing market. Increased student demand for housing, particularly rental housing, can drive up property values and rents, affecting the affordability of housing for the resident population and potentially leading to the displacement of former residents. This process is like that observed in cases of gentrification, where the arrival of new residents with greater purchasing power puts pressure on the property market, increasing housing costs and displacing traditional residents.

Sociocultural change is also a point of intersection between studentification and gentrification. The arrival of students in a neighbourhood can change the social and cultural dynamics, introducing new consumption habits, lifestyles and behaviours. This change can lead to conflicts between new and old residents, as well as tensions over the identity and character of the neighbourhood. Changing the socio-cultural profile of the neighbourhood is a central element of gentrification processes, with the arrival of new social groups imposing their values and customs, changing the local culture and potentially marginalising the old residents (Hubbard, 2009).

However, it is important to stress that the relationship between studentification and gentrification is neither clear nor linear. Gentrification can have positive aspects, such as the revitalisation of urban areas and the creation of new leisure and entertainment spaces that contribute to the economic and social dynamism of the neighbourhood (He, 2015; Kinton, Smith, Harrison and Culora, 2018; Prada, 2019). Moreover, the intensity and impact of studentification varies according to the local context, the public policies implemented and the specific characteristics of the student population and traditional residents.

In conclusion, studentification can be understood as a complex process, similar in some respects to gentrification, but with its own specificities. Analysing the case of Viçosa shows how the concentration of students in an urban area can affect the real estate market, socio-cultural dynamics and urban morphology, creating both challenges and opportunities for the city. Understanding the nuances of studentification is fundamental to formulating public policies that promote sustainable and inclusive urban development, reconciling the interests of the different social groups that inhabit the urban space.

METHOD

This study aims to comprehensively analyse the urban characteristics of the studentification phenomenon in Viçosa (MG). As Yin (2013) defines the case study method as an approach to a phenomenon in its reality, we employed exploratory research with a multidisciplinary method that integrated both quantitative and qualitative methods.

In order to evaluate the impact of studentification in Viçosa (MG), this study employed a methodological approach that integrated the examination of historical and contemporary data with field observations, aiming to construct a comprehensive understanding of the influence of this phenomenon on urban form. The data was gathered through bibliographic and documentary research, which included the collection of historical photographic records, satellite images, real estate records and the city's urban planning legislation.

A series of field visits were conducted with the objective of recording the physical characteristics of the urban environment, including the typology of buildings, land use patterns, and the presence of public spaces. Photographic records, including those of a sequential nature of the streets, were employed for the purpose of documenting the urban landscape and the various land uses. The data was then subjected to analysis through the systematic organisation of historical events, resulting in the creation of a timeline delineating the principal occurrences that have shaped the urban development of the study area in Viçosa, with particular emphasis on the expansion of UFV and the alterations to its student assistance policy. The urban area was mapped using a series of thematic maps which illustrate the evolution of the urban form over time. The maps include a variety of information, including details on the road network, the location and footprint of buildings, the height of buildings, the type and extent of land use, the presence of commercial establishments, and the availability of nightlife. The principal diagrams produced during the research are presented in Table 1, together with details of the sources and types of data employed in their construction.

Table 1. Summary of the diagrams drawn up for the research and their data sources

Diagrams	Data type	Data source
Figure-form	Street network over time (natural landscape, 1971, 2002 and 2023)	Google Earth imagery and Historical photography
Constructions	Buildings over time (1971, 2002, 2011 and 2023)	Google Earth imagery and Historical photography
Footprint map	Building footprint shapes over time (2002, 2011 and 2023)	Google maps imagery
Building height	Building height by number of floors	Google street view imagery; sequential street photography
Land use	Land use by type (empty lot, institutional, residential, commercial, mixed use or open space)	Sequential street photography
Commercial use	Types of commercial use at street level	Sequential street photography
Nightlife	Commercial use with night hours (open at 8:30pm-9pm)	Night street photography

The software employed for the processing and analysis of the data was Google Earth, which was used to obtain satellite images, historical maps and information on the road network, location of buildings

and land uses. Google Street View was also utilised to obtain panoramic images of the streets and to analyse the urban landscape and the different land uses. AutoCAD was employed for the drawing of the maps. The data was then organised into spreadsheets and databases.

Study area

Our study area is located within the adjacent block nearest to the main entrance to the Federal University of Viçosa (UFV) campus. The area is described as a center within the city as it ties the city's downtown commercial area to the campus (Figure 2).

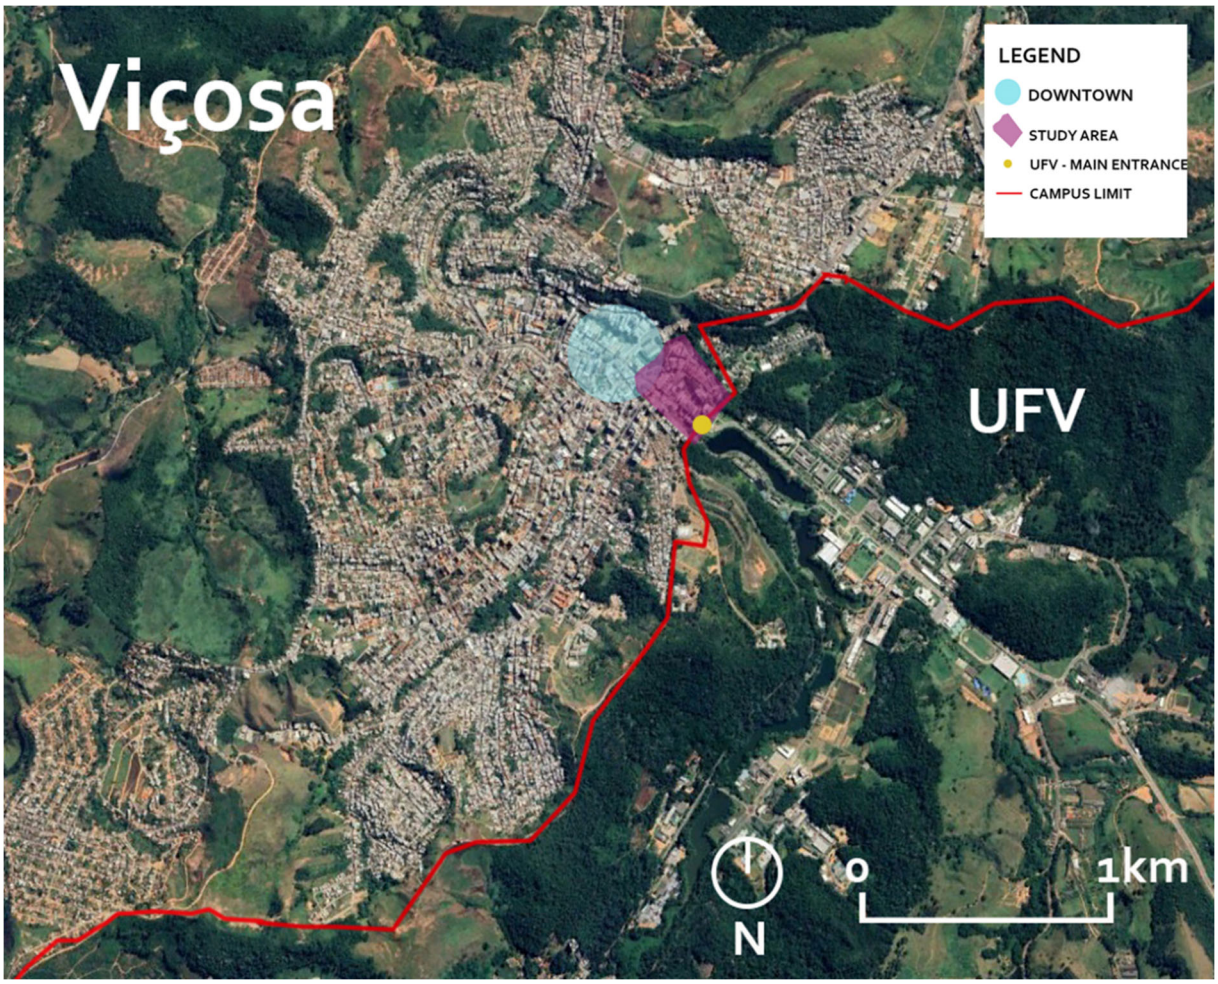

Figure 2. Data source: Google Earth with marks and highlights by authors.

RESULTS AND DISCUSSIONS

The analysis of the data collected revealed a series of significant transformations in the urban form of the study area over the last few decades. These transformations illustrate the influence of the influx of students on the city's dynamics. These changes are particularly evident in the morphology of buildings, land use, and the commercial dynamics of the area.

University campuses are associated with physical and functional alterations in their surrounding environments (Mohammed et al., 2022). As streets play an integral role in defining the overall character and functionality of urban environments (Dover et al., 2014), we have depicted the streets and paths of Viçosa over time (Figure 3).

Figure 3. Roadways and Blocks Over Time (natural environment, 1971, 2002 and 2023), credit: Authors, 2024

The maps illustrate the presence of the São Bartolomeu River, which serves as a significant morphological factor. This is not merely because rivers are a vital source of sustenance and growth; rather, it is also because Viçosa is characterised by a topography comprising numerous hills and steep inclines. Consequently, the river represents a relatively flat zone within the city. As the maps are examined in sequence, it becomes evident that the urban fabric becomes increasingly complex over time. In 1971, the presence of the railway, the Estrada de Ferro Leopoldina, is highlighted. This railway arrived in Viçosa in 1914 (CARVALHO, 2014) and was the first catalyst for the city's urbanization. In 2002, numerous new streets were constructed, with particular attention paid to the BR-120 roadway, which was opened in 1973 and connects Viçosa to major points across the country (COELHO, 2020). The old train tracks were covered, transforming Estudantes Street into a consolidated roadway. The railway was controversially paved in 2010. Finally, we present the current street configuration of Viçosa, which includes the opening of a new L-shaped street providing access to the river valley. This street has experienced significant urbanization since its opening in the 2020s.

By superimposing these maps, it is possible to trace the expansion of the city's roadways, emphasizing the significant alterations in infrastructure and spatial organization that have accompanied the growth of the student population. In addition to illustrating the construction of new roadways, the maps also document the subdivision of blocks, which exhibits irregular characteristics regarding both street length and street width. From this analysis, it can be concluded that Viçosa has developed new streets in the area, resulting in a high level of complexity and accessibility to all parcels of land.

To gain insight into the process of constructing buildings over time, we employed a visual sequencing method in addition to manually tracing building footprints. This allowed us to once again visualize the progression of the spatial occupation (Figure 4). The sequencing revealed a notable increase in the number of buildings, particularly in areas proximate to the university, reflecting an escalating demand for student housing. By means of a systematic tracking of these transformations, the maps provide a comprehensive view of how urban space has adapted in response to demographic pressures and market forces driven by the expanding student population. This offers valuable insights into the city's urban dynamics over time.

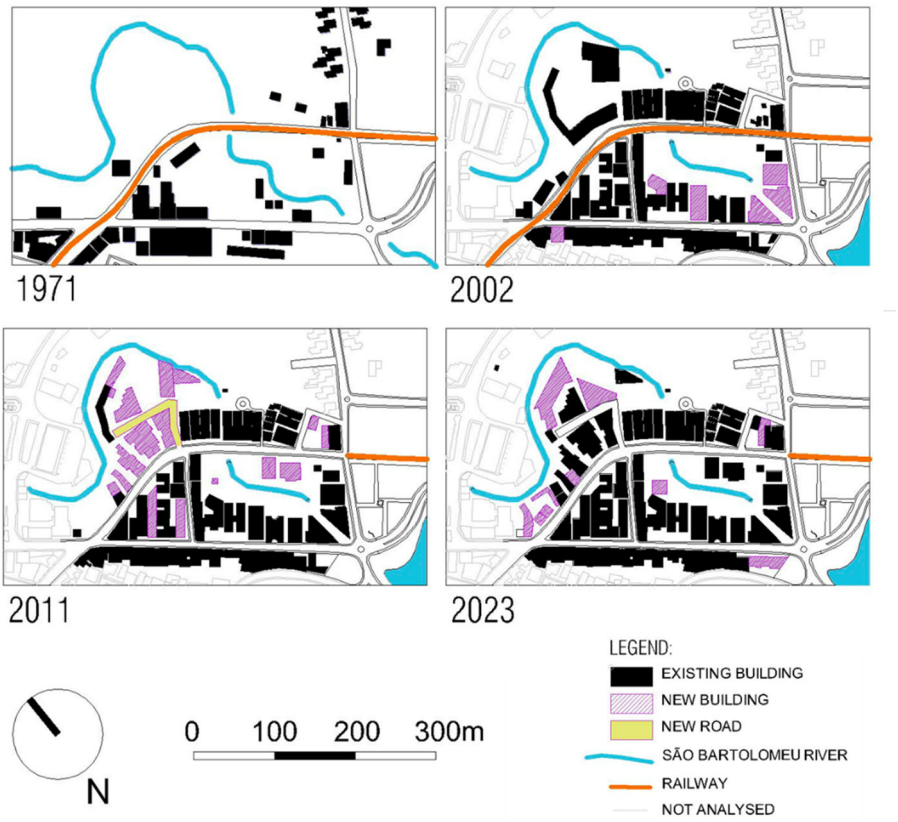

Figure 4. Building construction over time (2002, 2011, and 2023), credit: Authors, 2024

The federalization of UFV occurred in 1969, and in the subsequent years, the institution witnessed a notable expansion in the number of courses offered. By 1974, the institution had expanded its academic offerings to encompass 19 undergraduate and graduate programs. In 1975, the number of programs increased to 39 (MELO, 2021). Concurrently, in 1974, the university modified its student housing policy, effectively halting the construction of new student dormitories. Figure 4 thus lends further support to the notion that a housing shortage was already evident by the late 1970s and subsequently resurfaced in the late 2000s. This is evidenced by the fact that in 2008, with the introduction of the Program to Support Restructuring and Expansion Plans of Federal Universities (REUNI), UFV once again expanded its undergraduate and graduate course offerings significantly.

An analysis of the evolution of the built environment revealed notable changes in the form of the buildings' footprints (Figure 5). Pereira (2010) posits that architectural form is not merely a physical entity; it is also a signifier that conveys meaning. As an instrument of architectural translation, this sign serves to combine a concept with the image that represents and shapes it. An analysis of the architectural forms of new buildings revealed a clear tendency to adapt to the subdivision of land, occupying the available space to its fullest extent. Such edifices are frequently situated on residual plots of land whose shapes are irregular. This results in an architectural style that is shaped by the limitations and irregularities of the land. This may be a significant characteristic of the studentification phenomenon, as builders are so invested in a specific location that they are willing to compromise plan designs to fit their real estate in unconventional spaces.

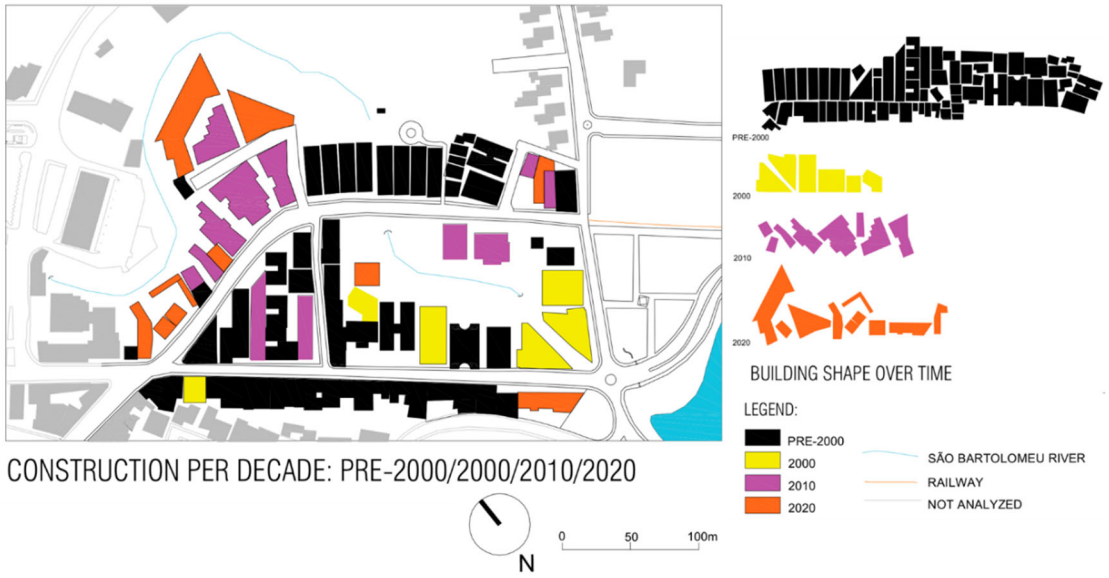

Figure 5. Building footprint over time (2002, 2011, and 2023), credit: Authors, 2024

The analysis of the building footprint reveals a notable intensification of plot occupation, with the construction of buildings of varying shapes and sizes, designed with the objective of optimizing spatial utilization. In response to the growing demand for student housing, real estate developers are modifying their projects to accommodate the available space, resulting in a diverse range of building shapes and sizes. Moreover, the height of the buildings has increased significantly, particularly since 2002, with the construction of buildings exceeding 10 storeys in height. This exploitation of the building potential of the plots is in accordance with the current urban policy. This verticalization of the area is indicative of the high demand for housing in proximity to the university campus and the pursuit of enhanced profitability by real estate investors.

Figure 6. Building heights, credit: Authors, 2024

Figure 5 thus offers a more profound comprehension of the ways in which the pressures of studentification and market demands have not only led to an increase in the number of buildings but also to significant alterations in their physical form. By mapping these changes, we can identify patterns in the way urban space has been optimized for student accommodation, resulting in more compact, higher-density developments.

The analysis of land use revealed a preponderance of mixed-use and commercial edifices in the study area, particularly following 2002 (Figure 7). This shift in land use reflects the growing demand from the student population for services and commercial establishments that offer convenience and proximity to the university campus. The concentration of real estate agents in the area also serves to illustrate the significance of location in the search for real estate, particularly in catering to the transient student population. Moreover, the research revealed a paucity of green spaces within the study area, with the exception of the UFV campus. The lack of recreational spaces and opportunities for public interaction may have a deleterious effect on the quality of life of the local population, particularly the student residents.

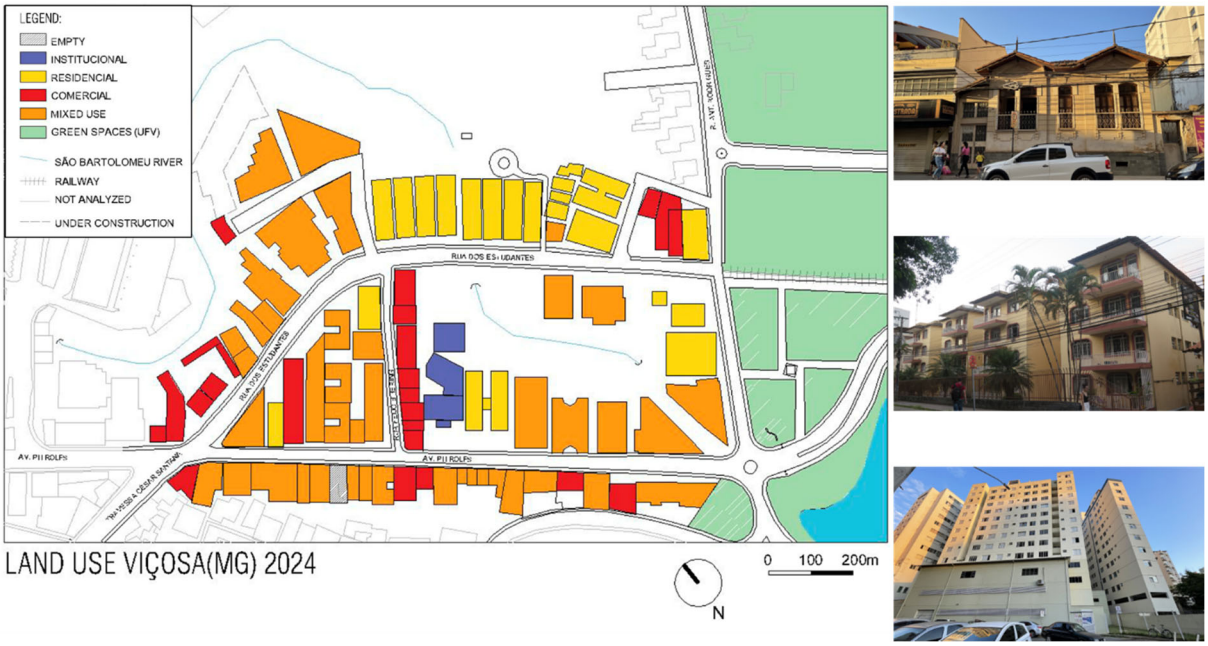

Figure 7. Land use patterns by type (empty plots, residential, commercial, mixed-use, and recreational green areas), credit: Authors, 2024

A comprehensive analysis of the commercial activities within the area revealed a diverse range of services catering to the student population, including restaurants, snack bars, and bars. The presence of gyms and nighttime services, such as markets and laundrettes, also illustrates the adaptation of local commerce to the needs of the academic community. The area's nightlife is notably vibrant, with numerous commercial establishments remaining open until late at night, catering to the student population's demand for leisure and entertainment (see Figures 8 and 9).

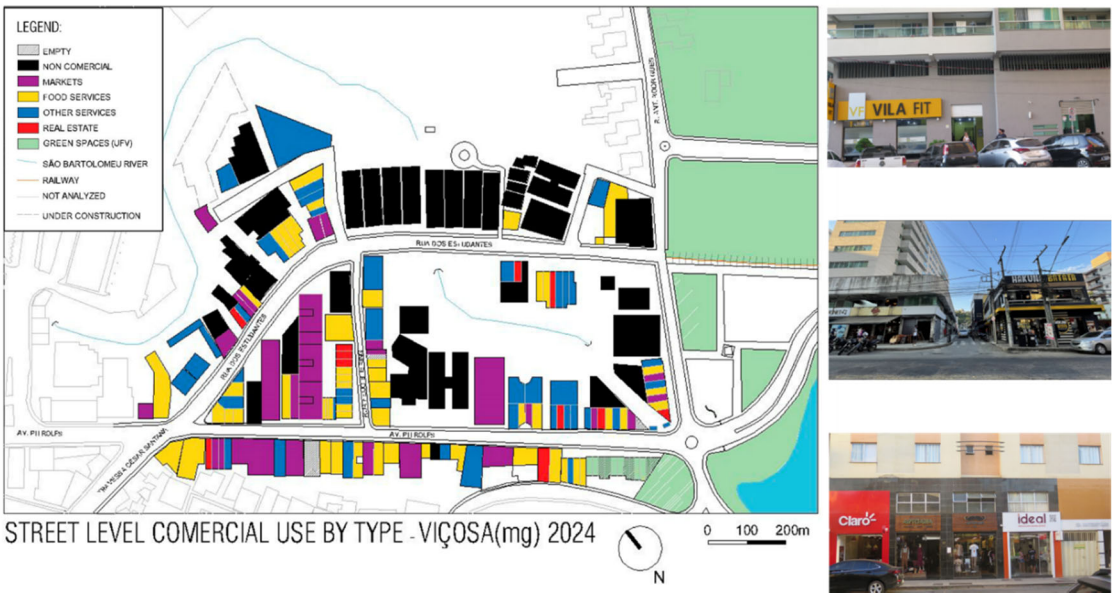

Figure 8. Commercial use by type (food services, general services, real estate agencies, and markets), credit: Authors, 2024

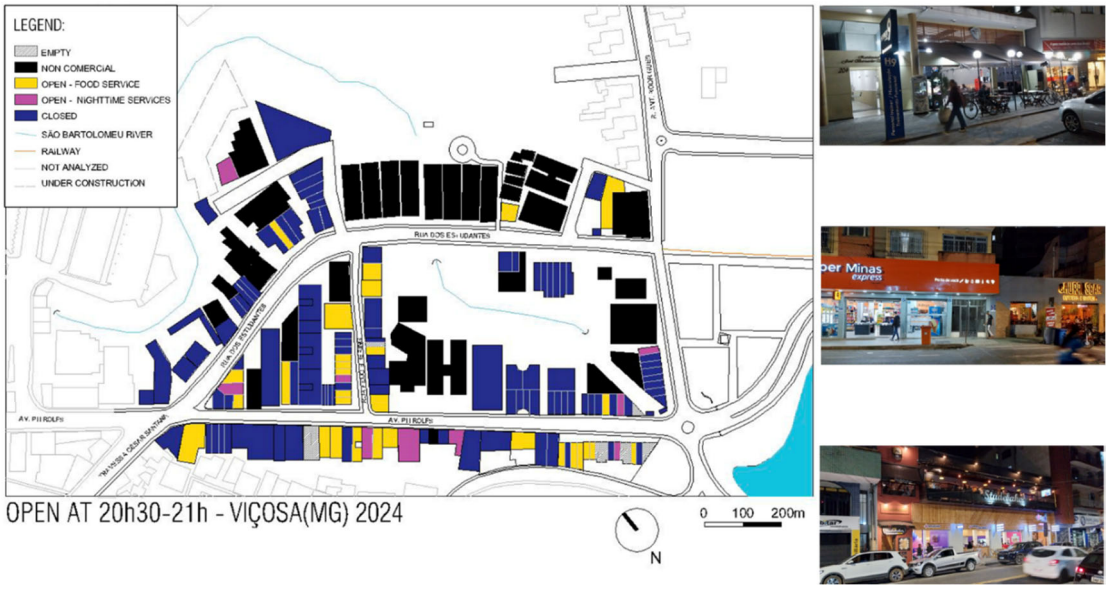

Figure 9. Nightlife - Commercial use by type, credit: Authors, 2024

The findings of this research are in alignment with those of previous studies on the impact of studentification on the urban form of university cities. As demonstrated by the research of authors such as Hubbard (2009) and Sage (2013), the intensification of the real estate market and shifts in socio-cultural dynamics are defining characteristics of studentification. The research demonstrated that Viçosa's central area has undergone a significant transformation, becoming predominantly commercial and mixed-use, characterized by high building density and verticalization. This has been driven by the necessity to satisfy the requirements of the student population.

It is essential to recognize the constraints of the research methodology. It is important to note that the study area was limited to a single block in close proximity to the UFV campus. This may not fully represent the totality of the dynamics of studentification in Viçosa. Moreover, the research was based on secondary data and field observations, which may have constrained the extent of the analysis. The

absence of information regarding the specific GIS software utilized and the unavailability of the computer code employed in the research also impedes the replicability of the study.

CONCLUSIONS

This study examined the impact of studentification on the urban form of Viçosa (MG), with a particular focus on a block situated near the UFV campus. The results demonstrate that the establishment of the university and the subsequent increase in the student population have precipitated substantial alterations in the area, including the intensification of the real estate market, the verticalization of buildings, the predominance of commercial and mixed-use developments, and the absence of green spaces. These findings align with those of previous studies on the effects of studentification in university towns, including the intensification of land occupation and changes in socio-cultural dynamics.

The research underscores the necessity for urban planning that is attuned to the ramifications of studentification, particularly with respect to the allocation of green spaces and public leisure areas, which were identified as inadequate in the study area. The incorporation of green areas into new developments and the implementation of land use policies that guarantee the provision of quality public spaces are essential measures to mitigate the negative impacts of studentification on the local population's quality of life.

It is important to note that the research is not without limitations. These include the delimitation of the study area to a single block and the reliance on secondary data and field observations. Further research could extend the geographical scope of the study to encompass other areas of the city affected by studentification. Additionally, the incorporation of qualitative methods, such as interviews with residents, students and local business owners, would facilitate a more nuanced understanding of the social and economic impacts of this phenomenon. An investigation into urban planning strategies and public policies that foster more balanced and inclusive urban development in university towns would also be a valuable avenue for future research.

Acknowledgements

The authors would like to express their gratitude to the Folha da Mata editor for facilitating access to the newspaper for the purpose of conducting historical and photographic research. Additionally, the authors would like to acknowledge the contributions of the anonymous reviewers and the managing editor of ISUF for their time and efforts in reviewing the abstract that was submitted. A special acknowledgment is due to Pedro Paulo Valente for providing the photographs captured at night. This research is independent and conducted by the authors without institutional support. Nevertheless, the authors extend their gratitude to their friends and family for their encouragement.

Mapping urban change using generative diagram

Rossella Gugliotta[1]
[1] Transitional morphology, Department of Architecture and Design (DAD), Architecture, Polytechnic University of Turin, Italy, rossella.gugliotta@polito.it

ABSTRACT

Looking at critics of the Italian typological approach on urban morphology, we can identify new realities within which the concept of type develops and changes over time. In parametric architecture, the idea of type is replaced by the more dynamic concept of genotype, in which information is interconnected, linking functions, forms, and data. The generative approach in design, which views the genotype as the primary constituent, does not envisage a single outcome but a multiplicity of solutions to counteract the global environmental changes linked to the city environment. This implies that even the approach to morphological analysis with typological declination must be developed in the new design direction. Diagrams, as a tool to comprehend the city, do not explain the urban environment as a simple object but as an object understood through complexity, as Morin states. While in the past, it was sufficient to analyse a few factors in urban analysis, the city's shape is now enriched with a data substrate that can be expressed through generative design tools. In this sense, this contribution delves into a deep understanding of the representation tool, transforming the significant approach of the Italian morphological school (analysing the work of Saverio Muratori, Gianfranco Caniggia and Augusto Cavallari-Murat) into a more diagrammatical one, beneficial for the computational design approach. In conclusion, interpreting the city as a logical system through the diagram has led to the development of a new approach to the analysis of the city, which can be valuable for a generative design approach and for addressing the changes in the urban environment.

Keywords: tool, Italian studies, diagram, generative design, reading contemporary urban change

CHANGING THEORETICAL ATTITUDE

The concept of type has historically played a central role in architectural theory, particularly in the Italian context, where the cultural debate on the historical city centre brought to the development of an Italian typological approach to urban morphology. This widely discussed approach emphasizes the concept of type as a classificatory system for urban forms based on recognizable, enduring characteristics, called permanences. However, other characteristics of this typological approach are helpful in the design of the city landscape. The building type in this context interests us more for the ideas that can be extracted from it through which it is possible to decode the mechanics and formation process of its specific characters, the expression of a specific cultural area and natural environment, rather than for the classification of its physical characters (Chiappi & Villa, 1982). The social reality

defining the spatio-temporal context of urban form affects its study and the language used to describe it. Current literature underestimates this aspect, favouring the historical foundation of the object of investigation instead (Marzot, 2021). However, evolving realities in urban design and architecture are shifting this perspective, leading to a better understanding of changing dynamics in the built environment and, so, progress in visualizing the city. In this sense, highlighting the crisis contemporary cities are undergoing leads to reevaluating the concept of the type as manner of reinterpretation of urban dynamicity.

Previously, the architectural type was the conceptual output of a relatively small number of indications, almost exclusively formal, referring to distribution rules and predefined codes. However, today, the concept of genotype, a more complex set of genetic information, has appeared. Together with the "parameters" linking the function, form, and other information that we commonly call data, this concept drives design using a parametric approach. The genotype stands for an adaptable framework that organizes information by linking functions, forms, and data in response to complex urban needs (Ventura, 2015). This shift from a traditional to a more adaptable and data-driven approach is a significant development in contemporary design. As environmental challenges increasingly affect urban spaces, the genotype appears as a versatile concept, capable of producing multiple solutions. Unlike the traditional approach that views the city as a fixed entity system, the genotype's adaptability encourages a rethinking of morphological analysis within a contemporary design context. This shift towards a generative approach in design, using the genotype concept, offers a reassuring potential to adapt to contemporary technology and address urban challenges.

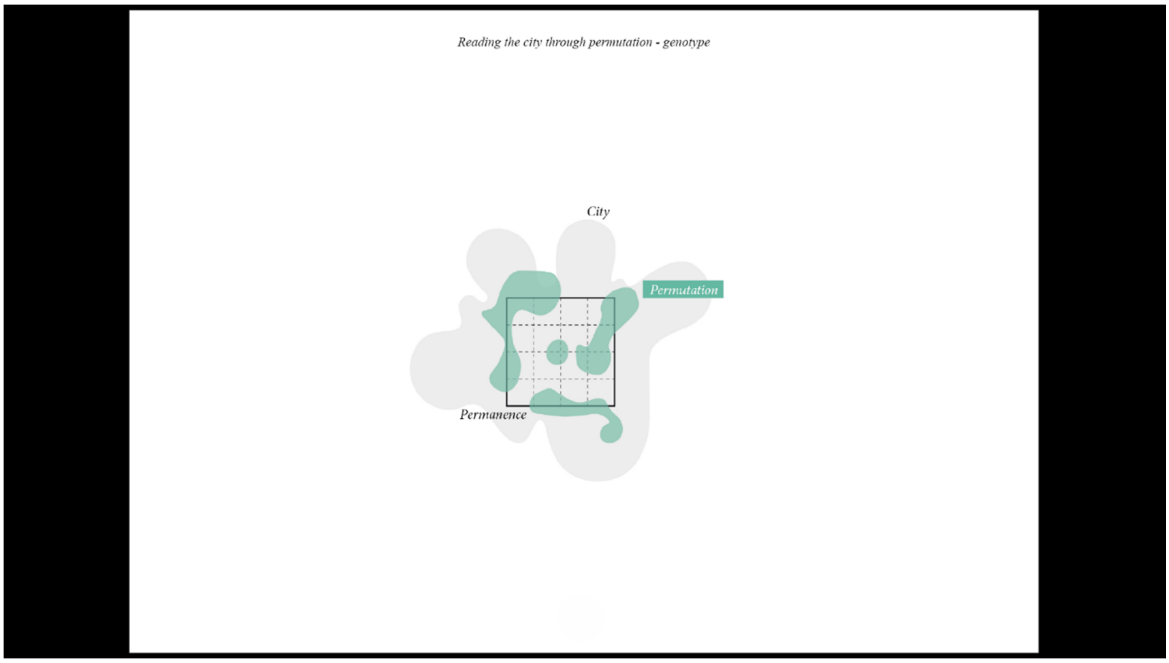

Figure 1. Changing the attitude towards space. From a city made of permanence to a city made of permutation. Photo credit: Author 2024.

This study revisits the Italian morphological approach, with a particular focus on the contributions of Saverio Muratori, Gianfranco Caniggia, and Augusto Cavallari-Murat. The aim is to reframe their typological approach through a diagrammatic lens that supports computational design methodologies. By doing so, the contribution aims to show how experiments with visual techniques

respond to the need to reconnect the issue of design with a changing theoretical attitude towards space. It can show a change in how the space is conceptualized and constructed.

FROM TYPE TO GENOTYPE

Currently, the city's science is intent on discovering how processes of different natures generate form and function by defining it as a non-linear system of actions and reactions (Marshall, 2009; Alexander, 1973). Architectural form and urban form are not only the result of a creative process but can contribute to setting up, fixing or transforming cultural foundations and social environments, producing spaces, times and vehicles of transmission (Kiss & Kretz, 2021). A theory of the city that does not consider dynamics can do little more than provide a descriptive explanation of how various economic and social forces can resolve themselves in sufficient time. Morphological analysis, which is one of the most important approaches in the study of the city, highlights how no amorphous zones exist, or where they do exist, they are found at moments in the process of transformation (Rossi, 1966).

Historically, the typological approach was grounded in key theoretical contributions that shaped different schools of thought. Argan (1956) conceptualised and marked the attention on the analogy between objects in terms of formal and functional criteria. Aldo Rossi (1966) viewed the essence of architecture as a union of tectonic, function, and stylistic elements. These contributions led to understanding type as a useful classificatory tool governed by distinct and precise rules to analyse the urban form. For Saverio Muratori (1959), the concept of type shifts from a recognition of similarity helpful for the classification to the definition of type as "a priori synthesis" lies in the architect's mind, and it is there before the object. Using the type as "a priori synthesis" means considering the type as an operative matter for design. Type serves as a structural form beyond its classificatory function, integrating spatial organisation with the more general concepts of shape (Martí Arís, 1993). Recognising types within the urban fabric led to recognising their permanence and urban structural role. However, contemporary cultural, environmental, and technological shifts redefine the architectural concept of type. Hillier (1986), in his work on space syntax, introduces the societal relevance of social value into the discourse. Saverio Muratori and Gianfranco Caniggia already mentioned the concept, but Hillier, with his approach, adds a critical informative dimension, emphasising the function of the type as both analytical and generative. Hillier, Hanson, and Graham (1986) introduced genotype as an informative entity clearly distinct from the physical building itself, while Bafna (2012), starting from their consideration, further defined genotype as a set of fundamental and culturally influenced instructions.

The genotype approach fosters new insights into urban transformation and design adaptability by conceptualising the city as a dynamic system. Through this lens, urban morphology is no longer just a matter of typological analysis, as we know from history. Now, it can embrace contemporaneity's complexities, providing a framework for generative design approaches that address contemporary cultural, environmental, and technological shifts.

In this view, the genotype emphasises the dynamic nature of urban environments, shifting the analytical and design focus from permanence to permutation. Parametric design, rooted in the computational formulation of instructions and operations, aligns well with genotype. Architects define parameters, such as dimensions, materials, and environmental factors, as input for software

programs, which then influence the overall form and structure of the building. The distinctive feature of changing a parameter and checking the results in a circular iteration allows for greater flexibility and adaptability, allowing architects to respond directly to specific site conditions and user needs and check at once the results of their reasoning.

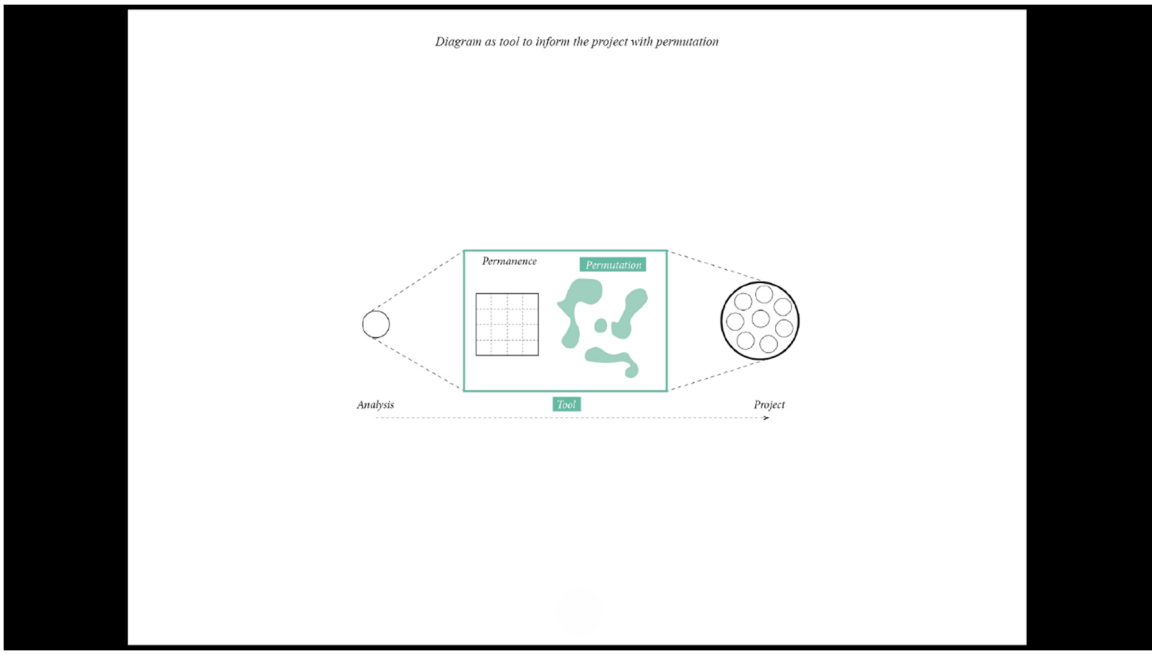

Figure 2. Diagram as a tool to inform the project with permutation. Photo credit: Author 2024.

To understand and guide the parametric approach based on genotype, it is helpful to think about diagrams as essential representations for thinking, problem-solving, and communication in design disciplines, particularly those related to creating physical forms (Do & Gross, 2001). The ability to develop multiple scenarios leads again to consider the diagram as generative, representing and analysing existing realities and envisioning realities that do not yet exist on paper or in time. It becomes a carrier for non-specific visions on the project. This assumption signifies a change in thinking, moving from the map as a guide towards an already specific project (Palma, 2001) to the map, or the diagram, as a speculator of various project possibilities. This consideration arises from using the diagram to generate new realities. The purpose is to escape the taxonomic nature of urban analysis and seek refuge in a universe of project possibilities where typology and topology engage in dialogue.

DIAGRAMMING PERMUTATION AS A WAY OF REINTERPRETING TYPE

In the Italian morphological approach, it is possible to see how Saverio Muratori and Gianfranco Caniggia informed the city evolution of Venezia and Como through an overlapping of maps of different constitutional period. Only Augusto Cavallari-Murat, a scholar from Turin, added the overlapping of the layers of the graph, similar to Hillier, to show how each part of the city centre of Turin was related one to the others. Adding the relation between different elements of the city helped to frame a new method in which the maps were not enough to hold all the information about the transformation. But now, as the city changed, it is possible to start from the method used in the past to reconstruct a process that is not just able to show what is visible in the classical representation but also what has not since now. To go further with this experiment, it is important to understand permutation in the urban environment.

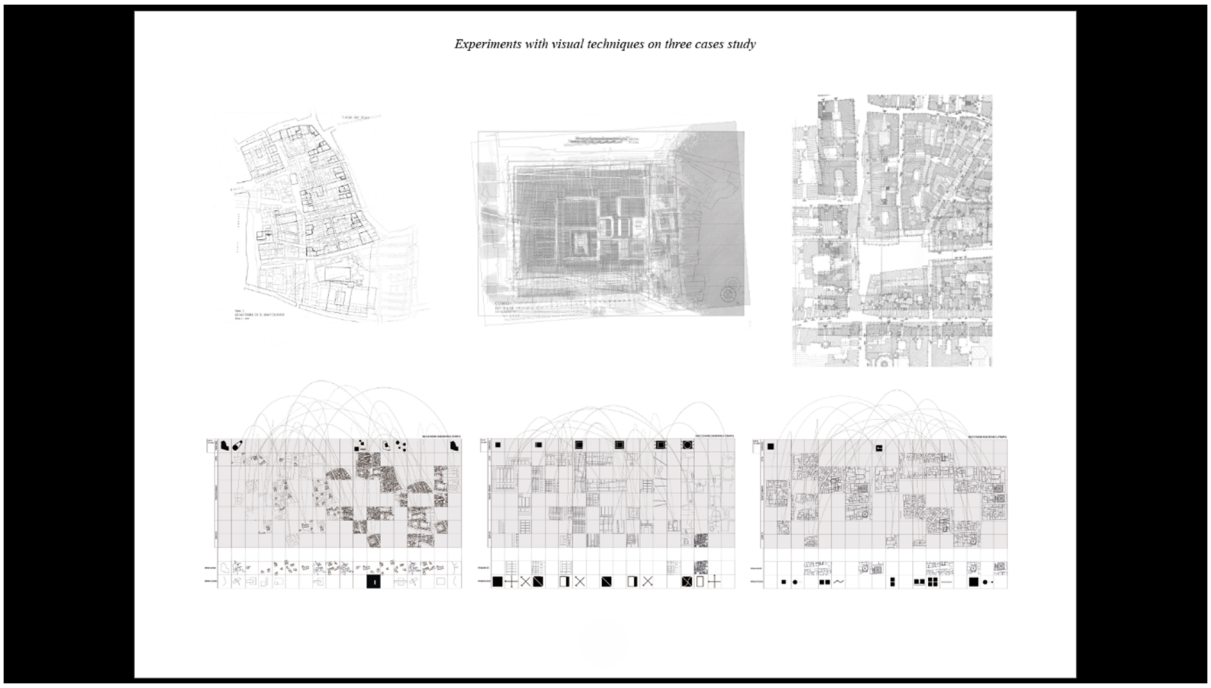

Figure 3. Diagrammatic matrix of the three cases study. From left: overlapped maps of San Bartolomeo in Venice by Saverio Muratori and subsequent matrix translation; overlapped maps of Como by Gianfranco Caniggia and subsequent matrix translation; overlapped maps of Piazza Palazzo di città in Torino by Augusto Cavallari-Murat and subsequent matrix translation. Understanding the connection between the emerging concept of genotype and the city's dynamicity requires a unique method. This approach not only reads the fixed elements in the urban pattern, as morphological maps do, but also interprets the permutations and their rules into morphological parameters.

The method used to inform the design through permutation starts from the assumption that each map used to represent the city can be read and understood as a diagram of a system of thought. The term "figures of thought" used by Gansterer in its publication finds correspondence with Astrit Schmidt-Burkhart in connection with a paper on "figures of order" of 2004 and serves as a basis for the investigation and analysis of scientific texts in visual culture, graphemics and diagrammatic. The term comes across as setting up various concepts, models, and processes to highlight the role of diagrams as tools of thought that can stimulate a collateral point of view on the environment analysed. Figures of thought can be placed on various levels of abstraction, and the process of abstraction can be repeated several times. One does not start with mathematically abstract operations or operations that can be followed purely verbally. Still, formulations are included in the diagram that can be grasped through drawing to describe the procedure or process. In the case of the contemporary city, the process of city transition. The use or application of these figures of thought thus leads to forms that can be grasped through drawing (Gansterer, 2011). The permutations in the city are made explicit through the reconstruction of these processes, which remain hidden within classical reading methods.

Reading the urban form with a diagram is only enough if the diagram is made to focus on permutation. All the traditional morphological analysis information can be combined and abstracted with a matrix containing both permanence and permutation of the urban environment. The matrix is considered a generative diagram that uses the assemblage theory to build a specific tool that supplies the need for

a dynamic city. Some elements need to be considered in this process of configuration of a new method, starting with some basic instructions and procedures used by the Italian morphological approach that was developed in the sixties. From this, each city needs to be studied by comparing different times (diachronic and synchronic) and different scales (from macro to micro scale), understanding not just a specific object but how this object is integrated into the urban system.

Considering a part of the city in which a transformation or regeneration process is taking place, which is therefore in an unstable state of transition, it is possible to visualise, through the matrix, the changes that have occurred or are emerging. The matrix used is made by a system of frames that helps to read the city at a different scale in different scales. To give an order, it is possible, in this instance, to consider the territorial scale as the first element analysed. Through this first reading, it is possible to recognise and visualise the macro-transformations of the case under analysis within the urban fabric. These are essential moments for reading and understanding the process of change in the urban form. Abstracted and represented with a symbolic language, the territorial scale tiles are inserted into the matrix. Going deeper in scale, it is necessary to quantify and map the micro-phases of the transformation and the subcategories of the macro-transformations found on a territorial scale (meso-transformation). The coring of the part of the city analysed aims, on the one hand, to find the affinity of the transformation with the different scales of analysis, and on the other to further divide the time of the transformation. With this step, the number of frames between one scale and the next can increase by extending the number of frames on the grid.

Each meso-area of transformation inscribed within a square is positioned in the matrix grid, as is done with each micro-area. The identification of these phases not only occurs a priori during the mapping of the individual parts of the city but is constructed simultaneously with the extension of the matrix.

During the study of every single part of the city that makes up the transforming aggregate, the dependency relationships between one micro-transformation and another are found. The relationships shown between the various parts at the same scale or between the same parts at different scales are then schematised. Direct and indirect relationships between parts of the city are defined and connected by lines to make them clear. As a result of the construction of the matrix and in the identification of the logic used for the transition study, two horizontal lines appear that summarise the permanences and the permutations, or the result of the matrix. The matrix not only photographs a state of the art but contributes to starting, through the completion of the line of results, reasoning of a design type.

The permanence and permutation concepts are linked by comparing them to each other in line. The unique capability of the tool is that it gives different information at the same time and displays, in the same matrix, multiple points of view on the city.

Through the matrix, considerations arise about methods for representing the city and its transition. The permutations identified in the maps find space to be normalised and used in a propulsive way for the project. For the investigation, it is not important to observe the specific permutations of individual contingencies but to identify a method that allows for their identification through the decomposition into rules and permutation variables. The specific contingency becomes a pretext for a method analysis. The objective is to identify the invariants and permutations not as straightforward to individual case studies but as a process for determining the general rule to be traced within the

diagram. The final contribution of invariants and permutations emphasises the dynamic contribution of the matrix and the diagram.

The results of the representations aim to underline the variety of analysis possibilities of the transition, defining the logical framework of the method. The diagram highlights the importance of diagrammatic logic, which becomes a tool for revealing hidden urban dynamics. This leads to the conclusion that the goal of the diagram is not merely the representation of a specific scenario. Still, it highlights its character of multiplicity in providing ever-different scenarios informing the design. The matrix is the diagrammatic object that composes the representation, but its diagrammatic logic is exportable and adaptable to new and different images. Beyond the meaning of the image, the purpose of visualisation becomes having a critical point of view, opening new perspectives on possible representations of the transitioning city.

For this reason, the diagrammatic reconstruction of the map is just one of the possible interpretations that, through the decomposition and exploitation of hypothesis relationships, aims to provide a new point of view on the city. As understood in this way, the diagram does not correspond to a single image but to a logical system. From this method, the starting point for the design is not the static part of the city but the one that is changed. The changes bring to light the propulsive feature of the urban environment.

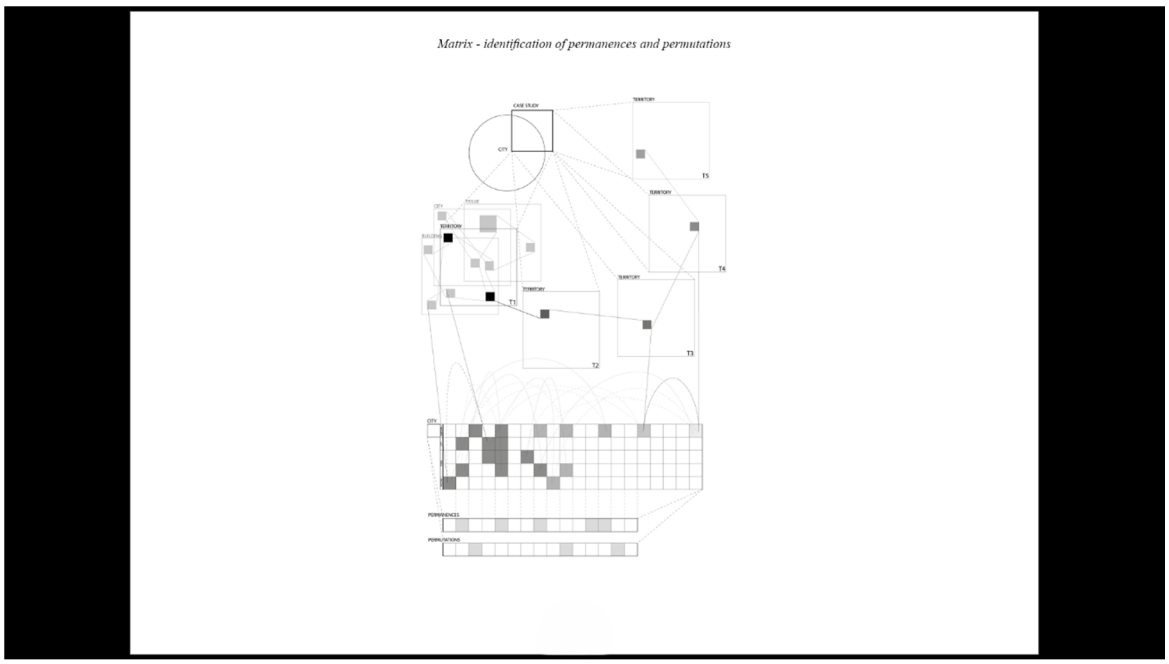

Figure 4. From a real urban change scenario to a matrix of transformation able to read permances and permutation. Photo credit: Author 2024.

PERMUTATION AS A WAY OF REINTERPRETING TYPE

As a result of the matrix, permutations are represented through symbols. This is because it is important to understand that each type of transformation is defined by a set of repeated variables rules. Symbol representation already allows a first schematisation and abstraction of this characteristic. The permutation system read through the matrix can then be subjected to a subsequent simplification by transforming the symbol into a system of codified rules. As we have seen

above, the parametric approach benefits from this type of abstraction. The methods can thus be intertwined and used simultaneously to understand and design urban transformations.

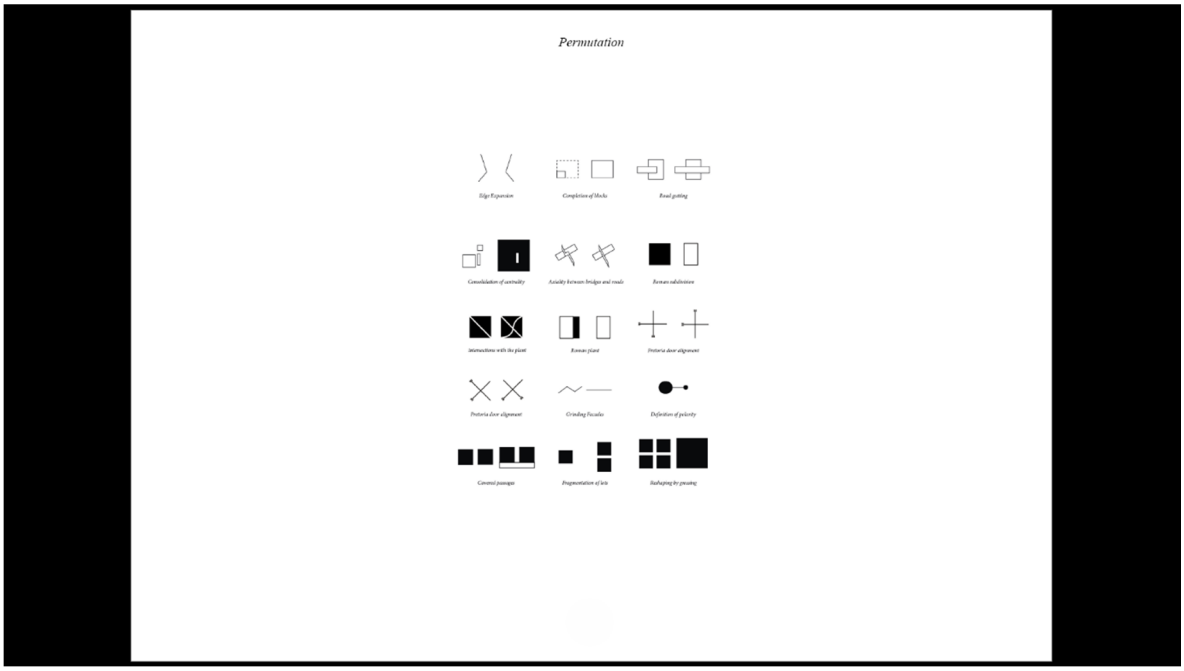

Figure 5. Permutation schematizations. Example taken from the analysis of the three cases study of Venice, Como and Torino. Photo credit: Author 2024.

One of the more popular ways of expressing design synthesis is parametric modelling, which precedes the history of rationalist architecture and computational modelling. A parametric model can be defined as an explicit representation of the design logic that maps the parameters in input to have a specific output (Davis, 2013). The literature uses many terms, such as generative system, generative model, and generative design. The term model refers to the representation of a system, an organisation of various parts to understand a specific phenomenon. Particularly in the preliminary stages of design, interaction with the partial representations is important for acquiring knowledge, creating a frame of reference, and reformulating the problem and solution in parallel (Cross, 2006). In this process, the designer constructs the design world within which the dimensions of the problem space to find solutions can be built (Schön, 1992). Subsequently, in the formulation stage, the designer develops the representations for the input, the output, and the algorithm to be encoded in the generator. It is here the codification of permutation can be inserted. This algorithm specifies the synthesis of the output design alternatives conditioned on the input information (Veloso, 2021).

In a more conventional ideation process, designers imagine worlds by interacting with drawing media; generative models induce the space of possible designs (design space) and how the designer can navigate between solutions. In the execution stage, designers interact with the generator by changing the input information and seeing design alternatives as feedback in the model's output. They can exploit a subspace of solutions satisfying specific goals or explore unexpected alternatives more easily than in the traditional method. Potentially, this stage can lead to a reformulation of the model that can be changed continuously. Generative models are constructs situated between design and computational logic. Various sources, such as human cognition, expert knowledge, social organisms, natural processes, and dynamics, can inspire their agency. They are a powerful and compelling alternative for a design that helps both from the rigour of scientific modelling and the open-

mindedness of the design artefacts (Veloso, 2021). The computational model can also frame itself, and the matrix can reshape itself and change needs in a more analogical way.

Translating the permutation into rules introduces a crucial variable to the model, moving away from the rigidity of permanence and the traditional typological approach. This process is essential in understanding and navigating the shift from the notion of type to the more complex concept of genotype. It is not just about the shape of the architectural element but about all the relations and characteristics defined within the matrix, which are of utmost importance.

AN ITERATIVE PROCESS BETWEEN DESIGN AND ANALYSIS

The diagram is a map that can be the starting point of computational design thinking and activates the development of multiple projects in the city from a specific configuration of the urban environment without excluding the architect from the design process in favour of a software-based approach based on a sorting process. Conversely, the information on permutation extracted from the diagram became the driving force for a new project. The architect is a "researcher-designer," defined by Lak and Aghmolaei, who designs and evaluates the project according to evidence (2020). Evidence that, in this case, is not based on quantitative analysis, number or index but is based on the logical construction of the analysis.

Indeed, there are contrasting interpretations of the term "diagram" in current discourse. On the one hand, some perceive diagrams primarily as tools for systematisation and problem-solving. They view diagrams as aids facilitating numerous perceptual inferences, making them highly accessible to human understanding. This perspective emphasises the role of diagrams in organising information and simplifying complex concepts.

On the other hand, an opposing viewpoint sees diagrams as catalysts for unfolding processes or as maps of movement. According to this perspective, diagrams go beyond static representations and capture dynamic and evolving phenomena. They are seen as instruments that provoke the exploration of various possibilities and reveal hidden relationships or patterns. Rather than providing fixed solutions, these diagrams encourage the generation of new ideas and the discovery of novel perspectives. (Gansterer, 2011).

The results of reading the city as a permutation through diagrams as maps of movement lead to the definition of a new paradigm in the urban environment. It opens a methodological discourse beyond the relation between causes and effects. Linking the genotype, the diagram, and the vision of the urban environment through permutation leads to a question about integrating the diagram in a more computational approach, as flexible media can be reshaped again and again, filling the gap between a more static analysis and a more technological and dynamic way of conceiving the project.

The experiment conducted in this research, conceived in a more institutional framework of a PhD dissertation, stresses the computational part to prompt a reflection on how we look at the city and the methods we use to analyse and design it. The aim is to promote a design that puts the process of reiteration between design and analysis back at the centre by making it explicit and comprehensible so that we can intervene at any time with changes and new requirements.

ABSTRACT

New pedagogical paradigms, combining research with education has over the last 10 years gained significant ground in the field of urban morphology (Oliveira and Liu; 2022). As extensions to the various analytical approaches, set in place by the historic schools of thought, new perspectives that tailor qualitative and quantitative data sets with design research have begun to emerge. Moreover, with the increasing awareness of regional and territorial questions (natural systems, bio-physical systems, and transitional habitational processes) coupled with increasing agglomeration of urban landscapes into new regional scales, there appears to be less dependency on established discourses as architecture, geography and town planning, and a greater need to strategize the development of regions and territories through new morphological lenses.

This paper explores the innovative application of urban morphology in tailoring 'regional morphological design' as a novel educational medium. The paper argues that urban morphology can be tailored to the regional design scale, creating urban territories that both reflect and enhance the unique characteristics of their spatial, geographical, cultural, and social contexts. The paper will present case studies and empirical data through studio work spanning 5 years in support of the regional morphology design arguments, contributing to the growing body of research on the applications of urban morphology.

The paper concludes with recommendations for integrating urban morphology into regional design practices and educational curricula, outlining the key questions and steps required for a regional morphological pedagogy, and its valance to conventional scales, urban elements, and analysis.

Keywords: Regional Morphological Design, Morphological Pedagogies, Transitional Design, Design-research

INTRODUCTION

Historical Context of Urban Morphology

The field of urban morphology has historically concentrated on examining the physical attributes and arrangement of urban areas (Moudon, 1997; Levy, 1999; Conzen, 2004).

Each of the three main morphological schools and their pedagogical streams (British, French, Italian) have had a significant impact on the analysis and conceptual development of new spatial concepts. As streams of thought, these schools have influenced the positioning of analytical takes as well as the delineation of spatial methods in relation to spatial patterns and their connections to typologies, developmental patterns, or societal relevance.

As well known, the British school, associated with M.R.G. Conzen, emphasizes the analysis of town plans, building forms, and land use patterns, through historical spatial patterns. This systematic approach focuses on the physical structure of urban areas. In education, it promotes a rigorous analytical framework, teaching students to dissect urban areas into constituent parts. The 'Conzenian' curriculum includes fieldwork, mapping exercises, and GIS technology to analyze urban patterns. The goal is to equip students with skills to critically assess urban environments and contribute to urban planning and design (Conzen, 1960). This school is known for its scientific methodology and detailed urban landscape studies.

The Italian school focuses on typology and architectural elements of urban forms, emphasizing building types and their evolutionary processes (Oliveira & Liu, 2022). Scholars like Saverio Muratori and Gianfranco Caniggia have been influential, bulding on the work of Muratori. This approach involves examining architectural styles and socio-cultural factors in urban development. While conventional methods have yielded useful knowledge about urban design, the Muratorian scope is generally limited to smaller dimensions, such as individual buildings or communities. In education, the Italian school encourages an architectural perspective, teaching students to analyze typological and morphological characteristics. The curriculum includes architectural history, design theory, and urban analysis, fostering appreciation for aesthetic and functional urban aspects. Students learn the interplay between architecture and urbanism, preparing for roles in urban design and heritage conservation (Muratori, 1960; Caniggia & Maffei, 1979).

The French school delineates the historical and geographical evolution of urban forms, focusing on how past events shape current urban layouts. This approach involves detailed cartographic analysis and historical documentation. Key figures like Pierre Merlin and Françoise Choay have contributed to this field. In education, the French school promotes a multidisciplinary approach, integrating history, geography, and urban planning. Students analyze historical maps and documents to understand urban development layers. The educational focus is on understanding historical contexts and their impact on modern urban forms, fostering a comprehensive view of urban evolution (Merlin & Choay, 2000).

While these schools were prominent during their respective eras, the validity of their approaches and their relevance to the current developmental challenges are still being questioned in two distinct lines of enquiry; (a) applicability to new urbanization trends and (b) teaching methodologies. As Oliveira and Liu (op.cit) highlights, the last decade has shown a notable increase in the use of innovative

teaching methods that integrate research and education in the study of urban morphology. For example, the influence of quantitative methodologies in the development of the discourse, proving fertile ground for the germination of computational and data-heavy methodologies such as Space Syntax and later variations of geospatial approaches.

From an educational standpoint, the new scalar structure and developmental challenges require new educational tools that are linked to the study of urban form as a scientific discipline. Considering Oliveira's (2018) summary on morphological education, we problematise morphology and pedagogy through four lenses. First, the dependency on Western and Eurocentric precedents lacks a wider perspective on global streams and developmental trends. Second, and especially for our purposes here, traditional scale orders lock down with the introduction of new scale variations that influence morphological concepts. And thirdly, the potential impact of morphological pedagogies linked to the continued historical reflection of urban form misses potentials for transforming morphological inquiry from an analytic to a projective discourse. And finally, how to harness pedagogies to effectively teach the interconnection between these three aforementioned outliers to sustain the future of the discourse?

In the wider spectrum, new educational paradigms are emergent. Some streams are making efforts to integrate both qualitative and quantitative data, allowing for a more comprehensive comparison of both spatial qualities and the factors that influence their change. Here we think of questions concerning climate, heritage development, and super-tall, super-vertical living. These paradigms enhance conventional analytical methods by integrating qualitative and quantitative datasets with design studies and design analysis. This combination facilitates a more thorough comprehension of urban structure and its consequences for present-day urban challenges. Qualitative data, such as interviews and field observations, can offer valuable insights into the social and cultural aspects of urban spaces. On the other hand, quantitative data, such as surveys and empirical measurements, can provide objective measurements of the physical characteristics of urban areas. The use of data and computational approaches, such as Big Urban data (Boeing, 2021), Smart City data (Marcus, 2017), and Agent Based Modelling, presents challenges to pedagogies in terms of approach, tools, and the integration of such.

Furthermore, the emergence of concepts like as urban compaction (Endemann, 2024) and regionalisation (Yang, et al, 2022) is placing significant demands on the development of other more morphological pedagogies (Trisciuoglio, 2024), due to the new and emergent qualities of the built landscape.

This paper addresses the challenges presented by the outline of giga and biophysical systems and the specifics of a pedagogical in the domain of urban morphology. The paper first discusses the challenges posed by the biophysical and scale complexities of giga areas as a morphological concern. Utilising the results of a master's level morphological studio, this study presents the combined results of a regional morphological approach that took place over a period of 4 years. The study provides ideas for incorporating urban morphology into regional design processes and educational curricula. It outlines the essential issues and actions needed for a regional morphological pedagogy, and highlights its relevance to conventional scales, urban features, and analysis.

Regional and territorial questions within pedagodgy

"Form no longer exclusively follows function, but now has its own capacity, its own power, its own value. Within certain limits, urban architectural form and urban space open up new possibilities for use and thus make various new programs scenarios possible" (Rosenmann, 2002: 44).

The increasing awareness of regional and territorial questions has led to a shift in focus from established discourses in architecture, geography, and town planning (Rosenmann, 2002; Meijer, 2004). Transitional habitational processes (Heckmann, 2022), such as globalisation processes influencing urbanization (Hu, 2015), United Nation's Sustainable Goals and other 'wicked urban questions' (Göransdotter, 2021), significantly impacts questions related to urban development and therefore, urban form. Conversely, natural systems, climate and topography such as rivers and forests, play a crucial role in shaping new urban strategies associated with bio-physical systems (Galaz) and their formal expression.

Rosenmann (op cit) argues that as urban areas continue to grow, merge or expand into larger regions, is an increasing need to plan the development of these regions using innovative spatial concepts. This approach aims to highlight regional morphological characteristics beyond just functional performance. Rosenmann's statement proposes directing the study of morphology towards new enquiries about scale, including regional clusters and geopolitical alignment to gradually integrate metropolitan areas, sections, and surrounding regions into a unified metropolis.

From our perspective, 'regional morphological design' (RMD) is a developing discipline that customises urban morphology to the scale of regional design and scales of planning. This method seeks to establish urban areas that accurately represent and improve upon the distinctive attributes of their spatial, geographical, cultural, social surroundings and equally the experiential qualities of regions. An instance of a RMD approach would take into account the natural and bio-physical systems of a specific area, together with its cultural and social settings, in order to create urban spaces that are both functional productive, even if they remain visually incoherent .

The urban agglomeration of the Greater Bay Area, China (GBA), includes 11 cities: Guangzhou, Forshan, Zongshan Bao'an, Dongguan, Zhuhai, Shenzhen, Hong Kong, Macau, Jiangmen, and Huizhou. These cities have a combined official urban population of more than 86 million (ref). The Greater Bay Area (GBA) comprises two Special Administrative Regions (S.A.R.) - Hong Kong and Macau, which are known for being global financial and casino centres respectively. It also includes two Special Economic Zones (S.E.Z.) - Shenzhen and Zhuhai, with Shenzhen being one of the largest migrant cities. Additionally, the GBA has three significant logistics centres, three international airports, and several ex-urban or former village areas such as Longgang, Shunde, and Nansha. The region exhibits a large diversity of spatial conditions and varying levels of uneven spatial development, all within an area of 56,000km2.

The integration of this global-scale megalopolis or mega-region agglomeration presents geographical and structural complexities. For example, the combination of infrastructure, logistics, and replication at a geographical level, such as the duplication of cargo handling facilities, or rivalry between cities in the Greater Bay Area (GBA), or the competitiveness for logistical preference.

The mega-region agglomeration phenomena present a knowledge gap. First, the extension of the morphological lens from a regional scale to the sub-national scale in morphological research has had limited examination with minimal data to challenge the morphological provenance at the sub-national level (cf. de Jong & Rosenmann, 2002: 37). Second, critical for our purpose here, from an educational standpoint, the limited capacities in address the new scalar structure and developmental challenges beyond the isolated regional view requires other educational tools specific to the study of urban form as a scientific discipline. It remains essential to requestion the absence of scalar thinking and the possible influence this has on morphological teaching methods. This includes further development of spatial attributes and the conceptualisation of future urban areas as expressions of scale. With all educational concerns and scales covered through the educational lens, the lack of other scales and strategies indicates a potential for scale development through both the units of morphological expression as well as its approach to developing new mega scale propositions.

RMD METHOD

The Regional Morphological Design (RMD) approach utilises the theoretical and conceptual frameworks to understand the megaregional situation and its manifestation in the GBA. We use the technique of speculative gameboarding as a pedagogical and scaling tool. Since 2018, this technique underwent testing in 12 studios, leading to the completion of over 60 group projects, including the involvement of more than 300 students.

Gameboarding is the foundational process for creating scenarios and is used as a tool in spatial planning and design research. In addition, gameboarding is based on the concept of scenario testing and proposition formulation in the area of spatial planning, specifically on a large-scale region known as the GBA (Bruyns, et al.). This is achieved by using gameboard concepts and procedures. The work presented challenges the use of strategic planning as a speculative tool to implement formal strategies at regional and territorial levels, including environmental systems and their large-scale regions, while also being grounded in the study of form and structure.

Speculative gameboarding is used in RMD design studios in a distinctive manner, which is influenced by three fundamental variables.

At first, the students only used tangible elements like as paper, cardboard, pins, stickers, and threats to depict their spatial plans on a physical gameboard, which consisted of a printed map of the GBA. The use of text and descriptive labelling is minimised, with digital technologies such as CAD and GIS only serving as spatial validators in the final stages of the strategic process.

Second, students are allocated morphological themes that focus on distinct geometric shapes, such as points, lines, rings, or crosses, as spatial components. The interpretation of these may be either as an urbanisation process or as a actual built object, and as choice is left to the discretion of each group. Additional abstract geometric notions, in what we define as morphological qualities as edge city, strip city, or radial city, have also been explored. In harnessing a single morphological theme, students are urged to convey their regional plans in unconventional ways and to cultivate morphological propositions in a more innovative manner.

Third, students are urged to construct their gameboard scenario’s in rapid succession. The purpose is not to meticulously create accurate strategic spatial representations of the megaregion, but to swiftly

develop spatial ideas through experimental steps on the gameboard. Students are restricted to a maximum of two days per development cycle, depending on the studio size and group compositions. Other studio's lasting one to two weeks, inspire students to create a new gameboard in only a few hours. The creation of "game conditions" facilitates the direction of the morphological concept, establishing leading tools for experimenting with various spatial situations.

Finally, students have the option to construct gameboards by assuming the roles of various stakeholders. This may cover the position of residents, farmers, historians, developers, ecologists, or infrastructure experts to help further determine aspects as land use, residential qualities, ecological and agricultural emphasis or, how to integrate infrastructure with historical areas or which land uses would be preferred by the residents of a certain location. This includes the definition of priority hierarchies, earmarking which functions would urban planners give the most priority to, or what types of density would be most preferable for real estate developer.

The objective of regional morphological design is to capture and convey the spatial attributes of the region through an 8 layer variable:

1. Building typologies: differentiation between different densities, heights, mix of functions, and street patterns.
2. Land-Use (built-up areas): functions typically related to areas, such as residential, industrial, commercial values.
3. Land-Use (non-built-up areas): functions found in areas with pervious surface, such as agriculture, forest, and other natural features.
4. Water: different features and hierarchies of the water itself as well as water related infrastructure; e.g. fresh and saltwater.
5. Transport/ Mobility: anything related to human movement; roads, rails and other functional units.
6. Administration: hierarchy of administrative boundaries and special zones; province, city, district, and villages.
7. Existing Plans: collection of administered plans to be implemented in the future; master plans, development plans, expansion plans; to be collected on different scales, not only for a city.
8. People: features that describe characteristics of residents, workers, visitors, etc. of a specific area; demographics, ethnicity, income, migration.

RMD's morphological evolution also considers several spatial features linked to emerging urbanisation principles. These themes have a significant impact on the present process of urbanisation, contributing to the development of increased variety within a group's physical layout or structure. For instance, these values encompass:

1. Commoning: A land-use paradigm that emphasizes the shared use of resources, making them public, sharing economy.

2. Self-Sufficiency: striving for a state in which a territory has the capacity to be largely independent from external production, electrical power, or food production.

3. Compaction: A development model that focuses on the intensification of built environments, multi-functionality, and transit-oriented development.

4. Shrinkage: The unconventional idea to reverse current development trends and focus on the parts of a territory that may be suitable to shrinking.

5. Informality: strengthening of systems that emerge beyond regulated administrative processes and planned spatial development, urban infill and urban villages.

6. Circularity: spatial patterns that encourage circular flows of resources, initiated by shared knowledge on innovative socio-economic practices.

During the process of developing spatial propositioning, ambiguous spatial values are transformed into specific morphological interventions. This transformation is guided by fundamental concerns that revolve around the processes of concentration, clustering, densification, and intensification at a morphological level, by questioning: Can the existing method of urbanisation in the GBA, which is mostly focused on constructing super dense and super tall buildings, adequately address the diverse range of demands that are shaped by societal values?

The last stage of the RMD involves integrating the strategies, taking into account their individual strengths and weaknesses across scales and forms of expression. In order to accelerate the process of spatially resolving these issues, the groups analyse the morphological characteristics of specific nodes. Each node is enlarged and further developed through the 1:200,000 scale of the GBA map. Nodal testing and integration facilitate the advancement of game boarding development by examining the proposition's connections to values and stakeholders' perspectives. This procedure is iterated at the 1:50,000 and 1:200 scales in order to elucidate the structural attributes and dimensions of the GBA, with a specific emphasis on unique conditions, as well as the integration at both higher and lower scales within the GBA.

RMD RESULTS AND DISCUSSIONS

The results obtained from the RMD research and its more than 60 scenarios have important consequences for the area of urban morphology, both in terms of the development of its discourse and its chosen educational methodologies.

1. The RMD serves as a foundation for discussing the wider consequences of the morphological findings obtained from the extensive testing of the speculative gameboarding technique, including both successful and unsuccessful implementations.

2. The success may be attributed to the variety of new morphological frameworks, as shown by the more than 60 proposal and its detailed resolution, which has produced a varied and comprehensive body of work on urban form that was previously deemed impossible.

3. The RMD as a body of design-research, indicates that conventional analytical methods must be modified to tackle current urban concerns, especially those pertaining to regional and territorial issues, beyond simple functional arrangement, typological composition, or social density. The inclusion of spatial considerations in morphological thinking has the potential to provide fresh perspectives on the development of both a field of study and the pedagogical approaches used in regional questions, and even possibly, links to other domains of study, as for example, environmental ecology.

4. In addition, customising urban morphology to the distinctive attributes of each region amplifies regional uniqueness, which was previously deemed unattainable owing to the large scale of governing systems in these locations. Normative scale limits associated with the block, plot, building, neighbourhood or region have in the RMD pedagogy, become inclusive of the sub-national and regional scales as part and parcel of morphological inquiry, supporting new scales for formal and configurative enquiry (cf. Bruyns, et al, ISUF, 2024)

5. Correlations between strategic aspirations and spatial patterns are crucial for understanding how urban morphology develops, serving as both an analytical framework and a teaching tool. The RMD results indicate that combining qualitative and quantitative data sets with design research may provide another layer in the comprehensive knowledge of urban form, and in our view attributed to the inclusion of the regional or sub-national levels of developing urban morphology. level. This approach also helps identify the issues that formal spatial characteristics would encounter due to emerging urbanisation patterns, spatial and environmental characteristics, or the significance and impact of resilience of cities as a formal reaction in the built reality.

6. Another advantage for the RMD technique is its emphasis, equally to the complexity of local conditions and their impact on regional systems and identities, on the relevance of various spatial configurations, typologies, and patterns in planning. The local scale in the RMD is nevertheless as crucial for perceived misunderstanding in which sub-national and regional scales replace local distinctiveness in favour of just regional concepts and methods. The RMD technique provides an advantage by emphasising the importance of various spatial arrangements, typologies, and patterns in planning, while also, in parallel, considering the particular local circumstances and their impact on regional systems and identities.

7. The RMD technique provides an advantage by emphasising the importance of various spatial arrangements, typologies, and patterns in planning, while also, in parallel, considering the particular local circumstances and their impact on regional systems and identities. The local scale in the RMD method is therefore crucial, in contradiction to what one would expect of regional scale strategies. The value of the local in the RMD strategic thinking scheme clarifies

scalar misinterpretation, taking into account the specificities of the local context, rather than prioritising regional ideas and methods at the expense of local distinctiveness. Local scale in the RMD curriculum is therefore a key resolver of embedding morphological specifics to contextual questions.

8. The limitations of the RMD method emphasise that the inclusion of urban morphology as part and parcel of design curriculum may need modifying several traditional features of educational delivery and the use of morphological/spatial data. From what we have observed, the willingness of students to include new data or adapt to new ways of strategic experimentation encourages further explorations.

9. Finally, the challenges presented by the RMD approach is only valid with the continuous renewal of design iterations, on an annual basis. The importance of maintaining the explorations of regional form becomes static and one dimensional if no comparison to other options, variations, or iterations are possible.

CONCLUSIONS

This research explores 'regional morphological design' as an innovative instructional tool in urban morphology. By adapting urban morphology to the regional design scale, urban areas can enhance and reflect the unique spatial, geographical, cultural, and social characteristics of their surroundings. This paper contributes to the growing body of research on urban morphology by presenting findings from five years of RMD studio work. As educators, we stress that speculative gameboarding should

not be directly applied to actual planning processes. Current urban development methods often overlook their negative impacts on environmental sustainability and social justice.

To effectively respond to the ongoing transformation of urban environments in the GBA and globally, it is essential for students, practitioners, and academics to adopt techniques that match the scale of megadevelopments. A key finding is that this approach to game development, particularly in morphology, relies more on strategic thinking than solely on data or additional factors. Design elements are integrated indirectly, highlighting valance with other fields of spatial inquiry such as engineering and data metrics. While beneficial to an extent, this approach has limitations when considering the future of urban landscapes on a larger scale, for example, the iterative guidance required and the consistent cross comparison between iterative steps. Still, despite such challenges, the integration of RMD into morphological sciences can offer significant advantages by envisioning new variations in the spatial qualities and characteristics of diverse places, as those outlined by the GBA territory.

Acknowledgements

The research detailed in this paper was fully funded by a grant from The Hong Kong Polytechnic University, Hong Kong, China (Project No. PolyU No 1-WZ8S). The authors would like to express their gratitude to the master's students from both The Hong Kong Polytechnic University (Hong Kong) and Delft University of Technology (The Netherlands). They also wish to acknowledge the www.deltamegaregions.net exhibition.

Streets of Goiânia: a cartography of (its) experiential heterotopias

Wagner Rezende[1], Elise Gouraud[2], Vitória Santos[3]
[1] Urban Planning Lab, Faculty of Visual Arts, Federal University of Goias, Brazil, wagnerrezende@ufg.br

[3] Urban Planning Lab, Faculty of Visual Arts, Federal University of Goias, Brazil

ABSTRACT

Based on the premise that public spaces can, under certain circumstances, take on the form of heterotopias, as approached by Michel Foucault (2013), this article proposes an analysis of the modes of appropriation of a common place, a street in downtown Goiania. The starting point is the question: How do street appropriations, in their various socio-spatial everyday configurations, evidence, reflect, and influence the emergence of experiential heterotopias? The attentive observation of a Parisian location, conducted by Georges Perec (2016), inspired our (sequential) participant observation of “Goianiense” public spaces. The text explains how everyday situations could articulate experiences and ambiences on the streets of downtown Goiania, through a cartography of heterotopias in the square of Rua Oito, in front of Octo Marques Gallery, located in the Parthenon Building, downtown Goiania. As part of a more complex research, that aims to understand patterns of sociability that could have an effect in the production of urban commons in public spaces of Goiania, we present analyses and reflections on the ambiences that emerge in this location, stemming from the experiences and routines of the local residents, along with a study on the person-environment relationship in the alley that is part of the morphology of this location. Describing public spaces from the perspective of heterotopic spatial configurations, we advocate for urbanity-as-becoming. These analyses contribute to urban studies by providing a theoretical foundation for the concept of "experiential heterotopia," a term referring to a space appropriated by tactical uses (monitored).

The following guidelines provide instructions to format your full paper, specifically on the way how text should be formatted, table and figures captioned, and references cited. The conference proceedings will be published in an electronic format. The paper should be submitted in a Word document (.doc or .docx) and shall be written in accordance with instructions of Urban Morphology Paper Submission Guidelines.

Keywords: experiential heterotopia, experience, street identity, urban intensity

INTRODUCTION: PLACE, NAME, AND TRANSFORMATION

Based on the premise that public spaces can, under certain circumstances, take the form of what Foucault (1967) suggested as heterotopias, this article aims to analyse the ways in which people appropriate a singular place in the centre of Goiania. We will observe, thoroughly, repetitive and banal events in Felicíssimo do Espírito Santo Square, popularly known as Gari’s Square, questioning the role

of street life, in their most diverse everyday socio-spatial configurations, and searching for experiential heterotopias. The question could be as follows: How do people (which we could call pedestrians, citizens, humans, and bodies that matter) can articulate modes of existence open to the otherness in the streets to resist the process of (de)memorization of public spaces promoted by public policies?

Gari's Square is located in the alley between the fourth and seventh street, in the Goiania Downtown, as we can see in the first drawings by Attilio Corrêa Lima, who designed various configurations of alleys for the city. It can therefore be deduced that its form is linked to the construction of Goiânia, in 1933. The official place name is in honour of the Brazilian military officer and politician Felicíssimo do Espírito Santo Cardoso (1835-1905). For many years the place remained abandoned and lacked urban design improvements. Some sources inform that before the Parthenon Building was built, a public market was in the same block (1940-1970). After that, it was moved to the third street, seven blocks away. Since the changes, the remaining plot is used for minor service activities. Its 'oblivion' is understandable. Despite this, many people use the place as a daily route, and the presence of the Otto Marques gallery may also have contributed to the place receiving more attention from society. As there was a requalification of the public space, a general refurbishment was carried out, with new accessible pavements, street lighting, benches, rubbish bins and flowerbeds.

Gari's Square is one of the smallest public places in a city that was planned to be monumental, with wide streets and many open spaces. It articulates very heterogeneous uses and functions but remains invisible to most of the Goiania population. Its official name is "Felicissimo do Espirito Santo", but it's best known as Gari's Square in homage to the trash collector who's author of the sculpture in that place. Some urban objects stand out in the landscape of the Gari's Square, a small piece of urban land (a rectangle measuring approximately (20x30)m), which allow us to identify the relationships that define the ethical/aesthetic regimes of experiential heterotopias: the Octo Marques Gallery; the (huge) (exaggerated) Parthenon Building; the abandoned grocery store; the streets surrounding the boundaries of the square; the snack bar; the second-hand clothing store; the shop selling plants, miscellaneous items, and household goods; the parking lot; the small office building; the clothing store; and the beauty products store. The photos show all these objects/buildings, their respective constituent elements, and the unusual relationship among them, as well. One of the highlights of the new square is the work of art 'The Samaritan', a sculpture created by Onildes Alves dos Santos, a garbage collector, in celebration of the city's 86th anniversary. As well as the sculpture, the square also received a water fountain surrounding the sculpture to emphasise the art even more. Today, the place is mainly maintained by volunteers of the surrounding shops, since the fountain no longer works. Something that stands out is the care taken by the neighbourhood regarding the square's vegetation, which has a strong presence in the landscape.

Contemporaries perspectives of heterotopia

"Of Other Spaces" (Des espaces autres), also commonly known as "Heterotopia", was initially a lecture carried by Michel Foucault to a group of architects in 1967. Emplacement means, according to Foucault, that relations between locations in space are the constitutive principle of space perception. We will therefore describe the streets as: a) deviant trajectories (deviation, crisis, instability: alleys are places of deviation / alleys located crises / alleys make transient cuts in space-time); b) mnemonic labyrinths (dysfunctional / hyper-functional / dysfunctional: alleys are organized according to sovereign agency / alleys induce power relations that result in confusing uses and functions); c) resonant rhizomes (juxtaposition / superimposition: on the (geographical) borders of alleys there is the juxtaposition of various microcosms (social, cultural, ethnic, political) / only relational topologies could describe the juxtaposition of these microcosms); d) rhythmic fragments (anachronistic situations: alleys allow the occupation of space in divergent temporalities / alleys induce incompatible rhythms of appropriation of everyday life); e) liminal places (disjunctive practices of exception: the existence of alleys presupposes a system of (implicit or explicit) border control); and finally, f) invented landscapes (synecdoche (or the part for the whole) (from the singular to the universal): through insurgent (surrealist) practices alleys associate utopias and dystopias that present themselves as generic landscapes or displaced landscapes). These analyses contribute to urban studies by offering a theoretical basis for the concept of 'experiential heterotopia', a term that refers to a space that is appropriated by tactical uses of (guarded) places.

From Foucault (2013), we learn that heterotopies are more than places or physical elements allocated in the real world. As an urban condition with "dissociative identity disorder", heterotopies are places where events play a crucial role in the complex web of everyday life interactions and situations, reenacting multiple aspects of cities' common spaces. Moreover, we can understand its six spheres of socio-spatial coherence as ways of relating to those heterotopies in the sensible forms of the city.

Thus, we adapted it to describe Felicíssimo do Espírito Santo Square or Gari's Place, located in Goiania Downtown. Following Foucault (2013), we tried an approach that pushed his ephemeral spatial turn beyond abstractions. Through the concepts of deviance, memory, resonance, rhythm, threshold, and illusion, we could, even tentatively, describe "place" as an (assemblage) of contradictory, heteroclite, and mostly disconnected, urban conditions. The relational spaces that emerge from this (material and immaterial) assemblage could be seen as interlaced dispositions (or social dispositives) as follows: a) deviant trajectories; b) mnemonic labyrinths; c) resonant rhizomes; d) rhythmic fragments; e) liminal places; and finally, f) invented landscapes.

A bibliographical review of Michel Foucault's concept of heterotopia can include a variety of authors who have commented on, expanded or criticized his ideas. Such authors include the works of Agamben (2010), Bachelard (2008), Edward Soja (1989), Kevin Hetherington (1997), Peter Johnson (2006, 2013), Michel de Certeau (1998), Henri Lefebvre (1991), Martins (2003), and Marc Augé (2009). Soja is an urban geographer known for his work in human geography and urban planning. He has deepened Foucault's concept of heterotopia in his own work, especially in his idea of 'Third Space'. Hetherington is a sociologist who has written extensively on spaces of identity and difference, including a critical analysis of the concept of heterotopia. Johnson is a geographer who has explored the concept of heterotopia in relation to geographical and cultural spaces, contributing to the theoretical and applied understanding of the term. An Italian philosopher known for his work on the state of exception, Agamben also discusses the concept of heterotopias, often in relation to his own concept of 'spaces of exception'. Although Certeau did not comment directly on Foucault's heterotopia, his work in 'The Invention of Everyday Life' offers perspectives that complement and contrast with Foucault's ideas, particularly in relation to the use and appropriation of urban spaces. Known for his work on the phenomenology of space, Bachelard offers a perspective that can be useful for understanding the concept of heterotopia, especially in his work 'The Poetics of Space'. His ideas on the production of space and everyday life in cities offer a critical basis for exploring and contrasting with Foucault's notions of heterotopia. Known for his concept of 'non-places', Augé offers a vision that can be seen in dialogue with Foucault's heterotopias, especially in relation to modern spaces of anonymity and transience.

An intriguing case for another account of heterotopia, less influential (and controversial) than the Foucauldian one, is made by Lefebvre (1991). It's important to be informed that the concept of heterotopia developed by Foucault (2013) differs radically from that of Lefebvre (1991): it delineates, potentially, liminal social spaces where some "differential condition" is not only possible, but fundamental for the definition of "revolutionary trajectories" (Santos Junior, 2014; Butler, 2012; and Purcell, 2002). In The Urban Revolution he outlines, dialectically, the recent history of urbanization and sustained his first critique of urban society, in which urban space is not defined in terms of industrial rationality, but as a dialectical process of contrasts, oppositions, juxtapositions, and tensions: a growing 'differential reality', with a potential for unstable transformation. Lefebvre (1991) searches for a paradoxical space, in which actual and virtual (presence and absence), characteristics of urban spaces, should be dialectically juxtaposed. He identifies and analyses three possibilities for this spatial approach: a) identical spaces – isotopies (spaces that can be compared, quantified, mapped, spaces of order, rational, contained spaces; b) non-places, or utopias, theoretically defined as spaces of consciousness, imagined spaces, ephemeral places of joy and contemplation; and c) other places, understood as heterotopies, spaces of difference, ambiguous, both excluded and interwoven,

as the (liminal) landscapes of the margins of nascent cities. It is the last that has transcendent possibilities, a virtuality already present that will absorb and overcome the other two topoi.

More recently, Alatalo et al. (2024), Zhu (2024), Sacco et al. (2019), and Stavrides (2007), offers new insights into the meaning of heterotopia as a lens through which the unstable conditions of urban environments could be understood.

Identity and intensity as dispositions for urbanity

Extensive and intensive spaces, actual and virtual spaces. DeLanda (2005) asserts that we experience artificial and natural environments, in the most varied situations and material conditions, according to two phenomenological paradigms, one of which is mediated by extensive attributes (zones of extension), while the other, less known, articulates intensive attributes (zones of intensity). The reflection on the distinction between these two paradigms remains at the level of philosophical abstraction, despite its relevance in the constitution of subjectivities. What is extensive differs from what is intensive as attributes related to quantities (additive and divisible) differ from those related to magnitudes (non-additive and indivisible). The knowledge of the dimensions of a given environment (perimeter, area, volume) is distinct from the average temperature in various zones of this environment. If the environment presents an isothermal tendency, dividing its area in half would not alter this tendency, preserving the same thermal magnitude as the previous, larger environment. For Deleuze (1994), in order to produce changes in intensive attributes, there must be a “difference” in the intensity gradient of matter, which is not produced by the mere addition of more of the same material (repetition), but rather a critical change in environmental conditions.

DeLanda (2005), in presenting a philosophical formula according to which differences of intensity are productive because they virtually result in bundles (sets) of unstable multiplicities, does not ignore the role of extensive differences in the (continuous) actualisation of the becoming of spatial structures. The distinction between the diversity of a world given to perception and that which is at the origin of this perceptual phenomenon by means of the concept of difference is a key element in Deleuze's (1994) ‘realist’ ontology and implies a certain essentialism in order to understand the production of ‘extensities’ (extensions) by intensities, of what is extensive by what is intense, of phenomenological attributes by the attributes of the world itself (nuomena, nuomenon). In other words, in certain conditions of instability, material or immaterial, of the constitutive elements (constituents) of (anthropized) environments, differences in the zones of critical intensity can lead to the emergence of extensities, extensive environmental conditions, whose spatial matrices follow criteria, or parameters, defined by non-metric qualities (projective, differential, topological), gradations, nuances, rhythms, intensities, among other magnitudes (of immanence). The differential spaces resulting from the interweaving of intensive and extensive parameters show flows rather than fixed flows, force fields that articulate (Brownian) movements measured in a non-metric way, resulting in a form of multiplicity, intrinsically defined, without being subject to external geographical references. If the sensible world consists of topological spaces that generate (construct) biological, physical, chemical and social processes, inhabited by extensive spaces, there is the possibility of mediations through restrictions of immanence.

METHOD: PEREC, FOUCAULT AND DELANDA

The paper adapts three methods for discovering smallness in public spaces. Firstly, we translated the way of seeing the street of Georges Perec (2016), a French writer who tried to understand the reality of smallness in the streets of Paris, to our context in Goiania. In his book, he describes the transit of people, animals, objects and interactions that take place during the period of his observation, in order to generate a reflection on the emergence and formation of the ambience of the place. The observations made by him in Saint-Sulpice Place in Paris, allows for an in-depth and contextualised analysis of the dynamics of sociability in public space, which was adapted to the Brazilian context. Therefore, in the many visits we carried out at the 'Gari's Square', we observed different everyday life situations. The operation was quite simple. The researcher chooses a spot and stays for around 15 minutes, carefully observing what happens, which singular event could develop in that timelapse. A list of interactions among humans, no-humans and objects, should be recorded in a fieldwork notebook. Everything you think is relevant, anything that catches your eye: people passing by, working, talking or interacting in any way, animals, the weather, cars, presence, absence, among other situations.

Secondly, we conducted visual analysis of 18 photos, chosen out of hundreds, decodifying the relationship among many elements of urban space. Doing this, we reconnect the variables to get meaningful insights about patterns of spatial conflicts. Thus, based on the six dimensions defined from the interpretation of Foucault's (2013) theory on heterotopia, we developed some propositions that could act as operational tools for identifying everything that was "out of frame" in the places we choose to observe: 1) Deviance (deviant trajectories) states that every culture has its own ethic codes, every society has its own rules and constraints, its own traditions, where behaviour that doesn't fit into these pre-established terms is considered deviant from the established norm. Thus, the concept of heterotopia varies depending on the society to which it refers, and its definition is not universal. 2) Memory (mnemonic labyrinths) is related to the function given to a certain element, object or place in society. Over time, 'a society can make a heterotopia that exists and that has not ceased to exist function in a very different way' (Foucault, 2013, p.117). Therefore, heterotopias can acquire different meanings and functions in themselves without ceasing to be present. 3) The third principle - resonant rhizomes - consists of the power of the heterotopia to 'juxtapose several spaces in a single real place' (Foucault, 1967, p.118). Once again, the culture of the place can influence the juxtaposition of internal microcosms that are often not perceived by those who are not part of that particular group or social circle. Photography is a device that can illustrate this principle, since the same place can take on different configurations, resulting in an invisible juxtaposition, which at a given moment no longer exists, but can be captured and witnessed by photography. 4) In the fourth principle - rhythmic fragments - heterotopias are associated with what Foucault (2013) calls 'cut-outs of time' (p.118), where there is a kind of rupture of traditional time. This 'heterochrony' can be defined both by the accumulation of elements, culminating in what would be a 'place of all times, which is itself outside of time' (p.119), as is the case with museums and libraries, which are configured as a place of accumulation and constitute heterotopias; but also by the ephemerality of everyday events, such as fairs, parties and concerts, which remain in a given place for a short period of time, giving a whole new meaning to what previously existed there. 5) The fifth principle - liminal places - is governed by a system of opening and closing where, at the same time as heterotopias are isolated, they also become penetrable. According to Foucault (2013) 'everyone can enter these heterotopic allocations, but, in truth, this is only an illusion: one believes one is entering and is, by the very fact of entering, excluded'

(p.119). Some places operate under certain social, cultural, political and economic circumstances, which exclude those who don't share them, a kind of intangible frontier that is only seen by those who 'experience' it from the inside, from a subjective perspective. 6) The sixth and final principle - invented landscapes - is related to the function or role it represents, 'the role of heterotopias is to create another space, another real space, as perfect, as meticulous, as well arranged as ours is disorganised, badly laid out and messy' (Foucault, 2013, p.120). This heterotopia of compensation arises when people want to project an image of comfort made up of the total opposite of what is undesirable. This is what shopping centres are like, unreal, invented places designed to function as objects of desire through shop windows and what cannot be achieved in real life. In general, this heterotopic principles functions as a kind of externalised desire, which can take different forms, not just that of the shopping centre, but which is based on a created and illusory space.

RESULTS AND DISCUSSIONS

In our description of public spaces from the perspective of heterotopic spatial configurations we defend urbanity-as-becoming. Even on the micro-scale of an urban block, there is the possibility of demonstrating that restricted public spaces can be constituted as "urban environments" that articulate forms of experiential heterotopias. These analyses contribute to urban studies by offering a theoretical basis for the concept of "experiential heterotopia", a view of relational space that is appropriated by tactical uses of (un)controlled places. During our observations, we spotted a curious detail: a white kombi that is always parked in the same spot in the square, in front of the Otto Marques Gallery. Apparently, no one owns the vehicle, and it seems to have been there for a long time. A quick search of the newspaper "O Popular" revealed that the Kombi has already attracted the attention of many people. In fact, it is abandoned, and its original owner has never been identified, which has transformed it into a kind of art gallery, hosting works by various graffiti artists in the centre of Goiania and becoming an interactive element in that neighbourhood.

Some urban objects of different scales stand out in the landscape of Gari's Square - a rectangle measuring approximately (20x30)m - which can inform the relationships that define the ethical/aesthetic regimes of experiential heterotopias: the Octo Marques Gallery; the Parthenon Building; the abandoned grocery store; the roads that surround the square; the boundaries of the square (); the snack kiosk; the used clothing store; the plant, variety and household utensil store; the parking lot; the (small) office building; the clothing store; the beauty products store. The photos show all these objects/buildings and their respective constituent elements. Even at the micro-scale of an urban block, we demonstrate that restricted public spaces can constitute "urban ambiences" that articulate forms of experiential heterotopias. We describe the streets as: a) deviant trajectories; b) mnemonic labyrinths; c) resonant rhizomes; d) rhythmic fragments; e) liminal places; and finally, f) invented landscapes. These analyses contribute to urban studies by providing a theoretical foundation for the concept of "experiential heterotopia," a term referring to a space appropriated by tactical uses (monitored).

Deviance. Deviant trajectories keywords: woman, green trunk, bunch of objects, parking lot, octo marques gallery, unexpected use of the street, and face mask. A woman walks in the street carrying a green trunk (cleaning container) with a bunch of objects. In the background is the entrance to the "Octo Marques" Gallery fence for protection and the concrete wall of the Parthenon Building parking lot. There is a black car parked and an empty bag next to the curb. The situation of deviation emerges

from the unexpected use of the street, as it is in the wrong direction literally, figuratively, and symbolically. The use of the face mask on her face implies another situation of deviation: the Covid-19 pandemic.

Memory. Mnemonic labyrinths keywords: Kombi, brutalist facade, loose leaf, cardboard box, abandoned, trash, utility vehicle, mnemonic mazes, and uselessness. This van, a Kombi, parked on the street for months, interacts with the "Octo Marques" Gallery and the brutalist facade of the Parthenon Building. On the sidewalk floor, a loose leaf and a cardboard box unbalance the monochromatic concrete tone of the pavement. The vehicle seems to be abandoned, with various objects piled up inside it, like trash. Its primordial function as a utility vehicle metamorphoses and reconnects us to mnemonic mazes where we could get ourselves seeing, feeling, and thinking in the surreal atmosphere of its emptiness and uselessness.

Resonance. Resonant rhizomes keywords: the deco building, beam of light, shadow, void, invisible buildings, fracture, woman, bench, and car. A view of the square from the parking lot entrance, located on the opposite corner of the "Neco Building". The standout visual element is a beam of light that occupies the centre of the image, resulting from the shadow and the void between two "invisible" buildings that pair with the other two in the right and left portions of the picture. There is a visual fracture in the landscape, through a rupture in space-time that crosses the square diagonally. Amid regions kept in shadow, a woman remains sitting on a bench in the square, next to a white car.

Rhythm. Rhythmic fragments keywords: incoherent elements, ghost, boots, clothesline, reading, cross-legged, paper, statue of a black woman, and gaze. Three apparently incoherent elements balance each other in a very peculiar situation. A "ghost" person, who's only legs and boots can be seen, washes green rugs hanging on an improvised clothesline in the street. Sitting cross-legged on a wooden bench, a man could be reading something (magazine? book? newspaper?), holding a rolled-up paper in his left hand (which means an anachronistic situation in the era of digital technologies). Finally, the statue of a black woman with wavy hair observes something over the square with its freezing gaze.

Threshold. Liminal places keywords: temporary garbage deposit, disposable packaging, bags, common trash, curb, trees, hazed landscape, and situation. The place is used as a temporary garbage deposit, as an assemblage of non-regulated, informal liminalities. Contingent use. Useless use. The disposable, the ephemeral. Disposable packaging and garbage bags accumulate next to a container with "common trash" written on it. The curb still exists under so many boxes, defining a strange threshold between the square and the street. The trees overlap the vertical elements of the Parthenon Building and, together with some parked cars, create a hazed landscape. Uncollected trash in the square becomes an occasional, transitory, and incoherent situation.

Illusion. Invented landscapes keywords: sculpture, black concrete, monument, female figures, amphoras, unreal, office building, joy, and "gods with us". The sculpture, made of black concrete, it's a kind of local monument in the square. Located in its central part, over a white base, it represents two female figures holding jugs (amphoras) pouring water on the ground. The monument has no real connection with local culture. It seems an (unreal) meaning of joy. In the background, the office building with arched windows dominates the urban landscape. The shops on the ground floor are

closed, and, in the left corner of the image, the private parking lot wall displays the message “God With Us”.

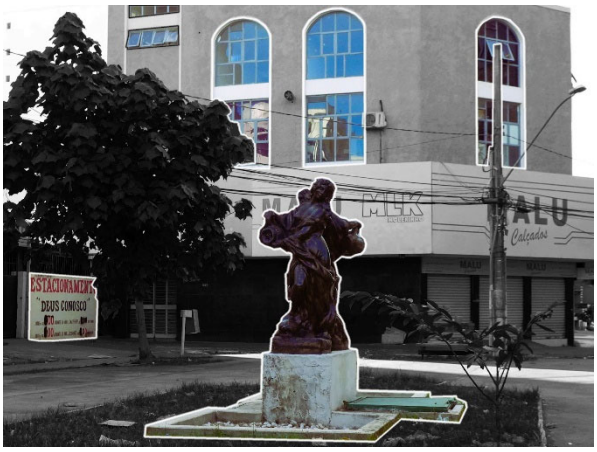
Deviance. Deviant trajectories. [woman, green trunk, bunch of objects, parking lot, octo marques gallery, unexpected use of the street, face mask]

Memory. Mnemonic labyrinths. [Kombi, brutalist facade, loose leaf, cardboard box, abandoned, trash, utility vehicle, mnemonic mazes, uselessness]

Resonance. Resonant rhizomes. [the deco building, beam of light, shadow, void, invisible buildings, fracture, woman, bench, car]

Rhythm. Rhythmic fragments. [incoherent elements, ghost, boots, clothesline, reading, cross-legged, paper, statue of a black woman, gaze]

Threshold. Liminal places. [temporary garbage deposit, disposable packaging, bags, common trash, curb, trees, hazed landscape, situation]



Illusion. Invented landscapes. [sculpture, black concrete, monument, female figures, amphoras, unreal, office building, joy, gods with us]

Thinking Liminal Spaces in Goiania Downtown

The existing literature on heterotopias usually reflects how “other spaces” can influence the dialectic of relational space in neoliberal urbanism, while articulating the political action in contested territories. The creation and arrangement of elements in the relational space is not a passive process, as it is directly related to economic forces and agents, being the object of power relations. Most of these elements can be strategically linked to institutions and their architectural forms, acting as landmarks in space and in the urban popular imagination.

The configuration of situations in the relational space is not a passive process, as it is directly related to economic actors and agency, being the object of asymmetrical power relations. These analyses intend to contribute to urban morphology research by providing a theoretical and empirical approach for the concept of "experiential heterotopia", which could help to understand how a space is appropriated and used as resistance territory. In our description of public spaces from the perspective of heterotopic spatial configurations we defend urbanity-as-becoming. Even on the micro-scale of an urban block, there is the possibility of demonstrating that restricted public spaces can be constituted as “urban environments” that articulate forms of experiential heterotopias. These analyses contribute to urban studies by offering a theoretical basis for the concept of “experiential heterotopia”, a view of relational space that is appropriated by tactical uses of (un)controlled places.

The synthetic framework we developed here describes the photos using two levels of meaning, one compositional, relating the elements to each other, and the other, analytical, explaining the ways and modulations of these relationships with heterotopias. Thus, we should only "cut out" the analytical level. We should cut out two or three elements related to the principles of heterotopia, according to Foucault.

The act of producing diagrams in the photographs, in order to emphasize heterotopias, follows the propositions listed by Deleuze (2007), consisting, firstly, of differentiating the colour black and white - it's good, but I need to emphasize more the elements that are going to be coloured - and I thought

about creating a white border around it, it could be a thicker border, it would interfere with the image, I want it to interfere with the image, we could even think about using colours for these borders afterwards, I didn't want to blur the image because that would impair the reading, because as you know, the whole image will show an environment that could be a heterotopia effect, we're only going to highlight some elements, but the whole environment is an effect, we're going to imagine the square as one kind of heterotopia.

CONCLUSIONS

We present analyses and reflections on the ambiences that emerge in this place, which are the result of the experiences and routines of the people of the region, as well as a study of how the relationship between person and environment works in the alley that forms part of the morphology of this place. In our description of public spaces from the perspective of heterotopic spatial configurations, we defend urbanity-as-devour. Although on the micro-scale of an urban block, there is the possibility of demonstrating that restricted public spaces can be constituted as ‘urban ambiences’ that articulate forms of experiential heterotopias. We present an analytical framework that reflects on the ambiences that emerge in Gari’s Square, which are the result of the experiences and routines of people in the region, in addition to a study on how the relationship between person and environment works in the alley that is part of the morphology of this place. In our description of public spaces from the perspective of heterotopic spatial configurations we defend urbanity-as-becoming. Even on the micro-scale of an urban block, there is the possibility of demonstrating that restricted public spaces can be constituted as “urban environments” that articulate forms of experiential heterotopias. We described the urban environment of a small place as: 1) deviant trajectories; 2) mnemonic labyrinths; 3) resonant rhizomes; 4) rhythmic fragments; 5) liminal places; and, finally, 6) invented landscapes. These analyses contribute to urban studies by offering a theoretical basis for the concept of “experiential heterotopia”, a term that refers to a space that is appropriated by tactical uses of (un)controlled places. The article complements existing literature on heterotopias and ambiences, questioning how "other spaces" can influence the dialectics of relational space in capitalism (neoliberal urbanism) while reflecting on contested territories.

The morphology of transformations in the form and landscape of the Metropolitan Region of Rio de Janeiro: analytical processes on urban fabrics and open spaces

Natalia Parahyba[1], Vera Tângari[2]

ABSTRACT

The research developed by the authors' research group focuses on the morphological analysis criteria applied to the Metropolitan Region of Rio de Janeiro, using geoprocessing techniques. We identify the morphological aspects in the transformation processes and their impacts resulting from: urban legislation codes and development plans; public infrastructure investments; socio-spatial inequalities; environmental conflicts; contradictions between current legislation, municipal macro zoning and urban occupation patterns. This article presents the classification of urban and rural fabrics and of public and private open spaces, especially in the metropolitan Eastern and Northern parts, seeking to understand how the configuration of these spatial systems takes place. We propose to describe degrees of urbanization, pointing out conflicts regarding the use and expansion of land occupation in these territories, and, in the process, we highlight the importance of water bodies as part of the planning and management of cities and regions. To this end, we survey the following aspects: the population evolution increases or decrease; the physical, territorial and environmental components; the context of the metropolitan economical basis; and the methodological strategies, as related to mapping activity. The preliminary results indicate the role of open spaces in their relationship with the resulting landscape, as well as the consequences of municipal urban regulations (master plans, management plans, macro zoning) and the current degree of urban fabrics' consolidation. In our analysis, we consider the indicative trends in morphological transformation, whether by the addition of new urbanized areas, the replacement of building types, or the increase of the built mass within the fabric. In accordance with our objectives, we conclude that our efforts to understand the various transformation processes, that affect landscapes, urban configurations and socio-spatial form, allow us to upgrade our theoretical and empirical debates as well as provide subsidies for the decision-making process in urban and regional planning.

Keywords: morphology, transformation, landscape, metropolis, Rio de Janeiro

INTRODUCTION

This paper presents the objectives, methodology, and preliminary results of research concerning the mapping of urban fabrics and open spaces in the Metropolitan Region of Rio de Janeiro (RMRJ),

developed by the SEL-RJ Group (PROARQ/FAU-UFRJ). By comparing municipal legal regulations and the current level of consolidation of urban fabrics, revealed by the mappings, we intend to analyze the socio-spatial processes and forms in the Eastern and Northern portions of the RMRJ.

The main objective is to apply territorial analysis criteria, using geoprocessing techniques, seeking to identify the processes of landscape transformation and impacts arising from urban legislation and urban development plans, public investments, socio-spatial conflicts and inequalities, environmental conflicts, contradictions between current legislation, municipal macro-zoning, and urban occupation patterns (Pereira et al., 2022).

To understand the impact of the set of transformations in the regional and urban space, we considered: data on income distribution; the significant presence of environmental components; the construction of new highways; and the installation of large urban projects (Oliveira et al., 2012).

In this sense, this paper presents the preliminary results and analyses of the mapping of open spaces in their relationship with the resulting landscape, the analyses of municipal legal regulations, and the current level of consolidation of urban fabrics, seeking to understand how the configuration and appropriation of these spaces work.

Study Area

The research takes as study area the Eastern and Northern portions of the RMRJ – areas in green and red, as shown in Figure 1 – consisting of a total of 16 municipalities.

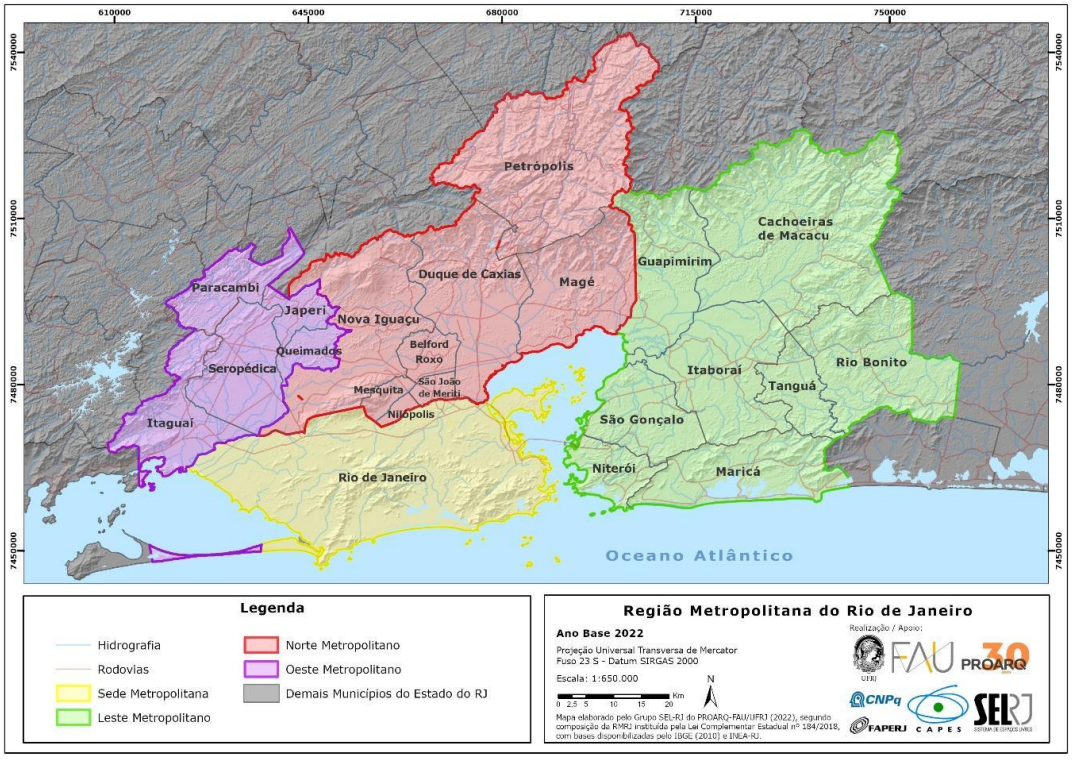

Figure 1. Map of the RMRJ and internal regionalization. Source: Prepared by the SEL-RJ Research Group, 2023.

According to the Brazilian Institute of Geography and Statistics (IBGE-2022), the total population of the two portions is 5.137,754 inhabitants, representing 42.7% of the RMRJ population, distributed over approximately 543 hectares, representing 72.1% of the entire territorial extension of the RMRJ.

Table 1 below shows the overview of population evolution in the municipalities studied in recent decades compared to the State Capital, the State of Rio de Janeiro, and the RMRJ.

Table 1. *Population and Territorial Area - Eastern and Northern Metropolitan Area. Source: IBGE (adapted by the authors).*

MUNICIPAL ITY	YEAR			POPULATION GROWTH		TERRITORIAL AREA (KM²)
	2000	2010	2022	2000-2010	2010-2022

Cachoeiras de Macacu	48.543	54.273	56.943	11,8%	4,9%	954,749
Guapimirim	37.952	51.483	51.696	35,7%	0,4%	358,443
Itaboraí	187.479	218.008	224.267	16,3%	2,9%	429,961
Maricá	76.737	127.461	197.277	66,1%	54,8%	361,572
Niterói	459.451	487.562	481.749	6,1%	-1,2%	133,757
Rio Bonito	49.691	55.551	56.276	11,8%	1,3%	459,458
São Gonçalo	891.119	999.728	896.744	12,2%	-10,3%	248,160
Tanguá	26.057	30.732	31.086	17,9%	1,2%	143,007
Eastern Metropolitan	**1.777.029**	**2.024.798**	**1.798.761**	**13,9%**	**-11,2%**	**3.089,107**
Rio de Janeiro (Capital)	5.857.904	6.320.446	6.211.423	7,9%	-1,7%	1.200,329
Rio de Janeiro (State)	14.391.282	15.989.929	16.054.524	11,1%	0,4%	43.750,425
RMRJ (22 municipalities)	**11.254.026**	**12.241.449**	**12.022.110**	**8,8%**	**-1,8%**	**7.530,938**

It is possible to observe that in the period 2000-2010, all municipalities had a population increase, with the Eastern Metropolitan area growing above the RMRJ average (8.8%). Between 2010 and 2022, there was a population decrease in almost all municipalities in the Northern Metropolitan area, except for Magé (0.4%) and Belford Roxo (2.9%), and the Eastern Metropolitan area with Niterói and São Gonçalo showing population loss. It is worth noting the growth of Guapimirim and Maricá in the period 2000-2010, with 35.7% and 66.1% respectively, which may have been motivated in part by the installation of the Rio de Janeiro Petrochemical Complex (COMPERJ). Maricá again had a population increase of 54.8% in the period 2010-2022.

Income Pattern

The analyses of the RMRJ population profile were complemented with income data (Figure 2). Although the IBGE base year is 2010[71], it is possible to observe that the highest average incomes are concentrated in the municipalities of Rio de Janeiro and Niterói – in sectors of the cities where

71 It is important to note that the IBGE database was affected by the non-occurrence of the Demographic Census in 2020 due to the Covid-19 pandemic. Although the survey was conducted in 2022, many of the data are still awaiting release

residential neighborhoods with higher real estate value are located. The concentration of jobs, income, services, and infrastructure in the metropolitan core is confirmed when we observe that 45.5% of the metropolitan GDP[72] of R$ 740.7 billion is concentrated in the city of Rio de Janeiro (IBGE, 2022).

This socioeconomic imbalance among RMRJ municipalities is further attested by the predominance of incomes from 0 to 3 minimum wages in almost all municipalities in the Eastern and Northern Metropolitan areas, except for Niterói, and some areas of income above 3 minimum wages in the municipalities of Petrópolis and Cachoeiras de Macacu.

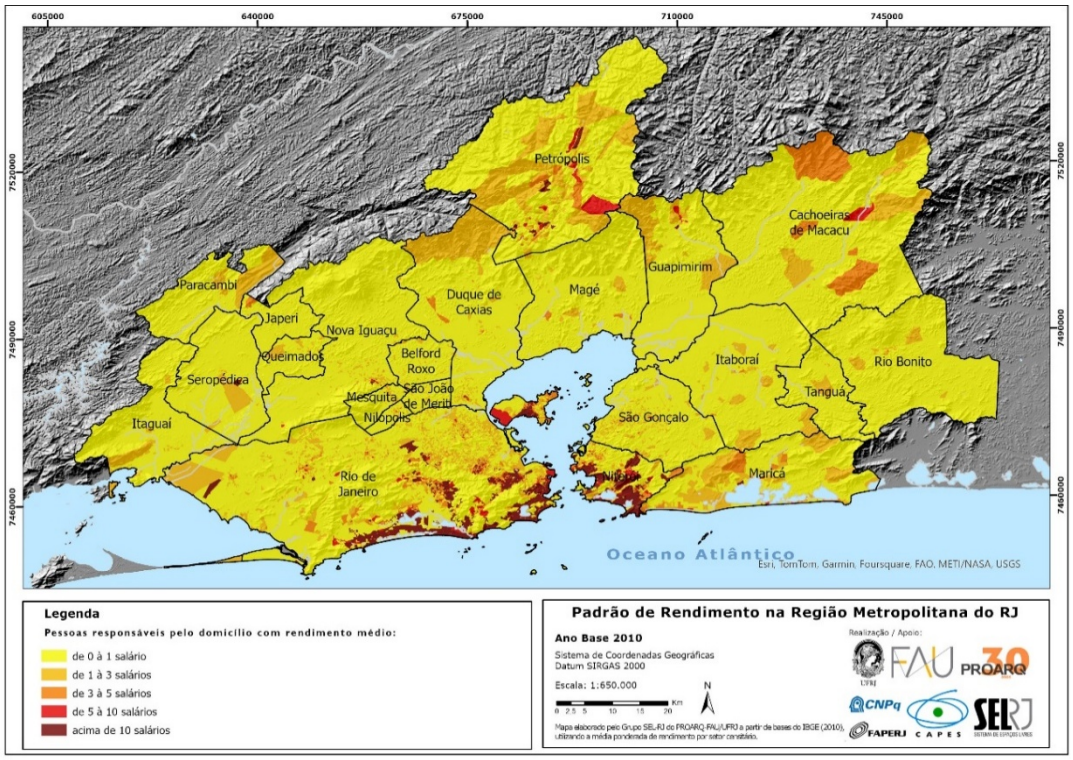

Figure 2. Income pattern in the RMRJ. Source: IBGE, 2010 (adapted by the authors, using the weighted average income by census sector).

Environmental Conservation Units in the RMRJ

The RMRJ territory has a strong environmental component, attested by the presence of restingas, sand ridges, dunes, forested slopes, springs, lagoons, lakes, beaches, marshes, and mangroves. In this sense, federal and state Environmental Conservation Units (UCs) were mapped to observe the existing degrees of fragility and preservation, as well as their relationship with the built environment (Figure 3).

The RMRJ has approximately 36% of its territory occupied by protected areas. In the Metropolitan North, a large part of the Integral Protection and Sustainable Use UCs are located, in occupied surface

72 GDP - Gross Domestic Product: it is the sum of all final goods and services produced in a region during a given period, reflecting the economic performance of that area

area. According to PEDUI[73] (2018), Atlantic Forest wooded areas correspond to 36% of the metropolitan territory, and the hydrography, whether freshwater or maritime, signals the need for attention to environmental components in any planning or development project for this territory. The research surveys found that, with rare exceptions, these areas were ratified by municipal spheres of environmental protection as areas of local relevance protection, organized into categories of Macrozones, Zones, and Areas of Special Environmental Interest, complementing the protection framework of the three spheres of power.

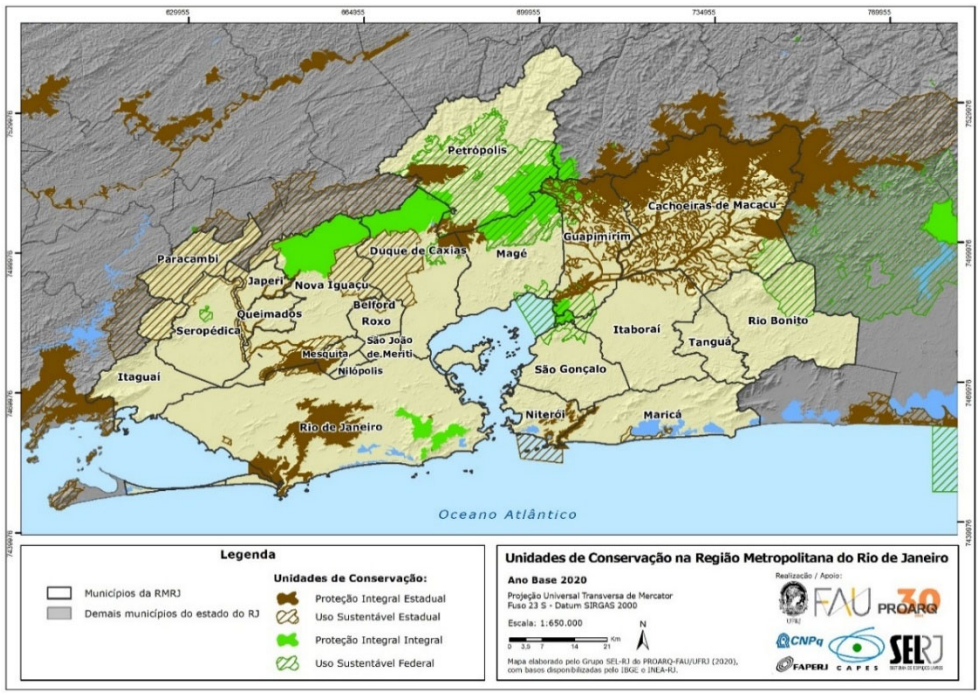

Figure 3. Map of Conservation Units in the RMRJ. Source: Prepared by the SEL-RJ Research Group, 2022.

The economic restructuring project of the RMRJ

From 2006, the RMRJ underwent an economic restructuring based on the oil matrix, with investments of R$ 180 billion between 2011 and 2013. The project included enterprises such as the Petrochemical Complex-COMPERJ, the Duque de Caxias Refinery-REDUC, expansion of the Port of Itaguaí, Metropolitan Road Arc, and the Jaconé Terminal (Figure 4). These actions drove intense demographic movement, supported by federal policies such as PAC[74] and Minha Casa, Minha Vida[75], directly impacting the municipalities in COMPERJ's area of influence. This megaproject motivated the restructuring of the RMRJ as a planned spatial unit and the creation of a metropolitan plan, focusing on economic development, regional integration, and job creation. However, the socio-spatial impacts exceeded its limits, causing the proliferation of environmental liabilities, abandonment of vast land extensions, intense real estate speculation, and growth of slums, among other aspects observed in the territorial organization of the metropolitan space (Binsztok, 2018; Bienenstein et al., 2018).

73 Strategic Plan for Integrated Urban Development of the Metropolitan Region of Rio de Janeiro

[74] Growth Acceleration Program (PAC) was a federal government plan, launched in 2007, aimed at encouraging economic growth through investments in infrastructure, sanitation, housing, and energy

[75] A Brazilian government initiative, created in 2009, to facilitate access to housing for low-income families, offering subsidies and facilitated financing for home ownership

Despite this, the project led to the reinstitution of the RMRJ and the creation of a governmental apparatus for its management.

Figure 4. RMRJ Spatial Structure Map. Source: prepared by the SEL-RJ Research Group, 2022.

In addition to these projects, several other local investments were also generated aimed at the economic sector, the preparation of a favourable environment for COMPERJ's operation, and the expansion of mobility within the metropolitan territory.

Finally, it is worth emphasizing the decline of the project, which was strongly reduced and removed from the priority agenda following the political changes that occurred in the 2018 elections, with the governmental bodies and instruments created to manage it being dismantled, leaving serious consequences for the municipalities directly involved.

THEORETICAL FOUNDATION AND METHOD

The mappings of urban fabrics and public and private open spaces in the RMRJ result from the adaptation of thematic cartography in a GIS[76] environment, built over the years by the national research network QUAPÁ-SEL, correlating open space systems (SEL) and urban forms in Brazilian cities through systematic and comparative landscape analysis (Macedo et al., 2007).

The mapping and characterization of open spaces in the RMRJ involved refining the classification proposal for categories applied to the mapping of public and private open spaces, in a preceding stage, in the municipality of Rio de Janeiro (Tângari, 2021).

Preliminary Surveys

[76] *"Geographic Information Systems are information systems specially built to store, analyze, and manipulate geographic data, that is, data representing objects and phenomena where geographic location is an inherent and indispensable characteristic for handling them." (CÂMARA et al., 1996).*

The first step was to understand the role of urban legislation in the production of urban space, starting from the understanding of urban complexity and morphological structure in relation to the conflicts and contradictions that permeate the appropriation and management of open spaces.

Data Modeling

Concurrently with the collection and analysis of municipal legislation, vector cartographic surveys were carried out at different scales, from various sources: Conservation Units, Permanent Protection Areas, hydrography, lagoons and mangroves (INEA-RJ); municipal, district, state, neighborhood and census sector boundaries (IBGE); delimitation of urban blocks[77] (Metropolitan Chamber), etc. The systematization of these surveys has been used in a complementary way to the mappings of urban fabrics and open spaces, contributing to critical analyses of the areas under study, undergoing constant updating.

Mapping and Classification

Urban Fabrics

The mapping of urban fabrics covers the entire municipal surface, including urban and rural territories, through nine classes and four subclasses, as shown in Table 2 and Figure 5. The adaptation of the methodology developed for mapping the municipality of Rio de Janeiro had as its main innovation the introduction of the subclasses Agrosilvopastoral Domain (use and agricultural aptitude of lands for a certain type of production, in forest covers or forage); Parceled and Occupied Urban Fabric; Parceled and Unoccupied Urban Fabric; and Unparceled and Unoccupied Urban Fabric (in areas of unconsolidated urban fabric[78]).

Table 2. *Classification of Urban Fabrics. Source: SEL-RJ Group/PROARQ/FAU-UFRJ.*

CLASSES	SUBCLASSES	DESCRIPTION
Forest Cover	-	Continuous patches with predominance of dense forest vegetation
	Agrosilvopastoral Domain	
Forage	-	Continuous patches with predominance of shrub vegetation, grasses or herbaceous plants
	Agrosilvopastoral Domain	
Rocky Outcrop	-	Exposure of rocks or rocky walls
Dunes and Beaches	-	Sand strips and sand ridges
Mangroves	-	Transition strips between terrestrial and marine environments
Water Bodies	-	Visible water surface (perennial or not)
Consolidated Urban Fabric	-	The reference is the urban block (or corresponding polygon) with more than 50% of its surface occupied
Unconsolidated Urban Fabric	Parceled and occupied U.F.	The reference is the urban block (or corresponding polygon) equal to or less than 50% of its surface occupied
	Parceled and unoccupied U.F.	
	Unparceled and unoccupied U.F.	
	Agrosilvopastoral Domain	
Domain Use Space	-	Union properties, Marine Lands, University campuses, airports, ports, etc.

[77] The urban block base for the RMRJ municipalities was obtained through a technical cooperation agreement with the Metropolitan Chamber of Rio de Janeiro, derived from an aerophotogrammetric survey at a scale of 1:2,000 of the RMRJ, within the scope of contract 001/2015, contracted by the Rio de Janeiro government SEGOV and UGP Metropolitana LOAN 8327-BR (2016)

[78] The research relied on visual interpretation of satellite images to identify recent changes in urban occupation patterns, as access to officially approved land subdivisions at the municipal level was not available.

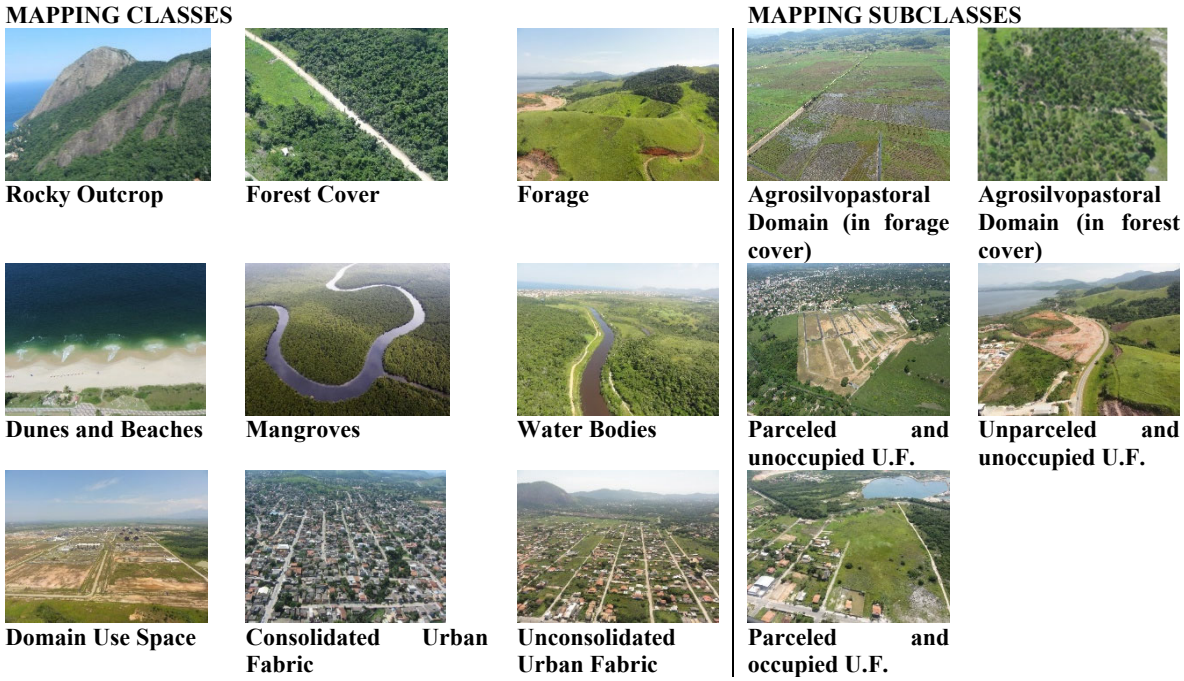

Figure 5. Aerial photographs exemplifying the mapping classes and subclasses. Source: SEL-RJ Group Archive, 2019 and O Globo, 2011.

Open Space System

The classification used is divided into six major classes and twenty subclasses (Table 3). The spatialization of this classification can be apprehended through the images included in Figure 6. Urban legislation and property situation were the aspects that helped us propose this subdivision (Tângari, 2018).

Table 3. Classification of Open Spaces. Source: SEL-RJ Group/PROARQ/FAU-UFRJ

PRIVATE OPEN SPACE			
CLASSES	**OPEN SPACES (%)**	**SUBCLASSES**	**DESCRIPTION**
PRIVATE	Up to 30%	Higher density	Block with up to 30% Open Spaces
	30 - 50%	Medium density	Blocks with open spaces between 30 and 50% of the area
	Above 50%	Lower density	Block with 50% or more Open Spaces
PUBLIC OPEN SPACE			
CLASSES	**DEFINITION**	**SUBCLASSES**	**DESCRIPTION**
ENVIRONMENTAL	Open space of environmental character, where leisure and recreation activities can also occur.	Conservation unit	Corresponds to areas covered by Integral Protection Conservation Units (Municipal, State, and Federal).
		Beach	"§ 3. Beach is understood as the area periodically covered and uncovered by water, plus the subsequent strip of detrital material, such as sand, gravel, pebbles, and stones, up to the limit where natural vegetation begins, or, in its absence, where another ecosystem begins" (Law No. 7,661/1988)
		Water bodies	Visible water surface, perennial or not, supported by INEA-RJ databases.
CIRCULATION	Open space of urban or rural character, related to the	Road median	Central or lateral road median or residual road adjustment located on or along public roads - with or without vegetation.

	circulation of vehicles or pedestrians, where activities of recreation, commerce, sports, culture, education, political actions, and festivities may also occur.	Parking lot	Public vehicle parking area - pocket or similar - that does not refer to parking spaces on streets.
		Pedestrian overpass	Elevated pathway for preferential pedestrian circulation and prohibited to motorized vehicles.
		Roundabout	Island, usually circular in shape, surrounded by roads for returns and intersections, with or without vegetation.
		Street, avenue, and sidewalk	Roads intended for the circulation of vehicles, draft animals, and pedestrians. Generally includes: streets, avenues, highways, roads, lateral sidewalks, passages, stairways, public easements, and related.
		Bus Terminal	Set of bus bays located outside the street's traffic lane for stops with shelters for pedestrian protection.
PERMANENCE	Open space of urban or rural character, related to recreation, sports, culture, education, political actions, and festivities.	Soccer Field	Isolated informal open space where people play ball. Does not include soccer fields in squares and parks.
		Parks	Public open space specifically decreed as a park. Visually defined, vegetated or not, with dimensions larger than an urban block, cross-referenced with the city hall's land use map.
		Square	Area determined in subdivision project as public open space for recreational activities.
INFRASTRUCTURE	Spaces of urban or rural character, related to administrative infrastructure of transportation, energy distribution, sanitation, etc.	Up to 30% open spaces	Dominial assets, i.e., public property, granted for special uses - railways, ports, airports, university campuses, cemeteries, gas pipelines, electricity transmission, etc.
		Between 30%-50% open spaces	
		above 50% open spaces	
UNIDENTIFIED OPEN SPACE			
CLASSES	**DEFINITION**	**SUBCLASSES**	**DESCRIPTION**
NOT IDENTIFIED	Public or private open spaces, of urban or rural character, with unidentified function, which may or may not be subject to occupation.	Vegetated area	Area with predominance of vegetation cover (low-lying or arboreal) that may or may not be subject to occupation, with unidentified subdivision and property, not belonging to Conservation Units or Parks.
		Not defined	Everything that is not covered in the other categories

RESULTS AND DISCUSSIONS

In this section, we will present the results related to the mapping, classification, and quantification of urban fabrics and open spaces in the Eastern and Northern Metropolitan areas. From the preliminary reading of the territory of the sixteen municipalities, it was possible to extract and quantify the data, presented below.

Mapping of Urban Fabrics

From the mapping of Urban Fabrics in the Eastern and Northern Metropolitan areas (Figure 7), except for the municipality of Petrópolis, which is still in progress, it was possible to extract data for preliminary analyses.

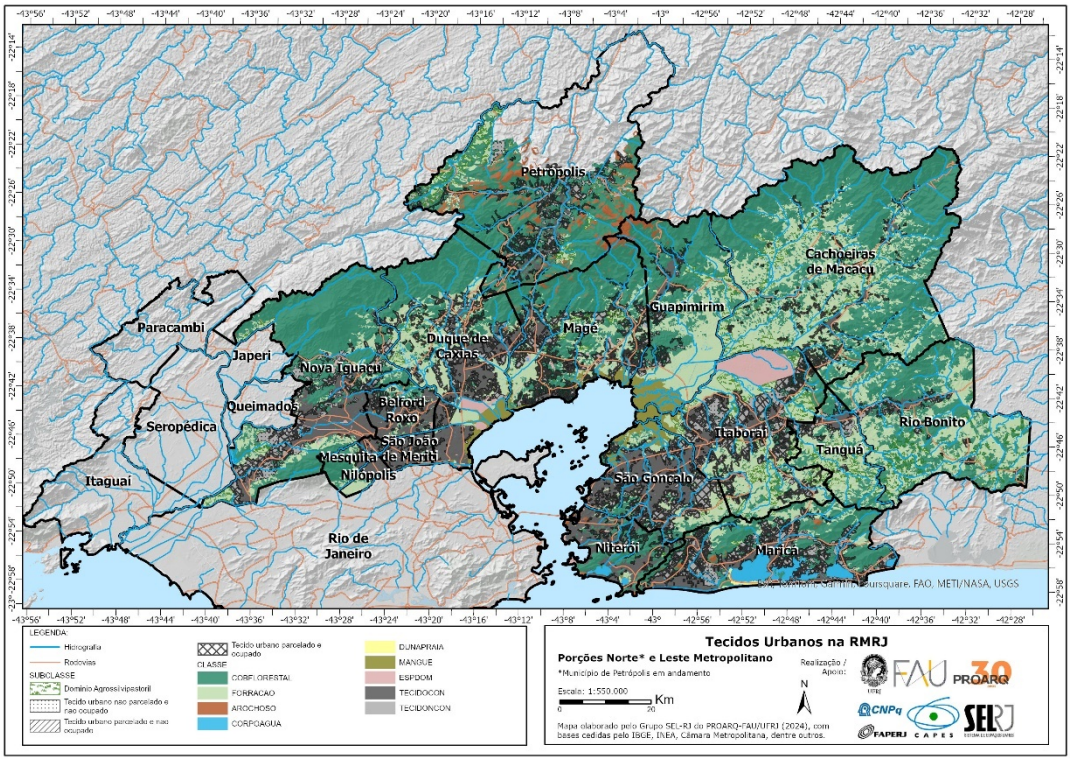

Figure 7. Urban Fabrics Map in the RMRJ. Source: prepared by the SEL-RJ Research Group

Data obtained in the study area (Figures 8 and 9) highlight the predominance of Forest Cover (41.5%) and Forage (27.5%) areas, due to the significant presence of Full Protection and Sustainable Use Conservation Units and the predominantly rural characteristics of some municipalities. The analysis also points to heterogeneity among municipalities. While the municipalities of Belford Roxo, Niterói, São Gonçalo, and São João de Meriti have more than half of their territory occupied by urban fabrics (consolidated and unconsolidated), the municipalities of Cachoeiras de Macacu, Guapimirim, Rio Bonito, and Tanguá have more than 70% of their territorial occupation composed of Forest Cover and Forage.

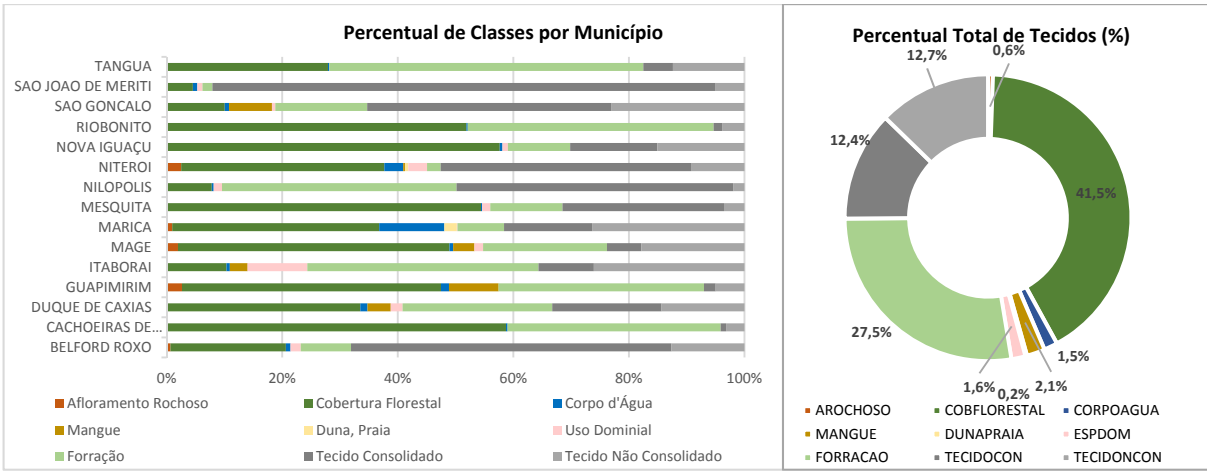

Figure 8. Graphs highlighting the percentages of urban fabric classes in the Eastern and Northern Metropolitan areas. Source: prepared by the authors.

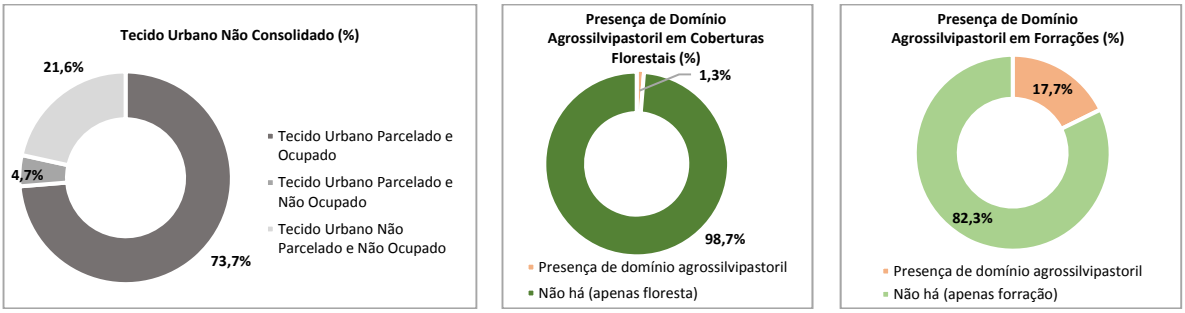

Figure 9. Compilation of quantitative results of urban fabric subclasses in the Eastern and Northern Metropolitan areas. Source: prepared by the authors.

In Figure 9, we have the quantitative results of urban fabric subclasses. It is possible to observe the predominance of parceled and occupied urban fabric in 73.7% of the unconsolidated urban fabric areas, indicating a strong process of urban fabric consolidation after the implementation of the megaproject. It is noted that there is no significant presence of agrosilvopastoral activity in Vegetation Covers; in contrast, they represent 82.3% of the total forage area, which still confirms the predominance of rural characteristics in some municipalities.

Mapping of the Open Space System

The mapping of public and private open spaces in the Eastern and Northern Metropolitan areas, except for Petrópolis and Duque de Caxias, which are still in progress, allowed for the extraction and quantification of preliminary data (Figures 10 and 11).

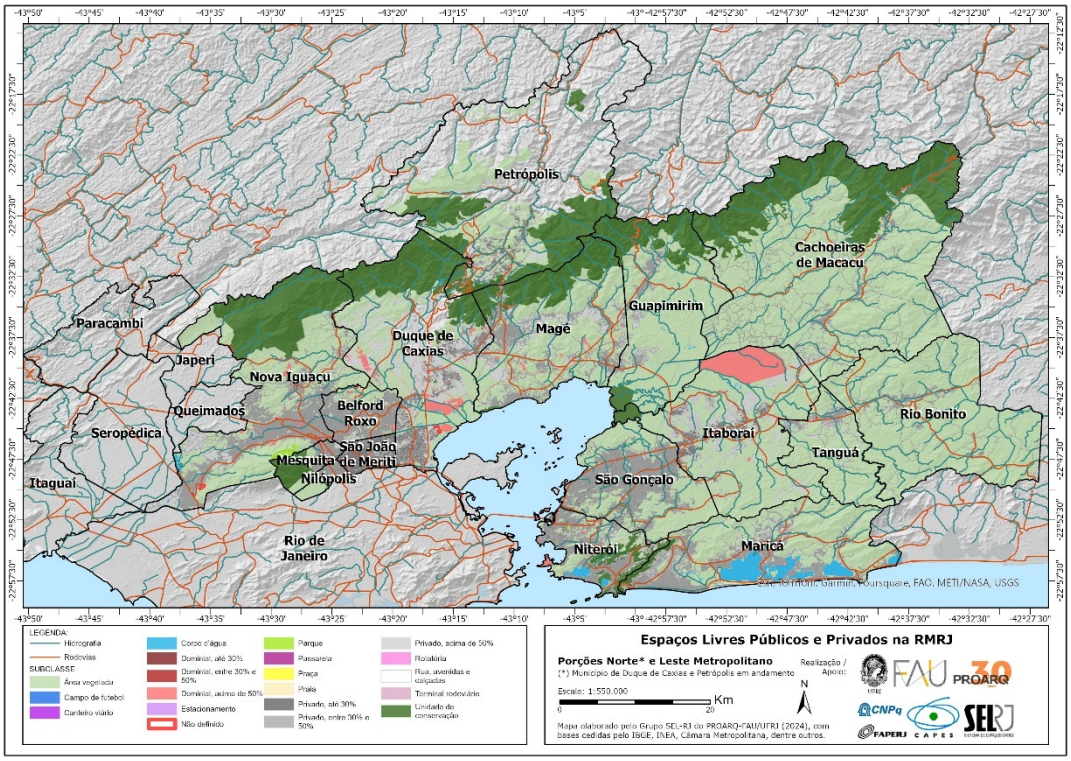

Figure 10. Open Spaces Map in the Northern and Eastern Metropolitan areas. Source: prepared by the authors.

In the graphs of Figure 11, it is possible to observe the massive predominance of public open spaces over private ones in the study area. However, the interpretation of percentages requires caution, considering the unequal distribution and accessibility of these spaces, as well as variations in urban occupation and the presence of rural and environmental areas.

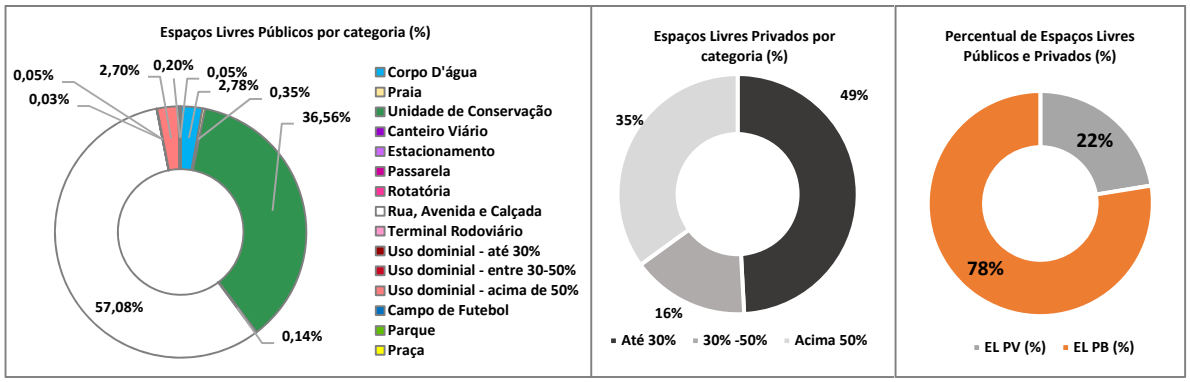

Figure 11. Synthesis of quantitative results of public and private open spaces mapping in the Eastern and Northern Metropolitan areas. Source: prepared by the authors.

Still, on these graphs, it is worth highlighting: the weight of Full Protection Conservation Units (36.56%), a relevant portion of conservation and environmental protection areas, which should be observed by local and regional land use planning; and the category Street, Avenue and Sidewalk (57.8%). Much more than just their capacity for vehicular and pedestrian flow, circulation spaces, as a rule, are the places of greatest expression of daily life, stage and product of urban cultural expression (Macedo et al., 2018).

In Figure 12, we have the percentage of total open spaces. The predominance of vegetated areas (62%) is related to the abundance of spaces with vegetation cover (low or arboreal) that may or may not be occupied, not belonging to Conservation Units. These areas may also be related to the extent of agrosilvopastoral activities, which was not always possible to detect through visual interpretation of satellite images, requiring further investigation, either through dialogue with local governments or field visits. In any case, the relative weight of vegetated areas should be analyzed on a case-by-case basis and related to the pattern of land use and occupation, and to the understanding of the historical evolution of urban development in each municipality.

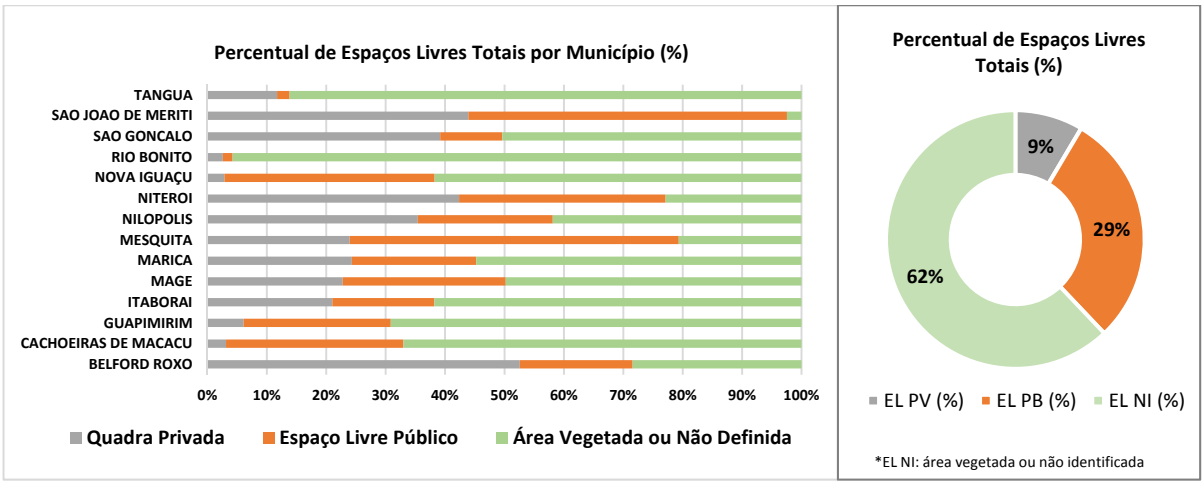

Figure 12. Graphs highlighting the percentages of total open spaces in the Eastern and Northern Metropolitan areas.

São João de Meriti, with more than 90% of its territory urbanized, has 97.3% of its public open spaces in the category Street, Avenue and Sidewalk, evidencing the need for a careful analysis of the data. In private open spaces, blocks with up to 30% of open spaces predominate, signaling the consolidation of urbanization in most municipalities and the chaining of spatial restructuring, with the introduction of large projects of regional impact, especially regarding impacts on municipalities in the immediate surroundings of COMPERJ. Like the municipality of São Gonçalo, with 71% of its blocks in this category. Niterói stands out in the category between 30% and 50% (27%), while Cachoeiras de Macacu leads in the category above 50% (84%), reflecting its recent urbanization process driven by the introduction of large projects of regional impact.

CONCLUSIONS

According to the objectives described in the Introduction of this article, we conclude that our efforts to understand the complex and multiple processes that affect the transformation of the landscape, and socio-spatial forms have allowed us to advance in reflecting on the theoretical and methodological debates of the SEL-RJ Research Group and to advance, refine and revise the methodologies adopted.

In general, we can affirm that in the research on the RMRJ, initiated in 2019, we observed disparities, contradictions, and sociodemographic, economic, and political-administrative imbalances, expressed directly in the landscape and indirectly in surveys of external sources as well as in the mappings carried out systematically for the fabrics, open spaces, and centralities existing in the municipal territories.

When we chose to initiate the research by analyzing legal and normative frameworks, this heterogeneity regarding future projections of urban and rural territory occupation signaled to us the importance of research that can inform public policies.

However, we more objectively hope that the information generated, processed, and analyzed, as presented in this article, can primarily foster dialogues between administrative instances, but above all, between public authorities, private agents, and the population. Thus, the processed information is made publicly available through workshops, colloquiums, meetings, and publications, to foster the desired dialogues and responsive actions with civil society, which can use them as a tool for social participation.

Acknowledgements

We would like to express our gratitude to FAPERJ, CNPq, and UFRJ for the Technical Support, Scientist of Our State, and Scientific Initiation scholarships, as well as the research grants provided.

Urban morphology, transit-oriented development (TOD), and planning: a case study from Aotearoa New Zealand

Yan Li[1], Kai Gu[2]
[1] School of Architecture and Planning, The University of Auckland, New Zealand, li.yan@auckland.ac.nz
[2] School of Architecture and Planning, The University of Auckland, New Zealand, k.gu@auckland.ac.nz

ABSTRACT

Geographical urban morphology provides a systematic framework for urban form research. In particular, it has been applied in planning, architecture, and urban design, towards seeking economically efficient, environmentally sustainable, and socially inclusive future built environments. Despite growing interest in transforming the intellectual ideas of urban morphology into operational tools, practical bases are yet to be fully achieved. In connection with an investigation in Auckland, New Zealand, where transit-oriented development (TOD) has been promoted as a planning response to excessive automobile travel and associated urban problems, this paper reports the use of urban morphology to reveal the development process of Auckland's railway station catchment areas. Clarifying the developmental or evolutionary process provides a foundation for future development to build upon, enhancing place identity and meeting future needs. Alongside global morphological and TOD studies, this research contributes to innovative sustainable development in New Zealand and enhances the practicality of morphological methods.

Keywords: urban morphology, sustainable urban form, transit-oriented development, New Zealand

INTRODUCTION

First established in central Europe in the late 19th century, geographical urban morphology (M. R. G. Conzen, 1960; Gauthiez, 2004; Whitehand, 1981) was later consolidated as an approach for studying urban form in research conducted by M.R.G. Conzen. Beginning in the 1950s, Conzen used town-plan analysis to clarify the geographical arrangement and distinctiveness of towns by systematically examining their constituent elements and tracing their evolution over time (Kropf, 2009). The framework not only enables a critical analysis of buildings and urban fabrics but also informs and shapes the design process (Strappa, 2023). Not surprisingly, it has since been applied in planning, architecture and urban design (Whitehand, 1981).

Despite the increasing interest in transforming the intellectual ideas of geographical urban morphology into operational tools (Gu et al., 2019; Whitehand, 2009), its full potential is yet to be realised. In particular, traditional morphological data collection and analysis require greater clarity. There is a need to improve urban morphology to enable reproducibility and methodological

compatibility across disciplines (Zhang et al., 2023) and establish a dependable methodology for measuring and classifying urban forms (Dibble et al., 2019), thus widening its applicability.

The morphological approach strives to disclose the 'genesis' or 'engendering process' of landscape forms as a developmental or evolutionary process. Alexander (2004) claims that in order for people to create a sustainable world and maintain its uniqueness, they need to recognise that the living environment transforms in a holistic and sequential unfolding process, inheriting and strengthening the good qualities of systems and rectifying the flaws. This 'structure-preserving (and enhancing) transformation' maintains and improves a place's existing structure or essence, the streets, squares, or urban neighbourhoods, even as they evolve and develop (Alexander, 2002). This morphological process uncovers what will emerge and is always informed by the form at the moment just before (Tan et al., 2024). City planning thus seldom begins with a blank canvas and the existing land uses play a crucial role in shaping future development (Atkinson-Palombo & Kuby, 2011).

It is argued that the challenges facing urban morphology are frequently related to ignorance of the dynamics of spatial-temporal processes. Seeking to address this gap, this paper explores the challenges facing urban morphology through the exploration of transit-oriented development (TOD). TOD offers a promising approach to achieving carbon neutrality, which remains an important priority for both local and central government. However, practical strategies and methods for TOD implementation are underdeveloped in New Zealand. Based on the 50% benchmark for usage of sustainable transport (Hale, 2014), many of the railway station catchment areas in Auckland show low usage of sustainable modes of transport (public transport, walking and cycling). According to the analysis of data from the 2018 New Zealand Census, 28 out of the 39 railway station catchment areas below 30% of travel by sustainable modes (Li, 2024). This underutilisation of rail transport is an obvious problem, and there has been no investigation of the causes from a morphological perspective. Geographical urban morphology provides a systematic approach to reveal the complex process of TOD development and redevelopment. Specifically, morphological approach is used in this study to analyse the relationship between the urban development process and the current underutilisation of railway stations in Auckland and provide suggestions for future TOD development.

Morphological periods, fixation lines and plan units are Conzenian terminologies (Larkham Peter J. & Jones, 1991). Urban developments can be conceptualised as a series of morphological periods that leave distinct residues in the urban landscape (M. R. G. Conzen, 1960). Each morphological period represents a portion of history that has distinctive forms based on socio-economic conditions. These forms leave varying degrees of residue depending on the requirements of the societies that follow (M. R. G. Conzen, 1988). The idea of fixation lines has been applied in various planning and design research. For example, the city walls of Pingyao are a fixation line that can be traced from historical maps as well as on the ground now, reflecting the influence of historical structure on built form (M. Conzen et al., 2012). While city walls and mountain ranges have been explored as fixation lines, there has been no research into railways as fixation lines in TOD. The railway line has a significant influence on urban form and urban development, dividing the land into parts and forming a frame or barrier for development. The ever-changing relationship between the railway and urban form is therefore worth investigating to ensure new development can be continuous and respond to problems left historically by prior development. The plan unit which is defined as an area having similar development qualities can be recognised from a town plan that is different from its surroundings – in terms of its combination

of streets, plots and buildings in the developmental process (M. R. G. Conzen, 1960). It takes various sizes, ranging from a single plot to a large portion of a town (Gu, 2014).

This paper therefore addresses the following questions: in what way and to what extent can morphological concepts support explanations of the development process of railway station catchment areas? Given the available qualitative and quantitative data for historical development, how can urban morphology be applied to help reveal the changing morphological process of TOD? Answers to these questions are provided by means of a critical examination of urban development and other changes in the area around the Panmure railway station in Auckland. The case study area has a rich history and has been deeply influenced by Auckland's complex transportation evolution and urban development. This paper reports an in-depth study of the 15-minute walkable catchment area around Panmure railway station. The transition to mobility in urban environments can start with these railway station catchment areas which are still in operation and have more potential for TOD than other areas of the city.

The paper is organised into two parts. First, the morphological periods of the study area are described in connection with the concept of fixations lines. The complex layering of the spatial-temporal landscape forms the basis for urban landscape assessment using historical maps and documents. The second part reports the morphological units based on data collected for each morphological period. The resulting plan units will support the continuity of future development.

METHOD

The methods used to explore the evolving relationship between the Panmure railway station and its surrounding area mainly derive from town-plan analysis, notably reconstruction of the urban development process through analyses of historical series of ground plans and documentary records. The systematic survey conducted for this study used multiple sources including historical maps, property data, Auckland Council Geomap, and field surveys to explore patterns of development (Gu, 2014). Plans and maps of Panmure are widely available, beginning with cadastral maps from 1860 (Auckland Libraries Heritage Collections, 1860a, 1860b). These historical maps play a crucial role in reconstructing the development history of the urban landscape (Gu, 2014). Property Guru offers a comprehensive collection of New Zealand property-related information. This dataset includes details such as the names of occupants and owners and the ages of most buildings. A plot-by-plot field survey allows land uses to be identified.

The use of geospatial technology, particularly an integrated GIS system, is increasingly important for analysing and synthesising morphological data. It enables multi-source data to be assembled into a single database for analysis. More importantly, it can spatially relate data from different sources and produce new or missing variables in separate datasets. In this research, the plans and maps of the study area were georeferenced in GIS (Tümtürk et al., 2024), and the ground plan information then digitised in ArcGIS Pro.

Panmure and its morphological periods

With 170 years of European history, Auckland is the largest urban area in New Zealand (Gu, 2010). The evolution of society since early colonial days has affected the building types and ground plan,

influencing the development and transformation of building forms, which often leave marks on the ground. About 18 per cent of Auckland's total urban land area lies within the 15-minute walkable zones around its 39 railway stations. The railway station area in Panmure provides an ideal case study, with its historical development and current form representative of many urban railway station areas. The study area was delineated as the surface included within a 15-minute walkable distance of the railway station.

Located in East Auckland, the Panmure station is close to the Auckland CBD and Manukau central business districts. The suburb of Panmure lies between Mount Wellington and Panmure Basin, offering a mountain view and water connections to the Hauraki Gulf and Waitematā Harbour. Throughout the years, key changes in planning, infrastructure, and policies have greatly shaped the development of Panmure and its adjacent urban areas (Beharrell, 2024).

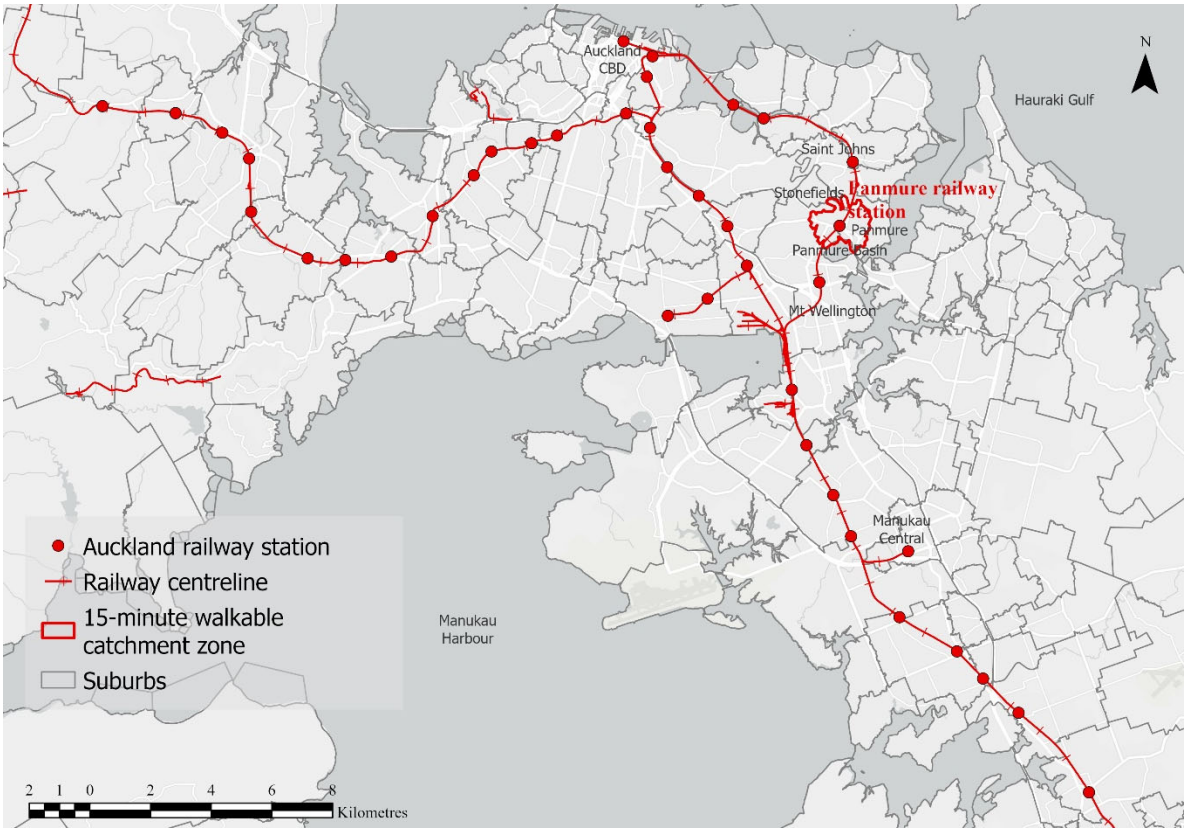

Figure 1. Railway stations in Auckland and Panmure railway station 15min walkable zone

Based on a review of the historical records of Panmure, its development can be categorised into four morphological periods of growth and change: pre-urban development (1840s–1880s), railway colonisation and expansion (1890s–1930s), segregation and fragmentation (1940s–1990s), urban redevelopment and revitalisation (2000s–now).

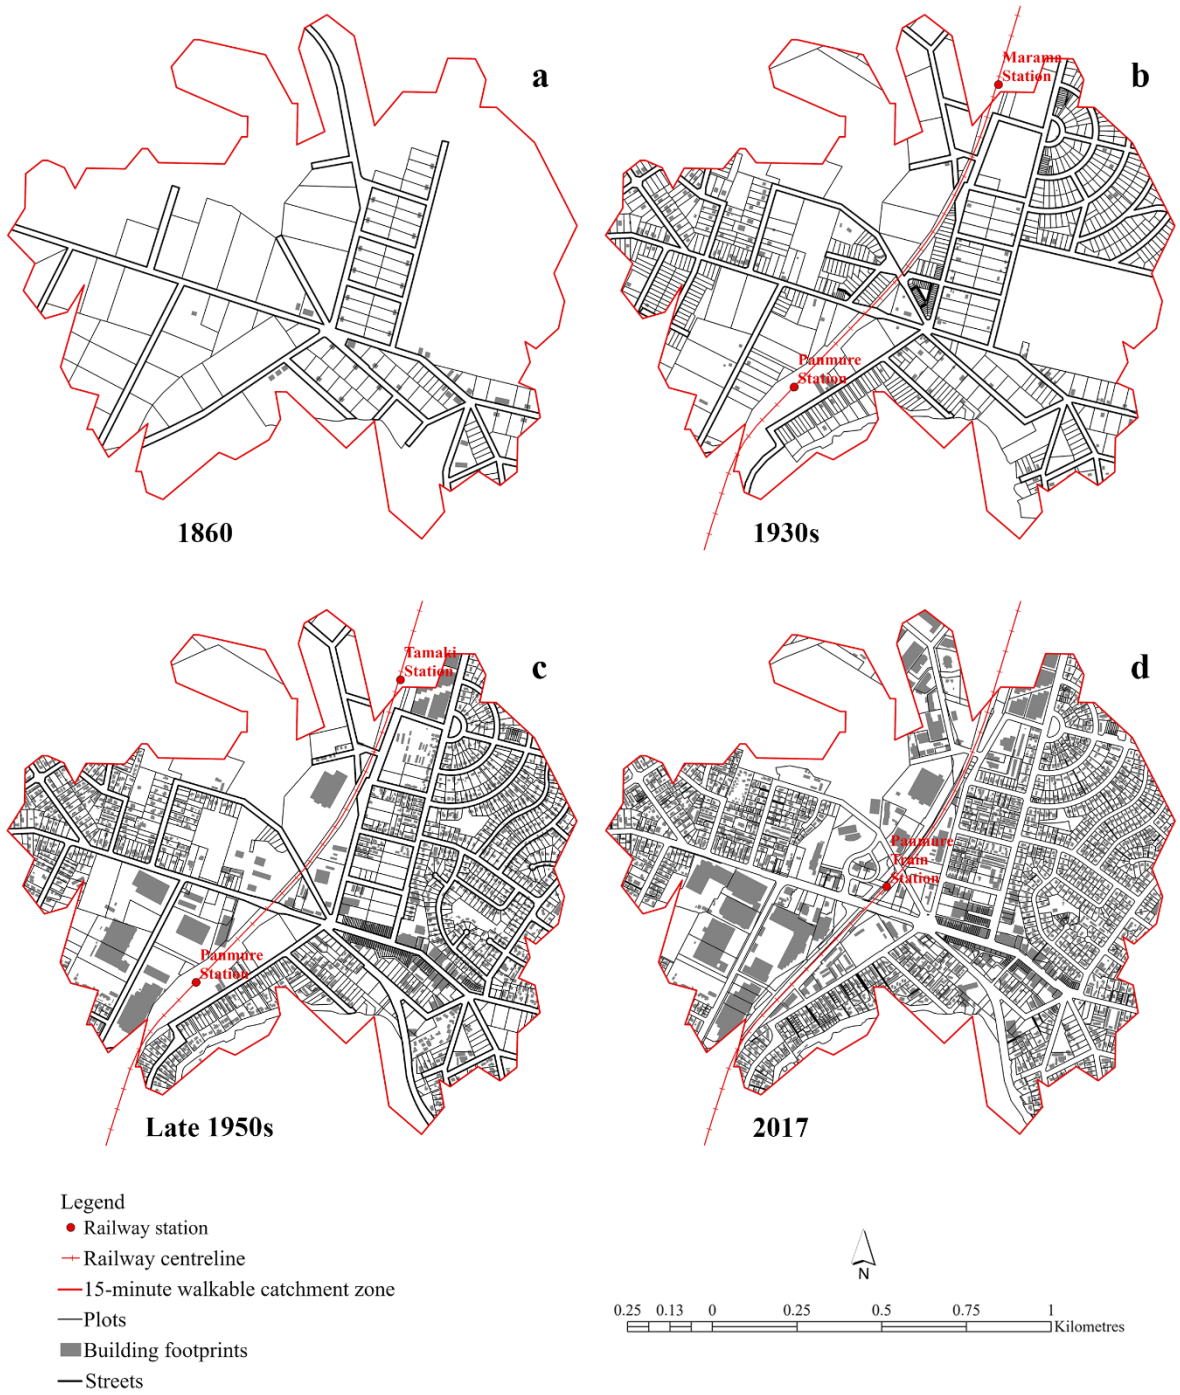

Figure 2. Streets, plots and buildings in the 15min walkable catchment area of Panmure in (a) 1860, (b) 1931–1940, (c) late 1950s and (d) 2017 (based on Auckland Council, 1958, 1959, 2024; Auckland Libraries Heritage Collections, 1860b; Auckland Libraries Heritage Collections Map 71, 1931)

Pre-urban development (1840s–1880s)

Panmure started as a defence post in the 1840s, when it was established as one of Auckland's fencible settlements (Hoffman, 2019) on divided farmlands. Situated along feared potential Maori invasion routes to Auckland after the outbreak of hostilities between Maori and the Crown in the north, Howick, Panmure, Otahuhu and Onehunga were the locations chosen to provide places for 2,500 Fencibles and their family members (almost double the population of Auckland at that time), who

travelled from the UK to New Zealand between 1847 and 1952 (Howick Historical Village, n.d.). The word Fencible comes from ‘defencible’, meaning ‘capable of defence’. The Fencibles had served as soldiers in the wars of Britain in the 1830s and 1840s. To emigrate to New Zealand under the Fencible scheme, retired soldiers were required to be under 48 years of age and of ‘good character and industrious habits’ (Howick Historical Village, n.d.). These retired soldiers were enlisted to serve for seven years in exchange for a cottage and one acre of land (Howick Historical Village, n.d.).

Panmure became a busy place in the mid 19th century, partly because of its location near the narrowest part of the isthmus, on the route between Auckland and the largest fencible settlement of Howick. People and goods were transported across the water by ferry at the narrow point below Mokoia Pa (Auckland Transport, 2018).

Figure 3. Fencible cottage and Panmure ferry in the 1860s (Auckland Libraries Heritage Collections 1031-P619-06, 589-0426)

Railway colonisation and expansion (1890s–1940s)

Railway construction in Auckland dates back to 1863 with the railway system starting to take definite shape in the 1870s (Davidson, 1931). Upon the arrival of railway to Auckland to carry not only goods but also passengers (Lowe, 1973), Panmure became a busy transport hub (NZ Herald, 2010). Steamers from Auckland stopped there on their way to the goldfields in the Coromandel and Firth of Thames. New developments and plans for land around the railway line also started during this period. The original Panmure Station opened on 16 November 1930, showing in Figure 2 (b), on a site to the south of the current station.

After World War I (1914–1918), the newly established profession of town planning and its advocates aimed to provide solutions for the challenges of postwar resettlement in both urban and rural areas, and showcase the effectiveness of town planning (Miller and Roche, 2003). Town planners in New Zealand adopted town planning concepts from Britain, and were especially influenced by the Garden Suburb model when accommodating soldier settlements (Miller and Roche, 2003).

Starting from the beginning of the 20th century, the garden suburb movement gained popularity, with the Tamaki Heights Garden Suburb designed by E. V. Blake (see Figure 4) showing marked garden suburb appeal. The subdivision shown in Figure 4 was marketed by brochures and newspaper advertisements from 1926 to 1928(Miller, 2004). However, the Garden Suburb experienced slow development and was eventually incorporated into the State Housing program, which led to changes in its layout (C. L. Miller, 2004).

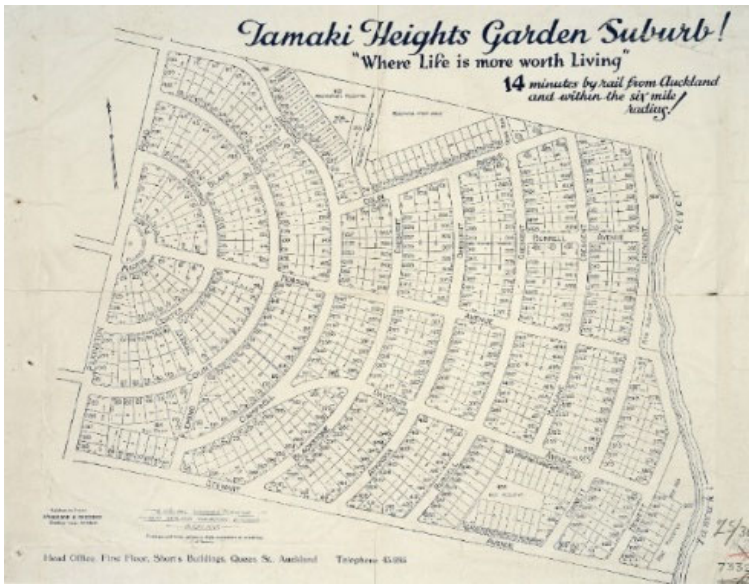

Figure 4. Panmure store and sales advertisement of Tamaki Heights Garden Suburb development allotments (Auckland Libraries Heritage Collections, 1920)

Segregation and fragmentation (1950s–1990s)

Up until the mid-20th century, Panmure remained a prosperous but predominantly pastoral area (NZ Herald, 2010). It was only after the explosive suburban development around it following World War II (1939–1945) and the construction of better bridges to Pakuranga (NZ Herald, 2010) that Panmure grew significantly and transformed into a commercial centre. During the period 1950–1955, Panmure grew from a small village with a few shops and a hotel into a busy suburban shopping hub with the development of the West Tamaki housing estate (Hoffman, 2019).

Figure 5. State houses on Pilkington Road and Main road (Queens Road) in the 1960s (Auckland Libraries Heritage Collections 895-A62539, Auckland Libraries Heritage Collections 786-A18-03)

In 1948, there was initial discussion about an eastern motorway to cater for Auckland's future growth (Cayford, 2011). In 1955 as part of a Master Transportation Plan, a South Eastern Motorway was proposed to link the central business area to eastern areas of Auckland, Mt Wellington Highway and the existing SH1 Motorway at Mt Wellington via Tamaki (Cayford, 2011). In the 1960s, the Eastern Corridor was part of the regional highway plan (1965 Report on a Comprehensive Transportation Plan for the Auckland Regional Authority), with land designated for a motorway. The intended motorway was changed to a limited access (arterial) road in 1967 (Cayford, 2011). In 1974, the eastern corridor was incorporated into the Auckland Regional Planning Scheme, with the

Auckland Regional Authority revisiting the idea of a four-lane arterial road in 1975. (Cayford, 2011). In 1993, the Auckland City Council designated the corridor route under the title Proposed Limited Access Road – Eastern Highway. Effective until 2004, the designation was then extended in August 2004 for ten years to 2014 (Cayford, 2011). The development of highways has meant the urban development of the area no longer centres on the railway. As a result, superblock types have formed with through roads for private cars and more cul-de-sacs (Figure 2 (c)).

The creation of the Auckland Regional Planning Scheme in 1988 established a framework for managing coordinated growth in the Auckland region, setting rules to manage expansion and development (Hoffman, 2019). It helped address the previous segmentation and fragmentation.

Urban redevelopment and revitalisation (2000s-now)

Since the beginning of the 2000s, there have been efforts to seek collaborative solutions for urban development and infrastructure improvements around railways. In 2004, the Hobson Bay, Purewa Creek, Glen Innes/Panmure, SH1 and Tamaki River corridors were recommended as the preferred routes between Auckland's CBD and the Tamaki River (Cayford, 2011). Local elections in October 2004 led to a reconsideration of the project by the Auckland City and Manukau City Councils and Transit New Zealand, with more emphasis on passenger transport and improving roads to carry passenger transport. Auckland City subsequently resolved there would be no highway component for the project north of Glen Innes. The Auckland-Manukau Eastern Transport Initiative (AMETI), which originated from the Eastern Highway project, is a package of transport improvements in the Glen Innes – Panmure – Pakuranga –Botany corridor. The project aims to provide a high-quality strategic transport link between Auckland City and Manukau City via their eastern suburbs. Requiring major public investment, AMETI includes land use zoning changes and an urban design approach, providing bus lanes and other bus priority measures, an improved road network, improved walking and cycling facilities, and travel demand measures (Cayford, 2011). Still ongoing, the Auckland Manukau Eastern Transport Initiative (AMETI) involves major public investment (Cayford, 2011). The area's transport infrastructure developments highlight its important role as a transport node and crucial interchange.

Panmure is also the focus of large public investment as part of the Tāmaki urban transformation led by the Tamaki Regeneration Company, a government-council joint venture. The project was set up with the aim of building 7,500 new homes and community facilities over the next 15−20 years. The area has seen a high level of local board planning, with strong political and community backing for change. Launched in 2012, the Tamaki Transformation Programme is the country's first urban regeneration programme. As described in the project plan for Panmure, many of Panmure's facilities and natural assets are underutilised due to poor local connections. The town centre needs to maximise the benefit of transport investments, including through AMETI, greenways, and improvements in walking and cycling. The area offers a wide range of local services, leisure and recreational facilities, including council amenities, that can be enhanced to support future growth (Panuku Development Auckland, 2018). Panmure's town centre is strategically located, featuring infrastructure and access to public transport. The area has the potential to meet the pressing need for sustainable and quality urban development.

The town centre regeneration plan by Panuku Development was approved by Auckland Council's Planning Committee in 2018. It seeks to strengthen links between Panmure Station and the town centre(Panuku Development Auckland, 2018). The Unlock Panmure Project includes planning for new

precincts and new projects within the precincts to create a thriving town centre, upgraded public spaces and more(Eke Panuku Development Auckland, 2023).

The Panmure railway station was relocated to its current site in 2007. Since the opening of the upgraded station in 2014, there has been significant growth in train boardings in Panmure. Based on 2018−2019 data, Panmure station has become the third busiest station, following Britomart and New Market station (L, 2019).

The morphological structure of the Panmure railway station area

Panmure in 1860 was characterised by large plots and empty land as shown in Figure 2 (a), which the railway line later cut through created a divide (Figure 2 (b)), many smaller plots resulted as large plots were subdivided. The two sides of the divide subsequently experienced different type of development, in part related to the location of the train station. The original garden suburb development is still evident on the northeast side of the study area. Seeking to reverse this trend, efforts are now being made to recover a coherent urban form through reconnecting the separate developments.

The plan units

Examination of change in the ground plan has been an important basis for the identification of six plan units in the Panmure 15-minute walkable catchment areas (Figure 6 and Table 1). The area with the longest development history is identified as the first plan unit. Subsequent development was the Garden Suburb unit. The railway station unit, suburban expansion unit and residential unit were developed in similar periods. Notably, the railway station unit is completely different from the other two residential units in terms of form and uses, the fixation line has a major influence on the result.

The fixation lines in the form of natural and artificial features, such as city walls, rivers, mountain ranges and railways, are often seen as a barrier to development (M. R. G. Conzen, 1960). It has major influences on the formation and changing direction of urban development and expansion. The spaces around fixation lines have many things in common. For example, these areas often act as corridors, and they have low density, exerting less pressure on land. A trend can be identified whereby socio-economic factors influence the lines, in this case, it is the arrival of the railway line, on one hand, the railway station site brings new development and commercial for the area, and it prospers. On the other hand, the railway track attracts freight yards, industry and housing to develop nearby (Bertolini, 1996). It is important to recognise the long influence brought by the railway line on the surrounding development forms part of the history and identity of the place.

Under certain conditions, urban development can move beyond the barrier to continue (Gu et al., 2022). In the railway line case, the divided environment has been an obstacle in station redevelopment projects, methods of going beyond the constraints include vertical crossing, or having the railway line below or above the ground (Bertolini, 1996). Even with the physical barrier removed, the characters of the developed area brought by the fixation line will still be part of the unique feature on the ground (Gu et al., 2022).

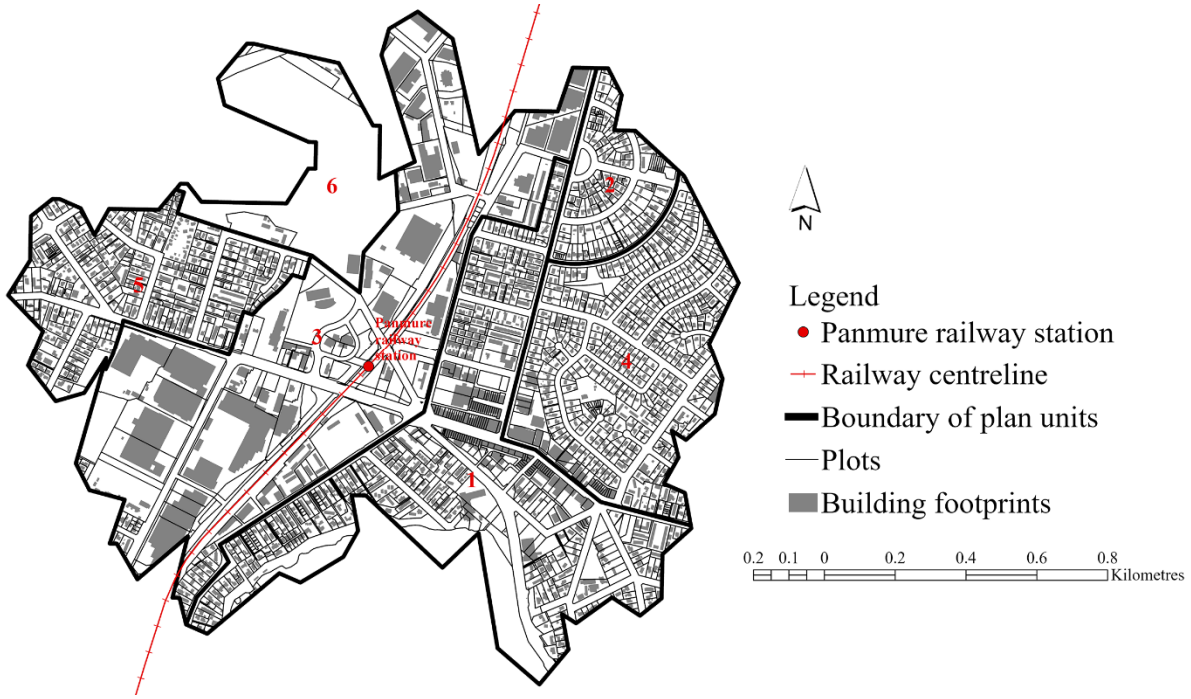

Figure 6. Plan units in the 15min walkable catchment area of Panmure. (1) Historical development, (2) Garden suburb unit, (3) Railway line unit, (4) Suburban expansion unit, (5) Western residential unit, (6) Mt Wellington Domain unit

Table 1. Plots and their metamorphosis and buildings and their block plan in the plan units (Authors own photo 2024).

Plan units	Plot	Building	Image
1.Historical development unit	Mainly small- and medium-sized plots mostly in the form of 1950s	Mixture of commercial, residential and recreational buildings	
2.Garden suburb unit	Planned layout with regular plots	Residential buildings and local commercial stores	
3.Railway line unit	Mainly large plots for industrial purposes resulting from plot subdivision and amalgamation	Industrial, public transport and commercial buildings	
4.Suburban expansion unit	Mainly small plots	Mainly residential buildings, will small portion of commercial and institutional buildings	

5.Western residential unit	Mainly small plots	Mainly residential buildings	
6.Mt Wellington Domain unit	Single large plot	Natural landscape, horticulture yard and recreational buildings	
TOD planning and design

Auckland Council's Plan Change 78 regarding intensification is underway and expected to be finalised by 2025. Prioritising rapid transit, it recognises that strategic planning and development around train station areas are urgently needed (Auckland Council, 2023). The provisions of the plan change have the potential to impact the Panmure station area, with provision for six-storey buildings within the 800-metre walking catchments of rapid transit network stations (RTNs) through rezoning residential land in RTN walking catchments to Residential – Terrace Housing and Apartment Building and rezoning all other existing urban residential land to the revised Residential – Mixed Housing Urban category, unless there are valid reasons not to (Auckland Council, 2022). The provisions of Plan Change 78 will likely increase the speed and scale of development in Panmure as the market responds to the new planning regime. As a result, residential intensification and population growth in Panmure will probably be faster and higher than projected in the Auckland Plan 2050 (Auckland Council, 2024b). The spatial distribution of future populations will change as a result.

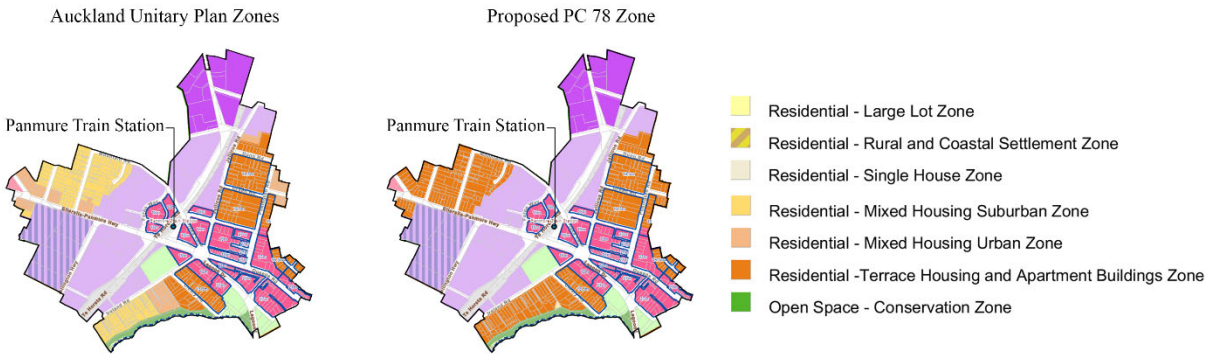

Figure 7. Auckland Unitary Plan Zones and Proposed PC 78 Zones, propose change residential-mixed housing suburban zone and residential-mixed housing urban zone to residential-terrace housing and apartment buildings zone (Auckland Council, 2022).

However, the PC 78 zones lack the consideration of the spatial-temporal processes of the areas and acknowledge little about the characteristics and their difference regarding to their development process (Gu, 2014). It will potentially lead to a fragmented landscape. To create a coherant landscape, the unit-specific (Gu, 2014) and place and form-based design is recommended. The 'pull factors'

including improved accessibility, pedestrian friendly, and close to public facilities (Gehrke et al., 2019; Zondag & Pieters, 2005) will be integrated in different units.

For the historical development unit, the town centre, the emphasis could be on the historical connection with the railway lines. Improving public space and roads, for easy access and ensuring a pedestrian-friendly environment. The Garden suburb unit had historical connection with the previous Tamaki station, work could be done to enhance the pedestrian-friendly travel from the residential area to the railway station. The western residential and suburban expansion units could focus on intensification.

The railway line unit which based on the PC78, has no change proposed. This area could be focused on having denser mixed-use development around the railway station, as there are many publicly owned land available which many of them currently used for open-air parking. Developing homes, employment, and supporting retail as well as other services immediately adjacent to, if not directly above the railway station. The roads need to be improved for easy pedestrian use and cycle and connecting to the other units in this walkable catchment area, to create a highly connected spatial layout to supplement TOD. To minimise the negative effect of rail tracks and maximise the development TOD neighbourhoods to accommodate people with various social status's desire of living in a TOD neighbourhood (Olaru et al., 2011).

CONCLUSIONS

Applying a morphological perspective to TOD study is important, as the physical form of TOD greatly influences its success. By following a morphological approach to TOD, continuity can be retained and enhanced, and local characteristics preserved, leading to a more successful development around railway stations. This paper examined the evolutionary process of Panmure railway station 15minute walkable catchment area. The distinct characteristics of each morphological period were identified by reconstructing the historical ground plan, analysing how the past influences the present, and determining the factors that future planning needs to consider by tracking the continuous transformation of form from one period to another.

Subsequently, the identification of morphological units can support future planning and design decisions, ensuring that the developmental process is incorporated into the morphological research and the planning and design guide (Gu, 2014). The resulting findings and the recommended strategies for each unit type contribute to research and planning practices aimed at recovering a sustainable urban form in the railway station catchment area.

ABSTRACT

Most residential areas in China are closed communities. The distance from residential units to public transportation stations increases due to the influence of neighborhood patterns. By assessing the extent to which different factors, such as community shape, area, entrances, and road networks, affect residents' public transportation usage, theoretical support can be provided for optimizing the design of residential neighborhoods. Using three residential blocks in Nanjing, China as samples, GIS was employed to calculate the shortest distance from each residential building in the neighborhood to the nearest subway station. The straight-line distance and detour index for each Origin-Destination (OD) path were calculated. On the other hand, the morphological factors of each neighborhood were analyzed, and a Pearson correlation analysis was performed to determine the relationship between the shortest distance and morphological factors. The results show a strong positive correlation between the shortest internal distance in a neighborhood and the area and perimeter of the neighborhood, and a significant negative correlation with entrance density.

Keywords: residential block, unit neighborhoods, morphological relation, public transportation route

INTRODUCTION

Residential areas serve as the starting or ending points of daily commutes for urban residents. The path length and comfort level significantly influence whether residents choose to walk. In Singapore, where walking and public transportation are well-developed, it is stipulated that 8 out of 10 households should be within a 10-minute walk to a metro or light rail station. In China, the establishment of subway stations strives to accommodate the needs of residents within a ten-minute living circle. However, Chinese residential areas, influenced by construction periods and policies, are often enclosed communities with varying shapes and sizes. Research has shown that enclosed communities have a significant impact on pedestrian paths through actual pedestrian tracking and network simulation comparisons (Sun et al., 2020). Current scholarly research indicates that, typically, grid-like street patterns are the most conducive to pedestrian traffic, while curvilinear layouts are the least (Sandalack et al., 2013; Cheng, 2017). However, the intricacies of residential block networks in

China are notable, with significant variations across different periods. This complexity arises from a multitude of factors, including the urban road network, the configuration of entrances and exits in both closed and open neighborhoods, and the internal road systems within closed neighborhoods. To date, there has been an absence of comparative studies examining the walking distances to public transit stops, the extent of detours, and other related metrics for residential neighborhood patterns that have emerged during the different periods. Therefore, analyzing the correlation between residential area form factors and the paths from building units to metro stations is crucial in distinguishing factors that promote public transportation usage.

This paper compares three residential blocks from different periods (Figure 1): Suojincun (1980s), Longjiang (1990s-2000s), and Aoti (2010s), observing the differences in path performance and detour situations to identify factors that support public transportation use.

Figure 1. Case selection: three residential blocks from different periods of time.

LITERATURE REVIEW

Neighborhood Plane Patterns in Different Era

In the 1980s, residential planning in China began to introduce comprehensive development methods, but the planning and design system was not yet mature, resulting in neighborhoods of varying sizes. The development of residential areas in China during the 1980s can be divided into two phases: 1980-1984, during the early stages of reform and opening-up, and 1985-1990, under a planned commodity economy system. During the early phase (1980-1984), most residential areas were built as welfare housing to address housing shortages. Company-built housing was the dominant form of construction, and Suojincun, the first case in this study, belongs to this category. In the later phase (1985-1990), residential areas were built during the transition from welfare housing to commercial housing. These

neighborhoods reflect the exploration and transition toward the commodification of housing (allowing real estate business operations). After 1984, various county- and city-level development companies in Nanjing were established, marking a gradual shift towards a planned commodity economy in the housing market. At that time, Nanjing adopted a "dual-track system" of both distribution and commodity housing to gradually transform the urban housing allocation system from low-rent state-owned housing to a commodity-based system (Wang, 2021).

In the 1990s, with rapid socioeconomic development, China embarked on the "Research on Urban Residential Housing for a Moderately Well-off Society." Residential layouts underwent significant changes during this period. As the commercial housing market emerged, residential construction expanded in scale, and high-rise buildings became more prevalent, resulting in more complex spatial layouts. Linear layouts remained the mainstream, but enclosed and point-type layouts began to be widely used. Residential planning also became more focused on human-centered design, incorporating more public activity spaces, optimizing traffic flow, and increasing green coverage to meet the growing residential needs (Kai, 2009).

Entering the 21st century, as cities expanded, new residential neighborhoods were developed through urban design, creating more regular block patterns. Neighborhood blocks became smaller in horizontal scale, while building heights increased. Public facilities, green spaces, and other amenities became more abundant, contributing to unique plane patterns, such as circular driveways and fire lanes.

Existing research has summarized the urban texture and contours, classifications of neighborhood road networks, patterns of street grids and block divisions, and the formation of neighborhood forms based on walled-and-gated systems. These studies highlight the impact of walled-and-gated systems on travel routes, and various indicators, such as shape index and road depth, have been used to quantify neighborhood forms. These studies support the classification of neighborhood plane patterns and the layout of public transportation stations (Zhao, 2015; Zhang, 2022; Wu, 2017; Ma, 2019; Li, 2020; Zhang et al., 2023).

Residential Road Network

Scholars at home and abroad often classify road network patterns based on shape characteristics and explore the features of different road network patterns in terms of traffic connectivity, safety, and land use vitality. McCluskey, J. (McCluskey, 1992) summarized road network patterns into four types: serial, radial, branch, and grid. Cai Jun (Cai, 2008) categorized road networks by their graphical features, including grid patterns, radial plus ring patterns, and grid plus radial patterns. Kang Wangquan (Kang et al., 2016) further classified residential road networks into grid, tree-like, closed loop, and "Poundbury" patterns. Previous studies have shown that grid-like road net-works with high connectivity (permeability) result in the highest travel efficiency, whereas curved roads lead to the opposite. However, public transportation efficiency, beyond just the road network, depends largely on land use mix and traffic structure. Various studies have analyzed the relationship between residential neighborhood pat-terns and public transportation trips, confirming that neighborhood patterns do affect public transportation use (Zhao et al., 2021; Sandalack, B. A et al., 2013; Cheng, 2017; Hajrasouliha and Yin, 2015; Peng, 2014; Wu, 2017; Zhang, 2022; Liang, 2022).

The current state of residential road networks in China generally presents the following structure: major and secondary roads divide large residential blocks or districts, while secondary and side roads divide unit neighborhoods (smaller residential areas). Roads within these neighborhoods often serve as internal roads, connecting to the city's main or secondary roads through 2-3 entrances. The structure of residential road networks thus simplifies into two levels: the road network between unit neighborhoods established by the urban road system, and the internal road network of each unit neighborhood and its connection to the external urban road network (Zhou and Qian, 2017).

METHOD

Model construction

To quantitatively study the relationship between residential neighborhood pat-terns and transportation routes, a GIS model was established based on the available data for the selected residential areas. The selected cases are urban blocks divided by major and secondary roads or natural barriers, with the land use within the plots primarily for residential purposes. The model uses urban arterial roads as its framework, including the road networks within the case study areas and their surroundings, as well as subway stations, gated community entrances, and the distribution of residen-tial building entrances.

In the simulation process of the GIS urban model, residential buildings are used as event trigger points, and subway station entrances are used as target points to find the shortest path. The choice model presents a relatively simplified representation of real-world travel decisions, operating as an idealized model. Due to the specific impact of China's gated community system, a single residential block may contain multiple unit neighborhoods. In most cases, the path choice is affected by the presence of gates (either the gate of the resident's community or those of other communities), leading to detours. Thus, an OD cost matrix is used to calculate the OD distance between each path, further calculating the detour index for each path. Through these steps, the shortest distance and detour index from each building to the nearest subway station can be obtained, allowing for the evaluation and analysis of the subway

Indicator statistics

To study the factors influencing the shortest distance from residential units to subway stations, the following table 1 lists potential influencing factors. Both online and offline research methods were used to collect relevant data for the three sample residential blocks—Suojincun, Longjiang, and Aoti—including information such as area, shape, entrances, intersections, and their correlation with public transportation use(Figure 2). For convenience, each factor is represented by simplified notation in the text.

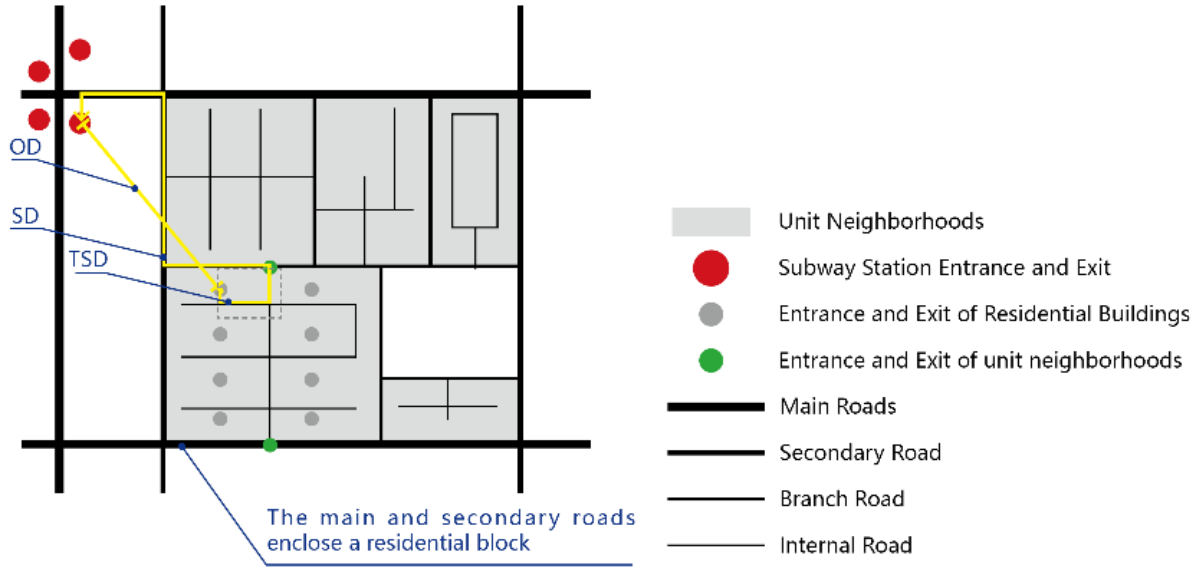

Figure 2. Possible Morphological Influences Graphic Supplement.

Table 1. Possible influences on neighborhood morphology of the shortest distance from residential buildings to subway stations.

Factor	Notation	Definition	Formulas
Shape Length	L	Shape length of unit neighborhoods	/
Shape Area	A	Shape area of unit neighborhoods	/
Shape Index	SI	the index of how much shape deviates from the circle.	$SI = \frac{L}{2\sqrt{\pi A}}$
Number of Entrances and Exits	NE	Intersections points of internal unit neighborhoods roads with public roads	/
Density of Entrances and Exits	DE	Number of entrances and exits for average area in unit neighborhoods	$DE = \frac{NE}{A}$
Total Length of Road Network	RL	Total length of roads within the unit neighborhoods	/
Road Density	RD	Length of road network for average area in unit neighborhoods	$RD = \frac{RL}{A}$
Number of Road Network Intersections	NIR	Number of intersection of two or more roads within a unit neighborhoods	/
Density of Road Network Intersections	DIR	Number of Road Network Intersections for average area in unit neighborhoods	$DIR = \frac{NIR}{A}$
Shortest Distance to Subway Station	SD	Shortest distance routes from building entrances to the nearest subway station under the influence of other unit neighborhoods gatedness	/
Shortest Distance to the Subway Station (Part of the Residential Blocks)	TSD	the part of SD inside the unit neighborhoods	/
Linear distance between Origin and destination	OD	Linear distance between Origin and destination	/
Pedestrian Route Directness	PRD	Indicates the directness of the pedestrian path	$PRD = \frac{OD}{TSD}$

Pearson correlation analysis

The Pearson correlation coefficient (r-value) ranges between -1 and 1 and is used to represent the strength and direction of a linear relationship between two variables. The closer the absolute value of the correlation coefficient |r| is to 1, the stronger the linear relationship between the two variables;

the closer it is to 0, the weaker the relationship. The significance level (P-value) is used to determine whether the correlation between two variables is significant. If the P-value is less than 0.05 (or 0.01), the correlation between the two variables is significant, meaning the null hypothesis (that the two variables are uncorrelated) can be rejected. If the P-value is greater than 0.05, the correlation between the two variables is not significant, and the null hypothesis cannot be rejected. In this paper, "" is used to indicate significant P-values: "" means the P-value is less than 0.05, and "**" means the P-value is less than 0.01.

DATA

Data sources

The data in this paper come from two main sources. The first is the GIS model data, which includes both the initial input data and the calculated data. Due to the difficulty of obtaining urban data, the basic data for the model was sourced from various places: the building and road network structures were derived from processing Baidu map files; the subway station coordinates used were obtained from Gaode maps; some gated community entrance data came from field research and CAD drawings. Using this data, the GIS model was constructed to calculate values such as SD, TSD, and PRD for the three samples. The second source is a list of correlation factors com-piled from field research and online data, as shown in Table 1.

Data processing

For data analysis, two levels of analysis were conducted: overall analysis (SD and PRD) and unit-neighborhood-level analysis (the relationship between TSD and other factors).

SD and PRD data processing

The GIS model was used to calculate the SD and PRD values for each residential building in the three samples, and the results were color-coded (Figure. 3). The gray lines represent the road network framework, and the black lines represent the key factors influencing public transportation trips: time and distance. To simplify calculations, a five-minute walking time was converted to a 400m walking distance, and a corresponding ten-minute walking time was set to 800m. In Figure 3, the unit neigh-borhoods data is layered with the building-level data. If the residential buildings within the unit neighborhoods are at the same level, the two will completely overlap; otherwise, the buildings will display different color scales on the unit neighborhoods map. This diagram shows that, depending on the unit neighborhoods 's shape, each building's SD can vary significantly.

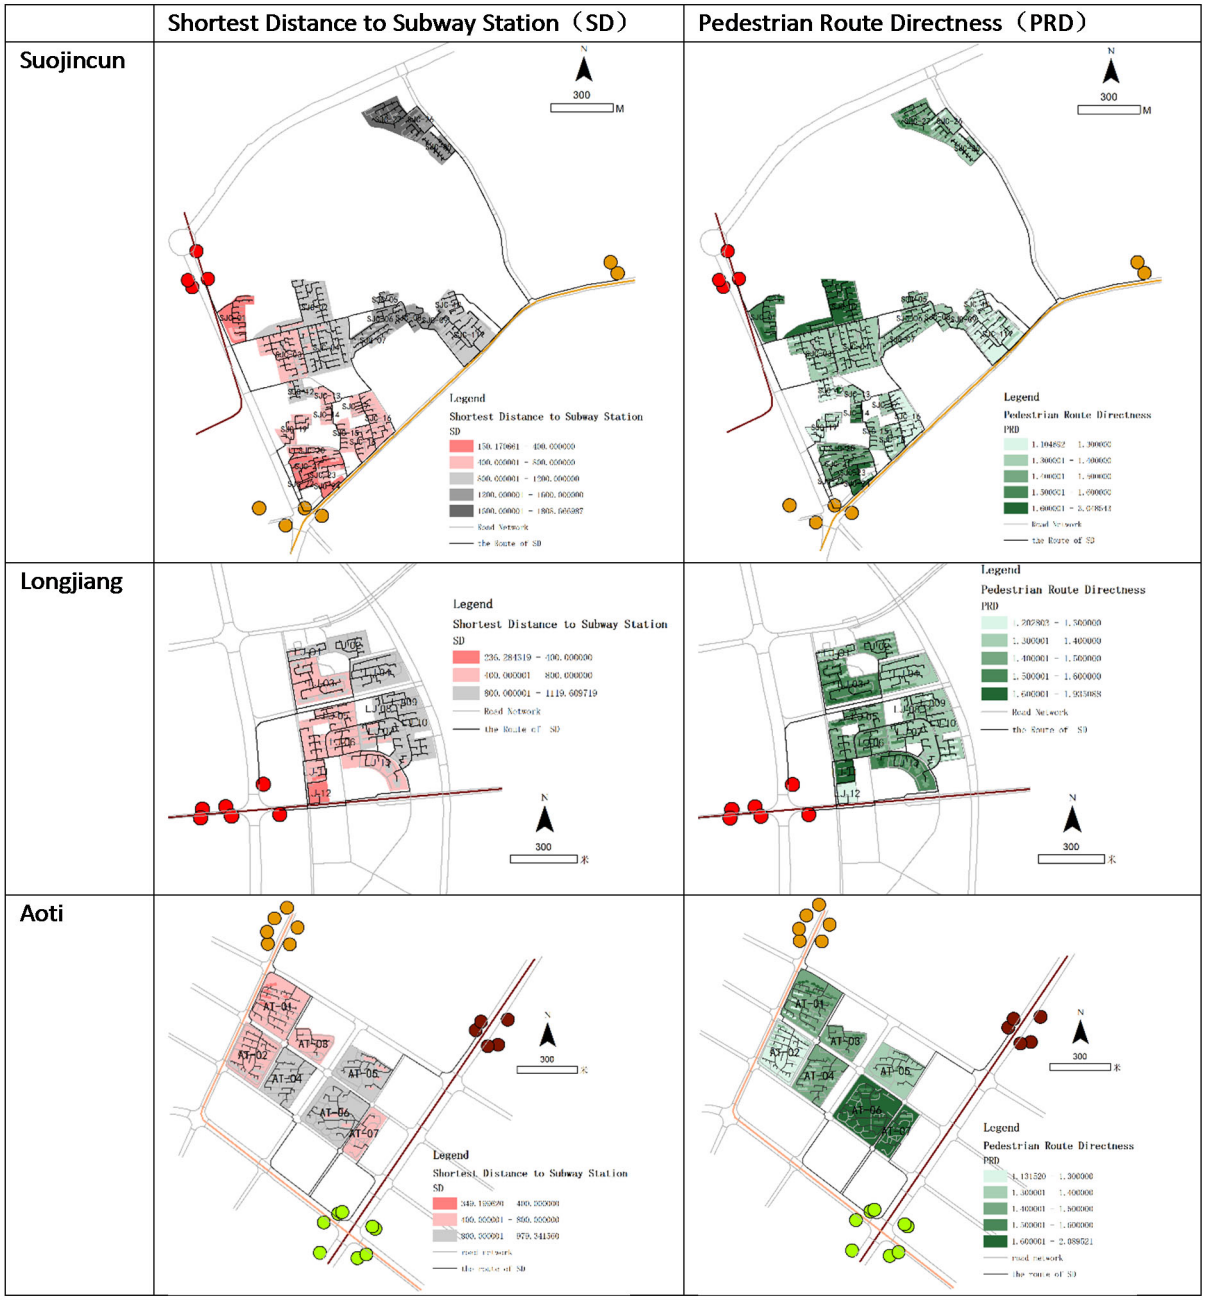

Figure 3. Visual representation of shortest distance SD and pedestrian route directness for three cases based on unit neighborhoods

To obtain more accurate data, the SD and PRD for the three samples were categorized into threshold percentages (Tables 2).

Table 2. SD and PRD statistics.

	Number of buildings	SD < 800	SD <800(%)	PRD <1.2	PRD < 1.2(%)	PRD>1.5
Suojincun	323	131	40.56%	12	3.72%	67
Longjiang	102	43	42.16%	0	0.00%	21
Aoti	106	62	58.49%	4	3.77%	24

TSD correlation data processing

At the unit-neighborhood-level, the aim was to determine the factors affecting the shortest distance (TSD) within the unit neighborhood. Therefore, from the indicators listed in Table 1, ten factors were selected for analysis: L, A, SI, NE, DE, RL, RD, NIR, DIR, and TSD. Pearson correlation analysis was conducted, and the results are shown in the heatmap (Figure. 4).

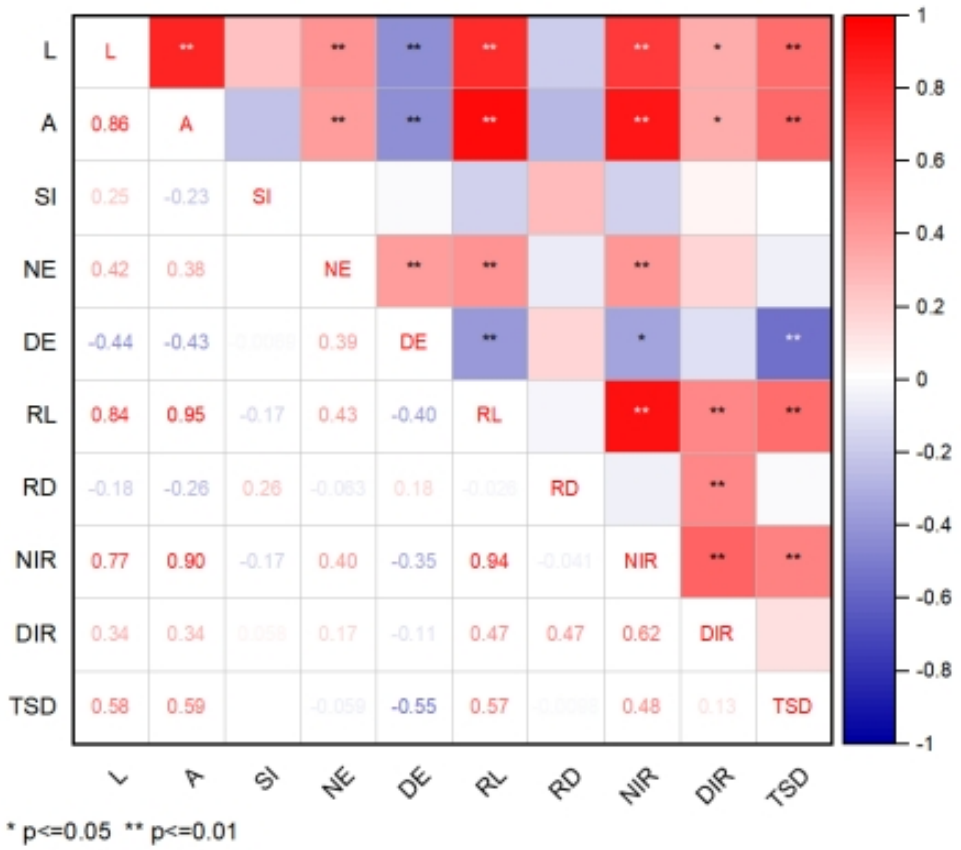

Figure 4. Graphical representation of Pearson correlation analysis

RESULTS AND DISCUSSIONS

Holistic analysis

Comparing Figure 3 and the SD and PRD values between samples, the following conclusions can be drawn: First, the relative location of unit neighborhoods to subway stations within a residential block has a significant impact on SD. This is more evident in large residential blocks. For example, in the Suojincun case, the closer a unit neighborhood is to the main roads and subway stations, the shorter its SD. Second, within the same unit neighborhood, SD between different buildings can also vary due to the road network pattern. Third, a major reason for the large SD and PRD values may be that the outer parts of residential blocks, defined by major and secondary roads, are primarily occupied by office and commercial buildings, which forces detours within the residential buildings. Fourth, it can be preliminarily concluded that the more entrances and stations there are, the more route options residents have, which can reduce SD to some extent. Additionally, the location of entrances is also important, particularly whether they are near the main roads leading to the subway stations.

From the data in Tables 2, the percentage of buildings within the sample neighborhoods that can reach the nearest subway station within ten minutes (800m) is 40.56%, 42.16%, and 58.49%, respectively. The percentage of PRD values within 1.2 (indicating a more direct walking path) is 3.72%, 0%, and 3.77%. The percentage of PRD values exceeding 1.5 (indicating significant detours) is 20.74%, 20.59%, and 22.64%. Based on these findings, the following conclusions can be drawn: First, none of the three sample neighborhoods meet the defined "ten-minute subway living circle" (800m) standard in China, nor do they meet Singapore's standard (where 8 out of 10 households can reach a subway station within ten minutes), and there is still a considerable gap from this standard. Second, disregarding the number of subway stations, the three cases show that SD tends to increase with the area size of the unit neighborhoods. In some cases, the unit neighborhoods are located inside the residential blocks, requiring significant internal travel. Third, PRD values show less overall variation but significant differences within individual unit neighborhoods.

Unit neighborhoods level analysis

Graphical explanation

From Figure 4, we can observe that the lower-left values represent the r-value, where |r| closer to 1 indicates a stronger correlation. The upper-right colors, red and blue, respectively, indicate positive and negative correlations, while "*" represents significant P-values. The figure shows that L, A, DE, RL, and NIR all have P-values smaller than 0.01, indicating significant correlations, while RD and DIR do not show significant correlations.

Conclusion verification

The figure shows that TSD has the highest r-values with neighborhood area and perimeter, at 0.59 and 0.58, respectively, and both are immutable factors. On the other hand, other factors, such as road network length (RL) and the number of intersections (NIR), may increase with area size. Therefore, L and A are identified as significant factors correlated with TSD. Due to the significant differences in area sizes among the sample unit neighborhoods, the correlations of RL, NIR, and DE with TSD need to be further verified. By sorting the sample data by area size (A) from smallest to largest and overlaying L, RL, NIR, and DE line graphs (Fig. 5), we can see that the L, RL, and NIR curves closely follow the area size curve, while DE shows a different trend as area increases. This may be due to the mutual influence of variables. The figure indicates that RL and NIR are significantly positively correlated with L and A. As unit neighborhood area increases, road network length and the number of intersections also increase, and TSD increases accordingly. The variables are interrelated, so a simple correlation between any two cannot be established. In fact, the correlation between TSD and RL/NIR is actually due to the correlation with area (A). Thus, it can be concluded that the shortest distance (TSD) within a neighborhood is significantly correlated with Shape Length (L), Shape Area (A), and Density of Entrances and Exits (DE).

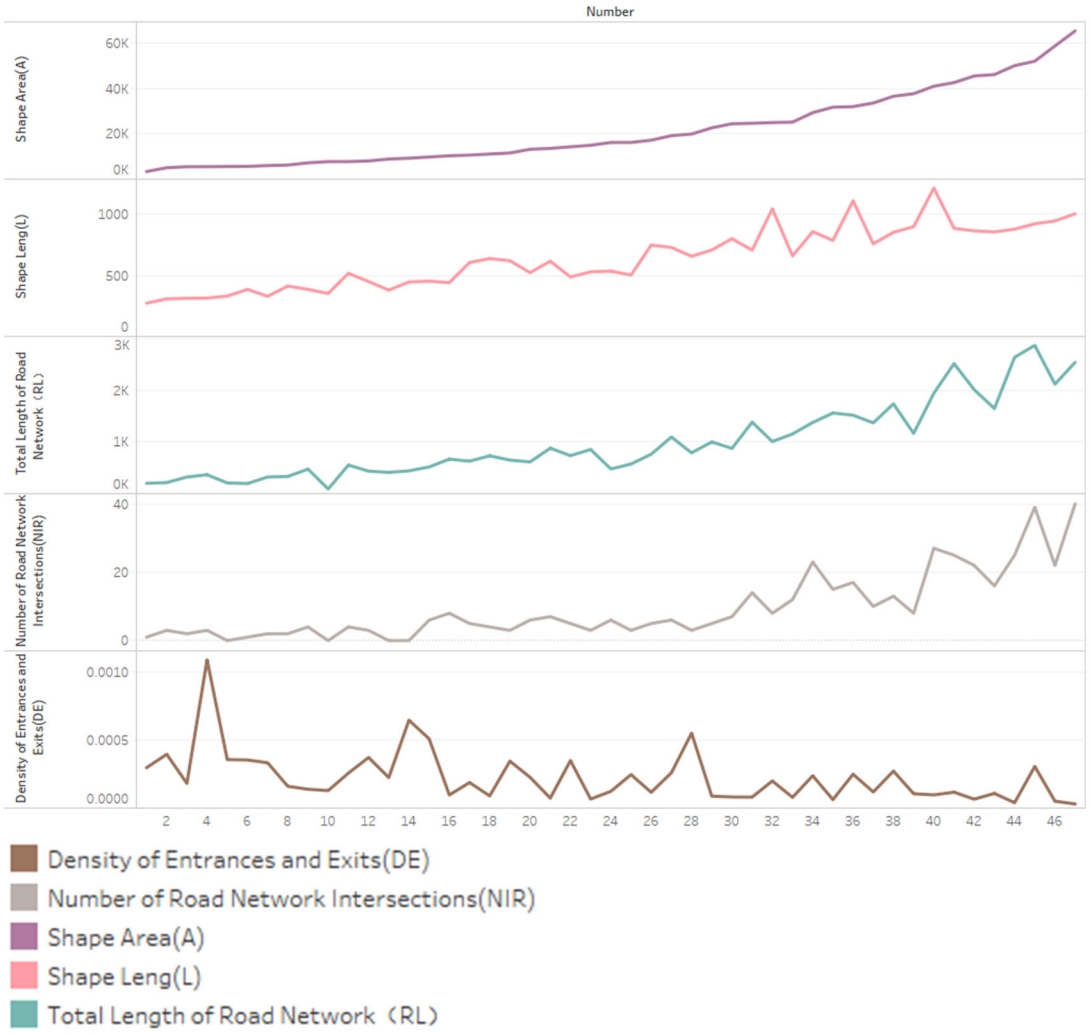

Figure 5. Distribution of L,RL, DE,NIR data in ascending order of shape areas （A）.

This study explored the relationship between subway travel paths and neighborhood morphological pattern, proving that neighborhood shape has a significant impact on residents' subway travel paths, specifically in terms of entrance density, shape, and area. this study further compares and quantifies potential influencing factors (such as entrances, shape, area, and road network density). This study found no significant correlation between the shortest path (TSD) within a unit neighborhood and road network density or intersection density. The reasons for this may be: First, statistical errors. Some non-residential buildings within the unit neighborhoods were excluded, leading to an overestimation of some areas (A), while the road network only included paths to residential buildings, possibly causing some errors. Second, certain special cases in the sample may not have been excluded, causing interference.

CONCLUSIONS

This study analyzed the relationship between residential neighborhood patterns and public transportation access, focusing on three residential blocks in Nanjing, China. By constructing a GIS model to calculate the shortest distances (SD) and detour indices (PRD) from residential buildings to subway stations, we identified key factors influencing public transportation usage in closed

communities. The findings reveal that the area and perimeter of residential neighborhoods have a significant positive correlation with the shortest distance (TSD) to subway stations. Larger neighborhoods, especially those with complex internal road networks, tend to require longer walking distances. Additionally, the density of entrances and exits (DE) has a significant negative correlation with TSD, meaning that increasing the number of entrances and exits can reduce travel distance and promote better public transportation access. However, the presence of gates in China's gated communities often forces detours, which negatively affects walking routes. The results suggest that optimizing the spatial layout of neighborhoods, particularly by increasing entrance density and improving internal road networks, can enhance residents' access to public transportation. These findings provide practical insights for urban planners and policymakers to promote public transportation usage and improve neighborhood designs for more efficient pedestrian travel.

However, the study also revealed some limitations. The GIS route choice model used in the simulation simplifies real-world pedestrian behaviors, as it does not account for factors such as comfort, infrastructure, or personal preferences. In reality, pedestrians may choose routes based on factors beyond just the shortest distance. Additionally, because the study was conducted using actual residential areas with varying characteristics, inter-neighborhood differences may have influenced the results, introducing potential errors. The mutual influence of different factors, such as area size and road network length, further complicates the analysis. To address these limitations, future research could incorporate virtual samples to control for specific variables and isolate their effects on public transportation usage. Additionally, conducting real-world surveys and comparing them with model simulations would provide a more comprehensive understanding of pedestrian behaviors and their relationship to neighborhood design. In conclusion, this study provides valuable insights for urban planners and policymakers. By optimizing the spatial design of residential neighborhoods—particularly by increasing entrance density and improving internal road networks—public transportation usage can be promoted, contributing to more sustainable and accessible urban environments.

ABSTRACT

Due to the global temperature rise and heat island effect, urban heat is expected to increasingly have consequences for both health and liveability of urban inhabitants, particularly among vulnerable groups such as elderly with less financial means. Although research has been conducted on urban heat and related human thermal stress, more research is needed for the elderly demographic group. This research investigates which design interventions are effective in decreasing outdoor heat stress around social housing for elderly in the urban context of Amsterdam, the Netherlands. The findings of this study have practical implications for decision-makers and contribute to building a methodology for recognizing and mitigating human heat stress for vulnerable groups. Three exemplary cases of buildings for elderly in heat-prone areas were selected. In a first phase, the microclimate was simulated with the use of ENVI-met for a representative hot day, followed by the PET (Physiological Equivalent Temperature) modelling in BIO-met. The analysis of resulting climatic values (air temperature, radiation, humidity, and wind) investigated their contribution to heat stress. In a second phase, mitigation measures were selected based on the probable main cause of heat stress and assessed on their efficiency through simulations. The results suggest that 1) outdoor spaces connected to social housing buildings in Amsterdam suffer extreme heat stress during heatwaves; 2) punctual interventions around buildings are insufficient in decreasing heat stress of elderly. Finally, the study discusses the need for systemic mitigation strategies and fundamental role of morphological characteristics.

INTRODUCTION

Urban heat stress and health

Due to the global temperature rise, the increasing frequency and intensity of heat waves, and urban heat island effect, outdoor and indoor overheating are expected to have significant consequences on the physical environment and the health, liveability and well-being of the urban population (Aghamolaei and Lak, 2022; Antoniou et al., 2024; Yung et al., 2019). Elderly, defined as people with an age greater than 65 years (CBS, 2023), are among the most vulnerable to climate-related diseases.

Their vulnerability is due to their decreased metabolic rate and cognitive functions, malfunctioning of neurosensory systems and thermoregulation, delayed responses to health risks and side-effects of medication that most elderly people use (Aghamolaei and Lak, 2022). Additionally, elderly are often facing difficulties finding adequate thermal conditions in their houses and neighbourhoods. This problem is exacerbated for those living in social housing, who have limited financial resources to afford active cooling or recover from the consequences of heat damage (Gemeente Amsterdam, 2020b). Both indoor and outdoor heat stress can cause a range of health problems, including thermal exhaustion, heat stroke and headaches, as well as severe breathing problems and aggravation of cardiovascular, respiratory, and cerebrovascular diseases (de Nijs et al., 2019; Pijpers-van Esch, 2015). Climate-related diseases result in over 150,000 deaths each year worldwide and 250 deaths in the Netherlands (RIVM, 2021). At the start of 2019, Amsterdam counted 108,000 elderly, however by 2039, this number is projected to increase by 68%, bringing the elderly population to 181,000 (Gemeente Amsterdam, 2022). With temperatures rising and the population of elderly growing in proportion to the total population, heat-related deaths are likely to increase (Aghamolaei and Lak, 2022).

Amsterdam, among other cities, is already working to develop effective climate action plans and create comfortable outdoor and indoor environments, to minimize the impact of urban heat on health and well-being of vulnerable elderly (Gemeente Amsterdam, 2021; Gemeente Amsterdam, 2024). Although catalogues and toolkits (Lenzholzer, 2010; Pijpers-van Esch, 2015; Osmond and Sharifi, 2017; Klemm, 2018; Kluck et al., 2020; Snep et al., 2021; Mounayar and Florentin, 2022) have been advanced in recent years offering comprehensive lists of solutions to mitigate heat stress, insufficient guidance is offered to designers and planners for selecting and tailoring measures for specific urban contexts. Studies have demonstrated the negative impact of urban heat stress on general urban inhabitants (Antoniou et al., 2024,) and the relation between morphological characteristics and thermal comfort (Maiullari et al., 2021; Peng et al., 2022). However, few studies address socio-economic factors (Indraganti and Rao, 2010; Yung et al., 2019). More specifically, there is little research related to improving urban microclimates for social housing and elderly groups in metropolitan areas. Therefore, to address this gap, the primary objective of this study is to identify which interventions are most effective in reducing heat stress in outdoor spaces in the context of Amsterdam. The paper will focus particularly on overheating risks of spaces frequently used by elderly groups, guided by the question "Among green facades, tree shade, and fountain misting, which urban design interventions are effective in mitigating outdoor heat stress around social housing for the elderly in Amsterdam?".

First, the paper describes potential cooling measures for reducing heat stress. Second, the urban context of Amsterdam and the three selected case studies are described. Following, the methodological steps taken to conduct the research are explained. Finally, the results are presented and discussed, followed by conclusive reflections.

Reducing urban heat stress

Thermal comfort, generally defined as the subjective feeling of thermal satisfaction, is influenced by multiple climatic factors (such as air temperature, radiation, humidity, air movement) (Nasrollahi et al., 2020) and personal factors (clothing, metabolic rate and activity level) (ASHRAE, 1992). Since urban microclimate is influenced by elements of the built environment, namely the city's morphology, materialization and landscaping, interventions on morphological and material characteristics can play a major role in mitigating heat and consequent thermal discomfort (see table 1). For example,

interventions on the form of buildings and urban fabric configuration can potentially influence air temperature by increasing shaded areas and guiding air flows, while increasing green coverage and using materials with high albedo would influence reflection of short-wave radiation and humidity levels (Kluck et al., 2020; Mounayar and Florentin, 2022; Pijpers-van Esch, 2015). While sometimes it's most efficient to combine multiple interventions, the findings of Arrar et al. (2024) indicate that in some cases this practice does not significantly improve the cooling effect and is less feasible compared to single measures.

One well-established urban cooling measure is to increase the vegetation cover. For social housing, Snep et al. (2021) concludes that vegetation is an effective and feasible option to tackle heat stress in outdoor spaces. Of all types of vegetation trees are most effective on thermal comfort (Kluck et al., 2020). Tree cover has a large impact due to evapotranspiration and intercepting short- and long-wave radiation at crown level (Lenzholzer, 2010; Pijpers-van Esch, 2015). Tree shading ensures that the direct short-wave radiation reaching surfaces (pavements, walls, and roofs) and the human body is 10 times smaller (Kluck et al., 2020). According to Klemm (2018) 10% tree coverage in a street profile reduces the temperature with 1.0 K. However, a downside of trees is that the air flow reduces due to the increased roughness of the urban landscape (Osmond and Sharifi, 2017).

A second measure is the implementation of green surfaces, grass cover as well as green facades. To reach the optimal cooling potential grass areas need to remain well-irrigated and can be combined with tree cover. For green walls, the air temperature reduction is in the immediately adjacent outdoor spaces (Osmond and Sharifi, 2017). Green facades are especially interesting cooling measures in dense cities, as they can be particularly effective in narrow streets (Kluck et al., 2020).

Another way to cool through evaporation, is the implementation of water elements. Fountains are effective cooling devices for small-scale urban spaces according to Kluck et al. (2020). Optimal evaporative cooling can occur with the aid of natural wind flow. When implementing evaporative-cooling interventions, one should bear in mind that the relative humidity is recommended not to pass 50%, because this will negatively impact perceived thermal comfort (Osmond and Sharifi, 2017).

Table 1. Measures to reduce urban heat stress.

Mitigation measures	**Cooling processes**	**Maximum temperature reduction (Osmond and Sharifi, 2017)**	**Potential PET reduction (Kluck et al., 2020).**
Green facade	Evaporation: cooling of surface temperature and air temperature	Surface temperatures: 5-15°C Air temperature: 2°C	unknown
Trees and Grass cover	Shading and evaporation: cooling of surface temperature and air temperature	Surface temperatures: Grass cover: 15°C, Tree shading: 15°C Air temperature: Combination tree + grass: 1 - 2°C	Trees: 0,4 - 4,9°C Grass: 0,4 - 4,9°C
Fountain misting	Evaporation: cooling of air temperature	Air temperature: 3 - 8°C	1,0 - 5,0°C

The case of Amsterdam

As previously mentioned, Amsterdam is selected as case study in this research. The climate adaptation plan (Gemeente Amsterdam, 2021) has clearly stated the priority to create comfortable outdoor and indoor environments, minimizing the impact of urban heat on health and well-being. To achieve this goal, the municipality is exploring new guidelines, with a particular focus on vulnerable locations such as childcare and nursing homes. Some research has already been conducted to formulate specific

analyses and guidelines for heat mitigation (Kluck, Klok, et al., 2020). Other studies have provided data by aggregating historical heatwave data using maximum Physiological Equivalent Temperature (PET) values from past decades (Klimaateffectatlas, 2023). Our preliminary analysis based on this dataset (figure 1), shows that almost all areas within the municipal administration of Amsterdam exhibit high PET values exceeding 35°C, indicating strong heat stress, with the old inner-city showing higher PET values of 41°C, indicating extreme heat stress.

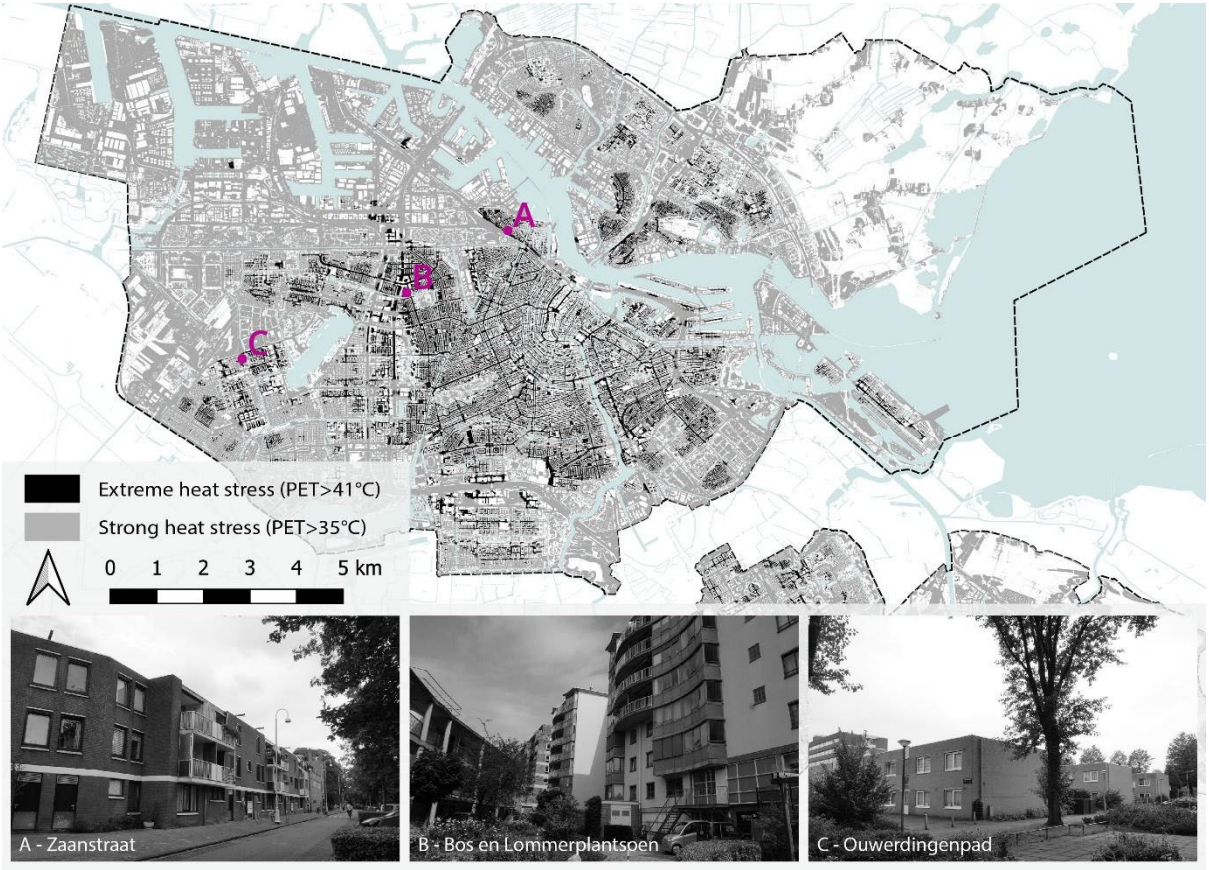

Figure 1. Strong heat stress (PET>35°C) and Extreme heat stress (PET>41°C) (based on: Klimaateffectatlas, 2023)

This city-scale heat stress analysis combined with socio-demographic data (CBS, 2021; AFWC, 2022) reveals that many elderly communities are located in heat-prone areas. For this study, the three most representative neighbourhoods with the top three highest number of elderly in social housing and percentage of the outdoor space exposed to extreme heat stress were selected.

METHOD

In order to provide insight into which urban design intervention is effective in mitigating outdoor heat stress around social housing for elderly, the research was structured in four consecutive phases (see figure 2).

First, spatial and climate data were collected for the three selected locations. On this base, input data for microclimate modelling were prepared: 1) Digital spatial model (area input files) with a 3m grid. 2) Material database including building materials, soil types and vegetation and 3) Weather data. In the second phase microclimate simulations of the status quo were carried out using ENVI-met and BIO-met. Results allowed us to analyse PET and its key climate components, such as air temperature,

radiation, humidity, and wind, to determine the main locations for heat stress interventions and climatic components to address. In the third phase, microclimate simulations were carried out for the three locations after including the selected heat stress mitigation measures (green facades, tree shading and water misting). Finally, for each location, a comparative analysis was carried out to evaluate the reduction of PET for different age groups (35-year-olds and 80-year-olds).

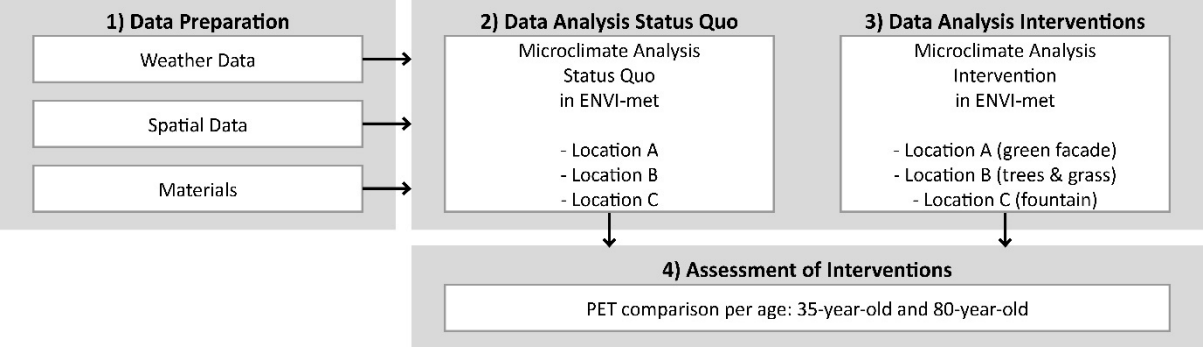

Figure 2. Methodology scheme

Data preparation for microclimate simulations

To model the microclimate in ENVI-met and subsequently, thermal comfort in BIO-met, spatial, and weather data were retrieved from national datasets. Specifically, for building the spatial model of the three locations data were retrieved for buildings, surfaces, and vegetation. For the morphological analysis on the neighbourhood scale the Local Climate Zones (LCZ) framework was employed. The buildings' geometry properties (height [m], footprint [m^2], etc.) were retrieved from the Kadaster database of the Netherlands (Kadaster, 2023). Vegetation cover, geometrical characteristics of trees (height, crown diameter) and plant types were retrieved from city datasets (Atlas Leefomgeving, 2020a; 2020b; Gemeente Amsterdam, 2020a). Existing datasets were enriched through the reporting of surface and building materials based on Google Satellite and Google Street View. For vegetation, soils and building materials the project mainly used the ENVI-met system database.

The Area Input File for ENVI-met was structured based on an equal grid size of 3m (x,y,z). In the previous GIS analysis, a 50m buffer from senior houses was created. To cover the entire buffer surface the extent of the area input file was 300m x 300m each. For the interventions simulation the same area file was used as the status quo, with only the cooling measure as alteration. At location A green facades were applied, at location B trees and grass were implemented and at location C a fountain was introduced, and the trees were replaced with smaller less dense trees.

Climate data were retrieved from the closest KNMI weather station at Schiphol Airport (KNMI, 2023). Since heat stress frequently occurs in summer, especially during heatwaves, the recent heat wave in August 2022 was selected. The warmest day of this heatwave, the 12th of August (KNMI, 2022) and the previous day were simulated by using KNMI data as climate boundary conditions with a Simple Forcing setting. Specifically, hourly values of air temperature and relative humidity were forced, while wind speed was set at the average wind speed of the day (4 m/s) with the predominant wind direction (55°).

Microclimate analysis of status quo and interventions

The air temperature, mean radiant temperature, direct short-wave radiation, humidity, wind speed and wind direction were modelled with ENVI-met and the physiological equivalent temperature (PET) for a 35-year-old male and for an 80-year-old male were modelled in BIO-met. BIO-met simulates the PET "based on the Gagge-2-node model, it relates skin and core temperature generated by the outdoor environment to the indoor air temperature resulting in the same temperatures. The calculation is based on stationary conditions (no movement through the environment)." (ENVI-met Applications Homepage, 2024). The calculation is based on a "standard human according to ISO 7730" (ENVI-met Applications Homepage, 2024). For both ages, the metabolic rate differed, while other parameters such as clothing factor remained the same. Finally, the cooling effect of the implemented measures was further analysed by using the following formulas (table 2).

Table 2. Measurements to assess cooling effect

Scale	Measurement	Formula
Block	Maximum difference PET [K]	$max_\Delta PET(i,j,H_{14:30}) = max_{ij} \mid PET_{map1}(i,j,H_{14:30}) - PET_{map2}(i,j,H_{14:30}) \mid$ Where, $PET_{map1}(i,j,H_{14:30})$ is the PET value at grid (i,j) at the hottest hour of the day $(H_{14:30})$ observed before the intervention (status quo), $PET_{map2}(i,j,H_{14:30})$ is the PET value observed after the intervention, and max_{ij} the function to identify the coordinate (i,j) that maximises the difference in PET values between two PET maps.
	Average difference PET [K]	$\Delta avg_PET(H_{14:30}) = avg_PET_{map2}(H_{14:30}) - avg_PET_{map1}(H_{14:30})$ Where, $\Delta avg_PET(H_{14:30})$ is the difference between $avg_PET_{map1}(H_{14:30})$ the average PET values of the central 75m of the status quo and $avg_PET_{map2}(H_{14:30})$ after the intervention at 14:30h.
Single human	Difference PET [K] at data point	$\Delta PET(x,y,H_{largest}) = PET_{map1}(x,y,H_{largest}) - PET_{map2}(x,y,H_{largest})$ Where, $PET_{map1}(x,y,H_{largest})$ is the PET value observed for the status quo at grid (x,y) on the PET map at $(H_{largest})$, the hour of the day where ΔPET is largest. $PET_{map2}(x,y,H_{largest})$ is the PET value at the same grid (x,y) on the PET map observed after the intervention. Grid (x,y) is the grid where the PET value was highest in the building's adjacent outdoor space, as observed before the intervention (Status Quo).
	Cooling timespan at data point [h]	$TS_{cooling}(x,y) = \{(H_{start},H_{end}) \mid \Delta PET(x,y,H) > \Delta T \; for \; all \; H \in [H_{start},H_{end}]\}$ Where, ΔT is the temperature difference threshold to be compared with ΔPET at the selected pixel (x,y); in this paper ΔT = 1 K, a perceived temperature difference, is used. H represent the time of the day. H_{start} and H_{end} are the start and end times of the cooling window, respectively.

RESULTS

The results of the heat stress modelling for three locations are here reported using PET thermal indices, accompanied by four underlying meteorological factors: air temperature, solar radiation, relative humidity, and wind speed. First, PET values in the status quo situation for a typical 35- and 80-year-old person at the hottest time of the day (14:30h) are visualised and described for the three case studies. Then, the variations in PET between status quo and intervention scenarios (for typical 80-year-old person) calculated and visualized at the same spatial scale and same time. Finally, PET values for all ages across the three points of interest (single human scale) are presented over 24 hours.

Morphological characteristics

The spatial and thermal conditions of these three areas and their outdoor spaces (Location A, B and C) are described in table 3.

Table 3. Urban Morphometrics (Atlas Leefomgeving, 2020a; Atlas Leefomgeving, 2020b; Centraal Bureau voor de Statistiek, 2021; Demuzere et al., 2019; Kadaster, 2023)

Scale	Metric	Location A (Zaanstraat)	Location B (Bos en Lommerplantsoen)	Location C (Ouwerdingenpad)
Neighbourhood scale	Local Climate Zone (LCZ) classification	LCZ-6 open low-rise LCZ-3 compact low-rise	LCZ-6 open low-rise LCZ-8 large low-rise	LCZ-6 open low-rise
Block scale	Building Heights [m] (50m buffer)	15.01 ±1.87	22.11 ±7.37	13.86 ±10.58
	Number of buildings	26	3	12
	Ground Space Index (GSI, 25m buffer)	0.18	0.25	0.26
	Floor Space Index (FSI, 50m buffer)	0.93	1.15	1.03
	Green Area [m^2] (50m buffer)	2473	3507	2938
	Tree Coverage [%]	5.81	1.44	3.85
Single building scale	Building Height [m]	10.16	9.38	5.07
	Building footprint [m^2]	977	236	575
	Building surface to volume ratio [m^2/m^3]	0.32	0.38	0.41

From a morphological and climate perspective, locations A, B, and C all fall under the same local climate zone (LCZ6 - open low-rise classification). However, Ground Space Index (GSI) and Floor Space Index (FSI) indicators reveal significant differences in building density and coverage across the three locations. These differences result in varying street aspect ratios and orientations, as well as distinct green coverages, making each location look quite different despite the same LCZ classification. Additionally, detailed morphological differences can be observed by comparing building compactness at the single-building scale.

Thermal stress levels at location A (Zaanstraat)

Status quo

The comparison (figure 3) shows that in both cases, the majority of the area is affected by extreme heat stress (PET>41°C), and a typical elderly is generally at a higher level of discomfort compared to a middle-aged person (2 to 6 K). The patterns of PET value distribution are, however, similar and highlight the high PET temperatures in the outdoor space adjacent to the building's southwest facade. The PET in the status quo situation reaches a maximum temperature of 57.78°C for 35-year-olds and 58.96°C for 80-year-olds. The average PET for 80y is 48.24°C (SD=4.53) in the area.

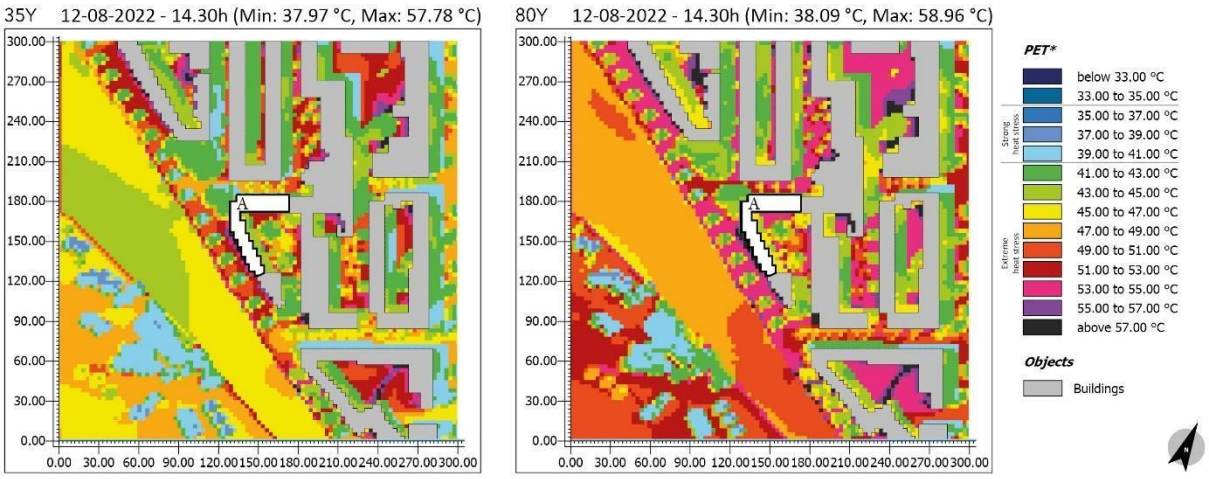

Figure 3. Status quo (35y - 80y)

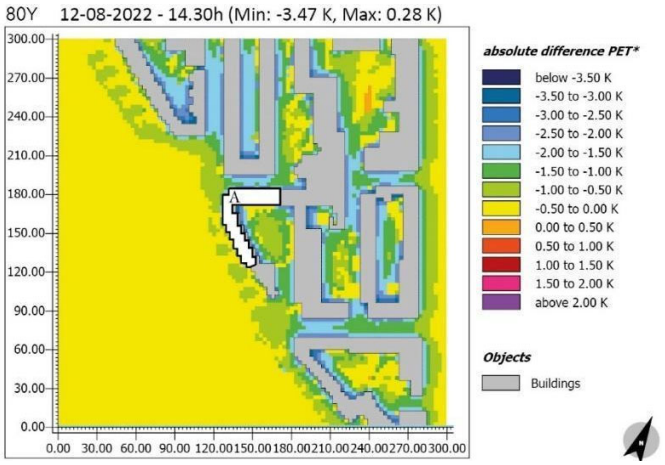

Figure 4. Implemented measures (80y)

The most influential parameters contributing to the heat stress in the outdoor space at the southwest facade are the high mean radiant temperature of max. 67.52°C and low wind speeds (max. 0.45 m/s). The mean radiant temperature is an indicator of high radiation and reflection. Based on this analysis, green facades were introduced on all existing building envelopes as mitigation measure to reduce thermal stress.

Intervention

Converting existing façades into green facades generally brings an increase in human comfort. At Location A the maximum PET reduction in the area was -4.64 K for 35-year-olds and -3.47 K for 80-year-olds. Around the social housing building PET reduction changes according to the building orientation. Compared to the status quo, in the green façade scenario PET decreased along the southwest street between -1.00 K to -0.50 K (figure 4) while on the north and east sides of the buildings decreased between -2.00 K to -1.00 K. The mean radiant temperature in the southwest street only decreased -2.50 K to -2.00 K, while at the north-east side of the buildings the mean radiant temperature decreased -3.00 K to -2.00 K. As a consequence of the intervention the relative humidity increased between 1.00% to 2.00%, however, on a hot and dry day, this is beneficial as it increases the relative humidity to a more comfortable percentage.

Thermal stress levels at location B (Bos en Lommerplantsoen)

Status quo

The comparison in figure 5 shows that for both ages, the majority of the area is affected by extreme heat stress (>41°C), with a typical elderly generally at a higher level of discomfort compared to a middle-aged person (2 to 6 K). The patterns of PET value distribution are, however, similar and highlight the highest PET temperatures in the street on the east side of the building. At location B the PET reaches a maximum of 57.78°C for 35-year-olds and 58.96°C for 80-year-olds for the status quo. The average PET for 80y is 50.11°C (SD=4.60) in the area.

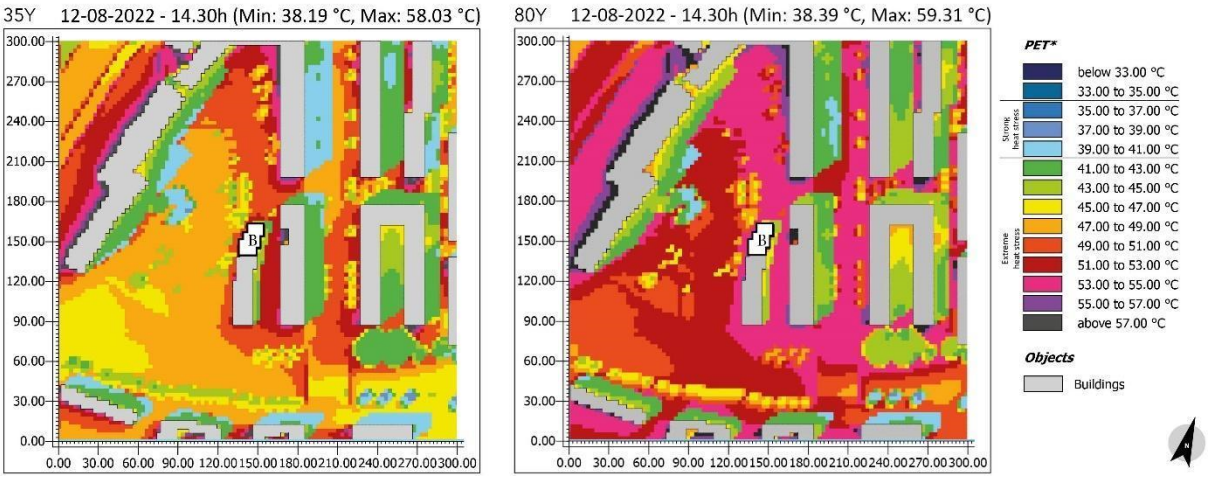

Figure 5. Status quo (35y - 80y)

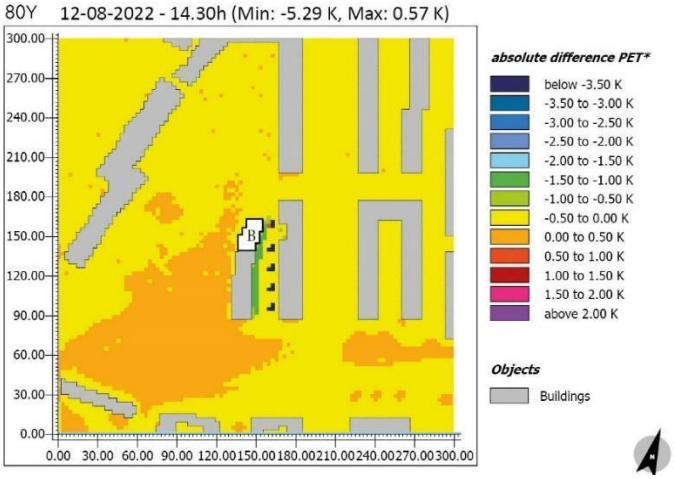

Figure 6. Implemented measures (80y)

The most influential parameters contributing to the heat stress in the east street are the wind (below 0.30 m/s), the direct short-wave radiation and the mean radiant temperature (max. 67.52°C). Because of the high radiation, assumptions were that the shading is insufficient, relating to the low building heights and low tree crown area, and the paving materials emit heat. Thus, as mitigation measure the vegetation cover, in the form of tree shading and grass cover, is increased.

Intervention

Increasing the vegetation cover generally increased the human comfort. At location B, compared to the status quo the PET reduction is between -1.00 K to -0.50 K on the grass surfaces and -5.36 K under the trees for 35-year-olds and -5.29 K for 80-year-olds, as visible in figure 6. The short-wave radiation has decreased (with -601.31 W/m^2) at the locations of the trees in the eastern street at 14:30h. The mean radiant temperature decreased by -2.00 K to -1.00 K.

Thermal stress levels at location C (Ouwerdingenpad)

Status quo

The comparison (figure 7) shows that for both age groups, the majority of the area is affected by extreme heat stress (>41°C), and elderly are generally at a higher level of discomfort (2 to 6 K). Again,

with similar patterns of PET value distribution, with the highest PET values found in the outdoor spaces on both east and west sides of the building. At location C the PET for 38-year-olds reached a maximum of 58.03°C and 59.27°C for 80-year-olds. The average PET for 80y is 49.01°C (SD=4.61) in the area.

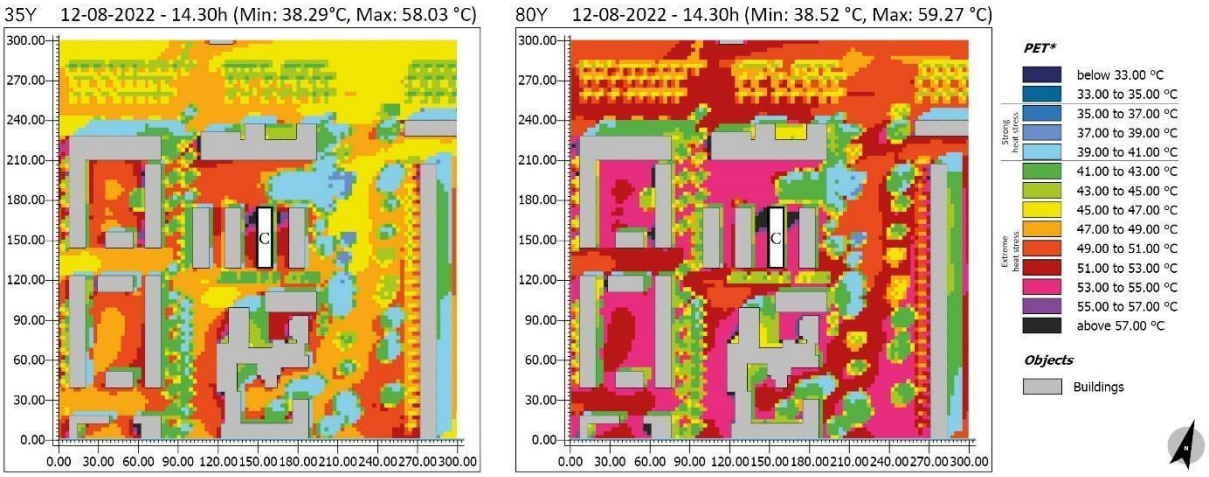

Figure 7. Status quo (35y - 80y)

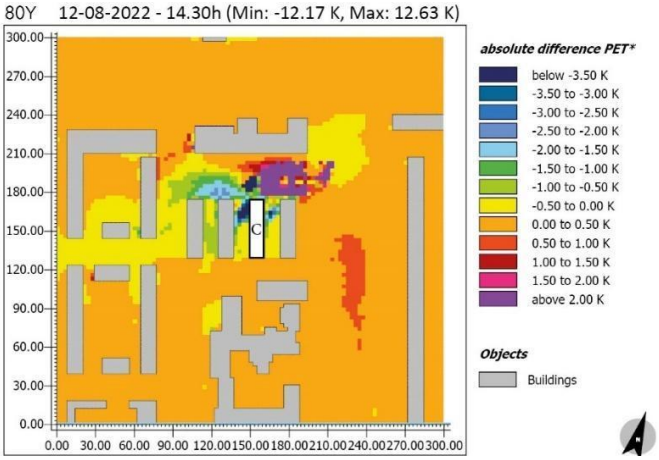

Figure 8. Implemented measures (80y)

The most influential parameters for Location C are the wind (below 0.15 m/s) and air temperatures (above 32.10°C). This could be caused by 1) streets not aligning with the wind direction, and 2) a lack of evaporative cooling from vegetation. To improve the evaporation the implemented measure of this location is a fountain implemented northeast of the building. To increase the impact of the fountain, the roughness elements are adjusted. Meaning, large dense trees are replaced by smaller trees north of the building, allowing more wind to flow through both streets.

Intervention

Implementing the water misting generally increased the human comfort. Compared to the status quo the air temperature decreased by 1.00 K and the wind speed increased to 0.55 m/s, resulting in a maximum PET reduction of -8.70 K for 35-year-olds and -12.17 K for 80-year-olds (figure 8). The wind direction is from the fountain north-east of the building, directly to the streets on either side, which spreads the effect of the fountain to the areas with high PET values. However, compared to the status quo, an increase in PET can be seen north of the building where the tree crown area was reduced.

PET per age group over 24 hours

The comparison of status quo and intervention scenarios shows that thermal stress reduction of the three cooling measures differs over 24 hours. The change in PET values of the three locations at a data point close to the building at which the PET before the cooling measure was highest was explored (figure 9).

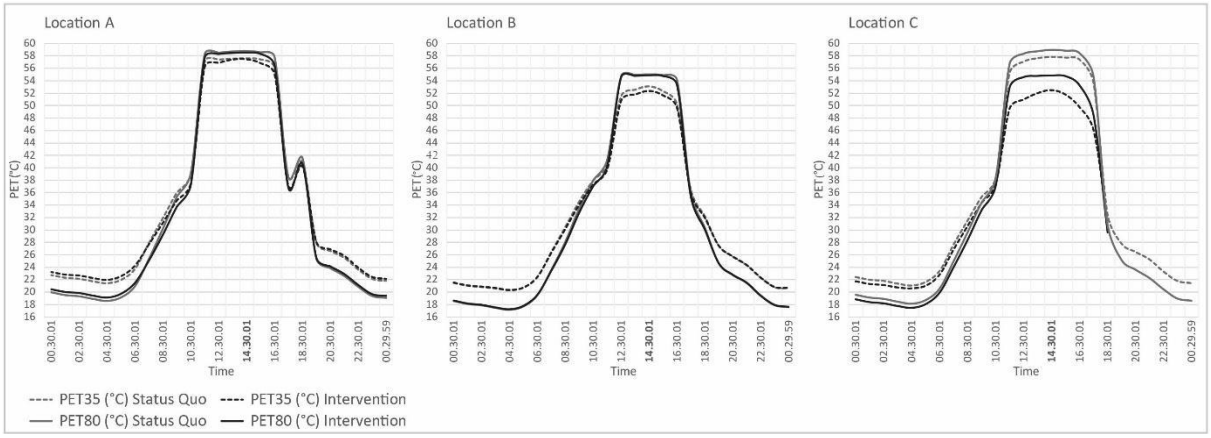

Figure 9. Data retrieved at the point of max. PET (small portion of data is missing in subfigure C, from 18:30).

It can be observed that the timespan of the cooling effect at the selected data point is different for all interventions. The differences in both efficiency and timespan of the different cooling interventions are detailed in table 4.

Table 4. Effectiveness of cooling interventions (in this paper, 14:30h is identified as the hottest time)

Scale	Measurements of cooling effect	Green facades (Location A)	Tree shading (Location B)	Water misting (Location C)
Block scale	$max_\Delta PET(i,j,H_{14:30})$	-4.64 K for 35y -3.47 K for 80y	-5.36 K for 35y -5.29 K for 80y	-8.70 K for 35y **-12.17 K for 80y**
	$\Delta avg_PET(H_{14:30})$	-0.83 K for 35y **-0,87 K for 80y**	-0.30 K for 35y -0,22 K for 80y	-0.31 K for 35y -0,04 K for 80y
Single human Scale	$\Delta PET(x,y,H_{largest})$ during daytime	10:30h -1.46 K for 35y -1.85 K for 80y	11:30h -0.80 K for 35y -1.05 K for 80y	17:30h -7.63 K for 35y **-6.30 K for 80y**
	$\Delta PET(x,y,H_{14:30})$	-0.21 K for 35y -0.27 K for 80y	-0.75 K for 35y -0.14 K for 80y	-5.28 K for 35y **-4.10 K for 80y**
	$\Delta PET(x,y,H_{largest})$ during nighttime	+0.61 K for 35y +0.63 K for 80y	+0.08 K for 35y +0.08 K for 80y	-0.45 K for 35y -0.65 K for 80y
	$TS_{cooling}(x,y)$	09:30–11:30 and 16:30–18:30 for 35y 09:30–11:30 and 16:30–18:30 for 80y	none for 35y 11:30–12:30 for 80y	11:30–18:30 for 35y 08:30–19:30 for 80y

Comparing the three measures, it appears that water misting has the largest impact on the heat stress for both age groups. Both the reduction in PET and duration of the effect are largest for this measure. The cooling effect ΔPET for 80y, is more than 1 K at during two short timespans for the green facades, while the tree cooling has one timespan, and water misting cools for the longest time. The cooling effect of the interventions is most needed at the hottest time of day (14:30). At this time of day, the intervention water misting has the highest cooling effect of the three, both in the area with Max_ΔPET of -12.17 K for 80y and at the selected data point with ΔPET -4.10 K for 80y. The cooling interventions of location A, B and C reach their maximum cooling at the selected data point at different times. The

maximum cooling effect of tree shading (location B) and water misting (Location C) are reached 3 hours from the hottest time of day, while the green facades reach their maximum cooling 4 hours before the hottest time of day. Location A and B both have an increase in heat stress during the night, while water misting keeps lower temperature at day and night.

DISCUSSIONS

To answer the research question "Among green facades, tree shade, and fountain misting, which urban design interventions are effective in mitigating outdoor heat stress around social housing for the elderly in Amsterdam?" a microclimate analysis of three vulnerable locations in Amsterdam during heat waves was conducted in this study.

The microclimate analysis of the status quo confirms that the heat stress in the building's immediate surroundings during a heat wave is extreme. For the status quo in all three areas there are no places to be found below the threshold of strong heat stress (PET=35°C) and only few places below the threshold of extreme heat stress (PET=41°C), especially for elderly (age 80 yrs). Some studies have found that BIO-met underestimates the PET values in case of high values (PET>32°C) (Yin et al., 2019, Zhang et al., 2022), therefore the actual PET values might be even more extreme. While having similar local climate zones, the three areas result in different microclimates and different thermal comfort levels. The scale of the Local Climate Zone appears to lack the capacity of reflecting and differentiating the thermal comfort of the three locations, confirming previous studies which highlighted the LCZ limitations in capturing the microclimate interactions between individual buildings and the surrounding environment (Maiullari et al., 2021). Noticeable was that at all three locations the wind speeds in the building's immediate surroundings are low (max. 0.45 m/s), which is likely one of the main contributing factors to the high PET values. This is confirmed in a review article by Nasrollahi et al. (2020) who has found that there is a direct relationship between area density and thermal comfort. Due to the limited ventilation of all three urban areas, the effect of the cooling measures might also be limited.

Comparing the different interventions, fountain misting has the highest cooling effect and longest timespan. These findings are in line with Kluck et al. (2020), a study in the same climate context. However, during the warmest time of the day (14:30h), the efficiency of all interventions is insufficient in decreasing the PET below the threshold of extreme heat stress (41°C). Noticeable was the increase in PET during nighttime for the interventions trees and green facades, this can be explained because an increased vegetation cover can cool through heat absorption during the daytime and traps the dissipated heat during the nighttime (Osmond and Sharifi, 2017). This research used single punctual mitigation interventions. The study by Arrar et al. (2024) suggested that combined mitigation measures increase the complexity and have limited cooling benefits suggested, single mitigation measures were more effective and feasible. However, the findings of this research suggest that single measures are insufficient in decreasing heat stress. Therefore, more research needs to be done to find optimal combinations of mitigation measures.

From an analytical perspective, this study suggests that digital tools can be used for mapping heat risks around neighbourhoods to inform designers and policymakers. However, the knowledge of cost effectiveness and maintenance of urban design interventions is equally important as understanding the cooling effects. Thus, both feasibility and suitability of the cooling measures should be part of a

larger assessment. Further research is needed to investigate which cooling measures might be favoured by different age groups to create more inclusive and safe thermal environments.

Limitations and further steps

The thermal comfort analysis in this research is based on ENVI-met simulations and PET calculations in BIO-met not validated through climate measurements. Many other studies have confirmed the accuracy of ENVI-met in Dutch case studies (Taleghani et al., 2015), while only a few studies exist on the accuracy of the PET calculation. However, one study confirmed that the accuracy of the PET calculations in BIO-met is sufficient with 7% (Tseliou and Tsiros, 2016). Therefore, in future studies, actual climate measurements of urban heat should be done to validate the ENVI-met result in these three locations and questionnaires should be carried out to examine if the heat can be tolerated by the elderly. Additionally, in this research individual parameters (like level of activity and clothing) are not considered despite their impact on outdoor thermal comfort.

Due to the computation costs of ENVI-met simulations a compromise was found on the model resolution (3m grid). Also, only one exceptionally hot dry day with low wind speeds could be modelled. The chosen interventions had a positive impact under these weather circumstances, but the consequences of the interventions during more humid or cold days might be different. Future studies should explore the effectiveness of mitigation interventions during days with different climatic profiles.

CONCLUSIONS

This study addresses the impact of urban heat on human thermal stress in Amsterdam. The research focuses on interventions to improve urban thermal comfort for elderly around social housing buildings. Three representative cases in heat-prone areas were selected and analysed during a representative hot day through microclimate modelling of the status quo in ENVI-met and modelling of resulting PET (physiological Equivalent Temperature) values in BIO-met. On this base three heat mitigation measures were selected and applied (green facades, tree shade, and fountain misting). A second assessment through microclimate and PET modelling allowed us to compare the level of cooling efficiency among measures and their cooling timespan.

The microclimate analysis of the status quo suggested that outdoor spaces connected to social housing buildings in Amsterdam suffered extreme heat stress during heat waves. Results show that the three vulnerable locations, despite falling in the same LCZ-6 open low-rise class, had very different morphological, microclimatic and thermal comfort characteristics bringing average PET values for 80y to 48.24°C (location A), 50.11°C (location B) and 49.01°C (location C). Additionally, the analysis of the heat stress mitigation interventions shows that punctual interventions around buildings are insufficient in decreasing heat stress for elderly at the hottest time of day. Green facades contributed to decrease the surface temperature of the facade and the air temperature near the facade, resulting in a maximum decrease in PET of -3.47 K for elderly at location A. Increasing the surface covered by trees and grass, decreased both the surface and air temperature, resulted in a maximum PET decrease of -5.29 K for elderly at location B. Fountain misting reduced air temperature, decreasing the PET by maximum -12.17 K for elderly at location C. Among the three measures fountain misting provided the

highest reduction in PET, however, none of the measures decreased the PET of the area below the threshold of 41°C PET, extreme heat stress, for elderly residents.

Finally, this study suggests a need for systemic heat mitigation strategies and for further exploring the role of urban fabric morphological characteristics to create inclusive and safe thermal environments. While the approach used in this paper has contributed to the knowledge base to guide design intervention for a cool and comfortable outdoor environment, future research should focus on the potential of combining several measures and on their suitability for elderly residents.

ABSTRACT

In the course of China's reform and opening up, Shanghai's Lujiazui District has emerged as one of the country's most important central business districts, undergoing political, economic and cultural changes over the years. The Oriental Pearl TV Tower, a representative landmark of Shanghai, is a part of the development of this district. Although the evolution of urban form in Shanghai has been a considerable research topic, previous studies have not explicitly discussed the impact of the Oriental Pearl TV Tower on urban form. This article focuses on how the TV tower has influenced the area's urban form. It covers the process of site selection, the urban design competition, and the tower's development after completion. In terms of urban planning, the preparation and location of the TV tower were intimately linked to the development of the area. Regarding urban design, most of the proposals submitted to the Lujiazui Urban Design Competition resemble the TV Tower that has yet to be built. Architecturally, it influenced the layout and form of neighboring buildings, for example the form of Shanghai International Convention Center. The article utilizes documentary research, drawing analysis, and oral history interviews, drawing on valuable materials from the Shanghai Municipal Archives and other sources, as well as interviews with individuals who experienced the events. Furthermore, this study will also serve as a complement to a practical example of the relationship between iconic architecture and urban form.

Keywords: urban form, CBD, the Lujiazui area, the Oriental Pearl Television Tower

INTRODUCTION

During the period of reform and opening up, China's economy and trade developed rapidly, and urban construction was in full swing, marking an important period of transition for modern China. The Lujiazui area of Shanghai serves as a key example of urban development during this period, with its urban form evolving in tandem with the changes and developments witnessed in the economic system, ideology, and other aspects.

The Oriental Pearl TV Tower, erected during this period, has become a prominent landmark in Shanghai and has played a pivotal role in the development of the Lujiazui district in Pudong. From the perspective of urban space construction, the preparation of the Oriental Pearl TV Tower is inextricably linked to the urban planning of the Pudong area. Additionally, it has significantly impacted the urban

design competition and the final planning. Following the completion of the Oriental Pearl Tower, neighboring buildings were constructed rapidly, and the form of the International Convention and Exhibition Center was also significantly influenced by the Oriental Pearl Tower. The buildings situated in close proximity to the TV Tower collectively contribute to the formation of a multi-level architectural layout and a distinctive skyline for the Lujiazui area. Ultimately, tourists visiting the area will have spatial experiences at varying locations due to the differing roles these locations play in the urban space.

The Oriental Pearl TV Tower has exerted a pervasive influence on the urban landscape and architectural form throughout its lengthy history, from the period preceding its construction to the present day. Accordingly, this paper employs a diachronic perspective, utilizing literature analysis, drawing analysis, and field research to elucidate the role of the Oriental Pearl TV Tower in the urban development of the Lujiazui area during the preparation, design competition period, and the complete time period subsequent to the completion of the tower. Furthermore, it endeavors to illuminate the relationship between the landmark building and the evolution of urban form.

The Oriental Pearl TV Tower and Lujiazui Urban Design

Site Selection of the Oriental Pearl TV Tower and Lujiazui Urban Planning

The Huangpu River divides Shanghai into two parts: Pudong (east) and Puxi (west). Before China's reform and opening up, development focused mainly on Puxi, while Pudong received less attention.(Fan Weida, 2004). In the early 1980s, Lujiazui in Pudong was designated for a riverside park under city planning efforts.

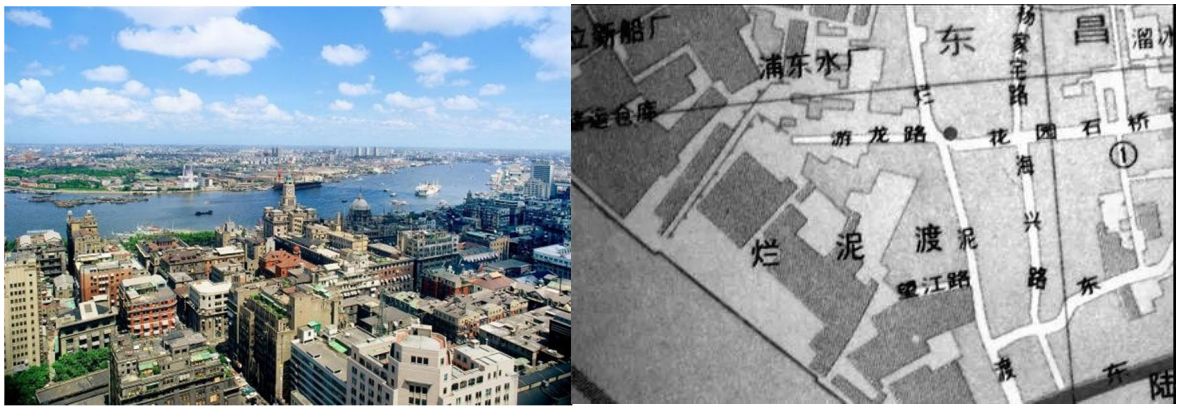

Figure 1, 2. The undeveloped Lujiazui area of Pudong

The Oriental Pearl TV Tower, a superlative telecommunications structure symbolizing China's modernization, was a pivotal element in the design. Four sites were initially considered. The locations under consideration were People's Square, situated in the heart of the city; the Nanyang Road area on West Nanjing Road; Jing'an Park; and the site of the former British Consulate, which was ultimately selected due to its superior urban development in Puxi. However, all were rejected due to issues like proximity to City Hall, existing leases, and the need for demolitions(Wu Jimin, 2014).

During the reform and opening up, the Shanghai Municipal Government identified Pudong as a key area for development. In 1984, discussions commenced, and on April 18, 1990, the Chinese government officially announced plans to accelerate the development of the Pudong New Area. The

Oriental Pearl TV Tower, as a symbolic project, marked the first significant undertaking in this development.

Figure 3. Description of Pudong Development in Liberation Daily

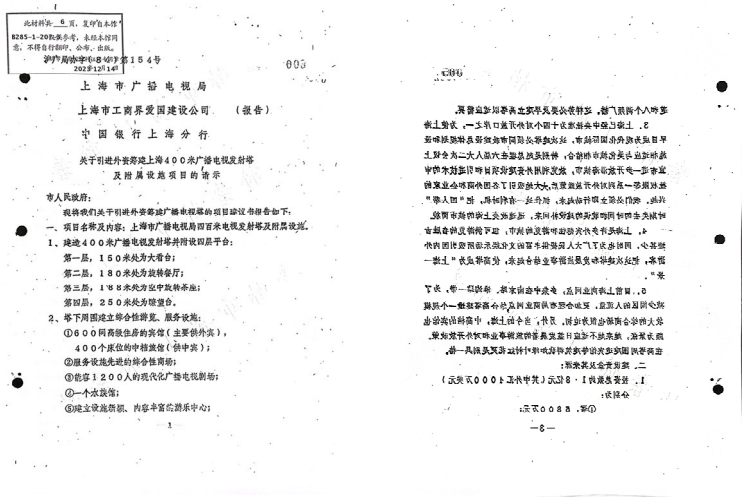

Figure 4,5. The Oriental Pearl TV Tower Request for Proposal Archives

Lujiazui’s strategic position at the confluence of the Huangpu River made it the ideal site, though initial plans were delayed by a Port Authority proposal for a shipping building. A pivotal meeting at the Shanghai Seven Heavens Hotel, led by Zhang Shaoliang, resolved this, with Ni Tianzeng agreeing to allocate the site for the TV tower and compensate the Port Authority. On August 23, 1984, the Shanghai Municipal Radio and Television Bureau submitted a report titled "Opinions on the Site Selection of the 400-meter TV Transmission Tower," outlining plans for the tower in Lujiazui. By March 1985, the "New TV Broadcasting Tower and Subsidiary Facilities" report was approved by the municipal government.

In May of that year, the Shanghai Municipal Planning Commission approved the report, finalizing Lujiazui in Pudong as the site for the TV tower. All stakeholders agreed that this prominent location should be reserved for the tower, given its symbolic importance to Shanghai.

The central government's decision to prioritize Pudong's development elevated Shanghai's national strategic role. Pudong's development was not only an economic initiative but also a key opportunity for China to showcase the success of its reform and opening up policies to the international community. The Oriental Pearl TV Tower stands as a prime example of this vision, justifying its location in Lujiazui.

The Oriental Pearl TV Tower and Lujiazui Urban Design Competition

Following the proposal for Pudong's development, urban construction in Lujiazui began. In May 1992, prominent firms including STUDIO FUKSAS, Rogers Stirk Harbour + Partners, Toyo Ito & Associates, Dominique Perrault Architecture, and the Design Group of Shanghai (composed of the Shanghai Municipal Planning and Design Institute, the East China Design Institute, and Tongji University) were invited to participate in the design competition(Yan Xubian, 2001).

A clear axis can be observed in the proposals by the Chinese consulting group, Italian firm Fuksas, and British firm Rogers. In these schemes, major roads or rivers serve as the axis. The Chinese proposal is particularly notable for its strong axial focus, aimed at creating a monumental, iconic effect. This axis takes the form of a wide boulevard leading directly to the Oriental Pearl Tower, offering unobstructed views of the tower at its terminus. Approximately one-quarter of the designated space is allocated for green areas and urban squares, reinforcing the tower's role as a major urban node. The symmetrical layout along the boulevard follows Lujiazui's arc along the river, with roads on both sides converging towards the central axis. The Oriental Pearl Tower acts as a focal point, enhancing the plan's directionality, visual emphasis, and spatial organization.

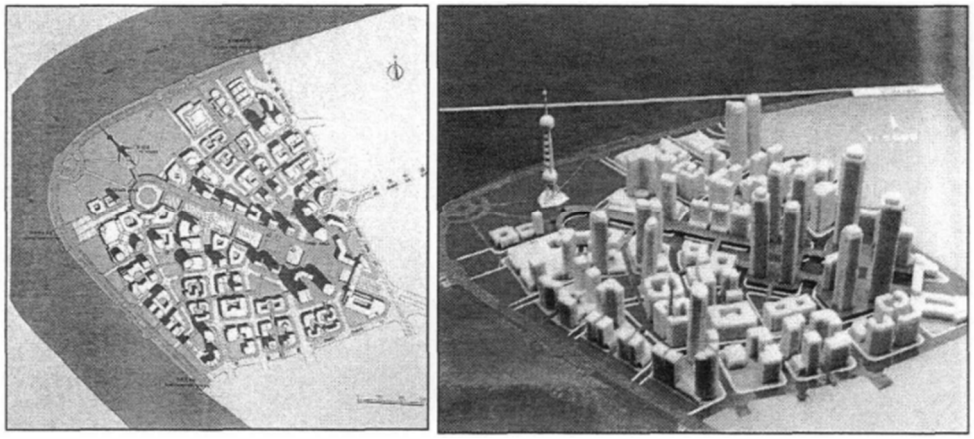

Figure 6. The proposal by the China Shanghai United Consulting Group

Both the Italian and British proposals incorporate curved lines, circular or elliptical elements, and enclosed spaces. While their axes are less pronounced, they also direct attention to the Oriental Pearl Tower. The British plan reduces the volume and number of buildings near the tower, creating an open space that frames the tower. In both schemes, the Oriental Pearl Tower serves as the terminus of the axis and the central node of the urban design.

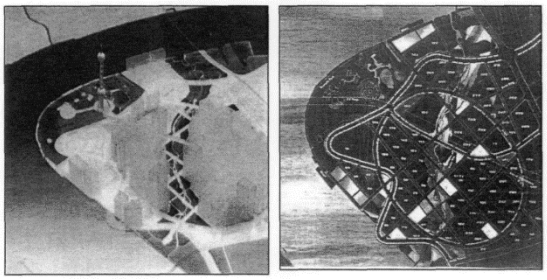

Figure 7. The Italian proposal

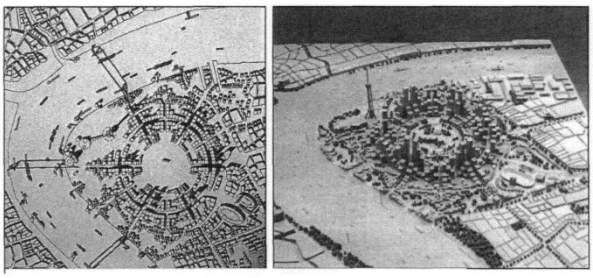

Figure 8. The British proposal

The French and Japanese proposals both adopt linear approaches. The French plan extends along the river in a right-angled configuration, forming the basis for a high-rise building layout. The Oriental Pearl TV Tower is positioned slightly off the corner at the second building location, and the plan lacks a clear axis. The Japanese proposal introduces a linear "ribbon city" concept to the south, with the Oriental Pearl Tower at the start of the first development ribbon. Neither plan emphasizes iconicity or

monumentality, so the tower does not play a central role in the design. However, due to its size, height, and location, the tower remains a prominent feature in both plans.

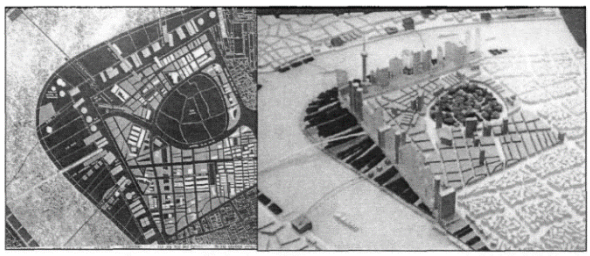

Figure 9. The French proposal

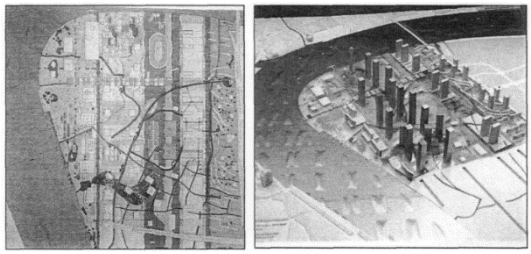

Figure 10. The Japanese proposal

After the initial phase of the competition, the Shanghai Government determined that a more comprehensive assessment was required. The Shanghai Municipal Planning Department agreed, leading to program modifications and the creation of three enhanced comparative plans, which were eventually unified. While the final plan differs from the originals in many respects, the road network, central axis, and orientation toward the Oriental Pearl TV Tower remain strikingly similar.

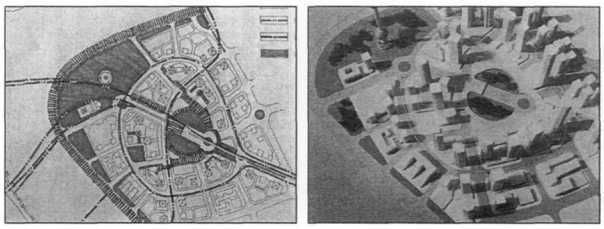

Figure 11. The deepening proposal 1

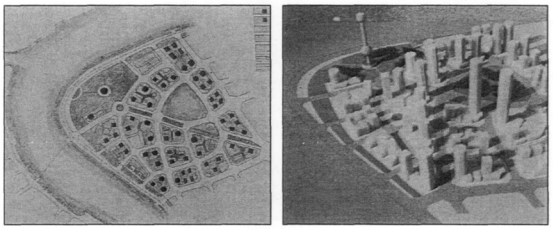

Figure 12. The deepening proposal 2

Figure 13. The final proposal

The positioning and objectives of the Lujiazui area's development were instrumental in shaping its final form. The initial goal of the Lujiazui master plan was to "face the world, face the 21st century, face modernization," aimed at presenting China's urban image to the global community during a transformative period of reform and opening up (Yang Jiying, 1998). This clear objective, rooted in political, social, and national consciousness, encompassed several intentions: creating modern architectural forms, preserving Chinese characteristics within a contemporary context, and

developing urban identity and imagery. The symmetrical layout and iconic Century Boulevard exemplify this vision. The Oriental Pearl Tower, with its distinctive design and status as an architectural icon, became the focal point of the design process and influenced the evolution of various proposals.

The Oriental Pearl TV Tower and neighbouring buildings

Planning International Convention and Exhibition Centre

The International Conference Centre, designed by the Zhejiang Provincial Architectural Design Institute and completed in 1999, received the 'Top Ten Gold Medal Buildings' award during the 'Fiftieth Anniversary of the Founding of the PRC Classical Architecture Selection.' However, the architectural community was critical, with none of the jury members voting for it. Despite this, the International Conference Centre secured ninth place in a selection made by leaders, citizens, and experts. Its form, location, and layout are closely interconnected with the Oriental Pearl TV Tower.

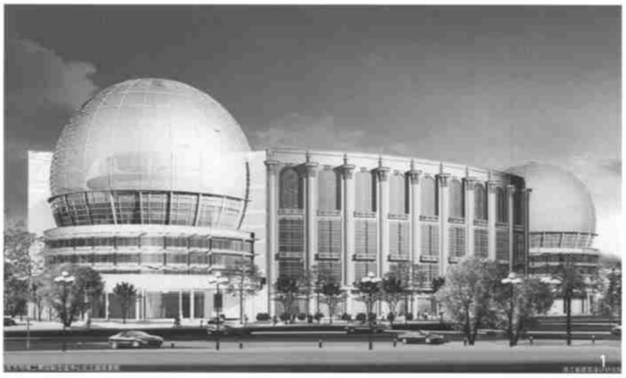

Figure 14. Programme rendering of the International Conference Centre

Figure 15.Riverside Exterior

The design of the International Conference Centre has been significantly shaped by the concept of leadership, with the Oriental Pearl TV Tower serving as a primary source of inspiration. The north and south sides of the centre are built on two- and three-storey podiums, respectively, featuring two glass-topped globes arranged in a grid pattern. The north globe has a diameter of 50 meters, while the south globe measures 38 meters, reflecting the large and small spheres of the Oriental Pearl Tower. The location and height of these spheres are deliberately linked to the tower, views from the Bund on East Nanjing Road are tangential to the tower's central sphere. This design echoes traditional Chinese concepts of the square and circle, resonating with the adage "the big pearl falls from the jade disc." The layout of the Conference Centre further reflects the tower’s influence, with the main entrance located on the east side of the podium, aligning with the south square of the Oriental Pearl Tower. Additionally, a 30,000 square meter green plaza at the main entrance serves as a key feature of the Pudong Riverside Tourism Zone(Li &Peng, 2000).

In light of the rushed circumstances and the need to satisfy leadership's intentions while advancing the project, the approach of responding to the Oriental Pearl Tower was the most feasible option available at the time. It proved to be the quickest and most effective strategy under the circumstances.

Lujiazui Architectural Layout

The Oriental Pearl TV Tower, the International Convention Centre, the Port Tower, the Customs Building and other edifices are situated in the Lujiazui area along the river. Within the central ring road, one may find the Jinmao Tower, the World Financial Centre and other structures. In the central green area, there are clusters of super-high-rise office buildings, including the China Insurance Tower and the Shanghai Securities Tower, among others. The Oriental Pearl TV Tower is notable for its distinct form and volume in comparison to the surrounding buildings. Together with the Jinmao Tower and the World Financial Centre, they represent a prominent feature of the area. The urban image of the Lujiazui area is inextricably linked to the configuration of these super-tall buildings.

The riverine space can be differentiated according to the relative distance between the location and the river. This results in the formation of three distinct levels: the riverbank, the central ring road, and the central green space. The river bank and the internal ring road constitute the first level of urban development. The buildings on this level face the opposite bank of the river, forming the primary visual aspect of the city. The Oriental Pearl TV Tower serves as a prominent symbol of the city. The second level of the Jin Mao Tower and the World Financial Centre represents the pinnacle of the urban fabric, a central point of prominence that is balanced by the surrounding context. The third level is characterised by a concentrated arrangement of buildings, with a compact distribution and narrow gaps, creating a strong sense of building groups.

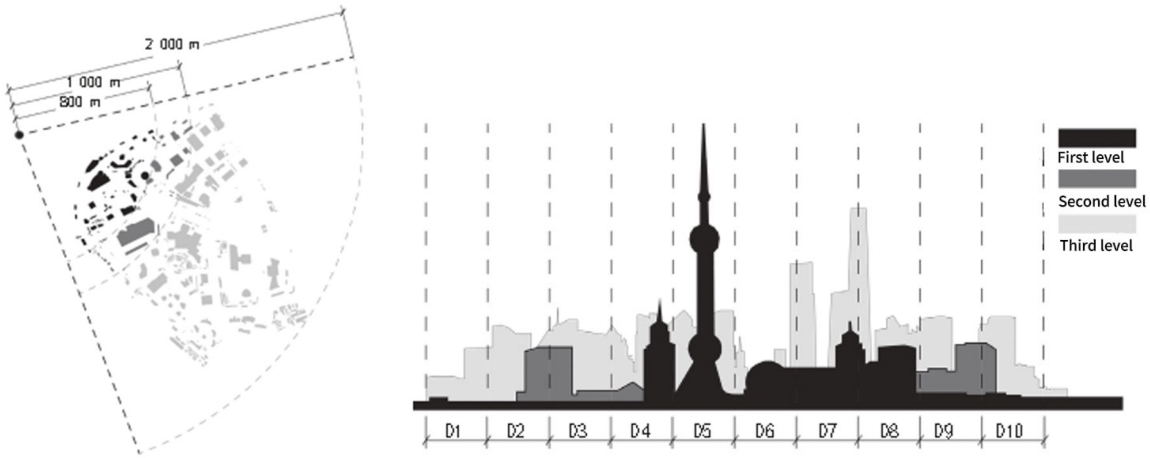

Figure 16, 17. Lujiazui Complex Levels

A skyline analysis is a method of abstracting the linear form of a group of buildings by removing the influence of the exterior surface and other details. The skyline of Lujiazui is a pervasive image in various media, serving as an emblematic representation of Shanghai. As illustrated in the accompanying figure, the image of Lujiazui is readily discernible in the photographs of the Oriental Pearl Tower and the Jinmao Tower. The Lujiazui skyline, observed from different perspectives, assumes various forms. However, it is consistently dominated by three super high-rise buildings: the Oriental Pearl Tower, the Jin Mao Tower, and the World Financial Centre. These structures serve as the high point, balancing the skyline of the entire centre.

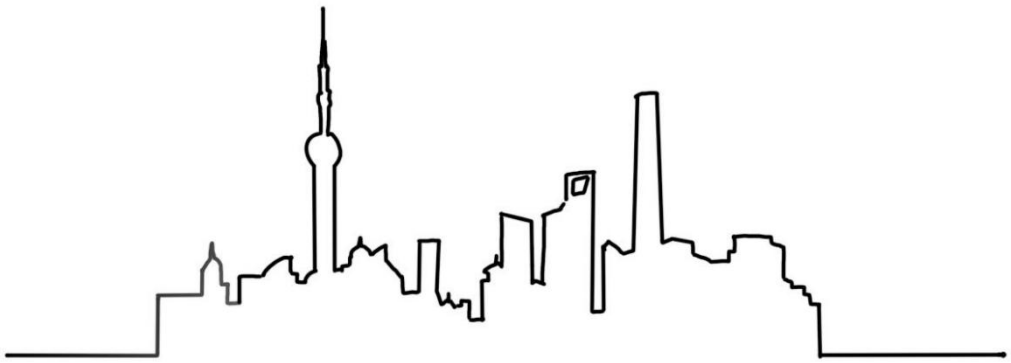

Figure 18. Lujiazui skyline

The Oriental Pearl TV Tower and the Spatial Experience of People

Road

The roads in the Lujiazui area are closely associated with urban landmarks, and Century Avenue itself is an iconic landmark in Lujiazui, representing an axis running through the entire area with an extremely strong pointing direction.

Firstly, with a length of 5.5 kilometres and a width of 100 metres, the road has an extremely wide sense of space and is planned to be an iconic landmark. The endpoints of the avenue are the Oriental Pearl TV Tower and Pudong Century Park, which point directly to the tallest landmark building in Lujiazui: the Oriental Pearl Radio and TV Tower. This serves as a visual guide, thereby reinforcing the avenue's strong directionality. Furthermore, the peripheral ring road and its connecting roads comprise a narrower road system in comparison to Century Avenue, which serves to reinforce the directionality of the road towards the end marker. From the perspective of the surrounding buildings, the majority are super-high-rise structures with a disproportionate ratio to the road. The buildings on either side have minimal impact on pedestrians, further reinforcing the sense of directionality. The observer is naturally guided by the high-rise buildings in front of them as they walk along the road, with the point of the road – the Oriental Pearl – appearing to be the destination.

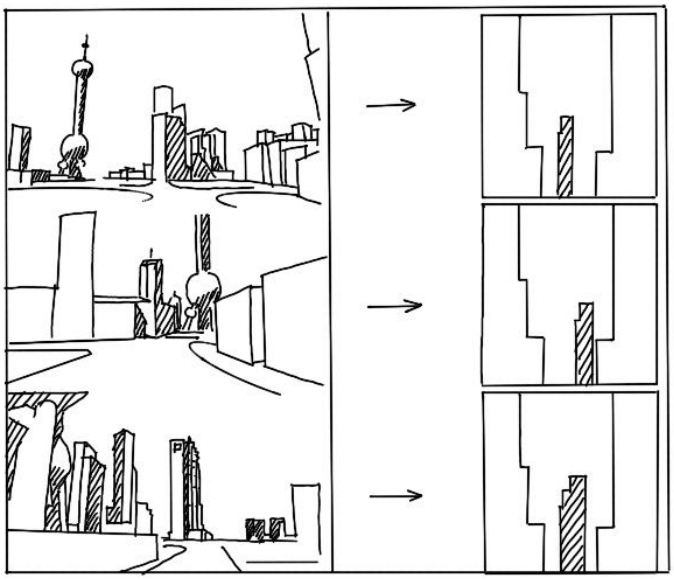

Figure 19.Visitors travelling on the main road in relation to the Pearl of the Orient

Boundary

Boundaries are linear elements within urban space, yet they are not identical to roads. Rather, they constitute interruptions and divisions between spaces. Boundaries delineate the boundaries of space and are integral to the formation of spatial perception.

The Oriental Pearl TV Tower is situated at the confluence of the Huangpu River and the Lujiazui area. The architectural image of the two sides of the river is markedly distinct. The Bund is a modern historical architectural conservation group, whereas the other side of the river, the Lujiazui area, is a modern super high-rise building group, symbolising the image of a modern city undergoing rapid development and progress. The disparate spatial systems give rise to divergent urban landscapes on either side of the border, engendering the impression of observing one another across the river. From this vantage point, observers can discern the comprehensive architectural and spatial configuration of the Lujiazui area, which offers a distinctive spatial experience that is challenging to perceive from within the area itself. The urban image on one side of the border is more often realised by looking into the area from the other side. Consequently, the location of the Oriental Pearl TV Tower at the border of the Lujiazui area serves to shape the image of the area as a whole.

The Lujiazui area CBD represents a significant departure from China's traditional approach to urban development. It is a testament to the country's embrace of foreign investment and international competition, showcasing a striking international display of political symbolism and economic development. Furthermore, it offers a conceptualisation of the city as a temporal entity, encompassing the past, the present and the future. The architectural style of this area can be described as a synthesis of nostalgic and modern elements. The Oriental Pearl TV Tower, with its traditional Chinese symbolism of 'big pearls falling from a jade disc', and the Jinmao Tower, with its dense eaves, serve to reinforce the traditional forms, whilst simultaneously demonstrating the novel aspects of modernity. The high-rise buildings of Lujiazui, situated across the river from the Bund, symbolise an imaginative vision of the future, with the past left behind. This district is defined by two distinct areas: the traditional 'old' Shanghai on the other side of the Huangpu River and the modern

districts that have developed around it. These two areas provide a clear contrast between the past and the present, and offer a vision of what the future may hold. The visual and physical distance between these two areas greatly enhances this contrast.

Nodal

From an urban perspective, a nodal space can be defined as a square, a green space, a corner, or an area (Kevin Lynch, 1960). In Western urban design, the central space of the city is frequently the square space. Monumental buildings are often situated at its centre and converge in the vertical dimension. To illustrate, the renowned clock tower of St. Mark's Square in Italy serves as a conduit between two squares, simultaneously establishing itself as the emblematic focal point of the space and influencing its significance in conjunction with its cultural attributes.

In the Lujiazui area, the node space of the Oriental Pearl TV Tower is particularly noteworthy. It comprises a green space and a ring road. The area surrounding the Oriental Pearl Tower is characterised by a high population density, reflecting its status as a popular tourist destination. In contrast, the end of the ring road on Century Avenue is characterised by a lower density of motorised vehicles and a greater diversity of human activities. The area is comprised of two distinct spaces: an open space designed for tourist use and a green space situated in front of the International Convention Centre, which serves the attendees of the conference. The open space also constitutes a set of urban images, namely the modern urban image comprising the Oriental Pearl Tower and the International Convention Centre.

METHOD

1. Literature Review

This study examines the history of the Oriental Pearl Tower using archival materials from the Shanghai Municipal Archives and construction records from the East China Architectural Design Institute. Urban planning resources are drawn from publications by Lujiazui (Group) Co., Ltd., with additional references from journal articles, theses, and news reports. These sources will be analyzed to explore the Tower's connection to urban design and spatial development in Lujiazui.

2. Blueprint and Image Analysis

Design blueprints, historical photographs, videos, and contemporary site images of the Oriental Pearl Tower will be analyzed to assess the Tower’s role in the design competition and its spatial relationship with the urban environment post-construction.

3. Field Investigation

Fieldwork was conducted at the Oriental Pearl Tower, including the exploration of its public spaces, forecourt, and surrounding buildings. This hands-on investigation aims to provide a clearer understanding of the Tower's influence on the planning and layout of the Lujiazui high-rise cluster and urban space.

RESULTS AND DISCUSSIONS

Provide a concise, clear and precise description of the results and their interpretation. You may use tables, drawings, figures, and diagrams to illustrate your findings. Make sure to dedicate enough space for discussing your results and to reflect on how they can be interpreted from previous studies' perspectives and the working hypotheses/research questions. The findings and their implications should be discussed in the broadest context possible, and the limitations of the work should be highlighted.

CONCLUSIONS

Firstly, with regard to preparation and site selection of the Oriental Pearl Tower: As one of the key architectural projects in the Pudong development, the Oriental Pearl Tower was intended from the outset to transform the cityscape and become a landmark of Shanghai. The final choice of the Lujiazui area in Pudong highlighted its important geographical location and its strategic significance in showcasing Shanghai's international image.

Secondly, in the Lujiazui Urban Design Competition, the Oriental Pearl Tower, a landmark that has yet to be constructed, exerted a considerable influence on the national programmes and the final programme. The final scheme, which has been further developed and refined, continues to place the Oriental Pearl Tower at its core as an iconic building. This is evident in the design of the roads along the main axis, the overall road system, the axial pointing, and the nodal spaces.

Thirdly, from the perspective of surrounding Architecture, the Oriental Pearl Tower, together with surrounding buildings, forms the skyline of Lujiazui and shapes the city's image. The design of the International Conference Center, constructed after the completion of the Oriental Pearl Tower, was profoundly influenced by the tower's design. Its design incorporates the imagery of "big pearl and small pearls falling on a jade plate," featuring a spherical and cylindrical shape that complements the sphere of the Oriental Pearl TV Tower.

Finally, in terms of urban space: the Oriental Pearl Tower plays a significant symbolic role in the Lujiazui urban space through three key aspects: guiding road systems, shaping regional boundaries, and forming node spaces. It serves as a crucial landmark that not only directs the layout of road networks but also helps define the edges of different urban zones. Additionally, it creates distinctive focal points within the city. By integrating these functions, the tower significantly contributes to shaping Lujiazui’s urban identity and the development of a complex, multi-layered urban space.

Acknowledgements

I am grateful to Professor Zhang Xiaochun and Dr Wen Zengxin for their guidance and assistance throughout this research and the writing of this thesis. Without their guidance, this research would not have been feasible. Furthermore, I would like to express my gratitude to the Shanghai Library and the Shanghai Archives for providing the majority of the literature sources.

[2] Bartlett School of Architecture, University College London, China, ucbq741@ucl.ac.uk

ABSTRACT

This study proposes a quantitative approach to measuring the urban vitality of historic districts, an area traditionally studied qualitatively. It collects Location-Based Services (LBS) data, social media check-in data, and urban sentiment data for the researched historic district, using these as dimensions to measure urban vitality. The study then utilizes the Analytic Hierarchy Process (AHP) to assign weights to these dimensions, creating a quantifiable index for urban vitality. Using GIS, the study analyzes potential physical space factors affecting the urban vitality of historic districts. The study applies the Spearman correlation to these factors, finding that the visibility of historic buildings has the most significant impact on urban vitality. Additionally, the percentage of green views and facilities also influences urban vitality of historic districts.

Keywords: urban vitality, historic districts, Location-Based Services (LBS) data, Analytic Hierarchy Process (AHP), spearman correlation.

INTRODUCTION: QUANTITATIVE ASSESSMENT OF URBAN VITALITY IN HISTORIC DISTRICTS

Urban vitality, a fundamental indicator of place-making and urban livability, has been widely analyzed through the lens of various urban big data sources. With the rise of smart city technologies and the increasing availability of large-scale data, researchers have gained unprecedented access to metrics that capture the dynamism of urban environments. These metrics can be broadly categorized into three distinct types based on their emphasis on spatial patterns, physical environments, and subjective experiences, each offering unique insights into urban vitality.

1) Spatiotemporal Distribution of Human Activity

This approach leverages Location-Based Services (LBS) data to monitor the intensity and spatiotemporal patterns of human activity (Jin et al., 2017; Jacobs-Crisioni et al., 2014; Li et al., 2016). By tracking the real-time movement of individuals, often through mobile signaling data, researchers can infer urban vitality by mapping the density and movement patterns of the population across

different times and spaces. These patterns, in turn, provide a proxy for understanding the vibrancy of urban streets and districts, particularly in highly trafficked areas.

2) Objective Characteristics of the Urban Physical Environment

The second approach focuses on the physical attributes of the urban environment, particularly the distribution of commercial establishments, urban amenities, nighttime lighting, and other built environment features. This is primarily achieved through Points of Interest (POI) data, which capture the spatial arrangement and density of key urban functions (He et al., 2018; Q. Li et al., 2022; Yue et al., 2019; Zeng et al., 2018). By analyzing POI data, researchers can assess how the configuration of the urban landscape influences social interactions and economic activities, and thereby measure the vitality of urban spaces. This method is particularly useful for understanding how different land uses and facilities contribute to urban vibrancy.

3) Subjective Perception of Urban Activity

The third category utilizes data derived from social media platforms to capture subjective experiences and perceptions of urban environments (Long & Huang, 2019; Ye et al., 2018). User-generated content such as texts, images, and videos posted on social media provides qualitative insights into how people perceive and engage with urban spaces. These subjective data sources offer a nuanced understanding of urban vitality, reflecting the emotional and experiential dimensions that traditional spatial metrics may overlook.

While these methods have proven effective in assessing vitality in conventional urban contexts, historic districts present unique challenges that complicate their application. The urban vitality of historic districts is deeply intertwined with cultural, architectural, and temporal factors that cannot be fully captured through standard POI, LBS, or social media data alone. Historic districts often embody a complex blend of preservation and modern adaptation, where the layering of history and contemporary use creates a distinct urban fabric.

In recent years, there has been increasing recognition of the need to preserve and revitalize historic districts within the broader framework of sustainable urban development. As urban growth shifts from expansion to stock renewal, the preservation of historic areas has become a key priority in urban regeneration efforts. Despite the growing attention to historic districts, there remains a significant gap in the quantitative assessment of their urban vitality. Existing methods, which focus on either the physical or social aspects of urban spaces, often fail to account for the intricate dynamics that define the vitality of these areas.

To address this gap, it is essential to establish a more comprehensive index that integrates contemporary quantitative urban morphology with big data analytics. This approach would allow for a more nuanced and efficient assessment of the urban vitality of historic districts. By incorporating data on the visibility of historic buildings, spatial configuration, and human activity, we can create a more robust framework for measuring vitality. The index we propose not only offers a means of quantifying vitality but also provides insights into the relationship between urban vitality and the visibility of historic buildings—an often-overlooked factor in the analysis of historic districts.

REVIEW: CURRENT RESEARCH AND GAPS IN MEASURING URBAN VITALITY OF HISTORIC DISTRICTS

Urban vitality of historic districts

Urban vitality is a multifaceted concept, encompassing the dynamic interactions of people, activities, and spaces within urban environments. Historically, urban vitality has been measured through various data sources, such as Location-Based Services (LBS) and social media, which capture spatial-temporal human activity and reflect the emotions and interactions of people in urban spaces. These data provide a more nuanced understanding of how vitality manifests in urban settings. The vitality of historic districts, as a subset of general urban vitality, should similarly be understood through a multidimensional approach. However, historic districts pose unique challenges, as they represent a blend of cultural preservation and modern urban usage.

Numerous studies have examined factors influencing urban vitality in typical urban districts, often focusing on elements such as street design and land-use diversity. For instance, Xu and Kang (2014) used questionnaire-based surveys to identify how physical design elements, such as sidewalk width and interface transparency, significantly influence street vitality. Their findings emphasized the importance of pedestrian-friendly environments in fostering vitality. Long and Zhou (2016) analyzed mobile phone POI data to identify functional mixture and population density as critical factors in promoting street-level vitality. These studies illustrate that urban vitality is shaped by both spatial configuration and the variety of functions present in urban areas.

Despite these findings, there has been limited research into the specific factors affecting the vitality of historic districts. Historic districts possess distinct characteristics that set them apart from typical urban spaces, including unique architectural forms, cultural heritage significance, and often more constrained development regulations. Some scholars, such as Li et al. (2024), have argued from a qualitative perspective that elements such as the layout, density, and visibility of historic buildings are particularly important in shaping the vitality of historic districts. However, the current academic discourse lacks a standardized framework for quantitatively measuring these factors in historic contexts. Thus, further research is needed to explore these unique aspects of vitality in historic districts more deeply and to develop more refined measurement methodologies that capture both their physical and experiential dimensions.

Visibility of historic buildings

The visibility of historic buildings plays a pivotal role in defining the character and identity of historic districts. Kevin Lynch's seminal work on urban imageability underscores the importance of spatial visibility in how people perceive and navigate urban environments. In the context of historic districts, the visibility of architectural heritage reflects a core preservation principle—the "authenticity" of place (Wan & Li, 2016). Ensuring that historic buildings remain visible and accessible to the public is crucial not only for preserving their cultural value but also for maintaining the historic district's role as a living part of the urban fabric.

Despite its importance, the visibility of historic buildings has not been effectively measured in many prior studies due to limitations in analytical techniques. Traditional research on historic buildings has predominantly focused on qualitative studies examining their architectural and cultural significance.

These studies often explore aspects such as the artistic elements, structural integrity, and cultural heritage embodied by historic buildings (Meng, 2024). However, they rarely incorporate quantitative measures of visibility, which could provide more precise insights into how these buildings contribute to the overall vitality of the district.

Recent advances in urban morphology and spatial analysis have opened new possibilities for quantitatively measuring the visibility of historic buildings. While some scholars have begun to explore correlations between the visibility of historic buildings and urban vitality, the field remains largely underdeveloped. Lu et al. (2023) provided some preliminary quantitative evidence suggesting that the visibility of heritage buildings may positively influence the vitality of historic districts. However, their research lacks comprehensive qualitative analysis that fully explores the experiential aspects of visibility. The absence of integrated qualitative and quantitative approaches leaves a significant gap in understanding how visibility affects not only the perception but also the actual functioning of historic districts.

Research progress & current gaps

Although significant progress has been made in measuring urban vitality in conventional urban areas, there remain several key gaps when it comes to historic districts. Firstly, while numerous approaches exist for measuring urban vitality, including LBS data, POI analysis, and social media-derived metrics, these methods have not been synthesized into a comprehensive index specifically tailored for historic districts. Given the unique cultural, architectural, and spatial characteristics of these areas, a more holistic vitality index is needed to account for their complexity. Secondly, in addition to the commonly studied factors affecting urban vitality, such as density, functional diversity, and spatial configuration, there is a critical need to identify whether there are distinct factors that uniquely impact the vitality of historic districts. For example, elements such as the preservation of architectural heritage, the integration of modern amenities, and the relationship between old and new urban forms may play a significant role, but they remain understudied. Thirdly, there is a notable lack of research on the quantitative measurement of the visibility of historic buildings and its relationship with urban vitality. While some studies have suggested potential correlations between visibility and vitality, comprehensive analytical methods that combine both qualitative and quantitative perspectives are missing. Developing these methodologies would provide more robust tools for urban planners and conservationists to assess and enhance the vitality of historic districts, ensuring that these culturally significant areas remain vibrant and livable parts of the city.

In summary, while the study of urban vitality has advanced considerably in recent years, the unique challenges of measuring vitality in historic districts call for more tailored approaches. There is a pressing need for integrated methods that consider the visibility of historic buildings alongside other factors, allowing for a more nuanced understanding of how historic districts function and thrive within the broader urban context.

METHOD

Study area

This study examines the Hengshan-Fuxing Roads Historic Protection Zone in Shanghai, covering an area of approximately 7 km^2 (Figure 1). Known for its rich collection of historic buildings, particularly the renowned garden villas, the area is characterized by heritage-protected roads and alleys that

reflect various historical periods. As a vibrant hub for tourism and everyday life in Shanghai, the district boasts a wide variety of commercial and entertainment activities. The diversity in architectural styles and building functions, combined with the dynamic street life, makes this historic protection zone an ideal case study for exploring the relationship between urban vitality and the preservation of cultural heritage.

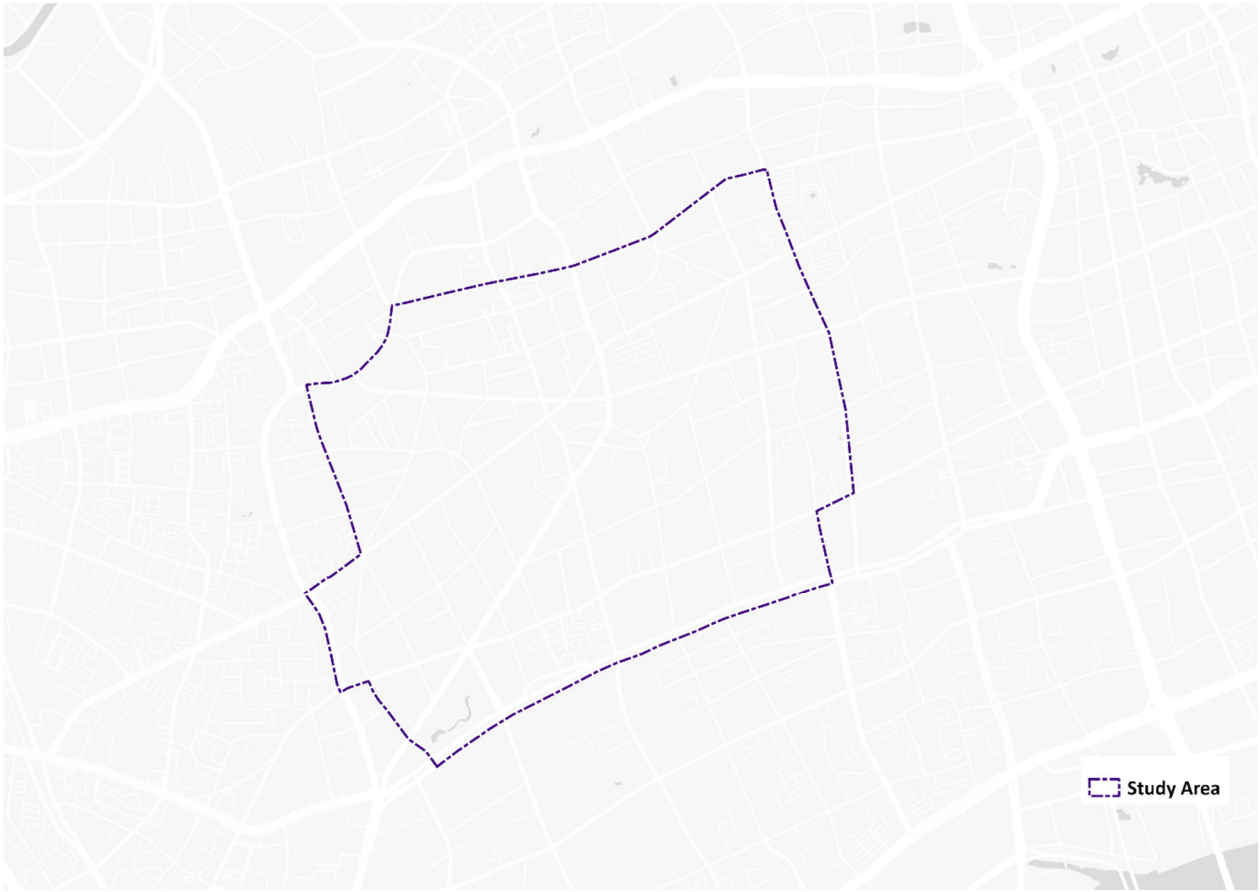

Figure 1.Study area: the Hengshan-Fuxing Roads Historic Protection Zone in Shanghai, photo credit: drawn by the author

Research framework

This study is structured into two primary components (Figure 2). The first component focuses on assessing the urban vitality of historic districts. Using the Analytic Hierarchy Process (AHP), expert evaluations are applied to data sourced from Location-Based Services (LBS), social media check-ins, and urban sentiment analysis. These evaluations are used to calculate weighted proportions, which are then integrated to derive vitality scores for each street segment.

The second component involves significance analysis. Initially, the study employs QGIS and machine learning-based street view image segmentation techniques to identify potential factors influencing vitality within historic neighbourhoods at the site. Following this, Spearman's correlation analysis is conducted to determine the most significant factors impacting urban vitality within the area.

The research is organized into four main stages: (1) data collection, (2) assessment of urban vitality in historic districts, (3) identification of factors influencing vitality in historic areas, and (4) analysis of the

significance of these factors on urban vitality in historic districts. This structure ensures a comprehensive understanding of both the vitality and the underlying factors that contribute to the vibrancy of historic areas.

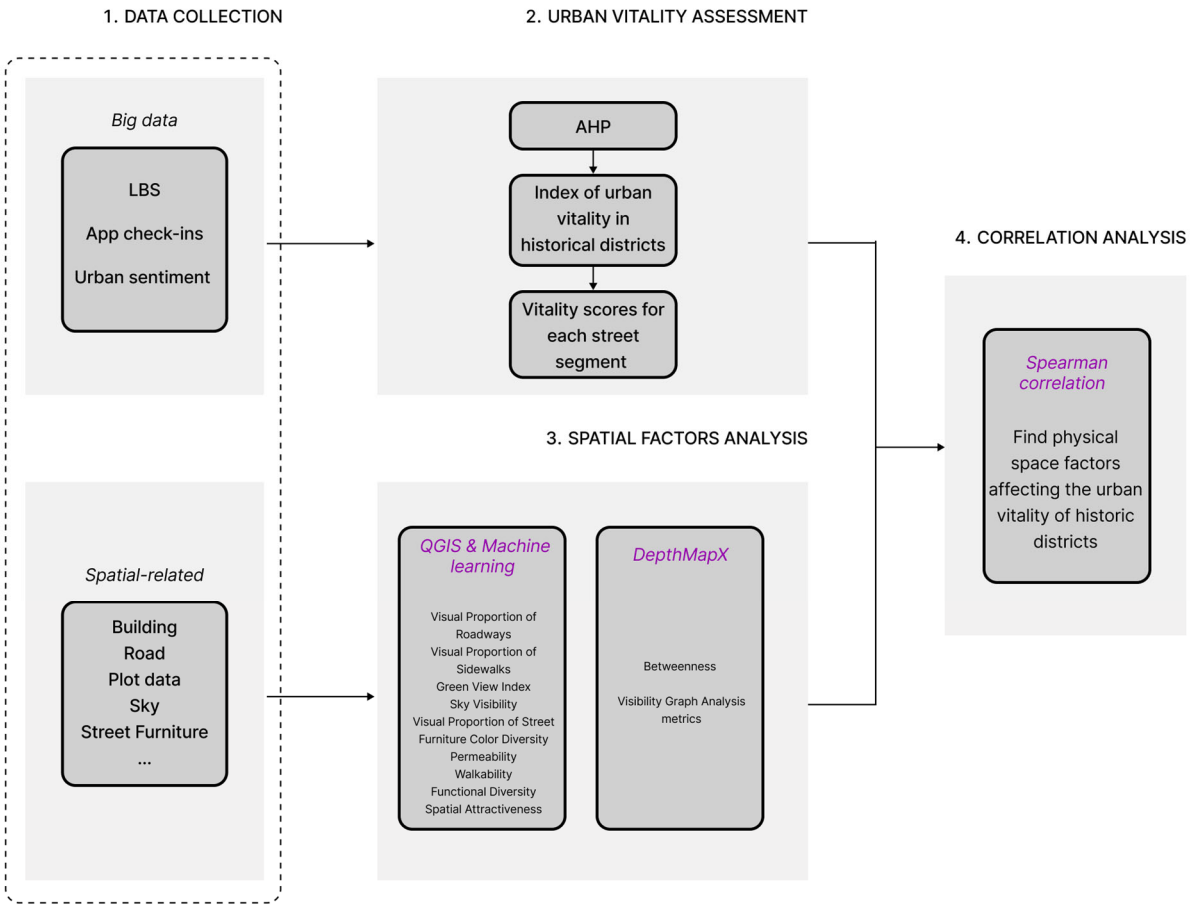

Figure 2. Research framework, photo credit: drawn by the author

Measuring urban vitality in historic districts

Collection of diverse data

Location-Based Service (LBS) data

This study utilizes anonymized geographical data from Baidu's Huiyan service, providing precise time and spatial location information based on user GPS. To represent population vitality, all LBS trajectory points at 16:00 every afternoon were aggregated for each week. Using GIS spatial connection techniques, the grid data was weighted to the roads, enabling the derivation of urban vitality values for each street segment based on LBS data. This data constitutes the first dimension of vitality measurement.

Social media app data

Data from "Xiaohongshu," China's popular social media app for check-ins and interactions, was selected. This dataset includes GPS positioning. For this study, 6452 Xiaohongshu data points with GPS positioning within the site were chosen, providing quantitative data on check-in numbers and textual data on specific notes.

An analysis was first conducted based on Xiaohongshu check-in data. Building on the previous step of road segmentation and GPS positioning, the number of check-ins on each street segment was calculated, forming the second dimension of vitality measurement.

A second analysis was conducted based on Xiaohongshu note design. Utilizing Natural Language Processing (NLP) for sentiment analysis, each note's sentiment was scored from 0 to 1 (with 0 representing more negative evaluations and 1 representing more positive evaluations). This process yielded the public sentiment on each street segment, i.e., the average sentiment values per street segment, constituting the third dimension of vitality measurement.

Index for urban vitality of historical districts

This research utilizes the Analytic Hierarchy Process (AHP) to establish the final measurement indicators for assessing the urban vitality of historical districts. AHP is a quantitative analytical method commonly applied to complex decision-making scenarios. We engaged multiple experts to evaluate and weigh three dimensions of vitality measurement for historical districts. The resultant weight distribution is as follows:

Index for Urban Vitality of Historical Districts=50%×LBS Data+30%×Xiaohongshu Check-in Data+20%×City Sentiment Analysis Data derived from Xiaohongshu Notes

Using this formula, the vitality scores for each street segment within the site are calculated, as depicted in Figure 3.

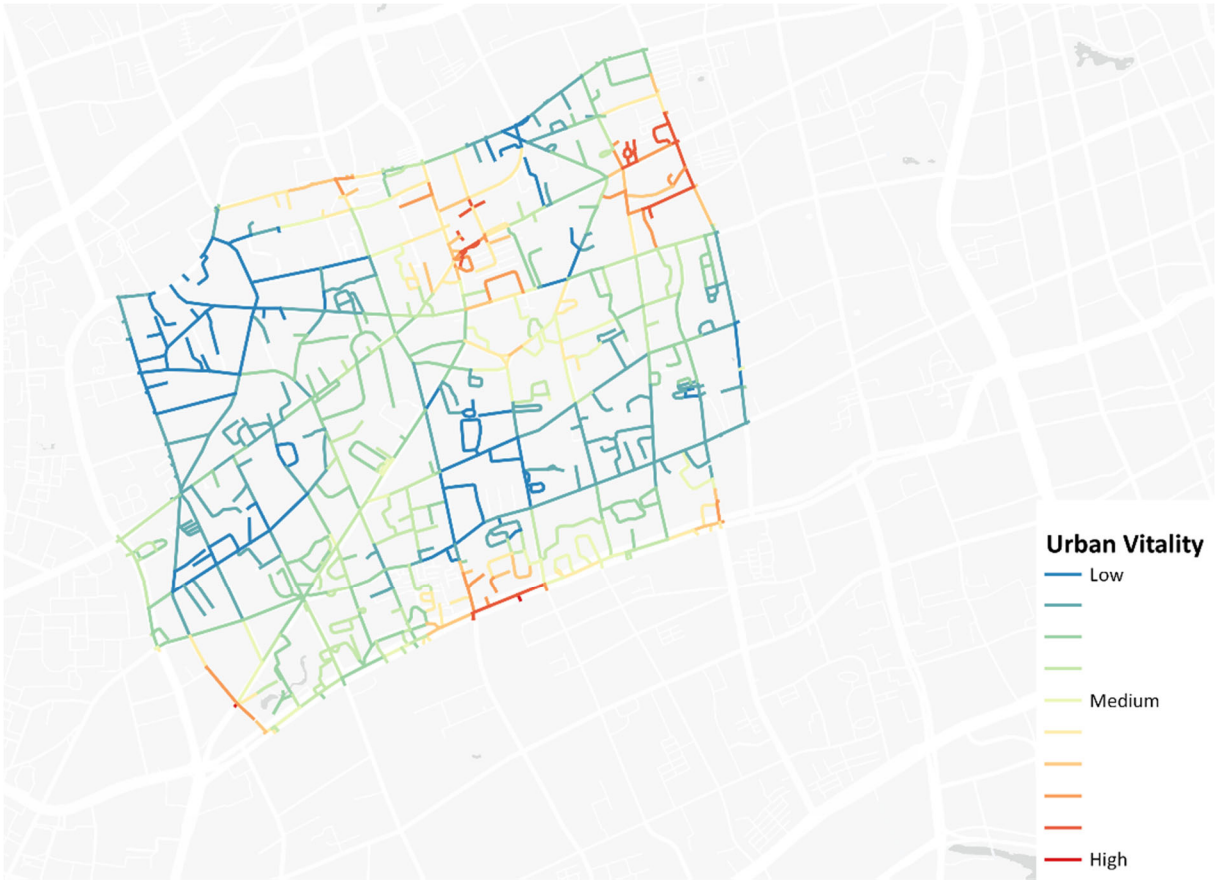

Figure 3. The vitality scores for each street segment within the site. Photo credit: drawn by the author.

Indicators Influencing the Vitality of Historic Districts

Drawing on the insights from Section 2.3 regarding factors influencing the vitality of historic districts, this study computed data for several potential influencing factors. Initially, spatial syntax-related data for each street segment, within a 1200-meter radius, was analyzed using DepthMapX to obtain street Betweenness and Visibility Graph Analysis metrics. Subsequently, Baidu Maps street view data and machine learning-based image segmentation techniques were employed to extract various visual metrics from each street view image. These metrics include Visual Proportion of Roadways, Visual Proportion of Sidewalks, Green View Index, Sky Visibility, Visual Proportion of Street Furniture, Color Diversity, Permeability, Walkability, Functional Diversity, and Spatial Attractiveness. Each image's GPS location from Baidu street views was used for visualization in QGIS, and spatial join techniques were applied to map point data onto road data, deriving specific values for each street segment.

Furthermore, to analyze the correlation between urban vitality of historical district, historical architecture, and district morphology from a quantitative morphological perspective, this study utilized QGIS to calculate the Edge Rate, Proximity Rate, Building Articulation Index, and Road Network Density for each roadway. The Edge Rate indicates the proportion of street walls or the continuity of the street interface, while the Proximity Rate measures the degree to which the street facade is close to or distant from the street boundary. The Building Articulation Index represents the variation in building height. Detailed results are presented in Table 1.

Table 1. *Indicators Influencing the Vitality of Historic Districts.*

Indicators

Space Syntax-related Indicators	Btweeness1200 (BtA1200) Visibility Graph Analysis (VGA)
Google Street View-related Indicators	Visual Proportion of Roadways (VPR) Visual Proportion of Sidewalks (VPS) Visual Proportion of Buildings （VPB） Green View Index(GVI) Sky Visibility (SV) Visual Proportion of Street Furniture (VPSF) Color Diversity (CD) Permeability Walkability Functional Diversity (FD) Spatial Attractiveness (SA)
Quantitative Urban Morphology-related Indicators	Edge Rate (ER) Road Network Density (RND) Proximity Rate (PR) Building Articulation Index (BAI)

Correlation analysis

Prior to conducting the correlation analysis, data cleaning was performed. Initially, among the original 926 street segments, 44 segments with an urban vitality score of zero (as derived in Section 3.2) were removed. Additionally, 226 segments where the Quantitative Urban Morphology-related Indicators were zero were also excluded, resulting in 654 effective street segments.

Subsequently, Spearman correlation method was employed to analyze the impact of various factors on the urban vitality of historical districts, aiming to identify the most influential factors within the site. Spearman correlation is a non-parametric statistical method used to assess whether there is a monotonic relationship between two variables. The term "non-parametric" indicates that this method does not assume any specific distribution for the data. Instead, it calculates correlations based on the ranks of the data rather than their actual values. The final analysis results are presented in the tables below.

Table 2. *The final analysis results*

Indicators	Beta	p-Value
VPR	36.64	0.145
VPS	-51.69	0.373
VPB	-45.21	0.022
GVI	-126.82	<0.01
SV	30.88	0.562
VPSF	222.02	<0.01
CD	-8.15	0.034
Permeability	88.38	0.237
RND	-6.02	0.101
Walkability	495.50	0.109
FD	-0.87	0.580
SA	0.74	0.504
BtA1200	-0.0083	0.103
VGA	110.06	<0.01
ER	-1.30	0.616
PR	-6.40	0.043

BAI	9.53	<0.01

Visibility Graph Analysis	Visual Proportion of Street Furniture	Building Articulation Index

Figure 4. *Indicator with the positive correlation.*

Green View Index	Visual Proportion of Buildings

Figure 5. Indicator with the negative correlation.

According to the analysis, the Visual Proportion of Buildings (VPB) has a significant negative impact on the Urban Vitality Index, with a coefficient of -45.21 and a p-value of 0.022, indicating that areas with dense building concentrations tend to have lower street vitality values. Similarly, the Green View Index (GVI) also exhibits a significant negative effect (coefficient of -126.82, p-value < 0.001), suggesting that higher vegetation coverage may be associated with lower street vitality. Conversely, the Visual Proportion of Street Furniture (VPSF) and Visibility Graph Analysis (VGA) demonstrate strong positive impacts (VPSF coefficient of 222.02, p-value = 0.001; VGA coefficient of 110.06, p-value < 0.001), indicating that the openness and quantity of street furniture are likely crucial factors in enhancing street vitality. Additionally, the Building Articulation Index (BAI) shows a positive influence (coefficient of 9.53, p-value = 0.001), further emphasizing the positive correlation between the variability in building heights and street vitality.

Although variables such as road proportion and sidewalks did not show statistical significance in this model, the significant results obtained provide important insights into potential factors influencing street vitality.

DISCUSSION & CONCLUSIONS

New insights

The findings from this study on the Hengshan-Fuxing Roads Historic Protection Zone provide several new insights into urban vitality dynamics. The significant negative impact of the Visual Proportion of Buildings (VPB) on the Urban Vitality Index highlights the challenges posed by high-density urban environments. It suggests that excessive building density might stifle the vibrancy and perceived accessibility of street-level activities. Conversely, the positive effects of the Visual Proportion of Street Furniture (VPSF) and Visibility Graph Analysis (VGA) underscore the importance of open spaces and well-planned street furniture in enhancing urban vitality. These elements appear to facilitate more engaging and active street environments, thereby boosting the overall liveliness of the area.

Methodological innovation

This study presents a significant methodological innovation in the calculation of urban vitality by integrating traditional Location-Based Service (LBS) data with emerging data sources from the Xiaohongshu platform, including urban hotspots and sentiment data. This innovative approach provides a more comprehensive and nuanced understanding of urban vitality, capturing not only the spatial distribution of population activities through LBS data but also the qualitative aspects of these activities reflected in social interactions and emotional expressions.

The inclusion of Xiaohongshu data is particularly innovative because it captures the spontaneous and subjective experiences of city residents and visitors, which are often overlooked in conventional urban studies. By analyzing check-in data and sentiment values from Xiaohongshu, this study gains insights into the popularity and emotional resonances of different urban areas, offering a more dynamic and human-centered perspective on urban vitality.

Furthermore, this methodological advancement leverages the strengths of machine learning in processing large datasets and in extracting meaningful patterns from complex urban data. The combined use of quantitative LBS data and qualitative social media data enhances the accuracy and relevance of the Urban Vitality Index, making it a powerful tool for urban planners and policymakers seeking to understand and enhance the liveliness of urban environments.

Future research could expand on this innovative approach by integrating additional data layers, such as real-time traffic data or weather conditions, to further refine the vitality index. Moreover, the methodology could be adapted to other social media platforms and urban settings worldwide, broadening its applicability and facilitating comparative urban studies.

Limitations & next steps

Despite the robust methodological framework, this study has some limitations that suggest directions for future research. One limitation is the exclusion of certain street segments due to zero values in urban vitality or morphological indicators, which could potentially skew the understanding of urban dynamics by omitting areas that are either underdeveloped or not adequately captured by the data sources. Additionally, the reliance on data from specific platforms like Xiaohongshu may limit the generalizability of the findings across different urban contexts or cultural settings.

Future studies could address these limitations by incorporating a more diverse array of data sources to capture a wider spectrum of urban activities and by expanding the analytical framework to include other cities or historical districts. Furthermore, longitudinal studies could be conducted to assess how

interventions in urban design influence vitality over time, providing more dynamic insights into the efficacy of urban planning strategies.

Acknowledgements

We would like to express our sincere gratitude to Professor Ye Yu from the College of Architecture and Urban Planning, Tongji University, for his invaluable guidance and insightful advice on this research.

ABSTRACT

The following guidelines provide instructions to format your full paper, specifically on the way how text should be formatted, table and figures captioned, and references cited. The conference proceedings will be published in an electronic format. The paper should be submitted in a Word document (.doc or .docx) and shall be written in accordance with instructions of Urban Morphology Paper Submission Guidelines. The Brazilian city of Santos, located in the state of São Paulo, Brazil, is home to largest port in Latin America, its history is directly related to the urban project designed and executed by engineer Saturnino de Brito at the beginning of the 20th century, which, due to its scale, was one of the first and most original planned cities in Brazil. The urban morphological study of the territory bequeathed by this project highlights the components of the urban landscape preserved from the original project that promoted (or not) the urban development of areas adjacent to those preserved from the original plan. Its analysis also highlights (emphasizes) the process of formal recognition and its project genesis established by its author, from an urban-sanitary nature. The city of Santos in Brazil, located in the state of São Paulo, is home to the largest port in Latin America. Its history is closely tied to an urban project developed and implemented by engineer Saturnino de Brito at the beginning of the 20th century. This project was one of the earliest and most innovative planned city initiatives in Brazil due to its large scale. An analysis of the urban layout left by this project highlights the elements of the urban landscape that have been preserved from the original plan, as well as how they have influenced the development of surrounding areas. Therefore, by applying the British school of urban morphology, the historical narrative explicitly revealed the existing morphological regions after a century. With this knowledge, especially in the highlighted region of the research, the Orchidarium Park, in confluence with the seaside garden, original and also previous morphological characteristics of Saturnino's plan. Another concept of the Conzenian tradition has been identified: the burgage cycle. This has also led to the identification of likely models of ongoing urban expansion that extend beyond the island, involving both vertical growth and the merging of neighboring coastal cities. This transformation is turning Santos into the metropolitan capital of its region. This article aims to explore the paths, streets, and buildings developed as part of Saturnino de Brito's Plan for Santos over a century. It seeks to deepen an understanding of the urban landscape, tracing its evolution from the initial planning stages to the eventual saturation of the originally designated area. This saturation occurred between the subsequent master plans implemented in 1968 and 2005.

Keywords: urban morphology, urbanism, new cities

INTRODUCTION

In the study of urban expansion, a single city can have diverse and changeable formal compositions. Cities are also understood by the results of their constant process of spatial evolution, thus giving them a certain spatial character. When combined with urban morphological analysis, research on these characteristics becomes a broader field of investigation. This is defined by M.R.G. Conzen (1969: 03) as "a combination of City Plan, the pattern of built forms, and pattern of urban land use" within a certain "urban landscape".

Urban morphology can be understood in two definitions adopted here. According to Anne Vernez Moudon (1997:1), "Urban morphology is the study of the city as a human habitat.". The second approach, which this article closely aligns with in terms of time, was conceptually defined by Stael de Alvarenga Pereira Costa and Maria Manoela Gimmeler Netto as follows: "Urban Morphology is the study of urban form, considering it a physical product of society's actions on the environment, which build it over time".(2015:29-31).

The morphogenesis of planned cities as a design intention.

The choice of the analysis is justified as it is essentially a project for a new city. Due to its projected and partially constructed dimension, it is considered part of the urban development movement known as Sanitary Urbanism. "It is essentially summarized in the work of Saturnino de Brito" (Villaça, 1999: 179). This choice further supports the hypothesis, as evidenced by Karl Kropf's research:

"The analysis of planned cities can help understand their origins by considering urban form as a physical representation of a specific cultural context. Urban morphology can address the emergence of different forms and why certain forms persist or spread". (Kropf, 2011: 159).

Therefore, the hypothesis that the urban evolution of Santos had at its origin the design intention of the author to implement an urban layout that manifested a certain cultural context. Furthermore, this hypothesis begs the question of "[...] how those forms shave been generated in terms of the elements they are made of, the internal relationships between the elements, the relationship of the whole with the larger structures of which they are part, and the generic processes involved in their formation?" (Kropf and Malfroy,2013:130).

I The inicial routes

To conduct an urban morphological study in the city of Santos, located on the coast of São Paulo. The study will focus on the evolution of the Urban Plan created by Saturnino de Brito, also known as 'A planta de Santos', starting from its origins." - integrating port, city, and coastline - until the creation of the first Participatory Master Plan in 2005. This study (Araújo, 2023) uncovered existing implicit pathways leading to the proposed city design and the preservation of part of the same plan.

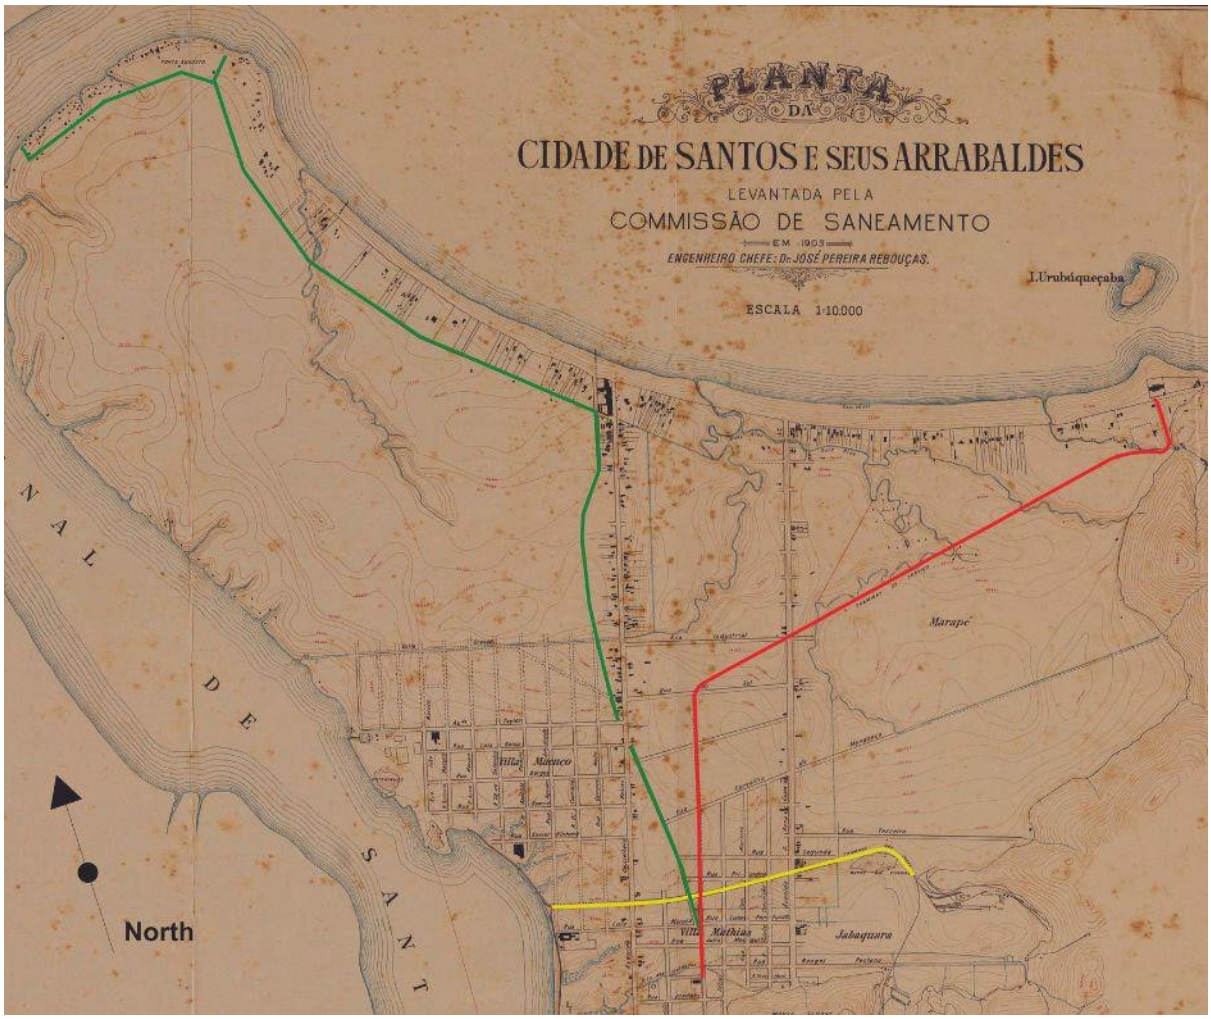

Figure 1 – Generational paths of the Saturnine Plan finding in the 1903 cadastral survey of Santos prepared by the Santos Sanitation Company (CSS).Scale 1:10,000. Source: Prepared by the authors based on CSS. São Paulo, ISUF 2024.

The survey points and axes established the basis for the urban and sanitary plan of the “Planta de Santos”, which was created by its author in 1910. This intention is evident in the choice of the meeting point for transportation routes and the primary sanitation network (red line), old preserved routes from the 16th century include (green line) the “Caminho da Barra dos Fortes Militares Augusto e da Barra do Estuário”, along with landfills built with borrowed material for port expansion (yellow line) – Tramlines for cargo have shaped the current neighborhood, giving it a toponymy similar to "Encruzilhada", Crossroad.

Background – From a Village to a port city

No more than three levels of headings should be used. When mentioning and referencing specific work, please use author and year in parenthesis (Surname, 2003). If you are citing several works at the same time, all relevant surnames and years should be included in parenthesis chronologically (Surname, 2010; Surname, 2014). Citations of works by two authors should have ‘and’ (not an &) between the names (Surname and Surname, 2015). Citations of works by three or more authors should have the first author followed by et al in italics (Surname et al., 2021). Furthermore, “When

you include a quote in the text, this should be in italic, contained quotation marks and listing in the reference author(s), year of publication, as well as page number or page range” (Surname, 2020: 5-8).

The hereditary captaincies were a system established by the Portuguese empire during the 16th century to make the occupation and exploration of Brazil financially viable. This system was inspired by feudalism and was continued by King João III, who succeeded King Manuel I and upheld the mercantilist project.

In 1532, Dom Martim Afonso, the grantee of the hereditary captaincy of São Vicente, disembarked his fleet at the port of ships. This port is in the current neighborhood of Ponta da Praia. He brought his first settlers and the sugarcane seedlings, which quickly spread throughout colonial Brazil. (Ribeiro, 2006:273). The "Vila do Porto de Santos" was officially founded in 1543 by Brás Cubas, a Portuguese member of the same fleet. He was tasked with building a new port on the banks of the Enguaguaçu estuary, located north of the island of São Vicente. This was a strategic and defensive choice, as it concealed the village from the sight of pirates dispatched by other cities. Pirates were sailing along the southern coast of Brazil at that time. In the same area, there were small hills where the village center was located (Ornelas, 2008: 22). This site was selected to protect it from frequent flooding caused by tides and long rainy periods, which are common in the coastal region of São Paulo. The site is situated in the Mangrove Forest, which formerly encompassed almost the entire island. This colonial cycle lasted for three centuries, coinciding with the conquest and founding of numerous villages in the interior of Brazil, while the village of Santos saw little expansion in terms of urban planning. Its port lost significance due to the inland region's pursuit of mineral wealth.

The first port on this route was São Paulo, elevated to city status in 1711. In 1790, the expansion of coffee production led to the construction of a paved road connecting it with the port of Santos. “Calçada de Lorena” was a winding route that wound its way up the steep slope of the Serra do Mar. Two critical factors led to the recovery of the port economy and the expansion of both cities at the beginning of the 19th century. One significant factor was the general opening of the ports in 1808 by

D. João VI, as part of his reorganization of Brazil's infrastructure and economy. In 1867, the São Paulo Santos – Jundiaí Railway (S.P.R.S.J) was implemented, and the port was expanded from 1890 onwards by the newly formed Santos Port Authority (“Companhia Docas de Santos”). This expansion involved creating a landfill to gain more space for logistics. When sanitation measures were introduced, endemic diseases were eliminated and the urban land value in the area was enhanced. In addition to attracting the elite of the coffee-growing elite, this also led to increased settlement on the Santos coastline, and in 1836 Santos was finally granted city status.

METHOD

An analysis of the urban layout left by this project highlights the elements of the urban landscape that have been preserved from the original plan, as well as how they have influenced the development of surrounding areas. Therefore, by applying the British school of urban morphology, the historical

narrative explicitly revealed the existing morphological regions in the city of Santos, after a century, as elaborated upon more fully in our previous research (Araujo,2023).

The urban morphological analysis of Saturnino de Brito's Plan for Santos (Figure 3), proved to be an efficient methodology for understanding urban evolution, especially regarding the description of its historical periods, in identifying the paths taken by the project's author from its initial point. Such a historical-geographical description sheds light and sharpens the focus on every detail that occurred in various areas of the city, at different times, even those before and after its implementation.

The theoretical foundation of this research was complemented by Carriço (2002), essential for understanding the Morphological Periods through the explanation derived from the existing legal framework in the city, and the construction of the historical-geographical narrative.

The Urban Plans and Legislation of Santos, which determined the evolutionary periods and their reflection on the physical planning of the city, revealed a more assertive historical-geographical narrative regarding the formation and correct identification of its morphological periods, and, in particular, the knowledge of its territory.

In her research on the interaction between the city and the law, specifically regarding urban policy and the formation of territories, Raquel Rolnik (1997:13) states: "... law ostensibly functions as a template for the ideal city, yet it dictates only a minor portion of the built environment. The resultant city is not a product of the model enshrined in law, but rather of the interplay between legal frameworks and real estate production, which simultaneously delineates territories both within and beyond the city limits." (Translated by the authors).

RESULTS AND DISCUSSIONS

Provide a concise, clear and precise description of the results and their interpretation. You may use tables, drawings, figures, and diagrams to illustrate your findings. Make sure to dedicate enough space for discussing your results and to reflect on how they can be interpreted from previous studies' perspectives and the working hypotheses/research questions. The findings and their implications should be discussed in the broadest context possible, and the limitations of the work should be highlighted.

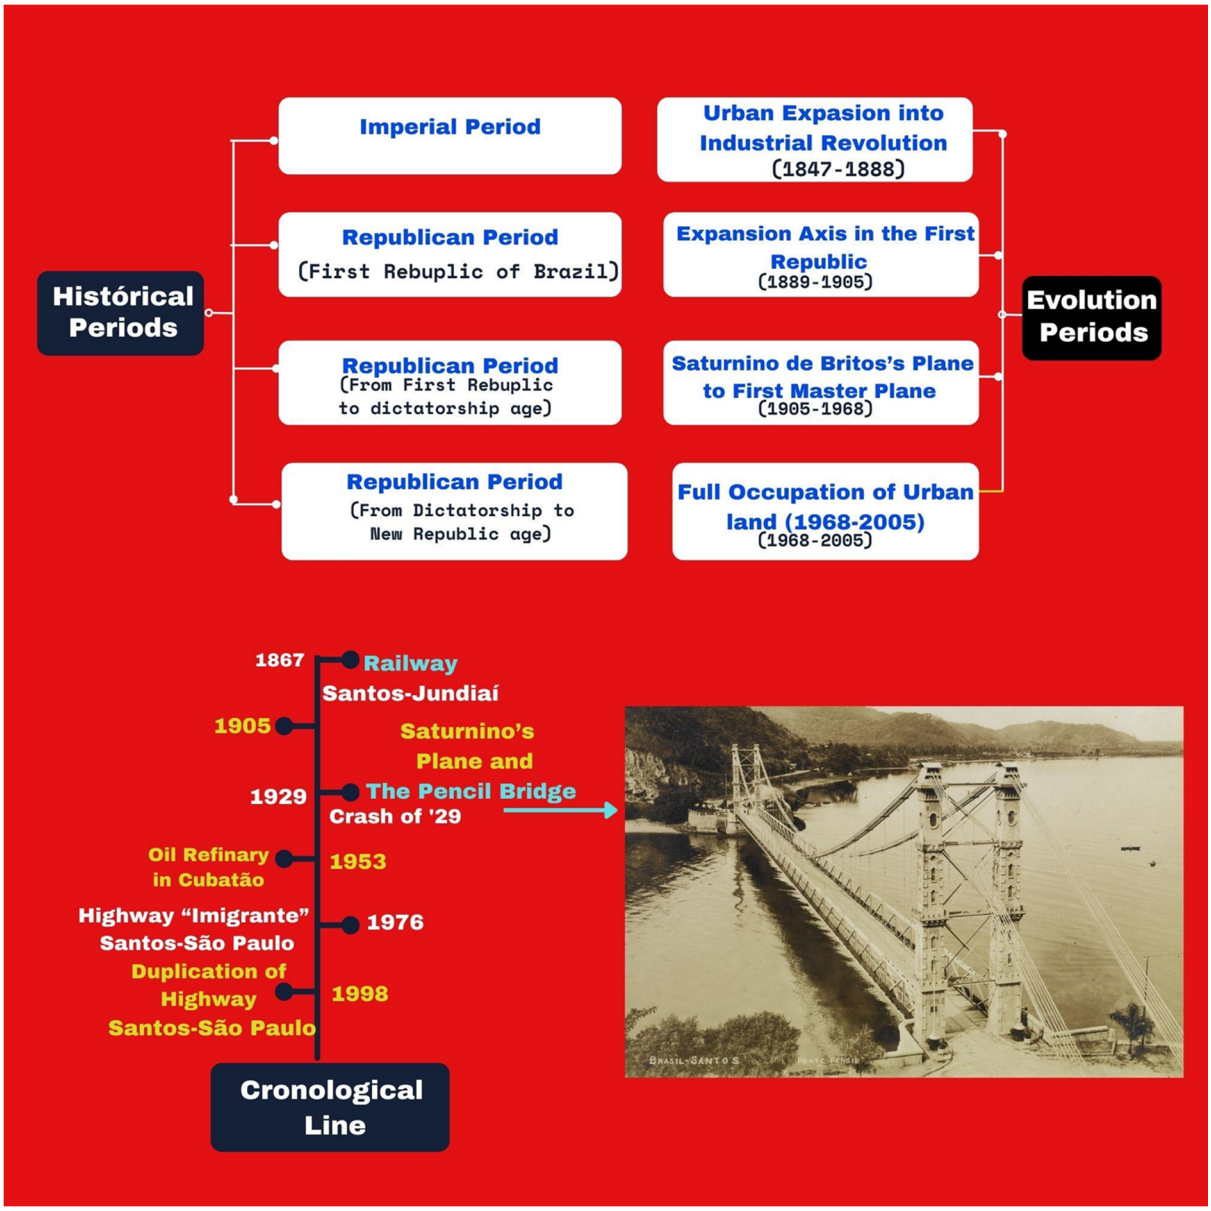

Figure 3. Resulting flowcharts of Historical Narrative method defined in research: Historical and Evolution Periods. Above, in the chronological line, and its events, with particular emphasis on the Pencil Bridge, designed by Saturnino de Brito to carry the sanitary sewage pipeline and connect São Vicente Island to its final destination—the old outfall located in the Isthmus of Itaipu, in the neighboring city of Praia Grande on the mainland. Photo credit: Prepared by the authors based on the Public Archives of the State of São Paulo. São Paulo, ISUF 2024.

Two results are obtained in a place delimited by urban expansion. First, the constructive interferences for the complex drainage system of the city ended up generating the interconnection of the island to the continent on its south coast, as well as for the continuation of the route with the largest city in South America: São Paulo. The use of existing systems prior to Saturnino's plan, which were taken advantage of, collaborate with this hypothesis. They are present from the axis adapted to the initial sewage system found in 1903, which formed the large diagonal avenue, which the author named "Avenida Sanitária" (Sanitary Avenue), in reference to his ideas from the school of positivism founded by Auguste Comte, which at the time influenced all engineering schools in Brazil. Therefore, in this research, this morphological period was named: Expansion Axis in the First Republic (1889-1930).

These and other periods are also motivated by the increase in urban legislation, which shapes the territory, giving it a characteristic physiognomy of place over time. The second result can be seen in the outcome of the laws and plans developed for Santos, which will - before and after the century analyzed here - create a conurbation on the coast of São Paulo, in which Santos will become the main urban nucleus. This result is exemplified by the actions of the subjects found in the legislative sphere and the consequent reaction - which renames the evolutionary period, as seen in Table 1 below.

Table 1. Principal Legislation and Historical Narrative Process of Santos City. Source: Prepared by Authors based in (Carriço, 2002).

Item	Legislation form	Number- Data	Subject	Evolution Period	Historical Period
1	Municipal Law	03/07/1847; 04/24/1857	City Hall conduct regulation	Port Expansion in the Industrial Revolution (1847-1888)	Imperial Period
2	Municipal Law	217 – 03/15/1897	City expansion Project	Town-Atlantic Sea Expansion Axis in the First Republic (1889-1905)	Republican Period (First Republic of Brazil)
3	Municipal Law	Lei 217 01/11/1906	Building Code	Saturnino de Britos' Plane to First Master Plane (1905-1968).	Idem
4	Municipal Law	675 - 07/28/1922	Building Law and Usage	Idem	Idem
5	Municipal Law	Lei 403 09/15/1945	Idem	Idem	Republican Period (Vargas Age)
6	Municipal Law	3.529 / 04/16/1968	First Municipal Master Plan	Idem	Republican Period (Militar Dictatorship Age)
7	Complementar Law	311/312 de 11/13/1998	Second Municipal Master Plan	Full Occupation of Urban land (1968-2005)	Republican Period (From Militar Dictatorship to New Republic Age)
8	Complementar Law	551- 12/27/2005	Municipal Law under Federal Land Policies of Urban Developed Instruments (10.257-07/10/2001)	Idem	Republican Period (New Republic Age)

This second results establishes a correlation between the knowledge of the original plan's preserved territory from the Subsequent Evolution Period and its level of legal protection. This correlation is evident in the morphological regions presented in Figures 4 and 5, designated as morphological region A (Saturnino Plan's preserved) and B (Burgage Cycle).

Lastly, the interplay between the aforementioned results suggests another factor influencing the continuity of the highlighted regions: the underlying intention of its author behind the urban sanitation project. This intention, rooted in both Sitte's principles of urban aesthetics and the Comtean positivist ideal of personal reform, manifested through a morphogenetic process of adapting and remodeling the existing urban fabric.

CONCLUSIONS

With this knowledge, especially in the highlighted region of the research, the Orchidearium Park, in confluence with the seaside garden, original and also previous morphological characteristics of Saturnino's plan. it was possible to identify another Conzenian tradition concept: the burgage cycle.

In designing his open drainage canals, his plan doubled the existing waterways, adapting them to the natural processes of the area on the southern coast of São Paulo. This created an integration with nature, in line with his ideological principles, which became a model and prerogative for public sanitation policies throughout Brazil, a fact that he personally helped to propagate by adopting the same system in several cities where he worked. By opting for complete planning, Saturnino de Brito transformed the city of Santos into a Sitte-like city, where the stage conducive to broad interaction of the population found its common and natural place in at least one large urban space, interconnected by public facilities: the beachfront garden. This also laid the foundation for new mobilities and interactions of its inhabitants with the entire urban area, on an island with equidistant locations from its new central geometric point. The intensification of tram transport, in conjunction with the drainage canals, enabled the interconnection between the historic center and the beachfront during the period described here as: Saturnino de Brito's Plan to First Master Plan (1905-1968). As a consequence, its elongated lots are visibly occupied by taller buildings (Figure 6b), at the beginning of what became known as "the sea wall," with a clear reference to the process of "climax and replacement" present in burgage plots, according to the Conzenian methodology. Nevertheless, it boasts a wide array of public amenities that, over time, multiplied throughout its entire length, becoming the largest urban park in the world, tree-lined and by the sea. The Sittean ideal (Sitte, 1903) thus continued, with a large garden integrated amidst monuments and small support buildings, entirely dedicated to the population.

In her study for another Brazilian city, Vila Rica, Stael Pereira Costa and Manuela Gimmler Netto (2015:18) confirmed this analogy when then affirmed: "The other variety of secondary accumulation is the overspill of the burgage cycle, or the gradual densification of the rear of plots by new buildings, which will involve the subdivision and subletting of the backlands of these plots. This process also has its origins in the medieval period, but it became more prominent during the industrialization era, in the form of a cycle with a succession of phases: institution, overspill, climax, and recession; culminating in the eradication of slums. This cycle is based on the introduction of units at the back of plots, without direct access to the streets, defined as the prototype for the densification of burgage plots" (Translated by the authors).

Acknowledgements

We extend our profound gratitude to the Mackenzie Presbyterian Institute and the Presbyterian Church of Brazil, particularly to its curator and president of the supreme council, Rev. Roberto Brasileiro Silva, for the scholarship that enabled the completion of one of the author's Master's studies in 2023, which forms the foundation of this article. We are also deeply indebted to the Postgraduate Program in Architecture and Urbanism at Mackenzie Presbyterian University for fostering a stimulating academic environment. Our sincere appreciation goes to our esteemed colleagues and newfound friends in Santos, faculty members at Santa Cecilia University, notably Prof. Jaqueline Fernández Alves from the Architecture and Urbanism program, as well as the professors at the Faculty of Philosophy at the Federal University of Rio de Janeiro, whose assistance in procuring technical materials pertaining to the work of Saturnino de Brito was invaluable.

ABSTRACT

Space syntax is an analytical tool based on visual perception to understand local space and connect it with broader spatial cognition. Traditional methods often overlook the visual experience of physical boundaries, while the "surface partition" and "endpoint partition" methods proposed by scholars such as John Peponis incorporate the visibility of spatial physical boundaries into the analysis. This paper extends the method from the analysis of interior spaces to urban street spaces, and from two-dimensional to three-dimensional, while also considering the limitations of paths and visible ranges on spatial cognition. Through empirical research on three streets in Nanjing City, this study uses the method of quantity, variance, and path analysis to examine the quantity, set relationships, continuity, and differences of spatial division, revealing the spatial perception characteristics of different interface streets. The results show that the method is convenient for spatial division and index analysis, and can significantly distinguish the spatial perception characteristics of streets. Future research will consider the impact of natural elements, develop automated programs, and combine VR and AR technology to provide a more intuitive spatial experience and assist in design decision-making.

Keywords: space division, physical boundary, street space, visual perception analysis

INTRODUCTION

Vision is the primary way we perceive architectural and urban spaces, providing the foundation for experiencing architectural effects. Space syntax, as an analytical tool, focuses on how people understand local spaces visually and connect them with a broader spatial cognition through movement. By decomposing continuous space into analyzable parts and dividing it into the most basic small-scale spaces, the three fundamental spatial methods are axial, convex, and isovist (Figure 1).

Isovist analysis, on the one hand, is based on the two-dimensional level where Benedikt (1979) introduced it for the analysis of architectural space (Figure 2-a). Later, Batti (2001) transformed Benedik's illustrative method to define the spatial isovist characteristics from multiple angles, such as average distance, area, perimeter, etc., quantifying the visual perception of spatial geometry (Figure 2-b). On the other hand, based on the three-dimensional level, Teller (2003) proposed a new measurement for complex open spaces, using spherical projection to analyze urban open spaces with

a spherical view (Figure 2-c), and Fisher-Gewirtzman (2003) introduced the concept of Spatial Openness Index (SOI). Isovist analysis is also used to quantify the visual implications contained in Kevin Lynch's elements of urban imagery (Morello & Ratti, 2009), as well as the Sky View Factor (SVF) which expresses the degree of sky visibility (Ratti 2004, 2005; Yang, 2007). At the same time, some studies only focus on the boundaries or interfaces that enclose space. Tucker (2004) explored how to visually analyze street landscapes through digital image processing technology, and Freitas (2022) designed interactive interface tools (SFMLT) through visual technology, providing visual feature visualization effects.

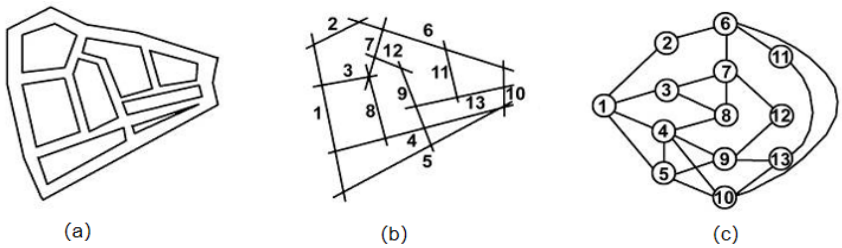

Figure 1 .Spatial syntax analysis of the axial lines in urban open spaces and its "spatial configuration". (a) axial (Jiang, B., 2002) ; (b) convex(Jiang, B., 2002) ; (c) isovist (Jiang, B., 2002)

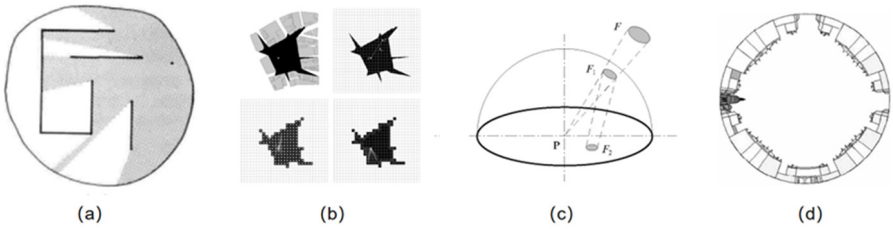

Figure 2 .Schematic diagrams of two-dimensional and three-dimensional isovist analysis. (a) Planar viewshed analysis (Benedikt, M. L., 1979) ; (b) Viewshed quantification analysis (Batti, M., 2001) ; (c) Measuring the visible sky range using the sky view factor projection method (Teller, J., 2003)

However, most spatial division methods focus solely on the space itself, often neglecting the close connection between vision and the physical interface in spatial perception. The effectiveness of spatial perception fundamentally depends on the observer's recognition of the substantive elements that define the space, namely endpoints, edge lines, and interfaces. These elements define the physical boundaries of space and play a key role in visual perception.

Thus, in the 1990s, scholar John Peponis innovated upon the analytical framework of space syntax, developing a new spatial division method based on "convex space" and "isovists." This method, known as "surface partition" and "endpoint partition," combines the visibility of the physical boundaries of space with spatial division methods. The specific approach is illustrated in Figure 3, where A represents a single interface that one must cross the extension of to see the space behind it; B represents an intersecting interface where pedestrians at positions 1 and 3 can only see one interface, while those at position 2 are at the intersection of the extensions of two interfaces, meaning they can see both interfaces at the same time; C is a schematic of intersecting interfaces and endpoints, where observers at positions 5 and 6 can see the endpoints on the opposite side, whereas in the area to the left of position 6, the extension of the endpoint is obstructed, preventing the observer from seeing the endpoint on the opposite side.

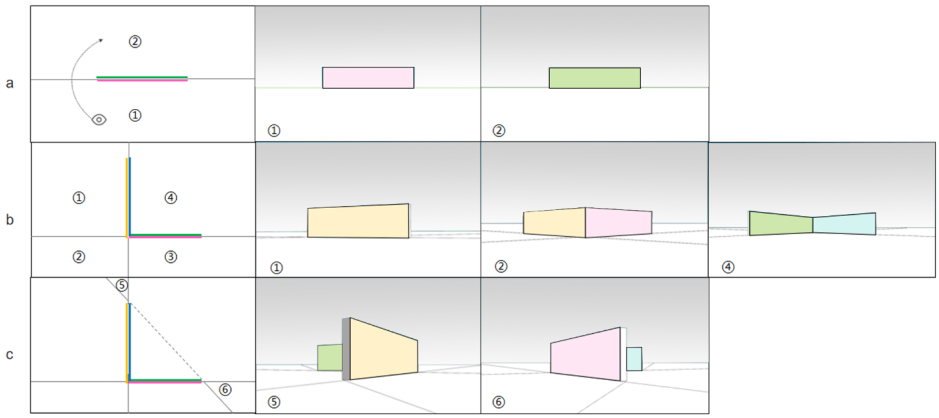

Figure 3 .Schematic diagrams of surface partition and endpoint partition. (a) Single interface; (b) intersecting interfaces - surface partition; (c) intersecting interfaces - endpoint partition, photo credit: Author's own drawing.

This method links the human perception of space with visual interfaces, providing a way to concretize spatial analysis and project it onto the surfaces of human activity. This projection not only aids in understanding how people move and perceive their surroundings in space but also facilitates spatial analysis.

Regrettably, this method has not received sufficient attention and development. This limitation mainly stems from several aspects: the restriction of application scope: it is primarily applied to the analysis of indoor spaces and has not been used in urban external spaces like other spatial division methods; the insufficiency in dimensional development: current analyses mostly focus on the planar dimension, lacking discussion on the vertical or longitudinal dimensions of space; the limitation of static analysis: it usually analyzes a planar feature from a static perspective, lacking the integration of human movement and dynamic viewpoints into the analysis.

Based on the limitations of current methods, this paper aims to further develop and refine the spatial perception analysis method that combines "space-interface."

METHOD

Material Selection

This study selects the Xinjiekou area in Nanjing as the case study object for the analysis of urban spatial form. As the commercial center of Nanjing City, the street space structure of the Xinjiekou area is not only typical in urban morphology but also shows significant complexity and diversity in architectural environmental studies. The street system of this area is composed of multi-level roads, including main urban roads, secondary roads, and branch roads, which together weave a hierarchical and functionally composite traffic and social network.

Specifically, this study focuses on Shigu Road, Fengfu Road, and Zhongshan South Road, the three main streets, which provide an ideal research window for exploring the morphological characteristics of street space due to their regular spatial layout and rich local visual dynamics. In addition, the even distribution of high-rise buildings in the area provides favorable conditions for line-of-sight analysis and spatial configuration research (Figures 4 and 5).

Figure 5 . Line drawing of the Xinjiekou block area in Nanjing City .

Material Reduction

During the process of material simplification, this study adopted a series of strategies aimed at enhancing the efficiency and accuracy of the analysis while ensuring the universality and applicability of the model. The following is an optimized description of the simplification methods for existing buildings and roads: Concave-convex feature simplification: A quantitative assessment is made of the local protrusions or recesses of buildings. If the size of these features is less than 3 meters and parallel to the main facade of the building, they are ignored in the model to reduce complexity; if the size exceeds 3 meters, they are considered to have a significant impact on the spatial form and are retained. Corner feature integration: Multiple small curved surfaces at the corners of buildings are geometrically integrated to form a unified geometric body. For large arc buildings at intersections, right angles are used to replace rounded corners to simplify the model and maintain its key visual and functional features. Building height standardization: According to the podium and tower parts of the buildings, this study has set a set of standard height levels, which are 24 meters, 50 meters, 100 meters, and 200 meters, respectively. This standardization process helps to maintain consistency and comparability in spatial analysis of different scales (Figure 6).

By employing these simplification strategies, the aim of this study is to highlight key spatial morphological features, facilitating in-depth analysis and intuitive understanding. It enhances computational efficiency to ensure the completion of high-quality research within limited resources and time. Furthermore, it strengthens the universality of the model, enabling it to meet the needs of spatial analysis of different scales and types.

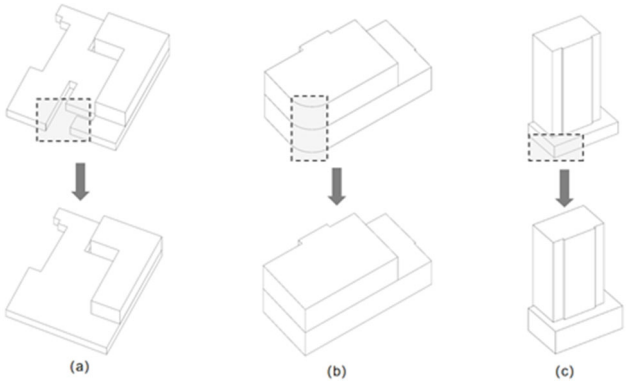

Figure 6 .Three methods of simplification. (a) Concave-convex simplification; (b) Corner integration; (c) Height standardization, Photo credit: Author's own drawing.

Partition Step

Drawing podium s-partitioning and e-partitioning

This step begins with surface partitioning (s-space) of the podium structure, extending the outer wall surface of the podium to define the spatial boundaries. Subsequently, endpoint partitioning (e-space) is implemented, identifying the corners of the podium and extending the partition lines to the limit of the line of sight, selecting only the partition lines that display a single visible corner to accurately divide the visual information units of the space (Figure 7).

Figure 7 .Podium s-partitioning and partitioning illustrations.(a) Podium interface partitioning; (b) Connections between podium endpoints; (c) Valid connection lines of podium endpoints, Photo credit: Author's own drawing.

Drawing Tower S-partitioning and E-partitioning

For the tower portion, the same surface partitioning (s-space) as the podium is performed to establish the three-dimensional spatial form of the tower. Considering that the endpoint partitioning (e-space) of the tower has limited visual perception for people at the ground level, this step omits the endpoint partitioning of the tower and focuses on implementing surface partitioning to simplify the analysis process (Figure 8).

Drawing the E-partitioning of Tower and Podium Corners

The interaction of the corners between the podium and the tower is perceptible directly at the ground level. Identify the corner points of both the tower and the podium, and then draw straight lines to connect the corresponding corner points, extending to the limit of the line of sight. In this process, only the partition lines that can reveal a single corner are drawn. (Figures 9-a, 9-b)

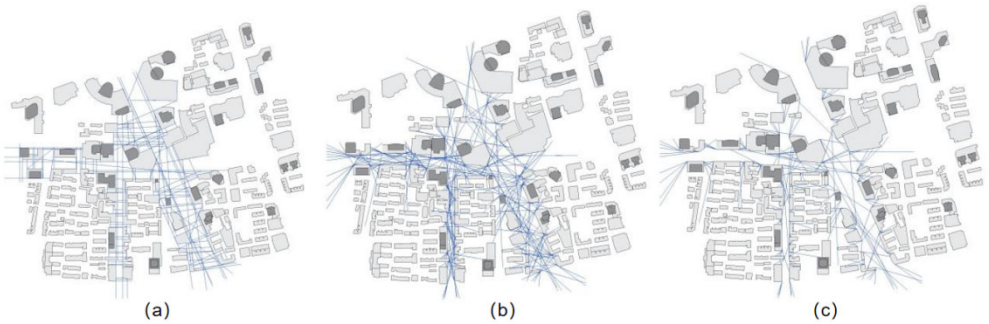

Figure 8 .Tower S segmentation and E segmentation.(a) Tower interface segmentation; (b) Tower endpoint connection lines; (c) Effective connection lines of podium endpoint, Photo credit: Author's own drawing.

Figure 9 .Corner segmentation of the tower and the podium at point e. (a) Connection line between the podium and the tower's endpoint; (b) Effective connection line between the podium and the tower's endpoint; (c) Vertical segmentation of the tower's endpoint, Photo credit: Author's own drawing.

Drawing the vertical segmentation of the tower at point e

This step focuses on the mapping relationship between the tower and the podium in the vertical dimension. By connecting the horizontal boundary line of the tower with that of the podium, an extended connection line is formed that extends to the ground. This line not only visually defines the spatial relationship between the two but also determines the visual perception of the observer at the ground level. When the observer is within the range of the connection line, the podium is obscured by the tower's boundary line and is not perceived; when outside the range of the connection line, the podium is clearly visible. (Figure 9-c)

After completing the above four steps of drawing the connection lines, we synthesize these lines to form a comprehensive spatial analysis drawing of the material. Based on these synthesized overlapping lines, the subsequent research will proceed to an in-depth discussion of the spatial structural characteristics and an analysis of the factors affecting visual perception (Figure 10).

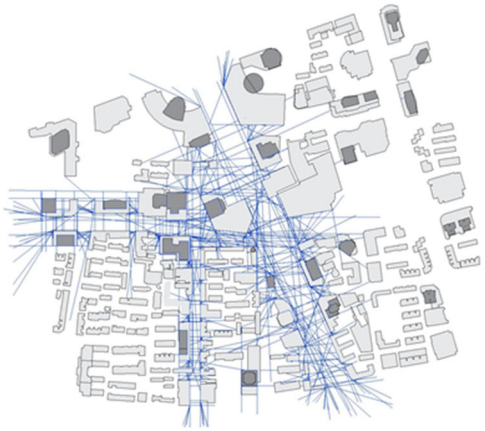

Figure 10 . Spatial segmentation result diagram. Photo credit: Author's own drawing.

Analytical Method

The structure and characteristics of urban external spaces are primarily determined by the street interface, which is jointly formed by urban roads and the buildings along them. The form of these spaces is not only defined by the physical width of the roads but is also greatly influenced by a series of characteristics of the street interface, including key parameters such as the porosity and continuity of the interface. These characteristics play a crucial role in shaping the visual perception and functional distribution of urban spaces.

Surface segmentation and endpoint segmentation serve as a method for understanding the composition of spatial structures and have certain applications in visibility analysis. Peponis has developed some variables for measuring local visual attributes, such as using the e-space's visible turning points and divergence, as well as the expansion coefficient of s-space (Peponis, 1997), to quantify and study issues such as the centrifugal and centripetal arrangement of architectural spaces, the clarity and vagueness of sub-space definition, and the diversity and discreteness of enclosure (Figure 11).

In light of this, the present study aims to employ three quantitative analysis methods to conduct an in-depth data analysis of the subspaces obtained through surface segmentation (s-space) and endpoint segmentation (e-space). To ensure the comparability and fairness of the analysis results, the selected street samples will be evaluated based on the same length of 200 meters. Through this method, it is expected to reveal how the characteristics of street space division interact with the characteristic factors of the street interface and affect the overall urban spatial form.

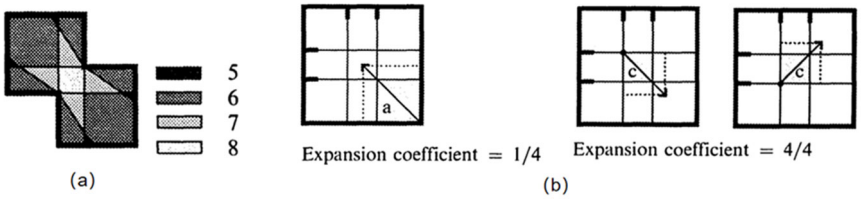

Figure 11 . Segmentation method. (a) Analysis of the visible turning points in e-space (Peponis J, 1997); (b) Analysis of the expansion coefficient in s-space (Peponis J, 1997).

The analysis method will also involve corresponding indicators, and the following will first introduce the definitions of the relevant indicators. The average road width refers to the average value of all

road widths within the 200m limited range of road length, and this indicator is used to quantify the overall level of the overall road width in the area. It is one of the key parameters for assessing the scale, openness, and visual perception characteristics of the street space. The number of junctions refers to the number of branches or intersections in the road, including crossroads, T-junctions, irregular intersections, etc., and is an important indicator for measuring the complexity of the road network and the efficiency of traffic flow organization.

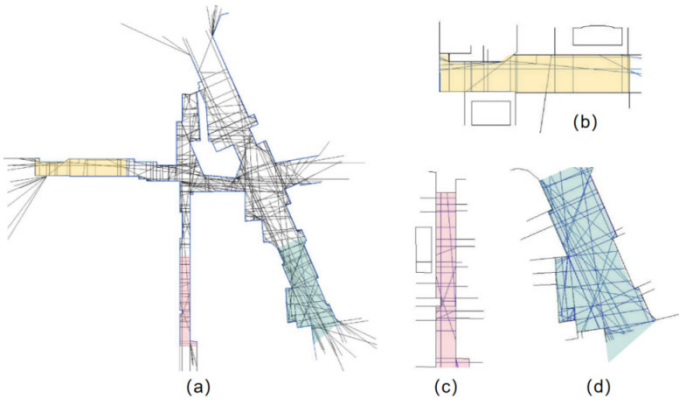

Figure 12 . Selection of street scope. (a) object distribution; (b) Shigu Road section; (c) Funghu Road section; (d) Zhongshan South Road section, Photo credit: Author's own drawing.

The number of building corners refers to the number of corners formed at the junction of the outer walls of buildings and the street within the research area. A corner is defined as a position where the building's outer wall surface undergoes a significant change, reflecting the complexity of the street space form and the diversity of visual perception. The number of interfaces refers to the total number of all street interfaces within the research area, including both the visible faces of the towers and the visible faces of the podiums. These interfaces are directly adjacent to the street, forming the visual boundary of the street space. The porosity rate is the proportion of the street space not occupied by the building interface, which can also be understood as the proportion of open spaces or gaps between the street interfaces. It reflects the openness and permeability of the street space and has an important impact on aspects such as ventilation, lighting, and visual communication of the street. Streets A, B, and C correspond to the interval streets as shown in Figure 12, with the yellow area b being Shigu Road, the horizontal road, the red area c being Funghu Road, and the blue area d being Zhongshan South Road.

Quantitative Method

The quantitative method primarily focuses on the number of regions obtained through segmentation for analysis. The key to this method is to count and compare the total number of regional units obtained through surface segmentation and endpoint segmentation on different streets. By employing this approach, we can quantify the complexity and diversity of street spaces and further assess their impact on spatial perception.

Variance Method

The variance method emphasizes the assessment of the degree of area variation among segmented regions. By measuring the area of each region and calculating its variance, this method can reveal the uniformity or irregularity of street spaces. A higher variance may suggest that the space has richness and dynamism, while a lower variance may indicate consistency and static nature.

Path Method

The path method is concerned with the differences in traversing segmented regions along continuous paths. This method simulates the walking path of people on the street, recording the changes in experience as they pass through different areas. The path method takes into account not only the physical characteristics of the space but also integrates the dimension of time to evaluate the changes in spatial perception during movement. The analysis involves selecting three routes on each of three streets to analyze the path conditions of the three streets at the same distance along the street (analysis a-1, b-1, c-1), as well as analyzing the path conditions of three routes on a single street (analysis a-1, a-2, a-3).

(a) represents the selection of three routes on Shigu Road; (b) represents the route selection on Funghu Road; (c) represents the section of Zhongshan South Road, Photo credit: Author's own drawing.

RESULTS AND DISCUSSIONS

Quantitative method: space division number and building Angle

In the study using the quantitative method, we conducted an analysis of three streets, each with a length of 200m. Through the division by building boundaries and building corners, these three streets respectively formed 105, 98, and 445 subspaces (Table 1).

Table 1. Statistical count of the number of subspaces divided by the three streets.

Parameter	Street A	Street B	Street C
The average width [m]	37	22	55
Number of forks	6	9	8
Building rotation	19	14	24
Subspace quantity	105	98	445
Voidage	0.31	0.24	0.22

From a professional data perspective, the number of subspaces divided shows a significant positive correlation with the number of building corners, which are 19, 14, and 24 respectively. It should be specifically noted that the number of building corners mentioned here includes both the podium and tower corners. We used the number of corners as the independent variable and the number of divisions as the dependent variable for a linear regression analysis, and ultimately derived the regression equation as $y=34.7x-443.3$, where y represents the number of divisions, and x represents the number of corners. Further analysis of this model shows an R^2 value of 0.7651 and a p-value of 0.0345. Given that the p-value is less than 0.05, this proves that there is a very significant linear relationship between the number of building corners and the number of subspaces. It is clear that an

increase in the number of corners will lead to an increase in the number of subspaces divided by the road. This conclusion is not only clearly reflected at the data level, but also, from the perspective of perceptual analysis, the more corners there are, the more likely they are to connect with other building corners, thereby achieving a more refined division of space(Figure 14).

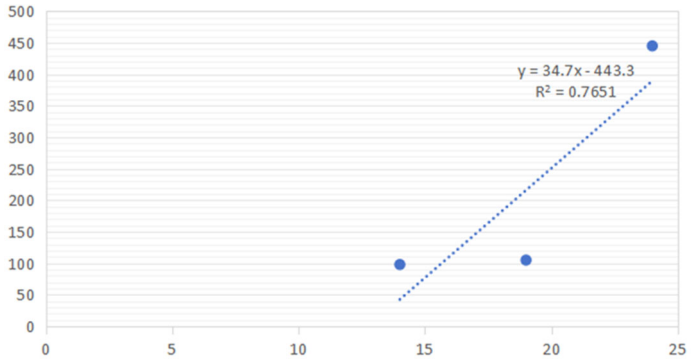

Figure 14. presents the regression equation and data for the number of corners versus the number of divisions, where y represents the number of divisions and x represents the number of corners , Photo credit: Author's own drawing.

Variance Method: Spatial Homogeneity and Interface Stability

After the street space is divided by boundary lines and corner connection lines, multiple subspaces are formed. Different subspaces correspond to specific areas. By summarizing the spatial area for streets A, B, and C (Table 2).

Table 2. Statistical summary of the areas of subspaces divided by the three streets

Parameter	Street A	Street B	Street C
The average width [m]	37	22	55
Number of forks	6	9	8
Subspace quantity	105	98	445
Average size[m]	67.3379	47.1161	31.5279
Variance	25140	4291	2191
Fluctuation condition	Max	Medium	Min
Fragment interface average [m]	30.51	19.13	20.77
Fragment interface maximum subtract minimum value [m]	78.48	48.8	55.2
Segment interface variance	23.81	14.93	14.36

The corresponding average areas are 67.3 square meters, 47 square meters, and 31.5 square meters, respectively. At the same time, the total area of all subspaces contained in each is counted, and the corresponding variance is calculated to measure the fluctuation of the subspaces' areas. The variances are 25,140, 4,291, and 2,191, in that order. It can be seen that Street A has the most intense fluctuation (Figure 15), Street B has moderate fluctuation (Figure 16), and Street C has the least fluctuation (Figure 17).

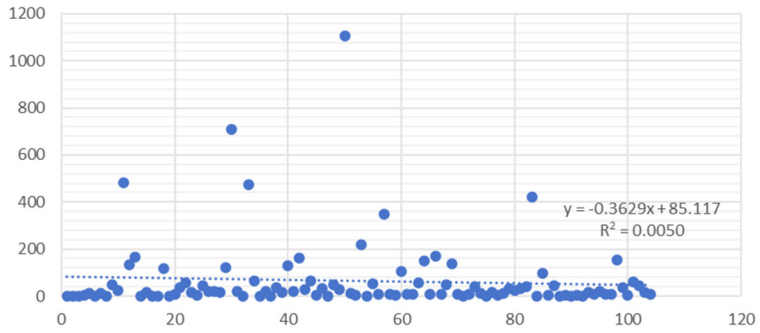

Figure 15. shows the distribution of subspace areas for Street A, where y represents the area of the subspace and x represents the sequence of subspaces, Photo credit: Author's own drawing.

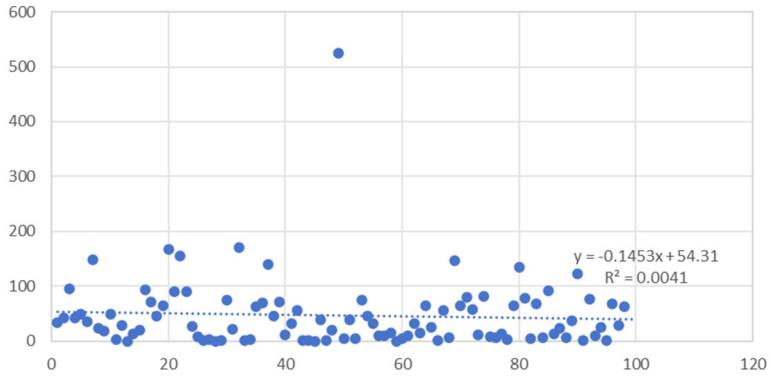

Figure 16. illustrates the distribution of subspace areas for Street B, with y denoting the area of the subspace and x indicating the sequence of subspaces, Photo credit: Author's own drawing.

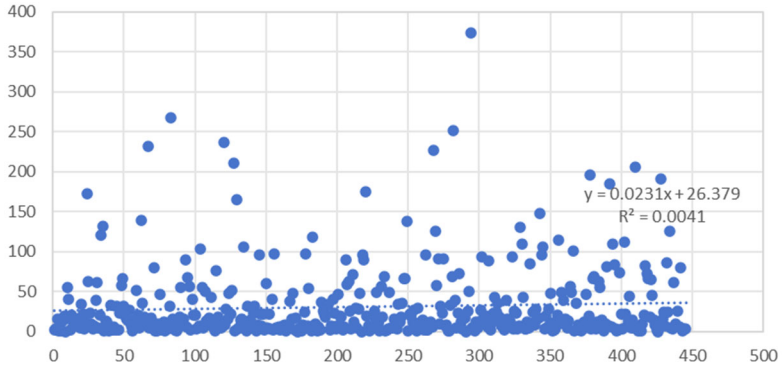

Figure 17. depicts the distribution of subspace areas for Street C, where y represents the area of the subspace and x signifies the sequence of subspaces, Photo credit: Author's own drawing.

When investigating the correlation between the fluctuation of subspace areas and potential causes, we find that the fluctuation is not related to the planar area. The average area is influenced by factors such as the width of the street, but the street width is not a constant variable. At the same time, further analysis of the area fluctuation reveals that streets are actually composed of solid building interfaces and void interfaces. Therefore, we further explore whether the fluctuation of street area is affected by the balance of interface widths. The widths and corresponding variances of the three interfaces (including building interfaces and road cross-sections) are 23.81, 14.93, and 14.36, respectively.Street A has a relatively larger variation in interface amplitude, while Street C has the smallest. The variation in interface amplitude is positively correlated with the fluctuation of the spatial area. It is also easy to understand from a perceptual perspective that if a street is evenly divided, the

road width and area will also be uniform, and the fluctuation of its space will be minimal. Therefore, it is obviously reasonable to infer the fluctuation amplitude of the road subspace area through the variation amplitude of the road interface, and it is positively correlated (Figure 18).

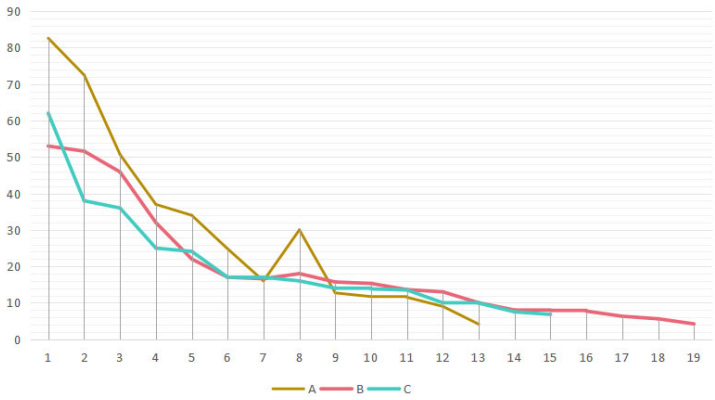

Figure 18. presents the numerical statistics of interfaces for the three streets ABC, where y represents the interface value and x represents the sequence number of the interface, Photo credit: Author's own drawing.

Path Method: Perceptual Richness

Three paths, each 5 meters from the right building interface of the three streets, were selected as the research subjects (Table 3). The corresponding paths of the three streets pass through 18, 26, and 30 subspaces, respectively. Each subspace has a certain difference in the number of tower and podium interfaces and corners seen, creating visual richness in different subspaces. Therefore, the more subspaces a path passes through, the more intense the visual experience is on the path.At the same time, the three paths of Street A, namely a-1, a-2, and a-3, were analyzed. The number of subspaces they pass through are 18, 18, and 21, respectively. It can be seen that the visual experience of a-3 is more intense, and through the variance value, it can be seen that the variance of the a-3 path is the smallest, indicating that the fluctuation of subspaces on this path is relatively small compared to a-1 and a-2. The variance of subspaces reflects the gentleness or abruptness of the spatial change experience during the walking process on the path.

Table 3. Statistical summary of the areas of subspaces divided by the three streets.

Parameter	Street A	Street B	Street C
The average width [m]	37	22	55
Number of Spaces traversed	18	26	30
Corresponding space area [㎡]	6.7, 199.7, 346.8, 128.2, 18.6, 160.5, 107, 63.4, 480, 120.5, 32.7, 710, 170, 421, 1107, 118, 21, 220	93, 78, 524, 135, 22, 25, 65, 15, 74, 76, 48, 123, 81, 37, 147, 90, 80, 155, 65, 91, 147, 167, 64, 56, 42, 63	80, 35, 376, 232, 14, 126, 18, 90, 191, 212, 67, 26, 165, 91, 83, 148, 135, 227, 236, 104, 74, 143, 41, 12, 2.5, 3.8, 185, 267, 19.7, 237

Table 4. Analysis of the three pathways for Street A

Parameter	a-1	a-2	a-3
Number of Spaces traversed	18	18	2

Corresponding space area [m²]	6.7, 199.7, 346.8, 128.2, 18.6, 160.5, 107, 63.4, 480, 120.5, 32.7, 710, 170, 421, 1107, 118, 21, 220	6.7, 200, 346, 128, 19, 160, 30, 63, 480, 120, 33, 710, 170, 422, 1107, 118, 21, 220	1.2, 38, 56, 14, 15, 3, 45, 20, 48, 56, 25, 6, 152, 20, 49, 165, 473, 95, 65, 13, 136

Some Prospects

In this study, we explored the relationship between street space richness and building corners through 2D and 3D spatial segmentation methods. We simplified the model initially by reducing complexity and highlighting key characteristics. However, to better simulate the real world, future research should consider external factors like roadside trees. Currently, our research relies on manual data statistics which is time-consuming and subjective. We'll develop automated programs for more efficient and objective analysis. Also, when analyzing podium-tower mapping, we ignored different observer heights. Future research should include this as a variable. Finally, we believe combining VR and AR technologies will expand and deepen the application of space syntax. These technologies offer immersive experiences and help designers and planners optimize spatial design. They can help decision-makers understand spatial impacts

CONCLUSIONS

This study conducted a quantitative analysis of the spatial structure of three streets in Nanjing City via the extended application of space syntax. Using quantitative, variance, and path methods, we accurately described and differentiated the visual perception characteristics such as corners and interfaces of street spaces.

In terms of quantitative methods, we found a significant positive correlation with the number of building corners by calculating the number of subspaces. Specifically, an increase in the number of subspaces directly reflects an increase in the number of building corners, a finding that was verified at the data level through linear regression analysis. The quantitative method effectively revealed the complexity and diversity of street spaces, with Street C showing the highest spatial complexity due to having the most building corners and subspaces.

In terms of variance methods, the variance method reveals the uniformity or irregularity of street spaces by measuring the fluctuation of the area of segmented regions. The results show that Street A has the greatest fluctuation in the area of subspaces, indicating the richest and most dynamic spatial form; while Street C has the least fluctuation, indicating a relatively consistent and static spatial form. The variance method highlights the differences in spatial homogeneity among different streets.

In terms of path methods, we focus on the walking paths of people on the streets, recording the changes in the experience of passing through different areas. The analysis indicates that the more subspaces a path passes through, the richer the visual experience it provides. For example, the a-3 path on Street A, while passing through more subspaces, also shows a smaller variance, meaning that the experience of spatial change on this path is more continuous and gentle.

ABSTRACT

In China, urban renewal has entered a new phase of optimizing existing stock, with "acupuncture-style" micro-updates gradually being applied and bottom-up resident participatory updates gaining increasing attention. However, there is a lack of focus on the micro-morphology of urban micro-renewal and its relationship with stakeholders from the perspective of urban morphology. This paper adopts a micro-urban morphology perspective, using the historical Chaotian-Gong District in Nanjing as a case study, to explore the relationship between spatial morphology and social dynamics. Given the complex situation of mixed historical, commercial, and residential districts, the study categorizes the stakeholders involved in urban renewal, focusing on the conflicts between commercial and residential functions due to the predominance of ground-floor businesses. It examines the different roles of various stakeholders in the micro-morphological changes of urban space. Building on this, the paper explores a bottom-up urban micro-renewal mechanism based on entities such as business associations and resident councils, and the concept of "multi-partner cooperation." The goal is to summarize a participatory renewal mechanism for mixed-use historical districts and its connection with urban spatial micro-morphology, providing a reference for future community-based urban micro-renewal projects.

Keywords: urban micro-renewal, micro-urban morphology, agents, multiple stakeholders, mixed-use commercial and residential districts

INTRODUCTION

Research background

China's urban development has transitioned from incremental growth to a new phase of stock renewal. The traditional model of large-scale demolition and reconstruction is no longer applicable; urban development increasingly focuses on micro-scale updates. This paper adopts a perspective from urban morphology to explore the changes in historical district morphology, emphasizing a more targeted micro-morphological study and examining the relationship between agents and urban micro-morphology in urban renewal. Urban morphology has a long history, with the Conzenian School, represented by M. R. G. Conzen and J. W. R. Whitehand, advocating for the analysis of urban form

through the division of independent plan units. This approach considers plan units, building types, and land use, combined with historical map data to infer the process of urban form development. Since 2007, Whitehand has progressively conducted urban morphology research in China (J. W. R. Whitehand and Gu, K, 2021), and several university teams have since conducted a series of studies on the localization of urban morphology (Duan, J., 2003; Duan, J. and Qiu, G. C., 2008). This paper applies the methods and concepts of the Conzenian School to the study of urban morphology in the Chaotian-Gong district of Nanjing, focusing on the micro-morphology in urban micro-updates and its relationship with agents.

Urban micro-morphology

J.W.R. Whitehand has identified micro-morphology as an independent branch of urban morphology research. He argued that researchers need to incorporate more granular spatial analysis elements to complement and enhance the structural study of urban plans, particularly emphasizing the formation and development of public spaces that cross property boundaries, such as public walkways, permeability pathways, and alleyways. These "capillary" spaces play a structural role in the organization of land use and social activities. This research method, which starts from the micro-scale of urban morphology and delves into the internal structure of space, provides additional spatial analysis elements beyond the "planar" structure of land use. It enriches the research dimensions of urban morphology and has become an important direction in the study of urban space.

Research on urban morphology and agents

In the 1970s, Whitehand explored the changes in the morphology of urban centers and their relationship with the characteristics of agents by studying building plan applications in the UK. Inspired by Whitehand's research, Rackham examined the built and newly constructed forms within historical and cultural conservation areas, confirming the significant impact of agents on architectural form innovation and dissemination. Rackham categorized agents into direct and indirect types. Analyzing the behavior of agents within different socio-cultural contexts has led to a deeper understanding of their role in urban morphology. The book Shapers of Urban Form: Explorations in Agency (2014) provided new perspectives for future research in urban morphology. Recent studies have also focused on the reconstruction of church buildings, the preservation of urban historical and cultural resources, and the morphological changes in suburban residential areas.

Current research status and limitations

In recent years, extensive research has explored urban renewal mechanisms and methods from a morphological perspective. Most of these studies focus on urban material spaces, investigating urban historical districts and residential space renewal strategies and mechanisms. For example, Garcia-Perez and Sergio examined urban morphological changes in residential area renewal in France and summarized their implications for urban renewal in Spain (Garcia-Perez and Sergio,2021). Wang Fang combined the study of block morphology changes with street network changes, focusing on the historical street morphology of Beijing (Wang F,2018). Additionally, numerous studies categorize block morphology or establish databases to better address future urban renewal. For instance, Dantas investigated the morphological conditions of the ninth district in Budapest and established a database

to improve quality of life while preserving historical information in future urban renewal (Dantas et al.,2023).

Existing urban morphology research predominantly focuses on medium to large-scale urban forms, such as street patterns and road networks, with limited attention given to the integration of micro-scale urban morphology and urban renewal. For example, Huang Kai conducted a micro-scale analysis of street cross-sectional morphology in the historical and cultural district of Xijie in Quanzhou, Fujian Province, quantifying street interface morphology and proposing measures for street protection and renewal (Huang K et al,2024). Macro-scale urban morphology research offers limited practical value for the stage of urban stock renewal; therefore, the study of micro-scale urban morphology and renewal mechanisms remains insufficient. Only a few studies address social relations in urban renewal contexts, such as Zhai Yuqi, who investigated historical urban morphology changes in the Guizhou West community in Shanghai, elucidating the interactive evolution of lane space structures and internal community changes, involving land ownership relationships (Zhai, Y. et al,2023). However, existing research lacks exploration of the role of urban renewal participants, i.e., agents, in the changes of micro-scale urban morphology.

Site introduction

The study site is located in the Chaotian-Gong Street of Qinhuai District, Nanjing, Jiangsu Province, China. Situated in the southwestern quadrant of the commercial and business center of Xinjiekou, the Chaotian-Gong Street is bordered by Zhongshan South Road to the east, the Outer Qinhuai River to the west, Shengzhou Road to the south, and Hanzhong Road and Shigu Road to the north. It comprises 11 communities and has historically been a crucial commercial and residential area.

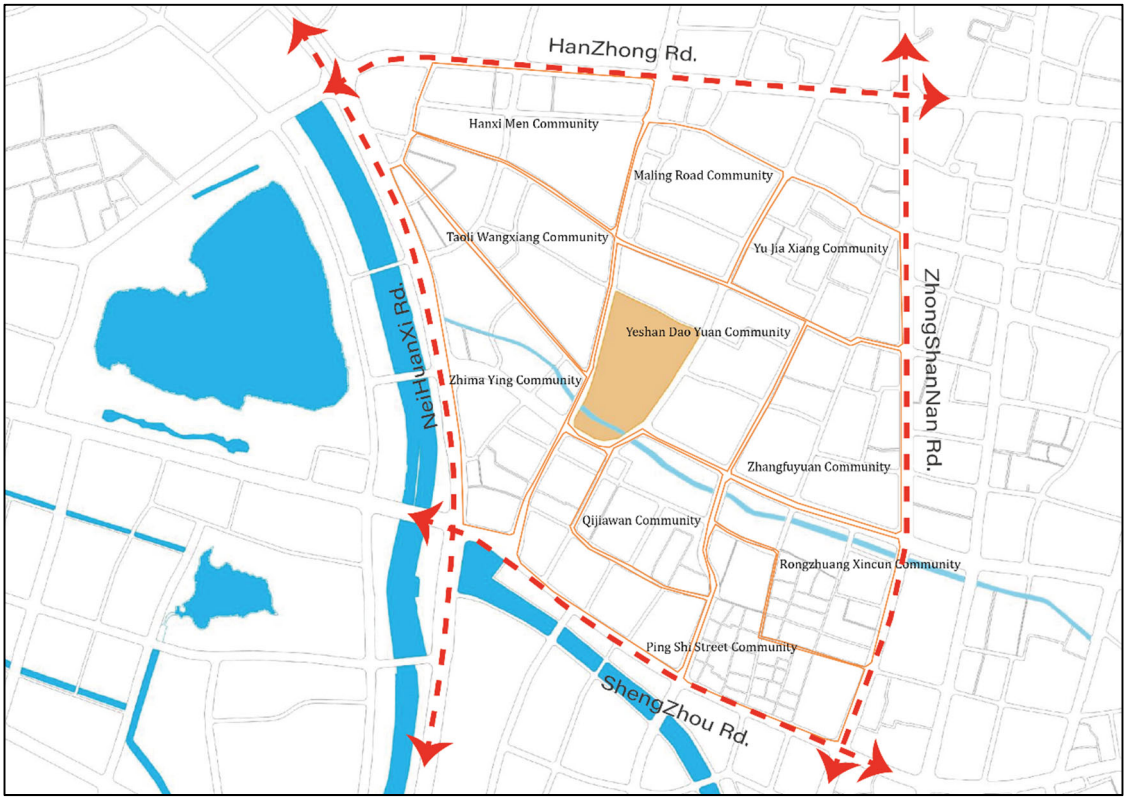

Figure 1. the community map of Chaotian-Gong District.

Named after the "Chaotian-Gong," the district has a rich history. As early as the 5th century BCE, the site where the Chaotian-Gong now stands was home to one of the earliest settlements in Nanjing. The Chaotian-Gong, constructed later, has undergone several fires and restorations. The most significant renovation in modern times occurred during the Tongzhi era of the Qing Dynasty, preserving its main layout and architecture, which is now housed in the Nanjing Museum. The district not only serves as one of the origins of Nanjing's historical culture but also represents a key intersection between modern urbanity and traditional culture. Therefore, conducting urban morphological research in this district holds significant importance for the preservation and renewal of historical districts.

In recent years, Chaotian-Gong Street has leveraged its unique comparative advantages to develop modern service industries, including finance and insurance, information technology, and cultural creativity. It has established a financial cluster along Zhongshan South Road and Jianye Road, with Wangfu Street, Mingwa Lane, Shigu Road, and Xinanli forming core areas featuring dining, shopping, and entertainment. Recently, the Chaotian-Gong district has focused its renewal efforts on the Chaotian-Gong Seven Lanes area, initiating a series of urban micro-renewal projects. This involves exploring a "multi-partner collaboration" mechanism for bottom-up urban micro-renewal, with trade associations, residents' committees, and other entities as key carriers, addressing the complex mixed nature of historical, commercial, and residential areas, and resolving the commercial-residential conflicts prevalent in the district.

Figure 2. Plan of the Chaotian-Gong District.

Through methods such as historical map analysis and comparisons, further understanding of the patterns and underlying causes of the urban morphological changes in Chaotian-Gong can be achieved, facilitating focused analysis of the micro-morphology of urban public spaces in subsequent studies.

Importance and significance

This study addresses the gap in existing research regarding the micro-scale urban morphology and agents in China's urban micro-renewal. Micro-scale urban morphology research not only provides structural information for urban spatial analysis but also enhances the identification and extraction of multidimensional spatial elements and the study of morphological bases for social publicness. By integrating the analysis of micro-scale morphological changes with agents in urban renewal, this research establishes connections between spatial transformations, complex social activities, and the evolution of urban space, property, and usage rights across different historical periods. This approach effectively aids planners in understanding the processes underlying social and economic contradictions hidden beneath spatial conflicts, thereby providing valuable information for the fine-tuned management of urban spaces.

Outline

Existing research has paid insufficient attention to urban micro-morphology and rarely integrates the analysis of agents within the city. This study addresses the gap in existing research on urban micro-updates in China by examining the relationship between urban micro-morphology and agents.This paper analyzes the urban morphology of the Chaotian Palace district in Nanjing, China, using research methods such as historical map studies, field surveys, and interviews. It examines the medium-scale changes in urban morphology and the evolution of social relations, focusing on fagents influencing road network and parcel division changes. The study then shifts to a micro-scale analysis, exploring the relationship between agents and urban micro-morphology in the context of urban micro-renewal. It investigates the participatory micro-renewal mechanisms involving diverse stakeholders in Chaotian-Gong and assesses the applicability of urban morphology and agent-based research to urban micro-renewal. The study aims to provide insights and lessons for participatory urban micro-renewal mechanisms.

METHOD

Study of the historical spatial morphology evolution of the Chaotian-Gong district

Late qing dynasty

In the late Qing Dynasty, there is relatively little recorded data on the maps of the study area. For this research, the more valuable references include the "Jiangning Provincial City Map," the "Jiangning Prefecture City Map," and the newly surveyed "Complete Map of Nanjing Province" from the Lushi School (Table 1). The 1853 Jiangning Provincial City Map does not precisely depict spatial positions but reflects the positional relationships between different land parcels. During this period, the overall spatial layout was centered around Chaotian-Gong, with key areas extending to the Hanxi Gate in the northwest and the Tianhou Palace and Shuixi Gate in the southwest. The map shows a network of waterways within the Chaotian-Gong district, with numerous bridges.

By 1898, the Jiangning Prefecture City Map provided a more accurate depiction of the internal street network, revealing an initial "five horizontal and five vertical" grid pattern. The road network was generally parallel and perpendicular to the water systems and Chaotian-Gong. Main streets and lanes radiated from the Shuixi Gate and Hanxi Gate nodes, converging at Chaotian-Gong. During this period,

the land parcel shapes were characterized by diagonal grids and a radial structure extending from the city gates to the west.

The 1910 Lushi School's newly surveyed "Complete Map of Nanjing Province" more accurately presents the spatial relationships and road networks. It shows many scattered waterways within the area, most of which have now disappeared. The northern street pattern remains relatively unchanged due to the presence of Chaotian-Gong and the surrounding mountains. In contrast, the southern street pattern experienced significant changes, with the road network becoming notably denser. This indicates that the natural base and land parcel attributes and uses during this period had a considerable impact on the changes in urban morphology.

From the republican era to the present

Following the formulation of the capital city plan in 1927, the urban morphology of Nanjing underwent significant changes. This period is well-documented, with one of the most impactful developments being the construction of Zhongzheng Road (now Zhongshan South Road) starting in 1929. According to the 1948 Nanjing map (Table 2), the most significant change in the block morphology compared to earlier periods was the introduction of the new grid layout in Xinjiekou following the capital city plan. The north-south roads in Xinjiekou intersected with the existing grid system, creating numerous irregular land parcels. The road networks on both sides of the waterways were slightly denser than before, largely defining the current spatial morphology of the Chaotian-Gong District.

Overlaying maps of the Chaotian-Gong District from different periods reveals that, similar to the planning period, the street pattern in the northern part of the district changed little, with minimal alterations near Chaotian-Gong and the surrounding mountains. In contrast, the road network in the southern part experienced substantial changes and continuous updates. The modifications to the waterways, along with the disappearance of city walls and gates, had a significant impact on the overall morphology of the district. Additionally, the new roads constructed under the capital city plan drastically altered the district's layout in a very short time, highlighting the role of agents in the transformation of urban morphology.

Research on the relationship between diverse agents and urban micro-update morphology

Analysis of agents in the Chaotian-Gong district

Based on the specific functions and roles of agents in the formation, change, and development of urban morphology, agents can be categorized into indirect agents, direct agents, and evaluative agents (see Figure 3). In the Chaotian-Gong District, indirect agents include government approval agencies such as the District Construction Bureau, Urban Management Bureau, and Landscaping Bureau, as well as the Chaotian-Gong District community departments and neighborhood committees.

Direct agents are primarily of two types: one type consists of builders, specifically White House Property Maintenance Co., Ltd. in the context of the Chaotian-Gong District urban renewal; the other type includes planners, architects, and designers, represented by the Southeast University design team and the Nanjing Creative Design Center.

Evaluative agents include consumers and users. In the Chaotian-Gong District, significant evaluative agents are merchants, residents, and staff from public institutions or government departments.

Agents exercise agency through various actions such as decision-making, design, supervision, and feedback, directly or indirectly shaping and transforming urban morphology. Due to differences in their roles, objectives, modes of influence, resources, and socio-economic backgrounds, agents play different roles in the process of urban morphology formation, resulting in a diverse range of urban forms. Conversely, urban morphology impacts aspects such as the economy, culture, and environment, which in turn affects the agents.

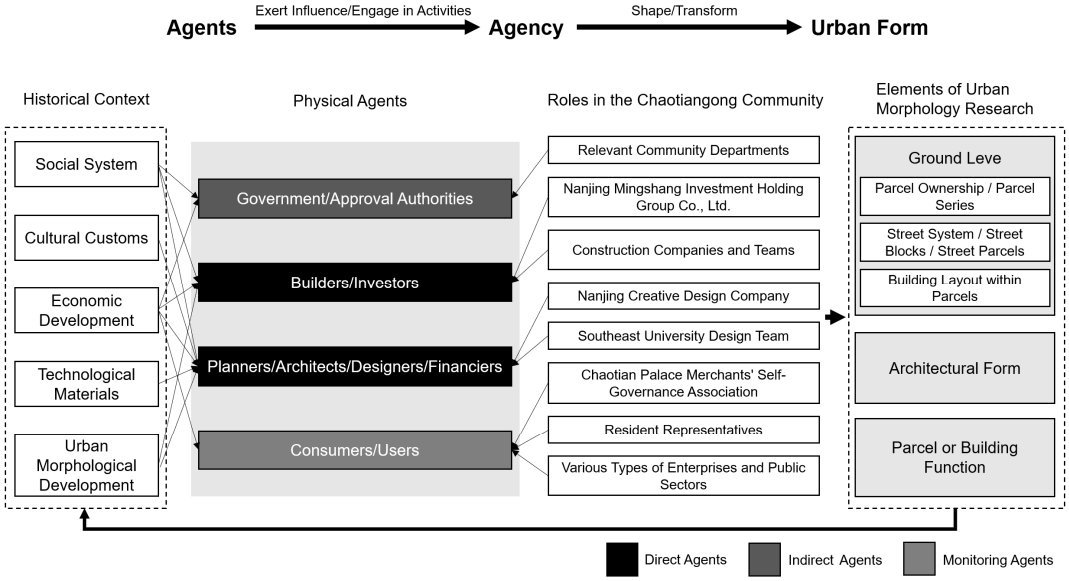

Figure 3. Types and Impacts of Agents in the Chaotian-Gong Area.

Analysis of the relationship between urban micro-morphology and agents in the Chaotian-Gong district

This study focuses on the Chaotian-Gong District, specifically from the Mingwulang area to the Daxing Furnace area (see Figure 3), to analyze the relationship between urban micro-morphology and agents. The area under examination involves a diverse range of agents influencing urban morphology. By observing and documenting the existing urban micro-morphology and conducting interviews with agents in this region, it has been found that evaluative agents, such as users and consumers, have a significant impact on the morphological changes of public corridors, permeable streets, and alleyways, which can be considered as the "capillaries" of urban space. This impact is particularly evident in issues related to the delineation of boundaries between different attributes and the utilization of grey spaces at boundary intersections.To further investigate, four representative plots within this area have been selected as case studies to analyze in detail how these agents affect urban micro-morphology.

Figure 4. Key Research Area for Urban Renewal in the Chaotian-Gong District.

Plot One is located at the boundary between the China Bank Campus and the residential area in the Mingwulang region (Figure 4-1). Plot Two is situated at the boundary between the Nanjing Overseas Business College and the residential area (Figure 4-2), with individual shops lining one side of the street. Both plots feature narrow pedestrian pathways and residential entryways. From the perspective of agents, institutional users such as banks and schools require spaces with strong enclosure, larger scales, and distinctive or ceremonial entrances. In contrast, residents need spaces that cater to social interactions, relaxation, parking, and the collection of deliveries. Merchants, on the other hand, prefer spaces that are open to the public to ensure customer flow. The behaviors and feedback of these agents shape similar micro-morphological characteristics in the two plots. First, institutions and departments create well-defined boundaries and spaces that are inaccessible to others, with large, conspicuous features such as flowerbeds and stone lions encroaching on some of the passage areas. Second, the residential alleyways are narrow, leading to the creation of overlapping spaces with ambiguous boundaries to accommodate various needs. Due to spatial constraints, some impromptu activities spill over into the permeable streets (Figure 5).

Plot Three is located at the entrance of the Chengmei Campus of Nanjing Fifth Junior Middle School (Figure 4-3). Key agents here include teachers, students, and parents. This plot exhibits notable temporal variation in use; during school start and end times, there is a significant influx of people, leading to a relatively wide passage space with designated waiting areas. However, the high building density in the Chaotian-Gong district still results in issues like parking difficulties and queue congestion. Plot Four is situated at the entrance space of the Daxing Furnace residential area, flanked by shops along the street. Compared to Plots One and Two, this plot features a larger entrance space with more ambiguous boundaries between different user areas. Functional spaces are often shared, highlighting the considerable impact of various agents on the micro-morphology of boundaries.

Overall, the Chaotian-Gong District is characterized by high building density and narrow passage spaces. The residential area entrances are typically narrow alleys. The mix of historical, commercial, and residential characteristics creates significant differences in the needs of agents in adjacent smaller areas, resulting in various types of boundary conditions. For instance, spaces occupied by institutional employees, government staff, and students have clear boundaries, are usually larger, and support relatively singular activities. These spaces undergo minimal changes and are less adaptable in urban renewal contexts. In contrast, spaces used by residents and merchants generally feature ambiguous boundaries with overlapping functional areas. Due to limited space, the study area frequently experiences temporary usage phenomena, such as flowerbed edges being used as seating, and open areas serving various functions like parking, queuing, and placing urban furniture at different times.

Figure 5. Recording of Chaotian-Gong District Urban Micro-Morphology.

In urban micro-renewal involving multiple stakeholders, different types of agents influence the boundaries, permeability, and other aspects of urban micro-morphology in various ways. The previously mentioned evaluative agents, such as users and consumers, modify and update the urban micro-morphology through their daily usage and feedback, aiming to meet their activity needs. During the micro-renewal process, indirect agents, such as government departments and planning agencies, guide and regulate the block's morphology through policies and regulations. Their decisions and management actions typically shape planning at a macro level, but in the case of Chaotian-Gong, regulatory bodies have detailed their efforts to address the micro-level aspects of the block, such as street improvements, landscaping, and public facility arrangements. These measures also align the morphology more closely with the needs of users and consumers. Direct agents, such as developers and architects, affect the physical morphology of the block through construction and renovation projects. Their actions are primarily influenced by design concepts, construction methods, and aesthetic goals. Through design and construction, direct agents have a tangible impact on the urban micro-morphology.

Figure6. Recording of Chaotian-Gong District Urban Micro-Morphology.

RESULTS AND DISCUSSIONS

Research conclusions

Applicability of urban microform studies and actor research in urban micro-updates

Based on the above research, this project targeted specific plots with prominent contradictions for focused micro-updates. For example, in Plot Three, analysis of the agents revealed that parents picking up and dropping off students lacked waiting space. In the renovation, the flower bed was redesigned into a node for waiting and resting. For nodes with high demand but limited space, multifunctional equipment can be appropriately installed to flexibly meet users' needs. This also illustrates how direct agents, such as architects, actively shape the physical form of the district through construction and renovation projects.

Overall, studying urban microform helps to identify the "capillaries" of urban spaces—such as public corridors, alleys, and green spaces—that are small but important spatial units. These units often become the focus of renovation in micro-updates. Detailed study of their form and usage allows for more precise renovation strategies, improving the efficiency and quality of urban spaces. The impact of agents on urban form helps better align user needs with physical forms during urban updates and

aids in understanding the interaction among various stakeholders in policy-making and implementation. By optimizing policy design and promoting active participation from diverse agents, it facilitates joint involvement of government departments, developers, architects, community residents, and merchants in urban micro-updates. Coordinating these relationships fosters collaborative efforts and ensures the smooth implementation of update projects.

Summary

In the study area of the Chaotian-Gong District, the activities of agents have a significant impact on the urban microform, particularly regarding the boundaries and alleyways. User and consumer agents, as evaluative agents, notably influence the shaping of boundary forms and alleyway configurations. Their daily activities and behavior patterns, such as pathways, waiting spaces, and interaction nodes, directly affect the layout and changes in the district's micro-spaces. These agents, through their roles and responsibilities, continuously update and optimize the district space, driving the dynamic development of the overall district form. In the study case, the passage roads are generally quite narrow, yet they still serve numerous functions beyond traffic. This is primarily due to the lack of public activity spaces within the district, causing the social activities of agents to temporarily shift onto these passage roads, occupying part of the space. Public corridors and alleyways between plots of different natures are gradually being squeezed, and the varying needs of agents result in different boundary forms on either side of these corridors and alleyways. A thorough study of these agents' activities and their impacts provides valuable references for urban micro-updates and promotes sustainable urban development.

Implications and limitations of the study

This study addresses the gaps in research on urban microform and urban agents in the context of urban updates, offering a new perspective on urban micro-updates. By exploring how urban microform is influenced by different agents, this paper reveals the complex relationships between microform and agents and expands understanding of the details and mechanisms in urban micro-update practices. This perspective helps identify and analyze the specific roles and interactions of various stakeholders in urban updates, providing theoretical support and practical guidance for formulating more precise and effective micro-update strategies.

While the paper briefly mentions the impact of users' temporary activities on urban microform in the Chaotian-Gong district, it does not fully summarize their mechanisms and research methods. Many countries and regions are now in the "second half" of urbanization, where space updates and functional transformations are very common. Exploring how to apply the frameworks of urban morphology and agency studies to phenomena such as industrial-to-commercial conversions, temporary land use, and the segmented use of living spaces in time and season warrants further consideration.

CONCLUSIONS

This study explores the historical urban morphology changes in the Chaotian-Gong District and their underlying causes from the perspective of urban micro-morphology and agents of change. It analyzes the relationship between the current micro-urban morphology of the Chaotian-Gong area and the

various agents involved. The identified conflicts and deficiencies in this analysis have been applied to the practice of urban micro-renewal. Through this application, the research provides valuable insights into the role of urban micro-morphology and agent dynamics in informing and guiding urban micro-renewal projects. The findings suggest that understanding the interactions between agents and urban micro-morphology can enhance the effectiveness of micro-renewal initiatives, ensuring that the needs of diverse stakeholders are met while improving the spatial quality and functionality of urban environments.

Acknowledgements

The authors would like to thank Kong Anqi, Liu Anqi, and Li Siqi for their contributions to the preliminary research and site analysis. The authors also appreciate the guidance and assistance provided by Liang Junsong, Zhao Jiawei, and Yang Kaixin in the urban micro-renewal design. Additionally, thanks to the Chaotian-Gong District Community Committee for their support and cooperation during the research and interviews, which provided essential information and data for the successful completion of this study.

ABSTRACT

As urban areas continue to expand rapidly, there is an increasing imperative to integrate microclimate considerations with urban morphology to enhance thermal comfort at the pedestrian scale. This study aims to optimize climate comfort indices—specifically solar radiation, daylight factor, and the Universal Thermal Climate Index (UTCI)—to identify effective urban morphology patterns for pedestrian environments in urban streets. Utilizing a quantitative approach, the research employs computational modeling in Grasshopper, enhanced by a genetic algorithm, to explore optimal density and occupancy levels for urban morphology in Tehran's streets. The study focuses on two primary land uses, residential and commercial, analyzing the impact of density and occupancy levels as key morphological parameters on the microclimate. Findings indicate that density exerts a more significant influence on thermal comfort with a fixed street network pattern than occupancy. These insights provide essential data for urban morphology and climate modeling, advancing the development of climate-responsive urban designs.

Keywords: urban morphology, urban climate, climate comfort, pedestrian scale, urban streets

INTRODUCTION

The rapid urbanization and concentration of populations in cities amplify their vulnerability to climate change, highlighting the need for strategic adaptation to address the evolving weather patterns linked to global warming. Projections indicate that average annual temperatures could rise by 1°C to 5°C by the 2080s (Harrs et al., 2024). In response, policymakers and urban planners prioritize sustainable and energy-efficient development strategies to cultivate resilience within urban environments (Monteiro et al., 2024). Urban expansion is evident in the projected increase of cities with populations between

500,000 and 1 million, expected to rise from 598 in 2016 to 710 by 2030 (Salmanian et al., 2024). This growth altered urban morphology, resulting in new multifunctional spaces and intensified energy demands while exacerbating environmental challenges, including the urban heat island effect (Ma et al., 2024). Urban areas, which host approximately 50% of the global population, account for two-thirds of primary energy consumption and contribute 71% of global greenhouse gas emissions (Salmanian & Ujang, 2021). As urban populations are anticipated to reach 68% by 2050, the strain on material and energy resources will only increase (Li et al., 2022).

In the context of escalating climate change impacts, urban areas have experienced a significant rise in temperatures, with global averages increasing by 0.8°C over the past century, alongside rising atmospheric CO2 concentrations projected to double by 2100 (Davis, 2017). Given the critical role of cities in addressing these challenges, frameworks such as the Paris Agreement and the Sustainable Development Goals have highlighted the importance of urban resilience and adaptive strategies (Bikomeye et al., 2016). Nevertheless, challenges remain regarding the equitable implementation of urban improvements. To tackle the adverse effects of climate change, it is essential to understand how urban morphology affects local climates and outdoor thermal conditions. Research indicates that design parameters such as green cover ratios and building heights significantly impact microclimatic variations (Shaikh Salim et al., 2020; Galal et al., 2020). Consequently, integrating climate-responsive urban design into planning strategies is vital for enhancing thermal comfort and reducing energy demands linked to cooling systems (Abd Elraouf et al., 2022). This paper aims to strategically model the interplay between urban morphology and climate in Tehran, utilizing computational techniques to establish effective urban design strategies that foster sustainable and resilient urban environments.

Literature review

Outdoor thermal comfort

Thermal comfort refers to the level of satisfaction or indifference experienced by individuals concerning their thermal environment. Definitions of thermal comfort vary among institutions and scholars, with the most widely accepted definition provided by the American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE). ASHRAE defines thermal comfort as a mental state reflecting satisfaction with the thermal environment. The glossary of terms related to thermal physiology describes it as a subjective indifference to temperature conditions. Gagge et al. points out that while "comfort" is a recognizable emotional state, it does not correlate with a specific sensory organ like the traditional five senses (Wang et al., 2018). Outdoor thermal comfort is a multifaceted concept influenced by various environmental, individual, and psychological factors. Environmental elements, including solar radiation, wind speed, air temperature, and humidity, directly impact the human body's thermal balance and sensation. Individual characteristics, such as age, gender, and physical activity levels, influence the body's capacity for thermal regulation and adaptability. Additionally, psychological factors—such as past experiences, expectations, and the purpose of activities—also play a role in determining thermal satisfaction and preferences. Consequently, a comprehensive examination of outdoor thermal comfort must account for the interplay among these factors (Han et al., 2024).

Given the complex nature of thermal comfort, no single factor can adequately capture individuals' subjective experiences in different thermal environments. To address this complexity, thermal comfort indices integrate various environmental parameters and human body responses into a unified

metric for a more accurate and convenient thermal comfort assessment. Since ASHRAE introduced the first thermal comfort index, Effective Temperature (ET), in 1923, research on thermal comfort has evolved significantly, leading to the development of approximately 165 different thermal comfort indices. These indices can be categorized into two main types: empirical thermal comfort evaluation indices and theoretical thermal comfort evaluation indices (Su et al., 2024).

Outdoor thermal comfort factors

Studies have shown that numerous direct and indirect factors influence outdoor thermal comfort. These include geographical and seasonal variations, climatic conditions such as temperature, thermal radiation, wind, humidity, individual physiological differences, social and cultural factors, and personal behavioral habits (Yongga et al., 2024). Empirical thermal comfort evaluation indices were primarily developed in the early stages of thermal comfort research. These indices assess heat and cold risks by examining the relationship between the physical environment and human thermal sensation. Typically, they focus on estimating the combined effects of air temperature, humidity, and velocity on individuals at rest. Empirical indices are generally divided into two categories: hot empirical indices and cold empirical indices. Hot empirical indices evaluate thermal comfort in high-temperature environments, while cold empirical indices are used for low-temperature settings. The main advantages of empirical indices are their simplicity in calculation and ease of understanding. However, these indices have notable limitations, disregarding individual physiological factors, activities, clothing, and personal characteristics such as height, weight, age, and gender. Additionally, their applicability can be constrained by geographical and climatic conditions. It is essential to supplement empirical indices with other indices, such as dynamic and adaptive indices, to enhance the accuracy and applicability of thermal comfort evaluations. This integrated approach helps address the shortcomings of empirical indices and provides a more comprehensive assessment of thermal comfort (Liu et al., 2023).

As the understanding of thermal comfort mechanisms has deepened, the focus has shifted from merely assessing the physical environment to incorporating individual physiological and psychological factors and dynamic balances. Consequently, theoretical indices have emerged. These indices are numerical models derived from the human body heat-balance equation, comprehensively considering environmental conditions and human body parameters. Theoretical indices exhibit diverse development due to different research institutions' varying methods and models. Based on their application scope, they can be classified into steady-state and dynamic indexes. Steady-state indices evaluate thermal comfort under constant environmental conditions, while dynamic indices account for fluctuating conditions. Theoretical indices offer a more objective evaluation of human thermal comfort in complex environments, resulting in more scientifically robust assessment outcomes (Hughes et al., 2018).

Steady-State Thermal Comfort Evaluation Indices

The steady-state model posits that human thermal comfort results from the continuous heat transfer between the human body and its environment, leading to a thermal equilibrium over time. In 1923, Houghton and Yaglou conducted pioneering experiments, defining the Effective Temperature (ET) as the temperature at which individuals in standard clothing perceive similar thermal sensations across

environments with differing temperatures and humidity. However, ET primarily accounts for air temperature and humidity (Chen et al., 2023). In 1971, Gagge et al. enhanced the concept of ET by introducing skin moisture into the equation, coining the term New Effective Temperature (ET) to incorporate the body's evaporative heat dissipation. In 1972, Gagge et al. proposed the New Standard Effective Temperature (SET) at a seminar, which integrates activity levels and clothing thermal resistance based on ET. This index adapts to varying physiological conditions and clothing scenarios, although its calculation complexity poses challenges. Most of these indices have been traditionally applied indoors, which may not accurately reflect outdoor thermal comfort due to differences such as solar and infrared radiation (Savi & Romero, 2024).

In 2000, Pickup and de Dear introduced the Outdoor Mean Radiant Temperature (OUT_MRT) and established the Outdoor Standard Effective Temperature (OUT_SET) to tailor the SET model for outdoor contexts. By comparing actual measured values with predictions, the OUT_MRT model effectively characterizes the outdoor radiation environment and calculates the total radiation absorbed by the human body. During the 1960s and 1970s, Danish scholar Fanger developed the Predicted Mean Vote (PMV) model, which utilizes a seven-point scale based on the human body's heat-balance equation to predict the average thermal sensation of individuals. The PMV model is widely adopted for indoor thermal comfort assessments. Concurrently, Fanger introduced the Predicted Percentage of Dissatisfied (PPD) index, reflecting the proportion of individuals feeling too hot or cold. However, since the PMV model is primarily designed for stable air-conditioned environments, it often yields significant errors in dynamic outdoor settings (Li & Zhao, 2023). Mayer and Höppe (1987) developed the Physiologically Equivalent Temperature (PET) model, based on the Munich Energy-balance Model for Individuals (MEMI) steady-state two-node model. PET remains relevant today, conceptualizing outdoor climates as effective indoor environments with comparable expected air temperatures (Keshavarz & Bahrami, 2023). Furthermore, Matzarakis et al. introduced the RayMan model in 2007 to facilitate PET calculations, enhancing its utility for outdoor thermal comfort assessment (Matzarakis & Amato, 2024).

Dynamic Thermal Comfort Evaluation Indices

The steady-state model assumes that heat exchange between the human body and the thermal environment remains constant, requiring stable environmental conditions and prolonged exposure. This model is typically applicable when individuals are exposed to outdoor environments for extended periods. However, because outdoor thermal conditions frequently fluctuate, the human body's heat load also varies. To address this limitation, dynamic models were developed to account for varying heat storage rates, recognizing that thermal comfort can be achieved even when heat storage is not zero. An example of such a dynamic model is the Universal Thermal Climate Index (UTCI), initiated by Commission 6 of the International Society of Biometeorology. The UTCI evaluates outdoor thermal conditions across various human biometeorology contexts. The UTCI is derived from the equivalent temperature calculated through over 100,000 thermal physiological simulations using the multi-node dynamic thermal physiology UTCI-Fiala model. This equivalent temperature reflects the environmental conditions required to produce the same physiological response observed in the natural environment. Although the UTCI accurately assesses outdoor thermal comfort across different climates and is applicable worldwide, its complex model structure is characterized by its complex model structure (Yongga et al., 2024; Steadman, 2023).

Morphological Aspects of Thermal Comfort

Thermal comfort in urban environments is significantly influenced by various morphological aspects, which play a critical role in shaping the microclimate experienced by pedestrians. This sub-section delves into the key variables pertinent to urban morphology and their impact on thermal comfort, mainly focusing on density, block dimensions, and spatial configuration as analyzed in the context of Tehran.

- Urban Density

Density is a crucial morphological parameter that affects thermal comfort. Higher urban density can increase heat retention and the urban heat island effect, impacting outdoor temperatures (Guan et al., 2023). Research indicates that higher-density areas experience elevated ambient temperatures due to reduced green space and increased impervious surfaces, which hinder natural cooling processes (Zhou et al., 2023). Consequently, optimizing density levels can enhance thermal comfort by balancing heat retention and dissipation in urban spaces.

- Block Dimensions and Internal Configurations

Block dimensions, including the height-to-width (H/W) ratio, significantly influence solar exposure and wind flow, which are critical for thermal comfort. A lower H/W ratio is associated with increased solar access, leading to higher surface temperatures during the day and affecting overall thermal comfort levels (Erell et al., 2023). Furthermore, internal block configurations can create microclimates that enhance or mitigate heat stress. For instance, more extensive internal courtyards can facilitate air circulation and provide shaded areas, thus improving thermal comfort for pedestrians (Lee & Loughnan, 2024).

- Spatial Configuration

The spatial arrangement of urban elements, including streets, buildings, and public spaces, is vital in determining thermal comfort. The buildings' orientation and streets' layout can influence wind patterns and solar gain. Optimal spatial configurations that promote natural ventilation can reduce reliance on mechanical cooling systems, thereby enhancing thermal comfort in densely populated areas (Wang et al., 2024). Moreover, integrating mixed-use developments can foster a pedestrian-friendly environment that encourages outdoor activity, further influencing perceived comfort levels (Kumar et al., 2023).

METHOD

The research methodology employed in this paper utilizes a quantitative approach coupled with computational modeling to enhance urban morphology for improved thermal comfort. A thorough literature review initially identifies key morphological characteristics that impact microclimatic conditions. This review emphasizes various urban morphology components, including building density, layout, and height-to-width ratios. These directly influence critical thermal comfort indices such as solar radiation, daylight factor, and the Universal Thermal Climate Index (UTCI).

Following the literature review, an urban model will be developed using Grasshopper, a visual programming language that facilitates dynamic simulation and analysis. The model will leverage genetic algorithms to iteratively optimize urban form configurations based on predefined thermal comfort criteria. Three distinct types of urban networks—12m, 18m, and 24m—will be incorporated into the model, allowing for flexible adjustments of block dimensions and internal divisions. This grid-system configuration is specifically tailored to the unique context of Tehran, enhancing the model's relevance and adaptability. Data collection will occur through simulations that evaluate the thermal performance of varying urban configurations. The analysis will focus on how changes in density and occupancy levels influence outdoor thermal comfort, providing valuable insights into optimal design strategies for sustainable urban development. Ultimately, this methodology aims to integrate microclimatic considerations into morphological configurations, promoting energy efficiency and enhancing pedestrian comfort in urban environments. Consequently, this analysis expands the urban planning workflow to incorporate inputs from climate models, as illustrated in Figure 1.

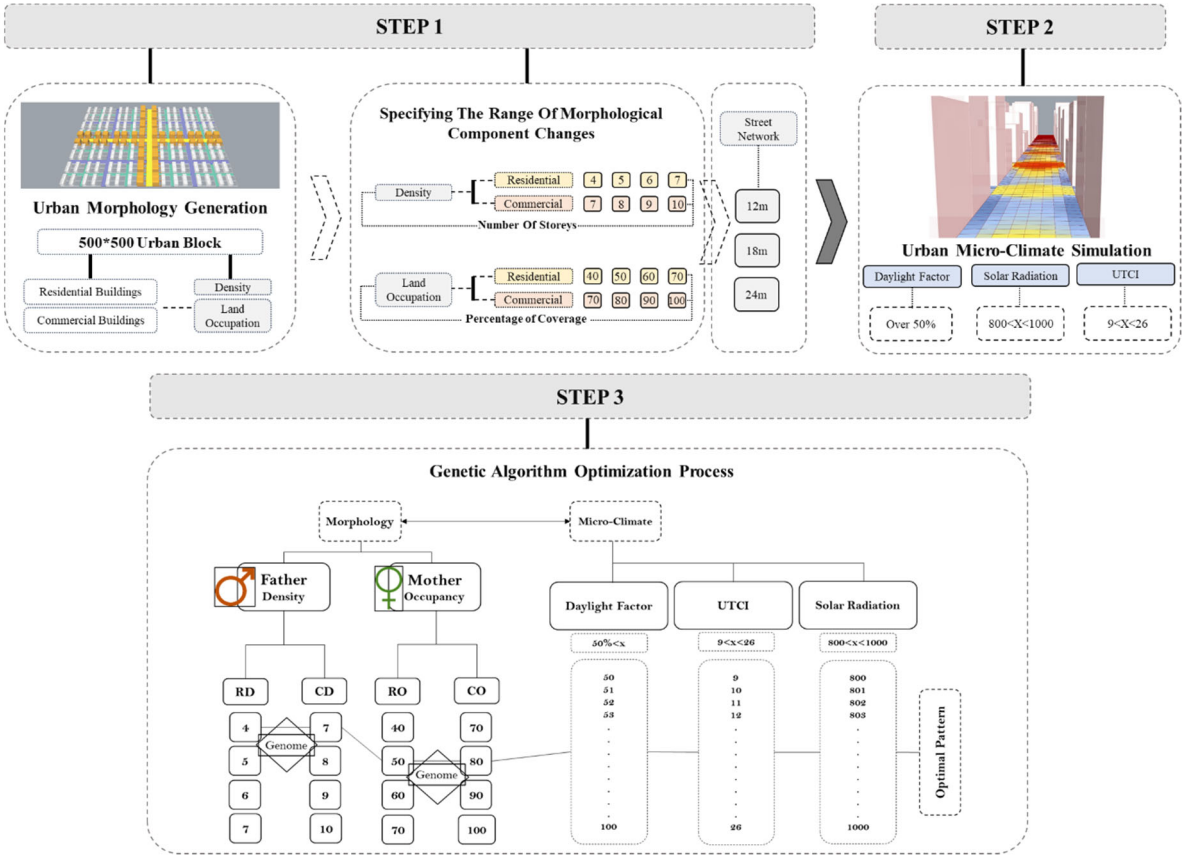

Figure 1. The study's workflow is in three main steps: urban morphology generation (Step 1), urban micro-climate simulation (Step 2), and the genetic algorithm optimization process (Step 3).

Generating urban morphology

The initial step involves developing an urban model capable of dynamically adapting to changes within the city's context while accurately representing Tehran's morphological characteristics, including its urban patterns and density. Depending on the context, this model should be flexible enough to adjust block dimensions, internal divisions, and other morphological properties.

To refine the analysis further, the subsequent step is to select an appropriate hierarchy within the urban network, which will facilitate more precise processing of the model. Currently, three distinct types of urban networks—12m (Fig. 2), 18m (Fig. 3), and 24m (Fig. 4)—have been integrated into the

urban block model using a visual programming language. Given the area and city being studied (Tehran), the network has been configured as a grid system.

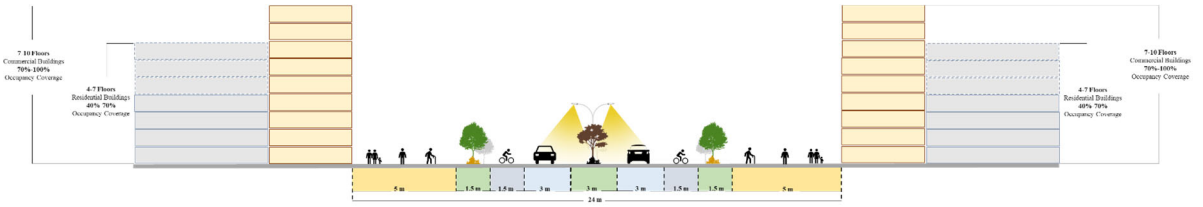

Fig. 4. Cross Section of Urban Street Type 3 (24m)

Urban micro-climate simulation

To begin the climate and microclimate analysis essential for future research, Tehran-specific climatic data is imported into the appropriate software as an EPW (EnergyPlus Weather) file. This foundational step establishes the groundwork for subsequent stages of the study, ensuring that the analysis is grounded in accurate and relevant climatic conditions. The data collected will be crucial in informing the various simulations and evaluations conducted throughout the research process. Following the data import, the subsequent steps involve a series of systematic analyses and simulations to understand urban morphology's impact on thermal comfort. Each phase is designed to refine the model and enhance its applicability to Tehran's unique climate, ultimately guiding the development of effective urban design strategies that prioritize occupant comfort and environmental sustainability:

Daylight Factor

Daylight calculations traditionally rely on the daylight factor, which does not consider prevailing weather conditions. While effective for overcast skies, this method falls short for clear-sky scenarios. In urban canyons, reflected sunlight from surrounding buildings and surfaces can significantly boost structure illumination. Early-stage design calculations, though simplistic, are vital for avoiding decisions that may degrade daylight quality.

Urban canyons can act like photometric integrators, where light becomes more uniform after multiple reflections, reducing dependence on the angle of incidence. This principle forms the basis for calculating the average total daylight factor, especially for sunny conditions, incorporating reflected light from urban environments (Brotas & Wilson, 2007). More recent studies confirm the importance of reflected light and highlight the need to integrate site-specific climatic data for better accuracy in urban settings (Konis & Selkowitz, 2023).

In daylight analysis using the Grasshopper plugin, the process begins by generating test points on a geometric model. To ensure accuracy, three fundamental parameters are defined: test geometry, grid size, and distance from the surface. Once set, the simulation proceeds with inputs such as test points, vectors, and a uniform sky model. These simulations consider morphological conditions and integrate climatic data, ensuring that results are more representative of real-world conditions. The results are then displayed in a color spectrum and can be exported to Excel for detailed analysis, aiding in visualizing daylight performance under various conditions (Reinhart et al., 2024). These recent methodologies provide a comprehensive approach, moving beyond traditional daylight factor calculations by incorporating local weather and urban morphology data to ensure optimized daylight performance in complex urban environments.

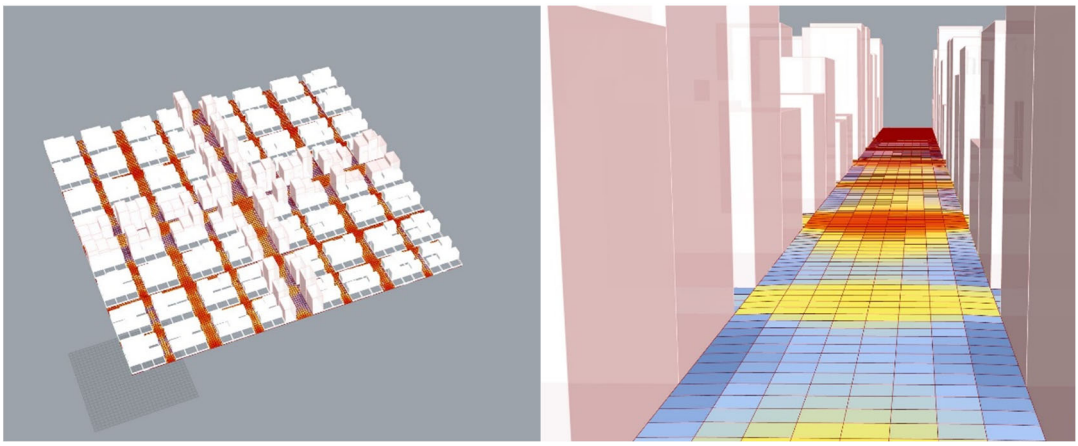

Fig. 5. The results of the daylight factor analysis in the Grasshopper plugin

Universal Thermal Climate Index (UTCI)

The Universal Thermal Climate Index (UTCI), developed to assess outdoor thermal comfort, is recognized as one of the most comprehensive tools for evaluating heat stress in urban environments. Originating from biometeorological research, UTCI is grounded in a multi-node thermoregulation model that simulates the body's ability to regulate core temperature despite external climate variations. Recent advancements in UTCI applications emphasize its importance in urban planning, particularly for addressing the challenges of rising global temperatures and urban heat islands. The UTCI reflects an equivalent environmental temperature that produces the same physiological strain on an individual as a reference temperature in a controlled setting. This makes it especially useful for accurate thermal assessments under diverse climatic conditions (Shen et al., 2024).

In urban climate analysis, tools like the Grasshopper plugin integrate local weather data into simulations, such as Tehran's EPW (EnergyPlus Weather) file. By incorporating essential inputs such as dry bulb temperature, mean radiant temperature, wind speed, and relative humidity, the UTCI index can be calculated more precisely. For example, the "Outdoor Solar Temperature Adjuster" simulates the mean radiant temperature, a critical factor in UTCI calculations, ensuring that all climatic and morphological variables are accurately represented. Once the inputs are established, the simulation provides a visual spectrum and detailed quantitative outputs, helping urban designers

evaluate thermal comfort more effectively in dense urban environments (Ryu & Kwon, 2023; Chen et al., 2023).

Table 1 illustrates the distinct characteristics of the Universal Thermal Climate Index (UTCI) compared to previous indices, especially in how it reflects comfort levels throughout the day. When considering monthly averages, the index shows no indication of thermal comfort at 9:30 am and 3:30 pm, whereas 9:30 pm presents a more accurate reflection of comfort conditions. For example, during winter (January, February, and December), the average values at 9:30 am and 3:30 pm show no thermal stress, suggesting comfortable conditions. However, at 9:30 pm, the data indicates slightly colder conditions. Similarly, in November and December, while the average values at 9:30 am and 3:30 pm suggest no heat stress and comfortable conditions, the evening values at 9:30 pm indicate a slight chill, highlighting the variation in thermal comfort across different times of the day.

Table 1. Evaluation of human comfort using the UTCI index

UTCI	9:30	15:30	21:30	Monthly Average
January	No thermal stress	No thermal stress	Slight cold stress	Slight cold stress
February	No thermal stress	No thermal stress	Slight cold stress	Slight cold stress
March	No thermal stress	No thermal stress	Slight cold stress	No thermal stress
April	No thermal stress	No thermal stress	No thermal stress	No thermal stress
May	Moderate heat stress	Moderate heat stress	No thermal stress	No thermal stress
June	Moderate heat stress	Strong heat stress	No thermal stress	Moderate heat stress
July	**Strong heat stress**	**Very strong heat stress**	**Moderate heat stress**	**Strong heat stress**
August	**Strong heat stress**	**Strong heat stress**	**No thermal stress**	**Strong heat stress**
September	Moderate heat stress	Strong heat stress	No thermal stress	No thermal stress
October	Moderate heat stress	Moderate heat stress	No thermal stress	No thermal stress
November	No thermal stress	No thermal stress	Slight cold stress	No thermal stress
December	No thermal stress	No thermal stress	Slight cold stress	Slight cold stress

Based on the data presented, July and August are identified as periods of reduced climate comfort due to the highest recorded temperatures in Tehran, as shown in Figure 6. These months consistently experience the peak heat, particularly at Mehrabad station, making them critical indicators for assessing thermal stress and identifying the comfort threshold. On the opposite end, January registers the lowest average temperatures, offering a stark contrast. Therefore, focusing on these months is essential to create an optimal climate model for Tehran. July and August represent critical points for evaluating the impacts of extreme summer heat on comfort.

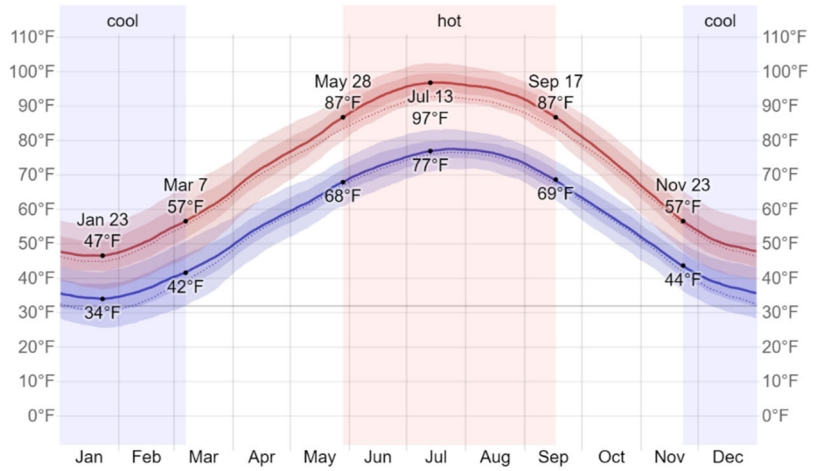

Fig. 6. The daily average high (red line) and low (blue line) temperature, with 25th to 75th and 10th to 90th percentile bands. The thin dotted lines are the corresponding average perceived temperatures (Source: weatherspark.com)

Solar Radiation

Shortwave radiation, which includes visible light and ultraviolet radiation, exhibits significant seasonal fluctuations in Tehran. The brightest period spans approximately 3.4 months, from May 9 to August 22, during which the average daily incident shortwave energy exceeds 7.4 kWh per square meter, peaking in June at 8.4 kWh. In contrast, the darker period, also lasting 3.4 months from October 31 to February 11, sees the average daily incident shortwave energy drop below 4.0 kWh, with December being the darkest month at just 2.9 kWh (Fig. 7). The calculation of this index is based on climatic data specific to Tehran. It uses a sunlight simulation tool that requires geometry, context, grid size, distance from the surface, and a selected sky matrix. The numerical output generated from this analysis will be used to inform a genetic algorithm developed with the Grasshopper plugin, aiding in the creation of an optimal model for micro-climate-driven urban morphology (Rocca & Morabito, 2024; Khan & Sinha, 2023).

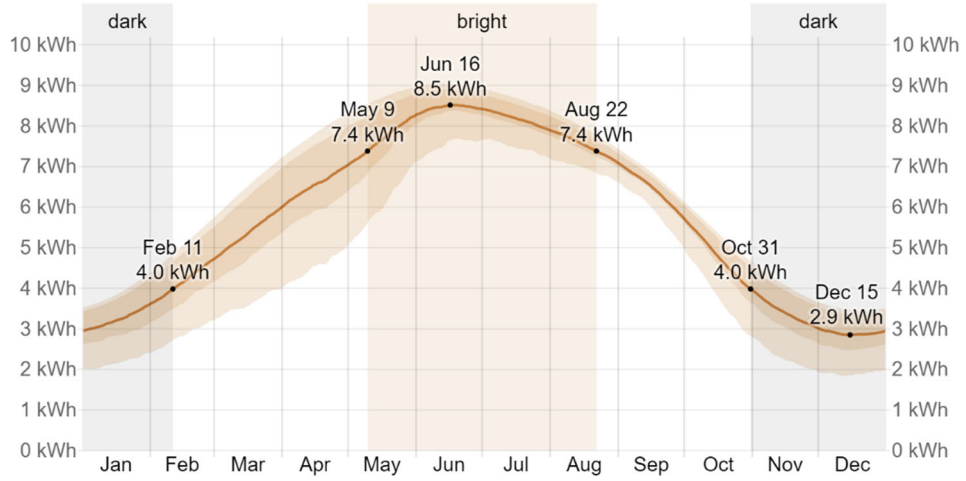

Fig. 7. The average daily shortwave solar energy reaching the ground per square meter (orange line), with 25th to 75th and 10th to 90th percentile bands (Source: weatherspark.com)

Genetic algorithm optimization process

Evolution-based heuristic techniques, such as Genetic Algorithms (GAs), represent a powerful class of algorithms for solving complex problems. Recent research has focused on enhancing the adaptive nature of GAs, showcasing their effectiveness across various applications (Jalal & Kaur, 2023; Kaur & Narula, 2024). These algorithms utilize a chromosome-like data structure and apply recursive recombination or search techniques. For a given set of sample points, denoted as $u= \{u_1, u_2, u_3,\ldots, u_n\}$, GAs can derive an optimal set through effective recombination and selection processes based on semantic analytics. From this initial set, subsets can be identified, such as $\{u_1, u_2,\ldots,u_i\}$ with similar properties and another subset $\{u_j, u_k,\ldots, u_n\}$ with distinct characteristics.

GAs operate on five fundamental principles:

1. **Initialization**: This phase defines the complete sample points or population set. Initialization can be achieved using database tables or direct input from real-world scenarios. Semantic analysis is transformed into statistical models through random number generators that create density functions when employing database tables. In cases involving real-time data, the process begins with natural language processing, followed by statistical methods (Hasan, 2014; Jalal & Kaur, 2023).

2. **Selection**: Grounded in Darwin's principle of survival of the fittest, selection involves choosing a subset from the initial population that logically connects at a specific time. This subset can represent various domains, such as customer shopping behavior or complaints, ensuring the selected data is relevant and meaningful (Kaur & Narula, 2024).

3. **Crossover/Recombination**: Crossover is a critical operation that distinguishes GAs from other methods. This process involves combining a gene representing an individual member of a set with a gene from another set. The recombination fosters the exchange of behaviors and trends, creating logical relationships while minimizing randomness. Typically, crossover occurs between two genes, while the rest remain unchanged (Hasan, 2014; Kaur & Narula, 2024).

4. **Mutation**: Mutation introduces genetic diversity within the population by altering specific gene properties (alleles) during crossover. This mechanism helps preserve individuality within the population and can lead to the emergence of significant alleles by combining different genes (Jalal & Kaur, 2023).

5. **Acceptance**: New offspring are generated as candidates for the next iteration after mutation. However, not all candidates are suitable for advancement. The percentage of beneficial features within each gene is assessed during the elimination phase. Like an activation function in neural networks, a threshold determines which genes advance to the next level. This iterative process continues until the differences between successive generations are minimal, ensuring the algorithm converges toward optimal solutions (Jalal & Kaur, 2023; Kaur & Narula, 2024).

By leveraging these principles, GAs can efficiently explore large search spaces, optimizing solutions for various complex problems in fields ranging from computer science to bioinformatics (Jalal & Kaur, 2023; Kaur & Narula, 2024).

RESULTS AND DISCUSSIONS

The output model is highly adaptable, allowing for customization through parametric components to meet specific analytical needs. In the next phase, as detailed in the Genetic Algorithm (GA) section, morphological components are treated as variables, while micro-climatic standards function as fitness measures. Various factors—such as space geometry, building height, occupancy, and open space ratio—are analyzed as variables. In contrast, climatic parameters, including Universal Thermal Climate Index (UTCI), Daylight Factor, and other relevant indicators, serve as the fitness functions within the algorithm. By employing Grasshopper alongside the GA, these morphological components act as "parents," guiding the selection of optimal solutions for the chosen genomes. Concurrently, the objective functions consist of micro-climatic standards that enhance the inherited traits from the morphological parameters. The result is an urban morphology that remains flexible and responsive to changes in the micro-climate.

Once the algorithmic process concludes, the output is an active city-scale platform capable of integrating various components—either default or customized—based on specific micro-climatic measurement requirements. This platform generates corresponding data that informs decision-making. To finalize the optimization process, the data produced by the Genetic Algorithm should be saved in an Excel file in CSV format and uploaded to the Design Explorer website for further exploration and analysis. This approach streamlines data management and facilitates a deeper understanding of how urban morphology can adapt to and enhance local micro-climatic conditions (Feng et al., 2023; Gupta et al., 2024) (Fig. 8).

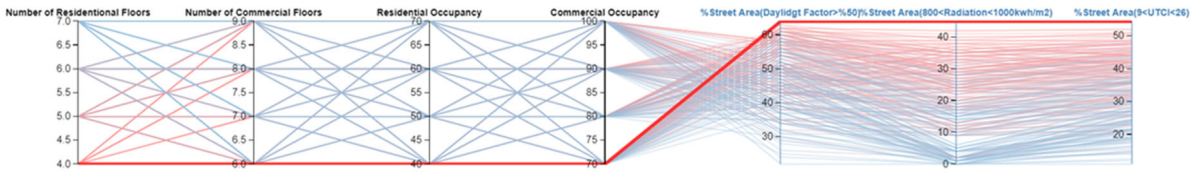

Fig. 8. Regulating the parameters (genomes) resulting from the Genetic Algorithm

The parametric model developed for this study exhibits high adaptability, allowing customization through various morphological variables. These variables, including space geometry, building height, occupancy rates, and open space ratios, were analyzed alongside key climatic parameters such as the Universal Thermal Climate Index (UTCI), Daylight Factor, and Solar Radiation. Using a Genetic Algorithm (GA) in combination with Grasshopper, the morphological variables served as "parents," guiding the selection of optimal solutions for the generated genomes. The objective was to optimize urban morphology responsive to micro-climatic conditions.

- Upon completing the optimization process, the resulting model was integrated into a city-scale platform capable of incorporating default and customized micro-climatic components. The data generated from this model was exported for further exploration and analysis, allowing for a deeper understanding of how urban morphology can enhance micro-climatic comfort (Feng et al., 2023; Gupta et al., 2024). From the 256 potential configurations generated by the algorithm, four optimal alternatives were selected based on their performance against climatic comfort criteria.

- Optimal Alternative No. 1 demonstrates a residential occupancy rate of 40%, indicating moderate utilization of residential spaces, while the commercial occupancy rate stands at 70%, reflecting a strong predominance of commercial activities. This alternative features a medium-density residential environment with buildings averaging four storeys, contrasted by commercial structures averaging six storeys. The micro-climatic performance shows an average Daylight Factor of 48.23%, peaking at 64%, which suggests that the area benefits from substantial natural light. However, variations exist in illumination levels across different zones. Solar radiation is recorded at an average of 18.58%, with a peak of 45%, suggesting that shading from surrounding building heights affects sunlight exposure. The UTCI averages 33.41% and peaks at 54.5%, indicating moderate thermal comfort but highlighting variability in comfort levels across different areas.

- In Optimal Alternative No. 2, the residential occupancy remains at 40%, similar to the first alternative, while commercial occupancy also holds steady at 70%. This alternative maintains a residential density of four storeys, but commercial buildings rise to an average of seven storeys. The Daylight Factor averages 48.23% with a peak of 62%, suggesting adequate natural light but highlighting the potential for improvement through design adjustments. The solar radiation metrics mirror those of Alternative No. 1, with an average of 18.58% and a peak of 42%, indicating limited direct sunlight exposure in shaded areas. The UTCI here also averages 33.41%, peaking at 52.5%, reflecting moderate thermal comfort.

- Optimal Alternative No. 3 shows a consistent residential occupancy rate of 40%, but the commercial occupancy rises significantly to 80%, indicating a commercially dominant area. The residential density remains four storeys, while commercial structures maintain an average height of six storeys. The Daylight Factor averages 48.23%, peaking at 62%, indicating that natural light is moderate, although some areas may experience reduced access due to the urban fabric. Solar radiation averages 18.58%, peaking at 42%, indicating limited exposure to direct sunlight. The UTCI results average 33.41%, peaking at 52%, signifying varying thermal comfort levels throughout the area.

Optimal Alternative No. 4 maintains a residential occupancy rate of 40% and commercial occupancy at 80%, reflecting a solid commercial focus in the area. The residential density remains four storeys, while commercial buildings average seven storeys, indicating a vertically developed commercial zone. The Daylight Factor averages 48.23%, with a peak of 61%, suggesting that although the area generally receives moderate to high levels of natural light, variations in daylight access occur based on building design. Solar radiation metrics show an average of 18.58%, peaking at 41%, indicating potential shading effects from taller commercial structures. The UTCI averages 33.41%, peaking at 51%, indicating moderate thermal comfort levels across the area.

The analysis of these four optimal alternatives reveals essential insights into the relationship between urban morphology and micro-climatic conditions. Each alternative demonstrates distinct characteristics, underscoring the need to balance commercial and residential uses while optimizing environmental quality. Across all alternatives, residential occupancy remains stable at 40%, while commercial occupancy ranges from 70% to 80%, indicating a predominantly commercial land use

pattern. Such patterns suggest strategies to integrate residential spaces into urban designs better to promote mixed-use development and enhance urban vibrancy (Smith et al., 2023; Johnson & Patel, 2024).

The moderate Daylight Factor across alternatives (48.23%) highlights the importance of building design in maximizing natural light. Improving daylight access could reduce energy demands and improve occupant well-being (Fernandez et al., 2023; Yang et al., 2024). The relatively low Solar Radiation (18.58%) suggests that shading from taller buildings affects sunlight exposure. Optimizing building orientation and enhancing vegetation can improve solar radiation and thermal comfort (Nguyen et al., 2024). The UTCI values (33.41%) indicate moderate thermal comfort, with variations suggesting the need for targeted interventions, such as implementing green roofs or strategic shading to enhance thermal conditions. Research supports that urban greenery and reflective materials can significantly improve overall climate comfort (Khan et al., 2024; Mansouri et al., 2024).

Implications for Urban Planning:

Analyzing the four optimal alternatives highlights significant insights into the studied area's urban morphology and micro-climate conditions. Each alternative presents distinct characteristics that underscore the importance of balancing commercial and residential spaces while optimizing environmental quality.

1. Morphological Parameters Across Alternatives:

- Residential and Commercial Occupancy: Across all alternatives, residential occupancy remains stable at approximately 40%, while commercial occupancy ranges from 70% to 80%. This suggests a consistent pattern of predominantly commercial land use, which could lead to potential challenges in residential integration. Studies indicate that urban environments with mixed-use developments promote higher livability and reduce travel demand (Smith et al., 2023; Johnson & Patel, 2024).

- Building Density: The residential density of four stories and commercial density varying from six to seven stories reflect a strategic approach to urban development. Higher commercial density, particularly in Alternatives 2 and 4, underscores the commercial significance. Recent research emphasizes that building height can impact urban energy efficiency and social interactions, influencing economic activity and community cohesion (Lee et al., 2023).

- Balancing Land Use: Given the predominance of commercial spaces, urban planning should strive to integrate residential areas more effectively. This could involve policies encouraging mixed-use developments, enhancing vibrancy, and reducing the risk of urban sprawl (Zhao et al., 2023).

- Optimizing Micro-Climate Conditions: The results indicate a critical need for urban design strategies to maximize daylight and solar radiation while improving thermal comfort. Implementing reflective materials and increasing green spaces can significantly mitigate heat and improve UTCI, ultimately leading to a more pleasant urban environment (Johnson & Patel, 2024; Fernandez et al., 2023).

- Enhancing Urban Layout: Future developments should prioritize the strategic placement of buildings to reduce shading effects and enhance solar access. Studies suggest that optimizing building layouts can significantly improve daylight access and energy performance (Lee et al., 2023; Yang et al., 2024).

2. Micro-Climate Indices:

- Daylight Factor (D.F.): The averages across the alternatives indicate a moderate Daylight Factor around 48.23%, peaking at 62%. Although the area generally receives sufficient natural light, variations exist due to building design and spatial configuration. Enhancing daylight access through thoughtful design can significantly improve energy efficiency and occupant well-being (Fernandez et al., 2023; Yang et al., 2024).

- Solar Radiation (S.R.): Solar radiation averages 18.58%, with peaks at 42%. This suggests limited direct sunlight in some regions, often attributed to shading from taller commercial structures. Addressing these challenges through optimized building orientation and spacing can improve solar exposure, enhancing thermal comfort (Nguyen et al., 2024).

- Universal Thermal Climate Index (UTCI): The UTCI values reveal moderate thermal comfort levels, averaging 33.41% and peaking at 52%. Variations in comfort across the area highlight the need for targeted interventions, such as implementing green roofs or strategic shading to improve thermal conditions. Research supports that urban greenery and reflective materials can enhance overall climate comfort (Khan et al., 2024; Mansouri et al., 2024).

CONCLUSIONS

This research underscores the critical importance of urban structure and form in enhancing climatic comfort within public spaces, particularly in Tehran's unique climate challenges. The findings demonstrate that strategic modifications to urban morphology—through geometric properties, density, and building orientation adjustments—can significantly mitigate thermal stress and improve overall environmental quality. By adopting a climate-based urban design approach, urban planners and designers can make informed decisions that leverage natural climatic advantages, ultimately leading to more comfortable and sustainable urban environments. The application of computational methods, particularly algorithmic programming and genetic algorithms, has proven to be a transformative tool in this study, facilitating the analysis of complex climatic and morphological data. These methodologies provide insights into the interactions between urban design parameters and climate comfort and establish a dynamic platform for future research. As highlighted, the ability to adapt this approach across various scales—from individual buildings to extensive urban developments—opens new avenues for integrating microclimate considerations into urban planning practices.

Moving forward, researchers and practitioners must explore the capabilities of genetic algorithms and other algorithmic tools to expand the scope of morphological and climatic variables. This will enhance the understanding of climate-responsive urban design, enabling the creation of public spaces that are not only aesthetically pleasing but also resilient and responsive to the needs of their inhabitants. By fostering collaboration across disciplines and embracing innovative technologies, urban designers can significantly contribute to developing sustainable cities, prioritizing ecological integrity and human comfort. In summary, this study lays a foundational framework for integrating urban design and climatic considerations, paving the way for future advancements in the field. Continued research is essential to refine these methodologies and their applications in diverse urban contexts, ultimately

leading to a more profound understanding of the interplay between urban morphology and climate comfort.

ABSTRACT

The strategic organization of public spaces in Transit-Oriented Development (TOD) areas is increasingly recognized as a crucial factor for enhancing urban vitality and optimizing space utilization. This study investigates the distribution and organizational characteristics of public spaces in TOD areas, focusing on 18 metro station precincts in Shanghai's central district. Through a quantitative analysis of key organizational indicators, the research examines three types of public spaces: plazas, green spaces, and pedestrian malls.To assess the relationship between these organizational features and public space vitality, activity surveys were conducted in 146 public spaces within the case study areas. Data on activity density were gathered through field observations and behavior mapping techniques. By analyzing both spatial layout and activity patterns, the study identifies distribution trends and evaluates the efficiency of various public space configurations.The results reveal critical spatial organization indicators for different types of public spaces, uncovering notable differences in the organizational requirements for plazas, green spaces, and pedestrian malls. Factors such as metro connectivity, walkability, and proximity to residential areas were found to significantly influence public space vitality.

Keywords: TOD area, public space, layout efficiency

INTRODUCTION

Metro station areas are not merely extensions of urban transportation infrastructure but essential hubs of public life, with public spaces playing a central role (Thammaruangsri, 2003; Bertolini, 1996). In recent years, global cities have increasingly acknowledged the symbiotic relationship between public spaces and transit nodes, recognizing their potential to enhance both urban vitality and transportation efficiency. In Transit-Oriented Development (TOD) areas, public spaces serve dual functions: efficiently managing passenger flows and creating venues for social interaction and leisure.

However, China's rapid urbanization has often prioritized high-density real estate development around transit stations, overlooking the holistic integration of public spaces (Yuan, 2015; Yang, 2023).

This imbalance has led to inefficient passenger dispersal and underutilization of spatial resources in metro station areas (Luo et al., 2024). Peter Calthorpe's introduction of the TOD model in the 1980s emphasized the organic integration of residential, commercial, office, and public spaces around transit nodes (Calthorpe, 1993). The model's concentric "commercial-office-residential" structure became widely accepted as a TOD blueprint. While this framework provides a general outline for public space distribution, it fails to distinguish between different types of public spaces and does not fully address the complexities of urban renewal in Chinese cities.

As China's major cities shift from rapid expansion to urban renewal, the improvement of existing built-up areas through transit infrastructure has become a key strategy. However, TOD theories grounded in Western urban expansion may not fully apply to the context of urban renewal in China's metro station areas.

This study seeks to conduct a quantitative analysis of the relationship between public spaces and the built environment in transit areas within Shanghai's central district, leveraging multi-source data. It examines the distribution characteristics of different public space types and assesses their vitality through behavioral mapping. Using quantitative modeling, the research identifies the impact and relative importance of various spatial layouts on public space vitality, offering recommendations to optimize public spaces in metro station areas.

RESEARCH DESIGN

Definition

Public spaces are typically defined as outdoor areas accessible to the public 24 hours a day, such as plazas and green spaces (Low, 2006). However, in many cases, public-private partnerships or privately developed open spaces also function as vital spaces for citizens' daily activities. For the purposes of this study, any space accessible without the need for specific identity verification is considered a public space. This definition primarily encompasses three types: plazas, green spaces, and commercial spaces.

In this paper, the term "metro station area" refers to the area influenced by a metro station. Defining the spatial scope of such an area involves determining the reasonable extent of its influence. Both domestic and international scholars generally consider an 8-10 minute walking distance to be the radiation range of a rail transit station. Calculating at a walking speed of 1-1.2 meters per second, the space influenced by a rail transit station is typically represented as a series of overlapping circular areas, each centered on a station entrance or exit with a radius of 500 meters (Pan et al., 2007).

The study of public space layout patterns mainly focuses on analyzing the relationship between the built environment of station areas and the organization of public spaces. Spatial vitality serves as an external indicator of how well public space resources are aligned with urban development needs. Previous research has shown that the topological characteristics of road networks at spatial nodes, as well as the accessibility of nearby retail facilities, are strongly correlated with spatial vitality (Peimani et al., 2020). For example, the ease of access to surrounding retail areas and enhanced motorized accessibility can attract more visitors to public spaces. In contrast, poor accessibility from residential areas, unfavorable road network structures, or proximity to major highways can hinder the vitality of these spaces.

Numerous studies have confirmed the relationship between public space organization patterns and spatial vitality from various perspectives. However, research specifically focusing on metro station areas remains relatively limited, and a deeper understanding of the relationship between public space organization and spatial vitality in these areas is needed. Additionally, there is a lack of comparative studies that assess how the same organizational indicators differentially impact the vitality of various types of public spaces. This gap underscores the need for further research in this area.Case Selection

Eighteen metro station areas were selected from Shanghai's central area(Figure 2), and 146 public spaces (51 plazas, 49 green spaces, and 46 commercial spaces) were screened as research subjects. The selection criteria for station areas were:1) well established built environment and mature urban development. All selected areas are located within Shanghai's Middle Ring Road, with long-established stations in well-developed urban districts. This criterion minimizes the impact of incomplete urban construction on public space vitality.2) High metro passenger flow and rich public activities. All selected stations have an average daily metro passenger flow of over 50,000, with most samples being hub areas where multiple metro lines intersect. This criterion reduces the impact of insufficient activity population density in station areas on public space vitality.3) Diverse urban function types. The selected station areas all include various urban functions such as commercial, office, and residential, avoiding the impact of insufficient urban functional mix on spatial vitality.

Additionally, public spaces with relatively enclosed boundaries or those requiring appointments for entry were excluded from the analysis to mitigate the influence of micro-environmental quality and space operation management on spatial vitality.

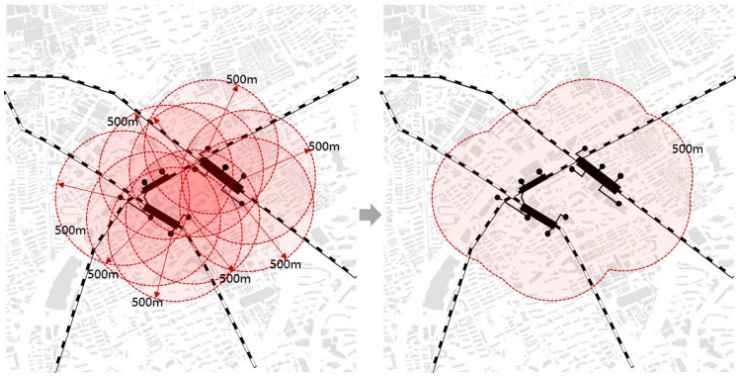

Figure 1. Definition of Metro Station Area

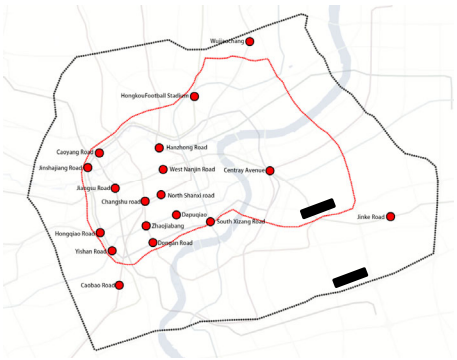

Figure 2. Case Study Selection

all figures in this paper are drawn by authors

Data Collection

Data collection was divided into two parts: public space layout and vitality. Public space layout data, were obtained through field surveys and mapping. This data was then integrated with open-source data from Gaode Maps(), including metro facility entrances and exits, building volumes, plot functions, and road networks, to establish a geographic information model of the metro station areas.

Spatial vitality data were collected by Public Space Public Life (PSPL) survey method proposed by Jan Gehl. Surveys were conducted for each public space on both a workday and a non-workday with

favourable weather conditions. Using the snapshot method and behaviour mapping, the number of people engaged in activities in public spaces was recorded across six time periods from 7 AM to 9 PM.

Layout And Vitality Indicators

This paper focuses on discussing the spatial organizational relationships between public spaces and transportation facility elements, street network elements, and functional area elements. ① Transportation facilities: The dense passenger flow brought by rail transit facilities is one of the main drivers of vitality in station areas. This study mainly focuses on the impact of the path distance from metro stations to public spaces (rail transit connectivity) on spatial vitality. ② Street network: The insertion of rail transit facilities affects regional walking and vehicular networks, often elevating the grade of motorways around stations. Public spaces located at network nodes with good connections to surrounding street segments (represented by betweenness) or easily accessible (represented by closeness) contribute to enhancing spatial vitality. This study primarily concerns the topological performance of walking and vehicular road networks at public space nodes and the grade of motorways. ③ Functional areas: Rail transit facilities often influence the distribution of urban functions in surrounding areas. Functional areas represent locations of different population attributes, such as commercial and leisure crowds, office workers, and community residents. Placing public spaces in locations easily accessible to potential activity groups can effectively enhance their spatial vitality. This study mainly discusses the proximity relationship between public spaces and surrounding urban functional areas.

Spatial vitality is often measured using activity intensity, activity diversity, and activity fluctuation amplitude. Previous studies have found that activity diversity is more influenced by the micro-environmental quality of public spaces, while the fluctuation amplitude indicator is mainly affected by the free time of the active population. Therefore, this study selects activity density (number of activities / public space area) as the quantitative indicator of vitality.

Table 1. Public space layout indicators.

Category	Indicator	Code	Formula	Description
Station	Proximity to Station	PtS	/	The route length between a public space and its nearest station entrance
Road Network	Pedestrian Network Closeness	PC	/	sDNA modelled the pedestrian network and measured MED500, BTE500,Div 500 values at R=500 for the street segment where the main entrance to the public space is located
	Pedestrian Network Betweenness	PB	/	
	Pedestrian Network Deviation	PD	/	
	Motorway Network Closeness	MC	/	sDNA modelled the motor way network and measured MED500, BTE500 values at R=500 for the street segment where the main entrance to the public space is located
	Motorway Network Betweenness	MB	/	
	Motorway Level	ML	/	The main entrance of the public space is adjacent to the motorway level
Urban Function	Proximity to Residential area	PtR	$\frac{\sum_{i=1}^{n} A_{ai} \cdot d(x,a_i}{\sum_{i=1}^{n} A_{ai}}$	Where Aa/Ab/Ac is the area of residential/office/commercial area, d(x,ai) d(x,bi) d(x,ci)is the distance from public space to residential/office/commercial area entrance
	Proximity to Office building	PtO	$\frac{\sum_{i=1}^{n} A_{bi} \cdot d(x,b_i}{\sum_{i=1}^{n} A_{bi}}$	
	Proximity to Shopping centre	PtC	$\frac{\sum_{i=1}^{n} A_{ci} \cdot d(x,c_i}{\sum_{i=1}^{n} A_{ci}}$	
Spatial Vitality	Activity Density	SV	$\frac{N_w+N_e}{2A_x}$	Where Nw and Ne is the number of activity people in weekday and weekend day, Ax is the behavior survey area of public space

Research Approach

This study includes three steps: basic data collection, spatial indicator quantification, and correlation mechanism analysis. 1) Identify public spaces within station areas, establish a sample database, and obtain spatial vitality data through field surveys and behavioral notation. 2) Integrate open-source map data and public space locations using GIS to build a geographic information model, and calculate spatial indicators through sDNA and network analysis tools. 3) Employ correlation analysis and regression models to explore the association mechanism between spatial layout and spatial vitality, determining core indicators and their impact weights.

ANALYSIS RESULTS

Public Space Layout Characteristics

To understand the coupling relationship between public spaces and the built environment around transit stations, we conducted a quantitative analysis of organizational indicators for public space samples and summarized their layout characteristics.

Plaza spaces are relatively evenly distributed, mostly concentrated within a 100-400 meter walking distance from subway stations. The average transit facility connectivity is 251.58. These nodes frequently intersect with surrounding pedestrian streets and vehicular roads, with average pedestrian betweenness and vehicular betweenness of 305.05 and 1369.32, respectively. They are closer to commercial areas and furthest from residential zones.

Green spaces are mainly distributed in the outer circle of the station area (average transit connectivity of 371.71), often located beside secondary and tertiary city roads, with the closest proximity to residential and office functions.

Commercial spaces are mostly situated around subway entrances, with an average transit connectivity of 101.44. However, their nodes intersect with surrounding streets the least, making pedestrian access difficult, and they are often located next to major city roads.

Table 2. Public space layout indicators.

Category	Indicator	Plaza	Green Space	Commercial Space
Station	PtS	251.58	371.71	101.44
Road Network	PC	329.7	331.98	398.31
	PB	305.05	246.51	201.24
	PD	1.38	1.41	1.54
	MC	1369.32	1369.97	1397.89
	MB	645.7	393.02	447.07
	ML	2.48	3.04	2.19
Urban Function	PtR	515.29	430.63	411.41
	PtO	367.89	637.54	204.07
	PtC	538.53	515.63	492.958

Key Indicator Selection

Core indicators for public space layout in station areas were identified through the analysis of the correlation between spatial vitality and public space organizational indicators. The analysis results

indicate that plazas with high vitality tend to be located near transit facilities and close to commercial areas, with good connectivity to pedestrian networks and minimal intersections with vehicular networks. Green spaces exhibit higher vitality when situated near residential areas and with few intersections with vehicular networks. Commercial spaces achieve optimal vitality when located close to transit facilities, with well-connected pedestrian networks, easy pedestrian access, and proximity to residential areas.

Table 3. Correlation between Public space layout and vitality.

DV / IV		Plaza Vitality	Green Space Vitality	Commercial Space Vitality
Station	PtS	-0.620**	0.232	-.417**
Road Network	PC	0.022	0.084	0.07
	PB	0.485**	-0.048	0.440**
	PD	-0.291	0.162	-0.284
	MC	0.17	-0.091	0.06
	MB	-0.376**	-0.281*	0.162
	ML	-0.016	-0.076	0.101
Urban Function	PtR	0.265	-0.321*	-.382**
	PtO	-0.521**	0.123	-0.16
	PtC	0.217	-0.141	0.099

**At the 0.01 level (two-tailed), the correlation is significant. *At the 0.05 level (two-tailed), the correlation is significant.

Correlation Mechanisms Between Public Space Layout and Vitality

Correlation analysis found that the vitality of plaza, green space and commercial space was significantly correlated with several spatial organization indicators. Therefore, multiple regression models of three types of public space were constructed with key organizational characteristics indicators as independent variables, station area energy level indicators as control variables, and spatial vitality as dependent variables.

The results of the fitting model reflect the different effects of different organizational indicators on vitality in the same public space. In the plaza model, the impact degree of each organizational indicator is ranked as: PtS > PB > MB> PtC, which indicates that the activity density of plaza space is mainly promoted by the pedestrian potential and the accessibility of rail transit facilities, and inhibited by the vehicle potential. In the green space model, the order of spatial organization index is as follows: PtR > MB, and the influence degree of the two is similar. In the commercial space, the degree of impact of each spatial organization indicator is sorted as follows: PB> PtS > PtR, indicating that the vitality of commercial space in the case station area is most affected by its relationship with the pedestrian network organization, and the relatively weak impact of rail connection degree may be due to the fact that commercial space in the selected station area is mainly clustered within 150 meters around the station area. There is little difference in the index of rail intersection degree.

The results also show that there are significant differences in the influence of different accessibility indicators on the vitality of public space, and the control variables have a positive impact on the vitality of three types of space. First of all, the degree of rail connectivity has a significant impact on the vitality of plaza and commercial space, and the good connection with rail transportation facilities plays a role in promoting the vitality of plaza and commercial space, with the degree of impact ranking as follows: plaza > commercial space. The topology performance of the pedestrian network at the node where the space is located is closely related to the vitality of the plaza and commercial space. The plaza is mainly affected by the walking intermediateness, while the commercial space is comprehensively

affected by the walking proximity and intermediateness. In terms of spatial and vehicular network organization relationship, high vehicular intermediateness inhibited the vitality of plaza and green space, and the inhibition degree was similar. In terms of functional area proximity, the proximity of residential area has a positive effect on the vitality of commercial and green space. The detailed analysis is as follows.

1) Public Space and Proximity to Metro Station

The correlation analysis and regression fitting model reveal a significant relationship between transit connectivity and the vitality of plazas and commercial spaces, while there is no clear correlation between green space vitality and transit connectivity. Proper planning and organization of the connection between public spaces and transit facilities can effectively enhance the vitality of public spaces in station areas.

Firstly, plazas with high vitality are often located within a 250-meter walking distance from transit stations. Plazas located beyond 250 meters exhibit vitality below the average (Figure 12). Plazas serve as transitional spaces between transportation facilities and the urban environment, helping to manage high-density passenger flows, improving public transportation efficiency, and providing waiting and resting areas for transit passengers, thus enhancing the service level of the public transportation system.

Secondly, although there is no statistical correlation between green space vitality and transit connectivity, only 37% of green spaces within 100 meters of subway stations have vitality above the average. Green space boundaries are often defined by vegetation and trees, with strongly defined internal paths that limit free passage for transit passengers, reducing the appeal of green spaces. Additionally, placing overly large green spaces around transit entrances can increase the distance for transit passengers to access other urban facilities, leading to detours. It is recommended that green spaces be located on the periphery of transit stations, while the core areas around stations should have green spaces with carefully designed environments to meet the needs of transit users for travel and gathering.

Lastly, 90% of commercial spaces located more than 150 meters from the subway have vitality below the average (Figure 14). It is recommended that commercial spaces be closely connected to transit facilities. The shopping, dining, and leisure services they provide can meet the needs of transit passengers during their journeys.

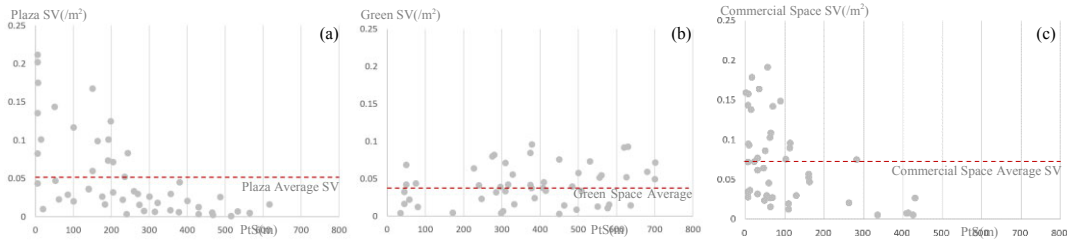

Figure 3. Relation between *Public Space Vitality and Proximity to Metro Station:(a)plaza SV and PtS (b)Green space SV and PtS (c) Commercial space SV and PtS*

2) Public Spaces and Road Network

The interaction between public spaces and the pedestrian street network significantly promotes the vitality of various spaces. Pedestrian betweenness measures the degree of connectivity between public space nodes and surrounding streets, and this indicator has a significant impact on the vitality of plazas and commercial spaces.

Firstly, pedestrian betweenness enhances the vitality of plazas, with only 5% of plazas having a vitality above the average when pedestrian betweenness is below 300 (Figure 15). Plazas generally have weak boundaries, a low sense of territory, and good permeability and inclusiveness. Therefore, placing them at nodes with high pedestrian betweenness can enhance their vitality.

Secondly, the results of multiple regression analysis indicate that pedestrian betweenness is the dominant factor influencing the vitality of commercial spaces. Among commercial spaces with a pedestrian betweenness higher than 250, 57% exhibit high vitality, compared to only 28% of samples with a pedestrian betweenness lower than 250 (Figure 16). Additionally, compared to green spaces and plazas, commercial spaces have the weakest connection with pedestrian streets, often resulting in an "island effect." Thus, integrating commercial spaces with the pedestrian network is a key strategy for further enhancing their vitality.

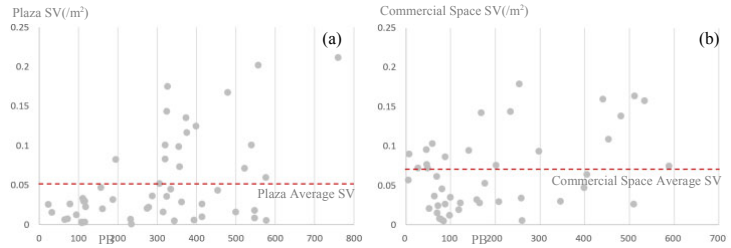

Figure 4. Relation between *Public Space Vitality and Pedestrian network betweenness:(a)plaza SV and PB (b)Commercial space SV and PB*

The organization of public spaces and motorway networks also affects spatial vitality, primarily through its negative impact on the vitality of plazas and green spaces. Excessive connectivity between public space nodes and vehicular networks can reduce pedestrians' sense of security. Dense traffic also brings noise pollution and air pollution, with these factors collectively contributing to the negative impact of vehicular betweenness on public space vitality.

Although the boundaries of green spaces often include vegetation as a buffer, this is insufficient to fully mitigate the negative effects of high vehicular betweenness.

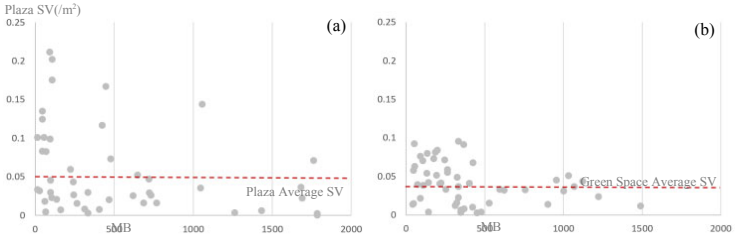

Figure 5. Relation between *Public Space Vitality and motorway network betweenness:(a)plaza SV and PB (b)Commercial space SV and PB*

3) Public Spaces and Urban Functions

Strategically integrating public spaces with various urban functional areas can effectively enhance their spatial vitality. The proximity to commercial areas has a significant positive impact on plaza activity density. When plazas are integrated with commercial areas, commercial facilities infuse plazas with a vibrant commercial atmosphere, attracting more activities. The open nature of plaza spaces showcases the vitality of commercial facilities to the city, further attracting surrounding crowds and creating a mutually reinforcing effect.

Additionally, the proximity to residential areas significantly enhances the vitality of green spaces, indicating that the primary users of green spaces are nearby residents. Therefore, the spatial organization relationship with residential areas is the foremost consideration for the layout of green spaces.

Besides green spaces, the vitality of commercial spaces is also related to their proximity to residential areas. This indicates that the activity in commercial public spaces near transit stations includes not only the passenger flow brought by transit facilities but also the population from nearby residential areas. Easy access from surrounding residential areas can enhance the overall service efficiency of commercial public spaces, helping to establish the transit station area as a center of vitality.

It is recommended to integrate plazas with commercial spaces and green spaces with residential areas while considering the proximity of commercial spaces to residential areas as needed.

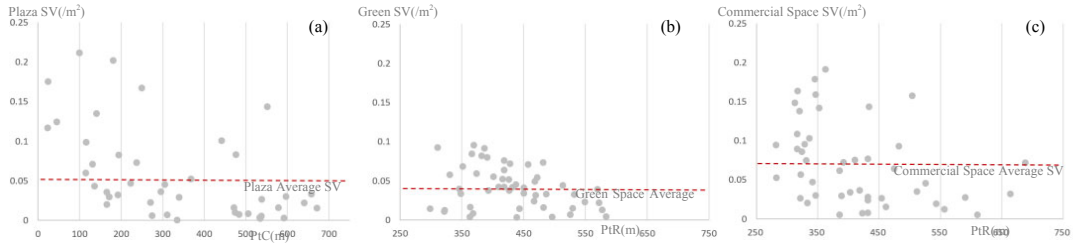

Figure 5. Relation between *Public Space Vitality and proximity to urban function:(a)plaza SV and PtC (b) green SV and PtR (b)Commercial space SV and PtR*

CONCLUSIONS AND DISCUSSION

This study explores the organizational patterns of plazas, green spaces, and commercial spaces around transit station areas in the central city of Shanghai and their impact on spatial vitality. The results indicate significant differences in location requirements for different types of public spaces, leading to the following optimization recommendations:

Rationalize the Spatial Relationship between Public Spaces and Transit Facilities: It is recommended to place plaza and commercial spaces at nodes closely connected to transit facilities to meet the needs of transit passengers for rest, passage, shopping, and entertainment.

Enhance the Interaction between Public Spaces and Pedestrian Networks: Ensure that the nodes where plazas and commercial spaces are located have good connectivity with surrounding pedestrian street segments, thereby increasing the likelihood of spatial activities. Avoid placing green spaces and

plazas at nodes with high vehicular traffic to reduce the negative impact of dense traffic on the vitality of public spaces.

Coordinate Accessibility between Public Spaces and Urban Functions: Integrate Plaza spaces with commercial buildings, ensuring high accessibility of green spaces to residential areas to promote spatial vitality. While maintaining good connectivity between commercial spaces and transit stations, it is suggested that they be positioned where they are easily accessible on foot from surrounding residential areas.

Although this study has identified the differential impact of organizational characteristics of plazas, green spaces, and commercial spaces within transit station areas on their vitality, it is necessary to expand the number of case samples. This expansion would allow for more precise quantitative methods to explore the suitable value ranges of indicators for different organizational patterns. Additionally, spatial vitality is influenced by multi-scale and multi-level environmental factors. Beyond the meso-level organizational patterns, the effects of micro-level environmental quality factors such as site scale and activity facilities on spatial vitality should also be examined in further research.

The heritage research on Macao's pier buildings from the perspective of morphological typology

Kaiwei Li[1]
[1] Kaiwei Li (Architecture, Faculty of Humanities and Arts, Macao University of Science and Technology), China, kaiweivivi@163.com

ABSTRACT

As an important support for the economy and livelihood of the island, Macao's inner harbour have an extremely close interaction with the development of the city, and along with the booming international trade, Macao's inner harbour has become the earliest space for exchanges between Chinese and Western cultures. However, with the rapid development of the economy and the structural changes of the city, the number of piers in the inner harbour is now declining, and the gradual unification of functions and the fact that some of the pier buildings are in an unused state make the style and function of the Macao inner harbour pier buildings clearly reflect the trend of disjointedness and exhaustion in the process of urban development. By using maps, old photos and other facts as the objective data, this paper takes the 35 existing pier buildings along the west coast of Macao Island as the research target, integrating the perspectives of history, architecture, human geography and sociology, and trying to sort out the important time points of the inner harbour piers at different stages of development, as well as their relationship with Macao's urban development, such as economy, trade, society and people's livelihood. This paper successfully analyses and summarises the physical conditions of the inner harbour pier buildings, such as their forms, characteristics and materials, and categorises them according to their relationships, with a view to adding a more detailed and systematic theoretical basis for the revitalisation and regeneration of Macao's inner harbour city.

Keywords: Macao, inner harbour, pier buildings, values, morphological typology.

INTRODUCTION

In the early sixteenth century, with the development of ocean voyages and the intermingling of different industries, the Portuguese embarked on a voyage to the Orient. Due to its favourable geographical location, climate, hydrology and sea and land transport conditions, Macao became the first window for trade, ethnic and cultural exchanges between the East and the West during the Ming Dynasty (Jie, 1961).Gradually, Macao has evolved into a cosmopolitan city, however, as in many international high-density cities (Wang et al., 2019), the contradiction between economic development and cultural heritage has slowly emerged with the rapid development of the society. Due to the existing rapid urban construction and the single rise of the tertiary industry, the architectural styles, cultural landscape systems, and historical view corridors of Macao's historic

districts, which were originally part of the early city's development process, are showing a tendency to become disjointed and depleted. Macao's inner harbour is included in this trend of depletion (Zheng et al., 2018).

Since the Ming and Qing dynasties, studies on Macao have begun to deal with the inner harbour of Macao (Jie, 1961; Shi, 1995; Long, 1997; Yan, 2006), and the number of these studies has been increasing over time. In addition to categorising Macao's inner harbour as a single study of Macao's urban history, these studies have also explored Macao more comprehensively through aspects and perspectives of political history, economic history, intellectual history, archaeological history, geopolitics, as well as the relationship between Hong Kong and modern China (Wu, 1998; Ye, 2013; Shi, 2019).

However, in the so-called 'Macao in a Global Perspective', there is no systematic analysis of the architecture of Macao's inner harbour from an architectural point of view, and little focus is placed on the pier buildings of Macao's inner harbour itself, and there is still a lack of systematic research on the evolution of its architecture and built environment.

METHOD

The research scope of this thesis mainly focuses on the inner harbour buildings (Figure 1), and the spatial scope is defined as the 35 waterfront buildings of the piers, including Pier No. 1 to No. 33 (Figure 2). It is mainly based on the latest information of the piers published in the Macao Online Map of the Macao SAR Mapping and Cadastral Bureau, combined with the Inner Harbour Reorganisation Plan of Macao Instruction no. 218/90/M, the Coastal Map of the Macao SAR approved by the Chief Executive no. 184/2018, the Macao Peninsula CAD map of 2010, and the field surveys.

Figure 2. Map of the current status of the 35 piers, photo credit: Author's own drawings.

As a new try, it is highly recommend to combine several research methods together, including online and offline research, to comprehensively integrate scattered information and make up the research gap in this area.

Firstly, the article adopts the document analysis method. By combing through the current relevant ancient books, public opinion maps and old photographs and paintings circulating in the community about the inner harbour. Due to the special historical reasons of Macao, some of the early historical materials are in Portuguese or mixed Chinese-Portuguese documents that need to be screened and organised. Secondly, the documents and periodicals and newspapers in Macao Archives, Macao Museum, Maritime Museum and other related units were searched and collected, as well as information from Macao Yearbook, Chronology of Macao, Macao Economic Yearbook, Chinese Commercial News, so as to comprehensively obtain information about the inner harbour.

Secondly, this paper adopts the field research method. From the perspective of architecture, we understand, confirm and record the pier building types and characteristics, topography, landscape and ecology as well as the usage conditions, and analyse and summarise the characteristics of the pier buildings in terms of building types and style characteristics. At the same time, according to the needs, we visited relevant libraries, archives, museums and planning museums to collect data and enrich the research content of human geography of piers.

Thirdly, comparative interpretation method is also used. Based on the comparative study between the current situation of the pier buildings and the early pier design plans, the veins, symbols and elements of the pier buildings in the early planning and construction are sorted out, and the inner harbour piers are placed under the dual vision of ‘time-space’, so as to deepen the interpretation of their cultural connotations and historical characteristics.

Lastly, the use of morphological typology plays an important role. To provide a theoretical basis and design entry point for specific planning and architectural design work. In the actual operation process, in the face of the aspirations and contradictions of different subjects, the design strategy based on Morphological Typology will also provide reasonable suggestions for the policy formulation and working mechanism for the protection and regeneration of historical lots. Morphological type interpretation is a comprehensive presentation of historical data and on-site research results. Through the process of morphological evolution and the classification of building and component types, it interprets and presents the Macao inner harbour from different levels. The study will provide a typological interpretation of the history and status quo of the pier architecture at different levels, as well as an analysis of the causes of the evolution, and will start to recognise and interpret the pier architecture from two aspects, namely, the evolution of the physical and spatial morphology, and the changes in the mode of production and life brought about by the changes in the socio-political and cultural environments.

Combining these four research methods together provides a comprehensive way to take a close look at the changes and current situation of Macao’s pier buildings, which can work as a useful tool for further researches related to this area.

RESULTS AND DISCUSSIONS

The formation and development of Macao's inner harbour

As the location where the Portuguese first landed in Macao, the inner harbor area has witnessed the rise and fall of the city and is a microcosm as well. Pier buildings have been constantly changing along with the changes of Macao's inner harbor, so sorting out the historical changes of Macao's inner harbor is a necessary prerequisite for analyzing pier buildings.

The initial development of Macao's inner harbour mainly began during the mid-Ming Dynasty (Deng and Huang, 1991), with the exact date dating back to 1557 to 1840 (Zheng, 2017). With the development of social productivity at that time, China gradually began to possess an objective demand for a commodity money economy. From the earliest plan of Macao found by the author, at the beginning of the opening of the port of Macao, the Portuguese focused on the construction of houses, Macao's inner harbour was only used as a docking area for ships and an auxiliary area for disembarkation. For this reason, at this stage of the Macao inner harbour coast presented the irregular shape, is its most primitive state(Figure 3).

Figure 4. Reclamation of the inner harbour of Macao from 1831 to 1889, photo credit: Das cabanas de palha as torres de betão：assim cresceu Macao (first from left) and Macao Archives (seco-nd from left and first from right).

In the context of the Portuguese monopoly of trade and the "one-lipped" trade, the Macao inner harbour gradually took shape as a result of the monopoly of trade, which led to the frequent landing and disembarkation of merchant ships and fishing boats. The Macao inner harbour Pier in its infancy was relatively simple in form, with no specific harbour buildings, only stone steps and a wooden plank pier made of wooden piles, with extremely rudimentary facilities. According to historical records, this part of the pier should belong to the original style of the pier in Macao.

After the Second Opium War, the port of Macao was marginalised by the natural harbour of Hong Kong. The Portuguese and Macao governments, through a number of policies and projects, made it possible for complete architectural entities and construction systems to emerge in the inner harbour, and the pallet-type piers were gradually abandoned. The reclamation and expansion of the inner harbour and the prototype construction of the Macao inner harbour pier were thus initiated (Figure 4). This stage proved that the Portuguese and the government of Portuguese Macao began to pay attention to the development of the inner harbour of Macao, and carried out the construction of facilities and repair of venues. The construction of the inner harbour was based on the expansion of the inner harbour form. Afterwards, the inner harbour shoreline was extended again and the location of the inner harbour was shifted westwards. However, the inner harbour in the formative period had

not yet formed a complete construction engineering system and specific building entities, and were still mainly in the form of pontoon pallet bridge piers, and the waterways were not yet able to adapt to the needs of modern large-scale ship transport.

In 1912, Macao started to reclaim the sea again, and by 1935, the reclamation and expansion of the inner harbour had completed the shape of the two ends of the inner harbour moving closer to the middle (with the emergence of Rua do Almirante Sérgio), and the planning of the new harbour had already taken shape. The widening of the inner harbour streets created favourable conditions for the planning of piers, and the construction of specialised piers also took shape and scale during this period (Figure 5).

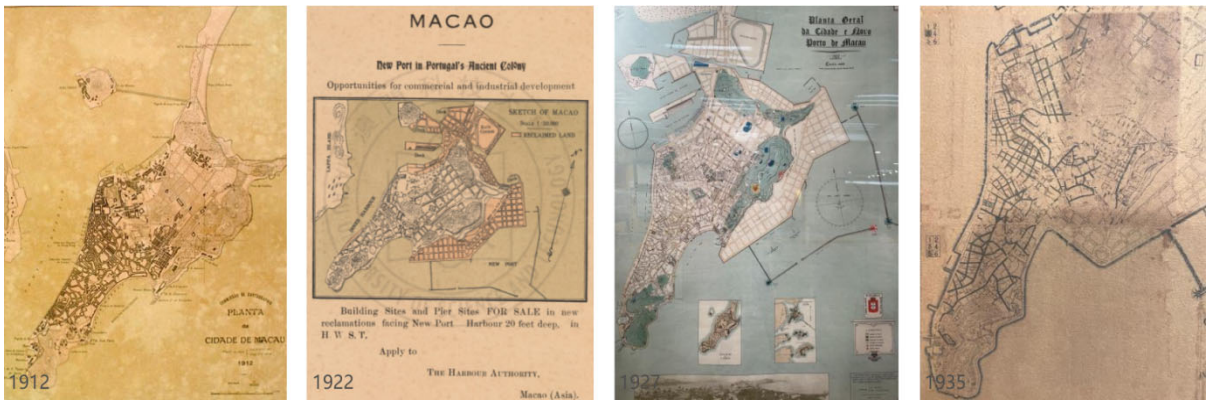

Figure 5. The Evolution of Macao's Planar Map, 1912-1945, photo credit: Macao University of Science and Technology.

Around 1940, the volume and scale of professional pier construction in the inner harbour began to be determined and the first round of construction peak began. Therefore, around 1940, the professionalisation of pier construction in the inner harbour began to take shape and scale, and the first round of construction peaked, and the modernisation of pier construction began. The reconstruction, new construction and restoration of pier buildings during this period almost laid the material foundation for the development of the inner harbour area and even the entire Macao port economy in the next few decades.

Later, due to the United Nations General Assembly Resolution 500 in 1951, which imposed a total embargo on China, Macao became the only window for China to break the embargo. The development of Macao's inner harbour once again reached a climax, which was also a special background for the prosperous phase of the inner harbour. The emergence of the demand and the gradual development of the industry put forward higher requirements for transport, which led the Macao-Portuguese government to promulgate a number of policies in order to comprehensively improve the status quo of the inner harbour. The complementary relationship between the inner harbour and the new area's transport facilities is gradually being highlighted. The inner harbour is now enjoying a period of prosperity (Figures 7).

Figure 7. Macao inner harbour port in 1932 (left) and 1950 (right), photo credit: Macao Guide.

With the transformation of traditional industries into manufacturing, the economic model of Macao, which was based on fishing and traditional handicrafts, gradually collapsed in the late 1960s. In the face of the ever-increasing number of people and goods, and under the challenge of the new trade situation, the inner harbour of Macao has become tired, which has put forward higher functional requirements for the construction of the inner harbour pier buildings. The pier buildings constructed in the middle of the formation of the inner harbour were mainly made of wood and concrete structures. The platform of the pier was basically made of wood. Due to the corrosion of the sea winds and the long time of construction, it has become dilapidated in many places and is unable to cope with the rapid increase in the volume of freight transport and the loading and unloading of containers. At the same time, there is a lot of unused space between the old wharves, mostly used by boats and sampans as berthing places, resulting in a waste of land use, the early old wharves are in urgent need of improvement.

As time passes by, the inner harbour area has been in decline since the late 1980s because of both external and internal reasons. Externally, Hong Kong's advantages of being a deep-water port and a free port have tempted businessmen to leave Macao and move to Hong Kong. Internally, the Macao-Portuguese government started to plan the construction of the outer harbour and the port of Kau O in 1989, and the functions of the inner harbour pier buildings were subsequently shared, which to a certain extent also diverted passengers and port cargo from the inner harbour area. In addition, as the processing and manufacturing industries moved to the Pearl River Delta during the same period of time, the industries in the inner harbour area shrank, and the inner harbour area lost its original commercial core function in the new round of economic restructuring, and was reduced to a marginalised old area in the industrial relocation and spatial competition.

At the same time, as the inner harbour is located at the mouth of the Pearl River, the river channel has been seriously silted up and is getting narrower, making it impossible for the inner harbour to accept ships with deep draught and large carrying capacity, and reducing the significance of shipping. What's more, the elevated water level of the inner harbour, coupled with the support of the astronomical tidal wave, makes it impossible for the accumulated water on the surface to be discharged through the city's drainage system in the case of extreme weather conditions such as rainstorms or typhoons, thus resulting in flooding, which has an adverse impact on the business environment. As a result of the above factors, the inner harbour area is in a state of decline.

Formal analysis of Macao inner harbour pier buildings

Form analysis

Due to the construction time, material characteristics, functional requirements and different design ideas of the designers, the architectural styles of the Macao inner harbour buildings are different from each other, and the most intuitive feeling of the architectural style is the façade of the pier buildings. The most intuitive feeling of the architectural style is the façade of the pier buildings. There are two more important periods in distinguishing the façade of the pier.

The first is the period between the 1930s and the 1950s, when the Macao government realised that the pier could be leased out for huge profits after refurbishment, and therefore undertook a large-scale renovation and reconstruction of the pier. The designers, led by João Canavarro Nolasco, used different colours of paint, geometries and lines to decorate the façades in a clear Art Deco style. The appearance and massing of these buildings are adapted to the function of the building. In addition, the piers constructed in this period also paid great attention to the design of the symmetrical composition of the doorways and the daughter walls, which are highly symbolic, characteristic and recognisable, and at the same time have a distinctive private design style. Today there are ten pier buildings of this style: Nos. 5, 8, 11, 16, 23, 25, 26, 29, 30 and 31.

However, almost half of the piers restored, rebuilt or newly constructed in the first period were wooden piers, which were susceptible to natural erosion. Therefore, in the second period (from the 1980s to the end of the 20th century), the government started the inner harbour Restructuring Programme, which led to the reconstruction of many piers. At this time, the Portuguese and Australian governments required the reconstructed piers to be uniformly 4-storey, and there were strict regulations on the total height and the height of each storey. As a result, the construction of inner harbour piers became uniform during this period. At this time, the pier building to get rid of the door as the centre, the sense of line as the decoration of the symmetrical composition of the facade, mainly to the column network, the horizontal and vertical wall surface for simple art treatment. The reconstructed piers are all modernist style pier buildings with only minor differences in the colour of the facade and the arrangement of the windows and doors. There are 22 existing buildings in this style: No. 5A, No. 5B2, No. 5C, No. 6, No. 6A, No. 6A2, No. 6B, No. 6C, No. 7, No. 7A, No. 9, No. 10, No. 11A, No. 12, No. 14, No. 21, No. 22, No. 22A, No. 27, No. 28, No. 31A, No. 33. The use of paint or tiles, aluminium windows and simple façade decoration are the characteristic language of the style.

In addition, there are only two other Portuguese eclectic style pier buildings, No. 1 (Cultural Building of Immovable Property of Macao) and No. 20 (Former Marine Police Inspectorate). The top of the main façade is decorated with the Portuguese coat of arms, lattice fencing and architectural decorative symbols such as the Portuguese Caravelle cross of the Age of Sail. In addition, the mixture of different styles mentioned above is also one of the characteristics of the buildings of the inner harbour.

The Macao inner harbour pier building is a combination of public and private property rights, which imposes certain restrictions on its use and repair. The last major renovation of the inner harbour buildings in Macao was organised in the 1980s under the Inner Harbour Reorganisation Plan, which imposed strict controls on the construction of the buildings. Since then, the 34 buildings along the inner harbour have complied with the four-storey maximum (with a few owners illegally adding up to five storeys), namely Nos. 5B2-7, 9, 10, 12, 14, 21-22A, 27, 28, 31A, 33, a total of 20 buildings. The

buildings have different functions, but they are all in the form of a regular cube and in the style of a clean and modernist style, with only some differences in the colours and decorative lines of the façade.

Compared with the pier buildings around the 1950s, the existence of different batches of piers can be distinguished very clearly. In the past, the wharves were much smaller and lighter in form, with no more than two floors, and were mainly used for loading and unloading of cargo ships and small boats. And from the facade will be more complicated, complex, varied graphics and façade decoration, rich in obvious identity and the designer's personal style.

Material analysis

The study of the basic materials of inner harbour piers focuses mainly on the finishing materials of the building's exterior, which are summarised and categorised into three main types: paints, mosaic tiles, and brushed stone (Figure 8). Firstly, the piers constructed around the 1950s were mostly made of paints. As the piers were located along the long coastline, the colours of the paints were more vibrant, mainly yellow and white, for easy identification and differentiation. However, due to the pier's coastal location, the objective factors of sea breeze erosion, water wash and sun exposure made it clear in the field study that the colours of the painted pier buildings that had not been refurbished were slightly grey and not as good as they had been in the past. In contrast, brushed stone materials with weather resistance and durability were used depending on the location of the piers. Piers 8, 11, and 31, for example, use brushed stone as a finishing material, and the surface of the brushed stone usually has a stone-like texture, giving a natural, rough feeling. This material creates a rustic and natural feeling, which makes the appearance of the building at the beginning of the construction is basically the same as that of today's survey.

In the piers built in the 1980s, mosaic tiles were used in most of the piers to achieve a colourful effect through the patchwork of colours, and because of the glazed colour of the tiles, they were brightly coloured and of a high specification, and were not easily eroded by sea winds. It is generally used by owners with better financial means and under the guidance of the government.

Figure 8. Elevation facing tiles (first from left, Pier 31A), coating practice (second from left, Pier 16), water-brushed stone practice first from right, Pier 25), photo credit: Author's own drawings.

Type analysis

From the pier platform characteristics (Table1), pier buildings have 6 wooden pier (Table 2), reinforced concrete pier platform 27, no specific pier platform form 1 (Pier 20). From the classification of the number of floors (Table 3), low-storey that is, the ground floor to two-storey pier building 13, basically built in the 1950s; multi-storey that is, three to five-storey (five-storey that is, four-storey + rooftop

illegal additions) 21, basically constructed in the 1980s of the twentieth century. After the formation of the inner harbour, Macao has only carried out two large-scale renovation plans for the inner harbour pier building. The first one was in the 1930s-50s of the 20th century, and the piers constructed at this stage generally had two storeys; the second one was in the 1980s of the 20th century, and the Macao-Portuguese government had a clear height restriction of 15 metres and a four-storey requirement for the pier buildings constructed at this time. Thirdly, in terms of building structure, there are 26 reinforced concrete structures and 8 brick structures (Table 4).

Overall, the styles of pier buildings showed a large time span in terms of platform features, number of storeys, scale and building structure. This co-existence of old and new pier buildings is the result and testimony of the needs of the times, and brings a valuable and diverse visual sense to the inner harbour shoreline.

Table 1. Classification of Pier Platforms.

Classification.	**Pier Number**
Wooden Pier	23、25、26、29、30、31
Reinforced concrete piers	1、5A、5、5B2、5C、6、6A、6A2、6B、6C、7、7A、8、9、10、11、11A、12、14、16、21、22、22A、27、28、31A、33

Table 2. Classification of Timber Pier Platforms.

Pier Number	**Construction Time**	**Redevelopment Time**	**Construction**	**Remarks**
23	1948	-	Reservation	Retention of wooden platforms
25	1942	-	Reservation	Retention of wooden platforms
26	1939	-	Reservation	Retention of wooden platforms
29	1949	-	Reservation	Retention of wooden platforms
30	1948	-	Reservation	Retention of wooden platforms
31	1940	-	Remould	Compared with the original design, the later phase of the renovation is bigger. However, the wooden platform is still retained.

Table 3. Breakdown of Pier Levels.

Classification.	**Pier Number**
Two-storey pier buildings and below (i.e. ground floor to first floor)	1、5A、5、11、16、20、23、25、26、29、30、31、33
Pier buildings above two storeys (i.e. three to five storeys)	5B2、5C、6、6A、6A2、6B、6C、7、7A、8、9、10、11A、12、14、21、22、22A、27、28、31A

Table 4. Classification of Pier Building Structures.

Classification.	**Pier Number**
Reinforced concrete structures	1、5A、5B2、5C、6、6A、6A2、6B、6C、7、7A、8、9、10、11、11A、12、14、16、21、22、22A、27、28、31A、33
Brick and mortar construction	5、20、23、25、26、29、30、31

From the on-site comparison, the author summarises, classifies, compares and concludes the current status of the buildings of the inner harbour in terms of their form, material and type. It can be found that although both were initiated by the government, there are two distinct periods.

They are the 30s-50s of the 20th century and the 80s of the 20th century for the reconstruction of the pier buildings in Macao. In the 30s-50s of the 20th century, due to the existence of the demand and profit, the pier buildings went from the simple forms of 'Shun Shui type' and 'Pallet type/pontoon type' to the simple forms of the pier buildings and the pontoon type. Demand and profit led to a shift from the simple form of 'down the bank' and 'palisade/pontoon' to the combination of pier and platform, with the two-storey symmetrical composition as the basis and the timber pier being the usual handiwork of João Canavarro Nolasco, the designer at the time. Combining the popular Art Deco style, Portuguese colonial colours, and the technology of the time, the decoration of different colours, geometries, and lines focuses on the design of the doorway and the nursery wall, which is highly symbolic and recognisable, and also has a distinctive private design style. However, due to the lack of weather resistance (e.g. paint and wooden platforms), some of the piers have become dilapidated.

In the 1980s, Macao organised the last major renovation of the inner harbour buildings, which on the one hand was a purely maintenance and management exercise, and on the other hand was an attempt to revitalise the Macao inner harbour. This phase of the renovation of the Macao inner harbour was subject to very strict regulations and controls, and combined with a modernist style, the four-storey concrete buildings with a total height of 15 metres were erected along the coast of the Macao Peninsula in the form of a very solid architectural 'box', with the only difference coming from their external colours and decorative lines. Although practicality (glass windows and mosaic tiles) was the first consideration in this phase of pier building, and the climatic characteristics were taken into account, the degree of match between aesthetics, style and functionality was not as good as it was in the 1930s-50s of the 20th century. Fortunately, in the 1980s, as the original pier owners had to invest in the reconstruction of the inner harbour piers, the Government granted land to the pier owners for the construction of standardised superstructures on the extension lots. However, due to the different interests of some pier owners, not all of them were able to do so. Therefore, judging from the present situation, most of the pier buildings are from the 1940s to 1950s.

The majority of the pier buildings are the early pier buildings constructed in the 1940s and 1950s and the modern new pier buildings rebuilt in the 1980s. They are arranged high and low along the waterfront from Avenida da Misericordiau de Sinares in Fa Wong Parish to Avenida do Lagoa do Sai Van in Fung Shun Parish on the Macao Peninsula, constituting the architectural landscape of the inner harbour piers nowadays.

Current use and protection of Macao's inner harbour pier buildings

After witnessing the prosperity of Macao's inner harbour area, these pier buildings gradually fade away from people's memory, which means that the current use and protection of these pier buildings are not that ideal.

The pier buildings that are still in operation mainly concentrates on the first half of the extension of the pier building from the A-Ma Temple to the north, and most of them were built in 1980s with

modern equipment. According to the field research, it is found that some of the pier buildings are not being used. However, others are in good use. Eight of the pier buildings in the Inner Harbour area are still used for fisheries (fish ponds or fish products), 12 are used for various commercial trading companies, and two are used as passenger harbour, partially for catering and warehouses, etc. The section encompassing this area is also one of the largest in Macao. The road it encompasses is also one of the busiest and most congested roads in Macao, from which many seafood products and daily necessities are wholesaled to the various markets in Macao, and the basic internal demand in Macao makes the use of the pier continue steadily but not as much as in the past.

In terms of conservation, the second half of the Macao inner harbour pier extends in the direction of the Saritou Market and the ground in front of the Land Temple to the south. The pier buildings are basically those constructed in the 1940s, and are the most poorly protected and visibly damaged part of the pier; the gradual idling of the pier at the end of the 20th century has left the pier space unmaintained and unrepaired, and this portion of the pier was mainly rented out to small shipping companies in the past. For this iron door and east-west ventilation makes the building facade skin erosion due to sea winds, coupled with the age of repair, the colour block peeling obviously, the wall in many places cracking, corrosion, mouldy, the internal structure of the part of the exposed, increasing the building safety hazards. And this part of the pier is mostly wooden platforms, and there is no weather-resistant nature of the existence.

CONCLUSIONS

This thesis is based on the Macao government's intention to renovate and revitalise the inner harbour area and the gap in the development research on the history of the inner harbour pier buildings. Firstly, a morphological typology is used to sort out and analyse the timeline of the development of the inner harbour pier buildings, assisted by the objective morphology of the relevant maps. The study aims to identify and summarise the historical causes and influences on the development of the inner harbour pier buildings in different periods (four major stages: the Macao inner harbour before its formation, the reclamation and expansion of the inner harbour, and the construction and development of the inner harbour piers), and to judge their overall orientation on the development of the piers. Secondly, field research on the inner harbour pier buildings was conducted from the perspective of preserving the existing inner harbour pier architecture. The architectural form, material and type that appeared in different periods were categorised and summarised to arrive at two main periods of pier construction and restoration (1930s-1950s and 1980s).

The causes, influences and time phases of these changes in building forms are explored through a combination of both of the above (representation of the current situation and narration of historical information). This will not only provide some theoretical support for the subsequent revival of inner harbour piers, but also provide insights into the academic and regional values of such buildings.

As for the limitations of this research, firstly, the historical value of Macao's inner harbour is not only limited to the pier buildings themselves, but also the ancillary buildings (such as warehouses) that complement the pier buildings should be discussed together in order to understand Macao's inner harbour in a more comprehensive manner. Secondly, the internal spatial arrangement of the pier buildings is a mapping of the functions and needs of the inner harbour buildings in different periods. If further consideration is given, the study of the inner harbour can be more in-depth.

ABSTRACT

Many European neighbourhoods particularly in Sweden were designed specifically for individual mobility and today are dominated by private cars and excessive automobile travel. In many new Chinese neighbourhoods, there is rapid motorisation and increase in car traffic followed by major investments in road infrastructure that results in wide road that create fragmentation and often make it very difficult for pedestrians to move along. This paper compares the neighbourhoods in Stockholm and Shanghai as typologies to discuss morphologically informed international urban design guidelines for Transit-Oriented Development (TOD) with mobility hubs. TOD is a development alternative to urban sprawl as suburban car-oriented model by synchronising urban form with public transport. Mobility hubs are new transport infrastructure aiming to boost the accessibility (the so-called last mile) by offering on-demand mobility systems as shared bikes and electric cars at public transport stations and in surrounding neighbourhoods. Suburbanization processes are very rigid that there is a strong momentum to develop car-oriented neighbourhood and transport infrastructures that favour the private car. The investments in infrastructure are enormous and the return on investment for the stakeholders are small if the surrounding urban area is not designed for or does not promote public transport or micromobility. It is important to identify typo-morphological methodologies in local and global contexts that could contribute to developing urban design guidelines for more sustainable urban form and climate-responsible mobility. The transport sector is a major contributor to climate change and there are various typological methods that can be used. There are long typo-morphological traditions in Sweden and China with different understanding of the types of neighbourhoods and methodologies to analyse them.

Keywords: typo-morphology, neighbourhood typology, Transit-Oriented Development (TOD), sustainable transport

INTRODUCTION

Achieving sustainable mobility is a major challenge in cities today and Transit-Oriented Development (TOD) is an urban planning and design policy that seeks to improve walking and better integrate public transport in neighborhoods. Research on urban morphology is pivotal in advancing Transit-Oriented

Development (TOD) and sustainable urban development, while also enhancing urban life quality. Urban morphology provides a framework for understanding the spatial relationships, structural composition, and interactions between elements within the physical urban environment. Numerous studies in transportation planning and urban design have explored the relationship between urban spatial elements and public transit stations (Batty, 2008; Oliveira, 2014; Fleischmann et al., 2021). This research emphasizes the development of compact, high-density, mixed-use, and pedestrian-friendly urban forms around transit stations to encourage green travel behaviors (Calthorpe, 1993). TOD has also been closely linked to studies examining the interaction between land use and travel behaviors at the neighborhood scale, with a particular focus on walkability, walking radii, and D-variables that define land use (Cervero, 1989; Cervero & Kockelman, 1997; Ewing & Cervero, 2010; Boarnet, 2011; Stojanovski, 2018). Various models, such as the place-node model, have been developed to assess the integration of station areas as nodes within neighborhoods, both as transit hubs and as places of activity (Bertolini, 1996; Papa & Bertolini, 2015).

The literature on the relationship between urban form and transportation is extensive (Anas et al., 1998; Kasraian & Maat, 2016). It is widely accepted that areas closer to transit stations are more attractive to residents and businesses, as they offer convenient services, access to employment, and enhanced customer reach (Redding & Turner, 2015; White, 1999). Consequently, development density is typically higher in proximity to transit stations compared to other urban areas. Moreover, areas with greater functional diversity and street connectivity around stations tend to better support walking behavior (Noriko Otsuka et al., 2021). The mix of urban functions near transit stations leads to increased walking activity, drawing attention to pedestrians' perceptions and experiences. Therefore, creating high-quality built environments and public spaces has become an increasingly important focus in urban design research (Schlossberg & Brown, 2014)

This principle seems broadly applicable to transit station areas across various contexts. However, the urban form around different transit stations is not uniform. Scholars of urban morphology contend that the variations in urban form are due to the complexity of cities and their gradual evolution over time (Scheer, 2016). Different phases of urban development have resulted in distinct urban areas, such as historic districts, urban centers, new districts, and expansion zones, each with unique interactions with transit stations (Adolphson & Fröidh, 2019). For instance, built-up areas like historic districts and old city centers face the challenge of integrating subway stations into their existing urban fabric while managing the influx of subway passengers through urban renewal. Conversely, new and expansion districts use subway stations as catalysts for shaping sustainable urban forms.

This study adopts the theoretical and methodological framework of urban morphology, particularly emphasizing walkability, to analyze the urban form characteristics around subway stations. By comparing typical urban areas in Shanghai and Stockholm, this research evaluates the urban form around transit stations from distinct cultural and developmental backgrounds. This comparative analysis enhances the understanding of the integration between urban form and subway stations in different socio-cultural contexts, providing a scientific foundation for the planning and construction of pedestrian-friendly transit station areas. Furthermore, the study discusses the differences between typo-morphological approaches, which take a historical perspective, and spatial analyses that prioritize morphological indicators and variables (so-called morphometrics, Venerandi et al., 2017; Fleischmann et al., 2021; 2022; Wang et al., 2023).

METHOD

The methodology starts with case selection and creation of a generic typology in Stockholm, Sweden, and Shanghai, China and description of morphological indicators and variables. A data collection and spatial analysis is executed to compare the cases for variables that are important for TOD. This paper seeks to compare and discuss typo-morphology as historical approach and spatial analyses. The typological tradition in urban morphology looks at urban history and emergence of architecture and urban forms as a process of creating types. Types are abstractions about urban forms (e.g. apartment block), the representative exemplar or prototype. Society creates types (of streets, buildings, neighbourhoods and so on) to simplify communication and promote values (Franck 1994, p.345). The spatial practices of any society both structure and are structured by the activity of creating and classifying types (Franck & Schneekloth, 1994). Similar to concepts in linguistic terms, a type packs much information into one icon: a set of architectural or environmental attributes; a set of rules for construction and for organisation of space; a set of behaviours and defined roles that take place within it; and a set of qualities it should exhibit (Schön, 1988; Robinson, 1994). The types have history, and they tell histories (Southworth, 2005). Types are not static. They change over time and vary considerably between cultures and between different groups within the same cultures. Even though the typologies vary across cultures, the activity of creating types exists within all societies (Schneekloth & Franck, 1994). Sweden has a long tradition in typo-morphology (Abarkan, 2009; 2013; Stojanovski, 2019a). Many architects, planners, architectural and urban historians, and geographers have created urban models of typical cities and typologies of buildings, streets, spaces between buildings and neighbourhoods. Gregor Paulsson (1950) in cooperation with the architectural historian Elias Cornell and a group of scholars, students and professionals wrote two tomes of Swedish city (or Svensk stad) describing the development of Swedish cities and urban lifestyles. Greger Paulsson introduced the Weber's (1949 [1904]) concept of "idealtype" as abstractions. Type is a construct to abstract characteristic features in reference to an idea and the ideal-type does not exist in reality, but it is useful to understand and describe the historical process and social construction of idea into building type, typical family, neighbourhood type and social stereotype. In the tomes of Swedish city Paulsson describes an ideal-typical Swedish city with ideal-typical houses and social classes (high and low bourgeoisie and working class) with ideal-typical floor plans, furniture and cutlery (Figure 1).

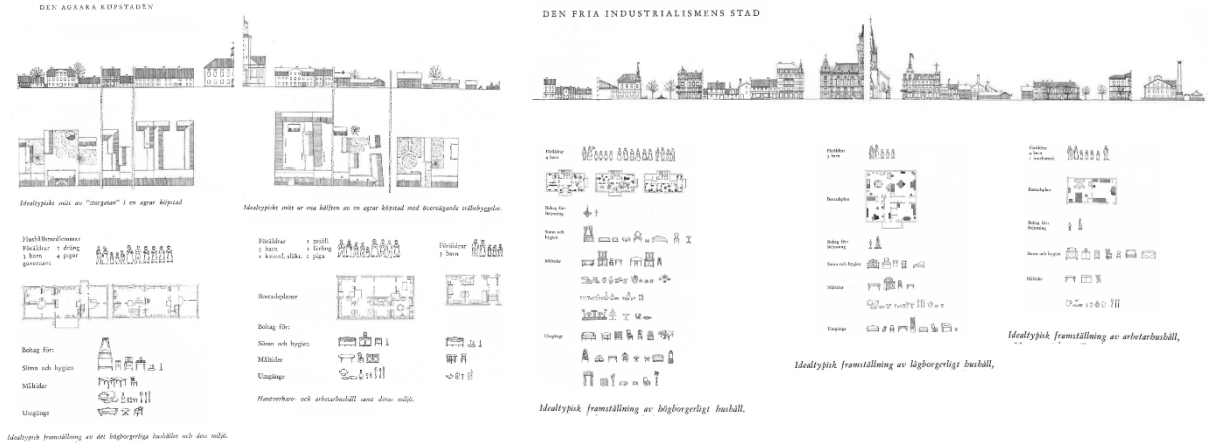

Figure 7: A section of an ideal-typical Swedish city with ideal-typical houses and social classes with ideal-typical floor plans, furniture and cutlery

The writings of Greger Paulssen, Elias Cornell and Björn Lynn inspired new typo-morphological research and conceptualizations in the 1980s aimed not only to contribute to urban history, but also to understand and guide urban planning and design practices. Terms such as, “typområde” (“typical places”, “place types” or even “area types”, in Engström et al., 1988), “stadstyper” (“urban types” in Rådberg, 1988; Rådberg and Friberg, 1996), “stadskaraktär” (“urban character” in SSBK, 1997; 2000; 2022;) were used to describe types of neighbourhoods and city blocks (as configurations of buildings). Since the 1980s, typologies have been developed according to building types and architecture styles specific for historical periods (Björk et al., 2003 [1983]; 2009; 2018 [2000]); planning and development paradigms (Rådberg, 1988; Rådberg & Friberg, 1996); and industrialization epochs (Engström et al., 1988). The trilogy Så byggdes staden, … (translates Thus was built in English) includes books that focus on apartment buildings, houses and cities (Björk et al., 2003 [1983]; 2009; 2018 [2000]). These books aimed to illustrate typical Swedish architecture and present it as part of the urban history by every decade (Figure 2).

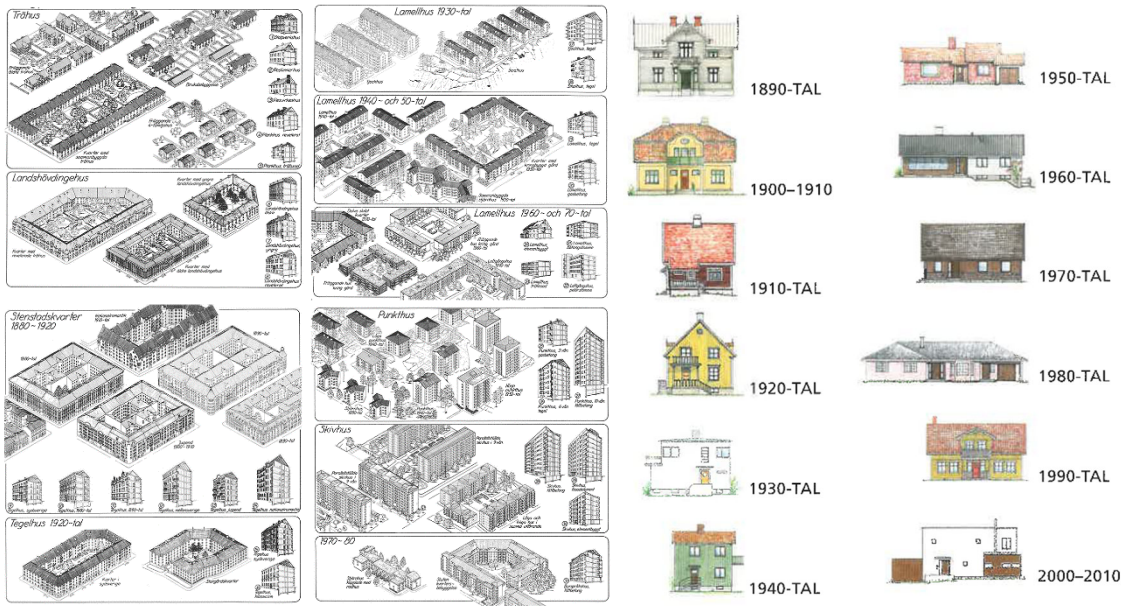

Figure 8: Typical apartment buildings presented as representative exemplars and in city blocks (Björk et al., 2003 [1983]) on the left and typical villas for each decade (Björk et al., 2003) on the right.

To show the historical expansion of the ideal-typical Swedish city, Figure 3 illustrates four major cyclical changes: the pre-industrial, industrial, modern and postmodern city (Stojanovski, 2019b). The y-axis shows historical timeline that includes changes in economy and society along with transportation revolutions and the emergence of new technologies. The x-axis indicates distance from the city center with cores and peripheries for each urban development cycle.

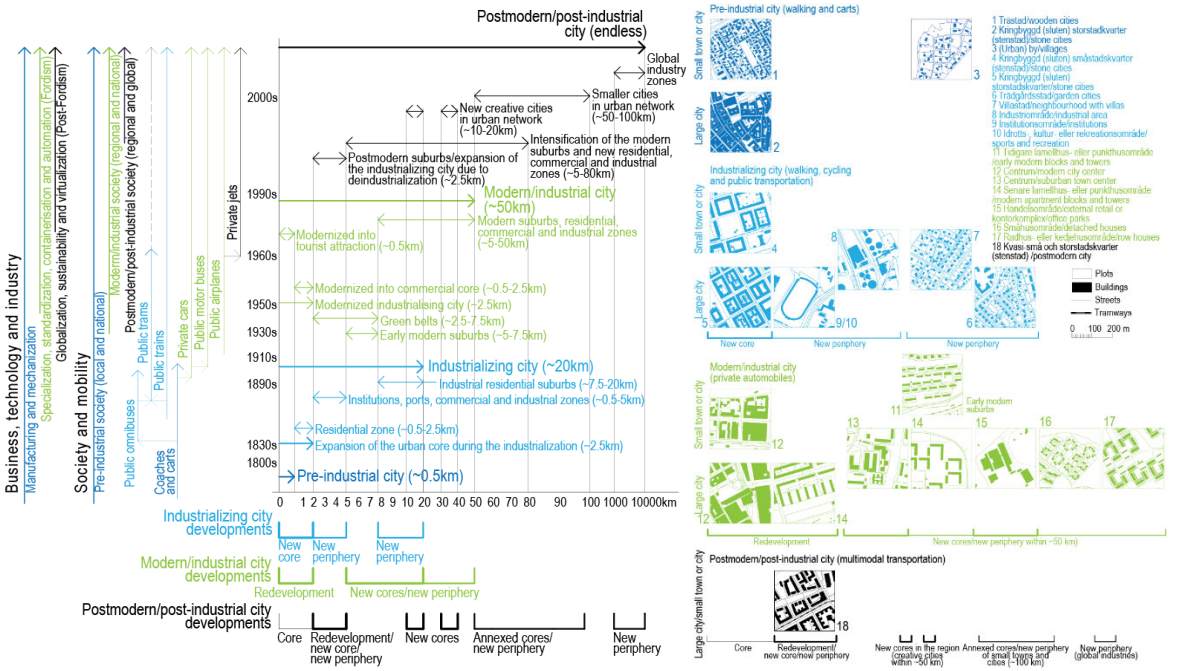

Figure 9: Cyclical changes and morphogenesis of Swedish cities during periods of industrialization of society, together with the urban cores and peripheries and urban patterns

Case Selection

Shanghai, China and Stockholm, Sweden have rich historical evolution, with urban morphology characterized by historic districts, old town centres, and new urban areas. Shanghai's old town development was influenced by Western planning concepts, creating similarities with Stockholm's old town. However, there are significant differences between the two cities, particularly in terms of urban scale and population density. The urban area of Shanghai (664 km²) is three times that of Stockholm (approximately 188 km²), and its population density (20,000 people/km²) is five times that of Stockholm (4,200 people/km²). Furthermore, the cities differ in their histories. Shanghai is prioritizing its metro network as a main mode of transport. that is largest in China (with an operational length of approximately 800 kilometres, over 500 stations, and a daily passenger volume exceeding 10 million), however, the new urban planning is primarily driven by rapid car-oriented development, lacking strong guidance for green transport planning. Stockholm developed historically along suburban railways and from the middle of the 20th century started to decentralize rapidly. Many new suburbs are dominated by cars, but there are new town developments that follows Western community planning TOD concepts. Stockholm is considered as "transit metropolis" (Cervero, 1996), but public transport remains an option for majority. In Shanghai, public transport is the default.

This paper seeks to create a basis for typo-morphological comparison between Sweden and China. The Swedish generic typology has around 20 neighborhood types where each type can have additional subtypes (Figure 3), whereas there are no detailed typological studies of Shanghai (except detailed analyses of its historical core, Whitehand & Gu, 2007; Whitehand at al., 2014; 2016). To explore the similarities and differences in the development of these two cities with different cultural backgrounds, population densities, and development models, a generic typology was developed to abstract similar historic districts, old town centres, and new urban areas as metro station areas and TOD case studies.

Figure 10: Satellite maps of the study areas in Shanghai and Stockholm, (photo credit: River Map, a software) ***Historic Districts:*** *Xintiandi in Shanghai and Gamla Stan in Stockholm are selected. Xintiandi is influenced by Western urban planning concepts, featuring a grid street network and building morphology influenced by Western row houses and enclosed block formations. This area has recently undergone extensive renovation, creating a juxtaposition of old and new urban textures. Gamla Stan is a well-preserved medieval district and the origin of Stockholm's development.* ***Old Town Centers:*** *Nanjing East Road and T-center are selected as examples. These areas are characterized by prosperous commercial activities and diverse mixed-use functions. Nanjing East Road has also been influenced by Western planning concepts and has undergone multiple rounds of renewal and reconstruction.* ***Old Town Residential Areas:*** *Changshu Road and Odenplan are representative cases.* ***New Urban Centres:*** *Lujiazui in Shanghai and Kista in Stockholm are selected as examples of new urban centers. These areas are hubs for high-tech enterprises and companies, with Lujiazui having a stronger commercial and business atmosphere, while Kista is a comprehensive development zone that integrates residential, commercial, and high-tech industries.* ***New Urban Residential Areas:*** *Century Avenue and Tensta are chosen as case studies.* ***New Urban Shopping Centers:*** *Jinke Road and Vällingby are selected as examples.*

Morphological Indicators

There is a long tradition in analyzing D-variables defining land use (Cervero, 1989; Cervero & Kockelman, 1997; Ewing & Cervero, 2010; Boarnet, 2011; Jiao, et al., 2017; Stojanovski 2018) that exist as a place-node model (Bertolini, 1996; Papa & Bertolini, 2015). To quantitatively describe the urban form around metro stations, this study identifies key morphological indicators from four aspects: land use, block patterns, public spaces, and building morphology, (Table 1).

Table 2: Morphological indicators to describe the characteristics of urban forms. Land Use: The Shannon Diversity Index is used to represent the diversity of urban functions. A higher value of this index indicates greater functional diversity and convenience in neighborhood life (Jun et al., 2015). Block Patterns: Indicators include average parcel size, street network density, and street node ratio. Smaller parcel sizes help reduce walking detours, making navigation easier. Low street network density can lead to higher vehicle speeds, which can negatively impact pedestrian safety. Additionally, low street network connectivity implies a higher number of dead-end streets, limiting walking route options (Emily Rose Hennessy, 2023). Public Spaces: Indicators for public spaces include the density and average area of green spaces and plazas. An appropriate number and size of public spaces support walking activities and enhance neighbourhood vitality (Carr et al., 1993). Building Morphology: Indicators include the average building footprint area, building density, and building frontage ratio. High-density building layouts and continuous building facades are generally associated with increased pedestrian activity and improved walking environment experiences.

Category	Indicator		Code	Formula	Description
Land use	Shannon Index(-)	Diversity	SDI	$-\sum_{i=1}^{n} P_i \ln P_i$	Where Pi is the percentage of land use and n is the number of land-use types.

Block/ Street	Average area of blocks (ha)	AAB	$\frac{\sum_{i=1}^{n} A_i}{n}$	Where Ai is the area of each block and n is the number of blocks.
	Street length density (km/km²)	SD	$\frac{\sum_{i=1}^{n} L_i}{\mathrm{A}}$	Where Li is the length of each street segment and A is the sample area.
	Link node radio	LNR	$\frac{\mathrm{L}}{N}$	Where L is the number of links and N is the number of nodes.
Public Space	Number of plaza per sq. kilometre (-/km²)	NP	$\frac{\sum_{i=1}^{n} P_i}{\mathrm{A}}$	Where Pi is the number of plazas and A is the sample area.
	Average area of plaza(ha)	AAP	$\frac{\sum_{i=1}^{n} A_i}{n}$	Where Ai is the area of each plaza and n is the number of plaza.
	Number of green space per sq. kilometre (-/km²)	NG	$\frac{\sum_{i=1}^{n} P_i}{\mathrm{A}}$	Where Pi is the number of green spaces and A is the sample area.
	Average area of green space (ha)	AAG	$\frac{\sum_{i=1}^{n} A_i}{n}$	Where Ai is the area of each green space and n is the number of green space.
Building	Build to line radio (%)	BLR	$\frac{\sum_{i=1}^{n} A_i}{\mathrm{n}}$	Where Ai is the length of each continuity street wall inerfaces and n is the length of all street.
	Average ground area (m²)	AGA	$\frac{\sum_{i=1}^{n} A_i}{n}$	Where Ai is the area of each building and n is the number of buildings.
	Ground Space Index	GSI	$\frac{\sum_{i=1}^{n} A_i}{\mathrm{A}}$	Where Ai is the area of each building and A is the sample area.

Data Collection

The calculation of the above indicators relies on urban mapping data provided by Tongji University and KTH, including satellite imagery, land use maps, parcel boundary maps, street network maps, public space distribution maps, and building footprint maps. Satellite imagery serves as the foundational map data, used to verify the accuracy of the other maps and to make necessary corrections. Land use maps illustrate the functional attributes of different parcels, reflecting the degree of land use diversity in the area. Parcel boundary maps, street network maps, public space distribution maps, and building footprint maps represent the physical attributes and organizational relationships of various urban form elements within the district. Given the differences in measurement methods for the foundational urban morphology data of the two cities, this study standardizes the calculation of indicators as follows (Figure 5):

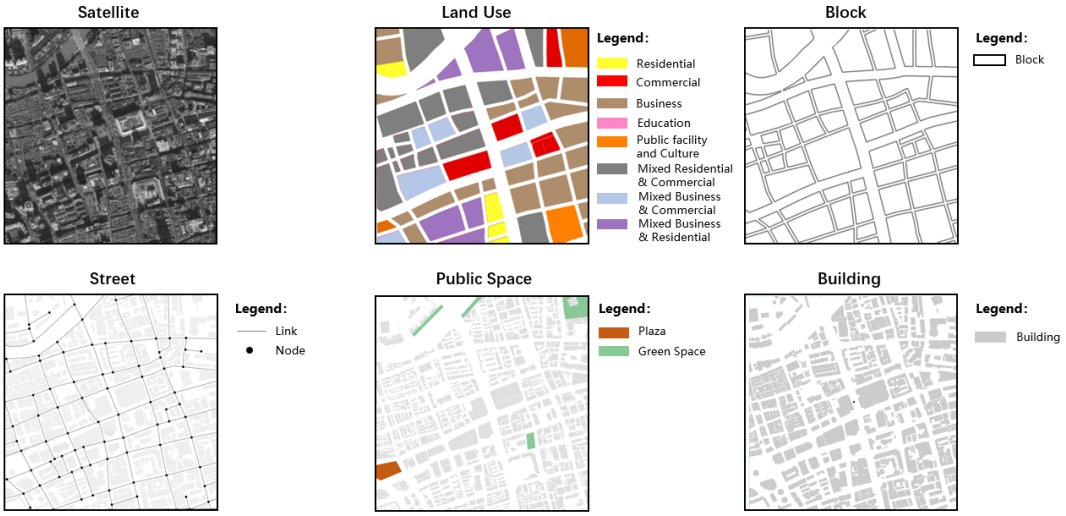

Figure 11: Six maps of study area: satellite map, land use map, block map, street map, public space map and building footprint map. ***Land Use:*** *Land uses are categorized into residential, commercial, office, educational, and cultural types.* ***Block:*** *Block are primarily defined using major urban roads as reference points.* ***Street Network:*** *The analysis focuses on major roads and excludes internal secondary roads within parcels.* ***Public Space:*** *The distribution maps are used to calculate the number and average area of plazas and green spaces.* ***Building:*** *Building density and footprint area are derived from building footprint maps, while the building frontage ratio is calculated in conjunction with parcel boundary maps.*

All foundational map corrections, overlay analyses of urban morphology elements, and calculations of physical attributes are conducted using GIS platforms.

RESULTS AND DISCUSSIONS

Shanghai and Stockholm have different histories and different morphology. This paper created generic typology that is applied in China and Sweden to analyze a set of morphological indicators: land use, street/block patterns, public space, and building forms. The urban morphological characteristics of the overall areas and core zones of 12 samples were computed, with the results presented in Table 2. To observe overall data trends, the results were normalized to ensure that all values fall within the range of 0 to 1.

Table 3: ***Morphological indicators for 12 cases area and core station area.***

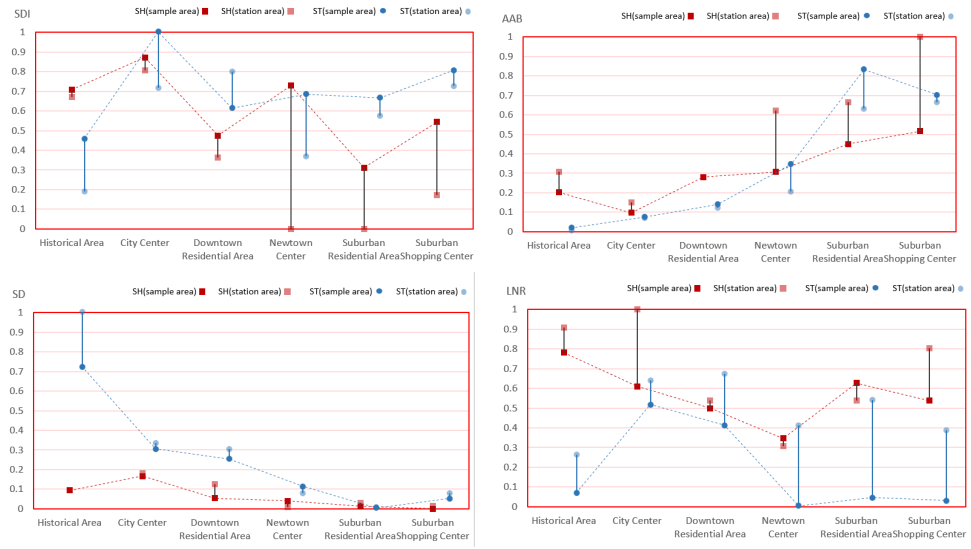
*Figure 6 shows all the For **land use** the functional mix in urban core areas (such as the old city center, new city center, and shopping centers) is higher compared to residential neighborhoods and historical districts. Within historical districts, ST-GT shows a significantly lower functional mix compared to SH-XT. The land use in ST-GT is predominantly residential with commercial elements (residential buildings with ground-floor shops) and cultural facilities (such as churches and palaces), resulting in a lower degree of functional diversity. Conversely, SH-XT, originally similar in land use to ST-GT, has undergone multiple rounds of urban renewal and redevelopment, incorporating commercial and office functions and significantly enhancing its functional mix.In residential neighborhoods, while the functional mix in Shanghai's cases is notably lower than in Stockholm's, the underlying reasons differ. The old town area in Shanghai (SH-CS) lacks the mixed-use developments with ground-floor shops found in ST-OP, whereas SH-CA is deficient in park and green space compared to ST-TS. A comparison between core and overall area functional diversity reveals that the core areas generally exhibit a lower degree of functional mix than the broader regions, with this trend being particularly pronounced in Shanghai's new city areas. The high population density in Shanghai has increased the demand for commercial and office services around metro stations, leading to a predominance of commercial and office land uses in the core areas. In contrast, the new city districts in Stockholm, with their relatively lower population density, feature smaller commercial and office areas. These core areas often include educational and mixed-use developments, catering to the diverse needs of metro users and pedestrians, and providing a more comfortable and convenient neighborhood environment for residents.*



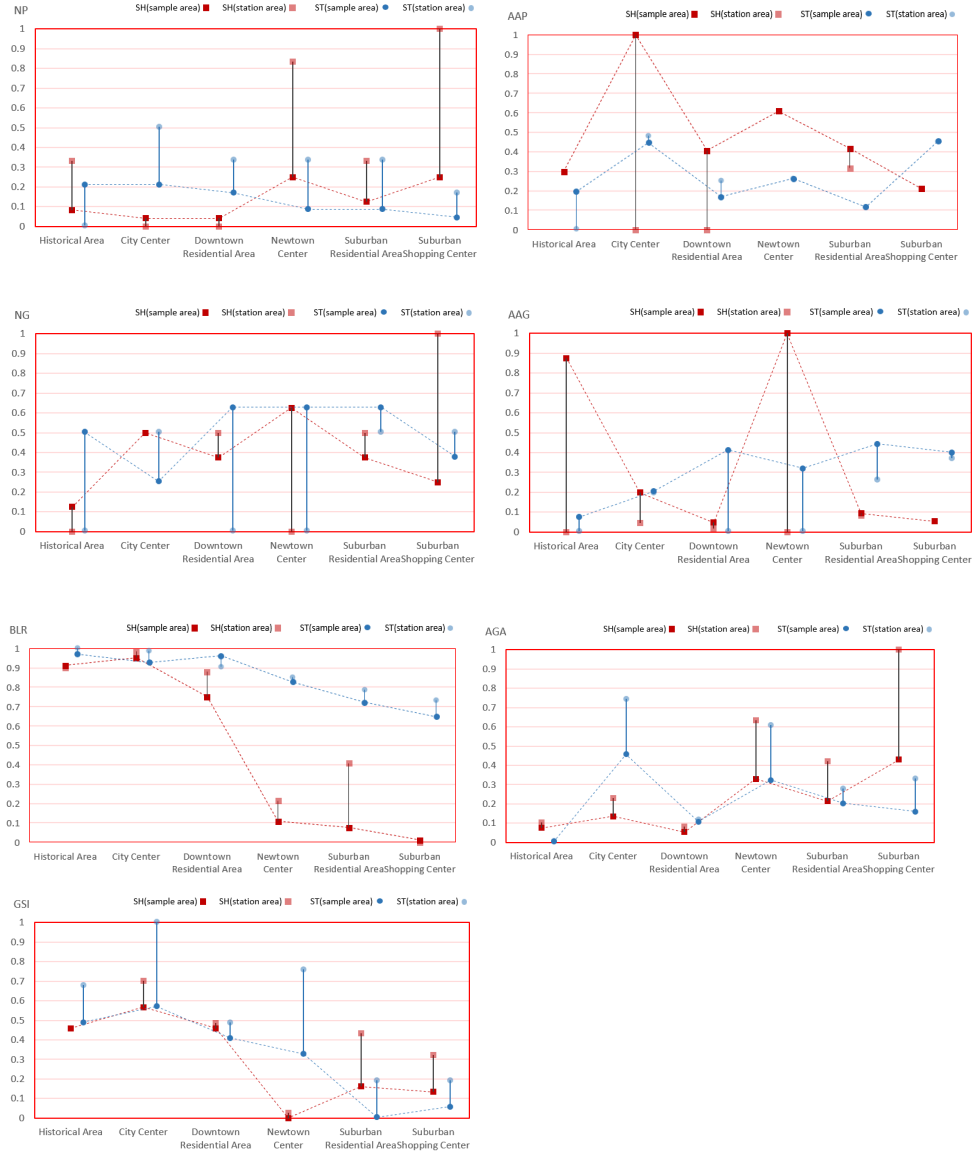


Figure 12: Comparison of morphological indicators

The block/pattern analyses reveal a clear trend of increasing AAB (Accessibility and Activity Buffer) and decreasing SD (Street Density) from old town to new town areas, indicating that the cost of walking trips is gradually rising. This change is attributed to differing urban development models. In Shanghai's new cities, the development is oriented towards motorized transport, with larger land parcels and sparse road networks facilitating rapid vehicle movement. Conversely, Stockholm's new city developments follow Clarence Perry's "neighborhood unit" concept, featuring sparse road networks and larger parcel sizes to mitigate the impact of motorized traffic on the pedestrian environment. This approach also includes non-continuous dead-end streets or circular paths within parcels (as seen in Figure TENSA and VB's road networks). Comparing the AAB indicators for core and overall areas, it is evident that cases with significantly increased AAB are found in Shanghai's new city areas. This is due to the high population density, which leads to the concentration of commercial service facilities. The government encourages the development of large commercial complexes to boost economic growth and enhance urban image, often resulting in large development parcels near metro stations. In contrast, while Stockholm's new city areas also feature commercial developments, the lower population density results in smaller commercial parcels, better aligning with pedestrian-

friendly urban design principles. When comparing the SD indicators for core and overall areas, cases with significantly increased SD are ST-GT, ST-OP, and SH-CS, all located in the old town areas. The higher SD values are attributed to the metro station location strategies. The ST-GT station, located adjacent to a dense grid road network, is relatively distant from sparse road networks near the church and palace clusters. Meanwhile, the ST-OP and SH-CS stations in old town residential areas are positioned at the core of radial road networks, providing strong connectivity to surrounding areas. The variation in LNR (Land Network Ratio) between Shanghai's old and new towns is relatively small due to the consistent use of grid network patterns. In Shanghai, the SH-NJ and SH-CS areas, influenced by Western urban planning models, show LNR indicators similar to those of the historical areas ST-TC and ST-OP in Stockholm. Stockholm's historical, old, and new urban districts exhibit distinct LNR characteristics: the historical districts feature spontaneous medieval street networks with a fishbone-like structure, high spatial privacy, and low connectivity; the old town areas are characterized by homogeneous, dense grid networks with high connectivity; and the new town areas, influenced by garden city and neighborhood unit planning concepts, exhibit sparse road networks with low connectivity. This highlights the limitations of LNR as it primarily reflects the structural characteristics of road networks and their public-private nature but does not fully represent the walkability of a district. For example, the ST-GT historical district, despite its low connectivity, reflects convenient walking conditions due to its high road network density. Therefore, the walkability of street networks should be assessed using multiple indicators. Comparing LNR indicators between station core areas and overall areas, it is noted that Stockholm's new town cases, despite showing lower overall road network connectivity, exhibit higher connectivity within station areas, reflecting a strong public nature. This is due to different planning patterns in functional zones; in Stockholm's new town cases, the station core areas feature relatively dense and accessible road networks to ensure the public nature of commercial, office, and public service functions, while the surrounding residential communities have more sparse road networks to maintain vehicle-pedestrian separation and privacy.

The public space analyses show that the NP (Number of Public Spaces) in Shanghai's new towns is higher than in the old town areas, while the opposite is true for Stockholm. This result reflects the influence of social, cultural, and construction models. Shanghai's old town areas, despite Western urban planning influences, still retain a more inward-looking spatial structure with fewer public squares. In contrast, new town areas around Shanghai's metro stations often feature large commercial complexes, which include multiple public squares. In Stockholm, the number of squares decreases from old to new town areas. In Western cultural contexts, squares are seen as central to urban public activities. In historical districts like ST-GM, squares are located at key nodes such as churches, palaces, and major road intersections. In old town areas like ST-TC and ST-OD, squares are positioned at intersections of major streets and public transport routes, often near commercial centers. In new town areas, public activity spaces shift from squares to green spaces, leading to a decrease in square density. Additionally, apart from suburban commercial centers like SH-JK, Shanghai's squares are significantly larger on average than those in Stockholm, mainly due to population density differences. Shanghai's daily metro ridership (approximately 13 million) is about ten times that of Stockholm (around 1.26 million), necessitating larger public squares to accommodate passenger flow. Comparing NP and AAP (Average Area of Public Spaces) indicators for station core areas and overall areas reveals that many cases in both Shanghai and Stockholm show higher square density in metro core areas. This

is due to the inclusion of public squares within commercial complexes adjacent to metro stations, serving both metro passengers and commercial customers. However, in the old town cases of SH-NJ and SH-CS, the metro core areas lack sufficient square spaces. The SH-NJ station, located in the old town and adjacent to a wide commercial pedestrian street, relies on this street to handle passenger flow from the station, resulting in less new square space in the surrounding redevelopment areas. Except for the core area with missing squares, the difference between core area and overall AAP is minimal, with squares typically concentrated in the core station areas. For instance, the SH-NJ area includes a large urban square (approximately 160 meters by 70 meters) located in the center of a commercial pedestrian street, which is not closely related to the metro station, resulting in a lack of square space within the metro core area. The metrics for NG (Number of Green spaces) and AAG (Average Area of Green spaces) in Shanghai exhibit no clear pattern, while in Stockholm, AAG increases from the old town to the new town. This variation in Stockholm is influenced by urban development models: the old town, characterized by compact block arrangements, has limited green space often associated with churches and educational buildings. In contrast, new town development in Stockholm, guided by community planning principles, incorporates large green spaces within residential areas to facilitate daily recreational activities for residents. Comparing the metrics for station core areas and overall areas reveals that in Stockholm, half of the station core areas lack green space, with most green spaces located in the peripheral areas around the stations. In some Shanghai cases, the density of green spaces in core areas increases, often consisting of landscape-type green spaces that are difficult to traverse (see photos). Additionally, both in Shanghai and Stockholm, the green spaces present in the core areas are relatively small.

The building form analyses illustrates that the BLR (Building Line Ratio) in Shanghai’s and Stockholm’s old towns are quite similar and both have high frontage ratios. This similarity is due to the historical development contexts of the cities. Shanghai’s colonial history has led to a blend of Eastern and Western architectural forms in the old town, with traditional lane houses arranged in a manner similar to European row houses, creating a “clustering + row” type with commercial areas on the periphery. Stockholm’s old town, in contrast, features typical enclosed block structures. Although building line ratios in both cities' new towns have decreased compared to the old towns, Shanghai’s new construction practices, moving away from Western planning influences, have favored enclosed residential districts with boundary walls, resulting in a significant drop in building line ratios and less defined street frontages, thus negatively impacting the walking experience. In contrast, Stockholm's new town construction, while differing from the old town, maintains a relatively high building line ratio, contributing to more intimate street spaces. Comparing the BLR metrics for station core areas and overall areas, it is observed that in cases such as SH-CS, SH-CA, and SH-JK, there is an increase in building line ratios within the metro core areas. The buildings near metro stations with high frontage ratios create continuous commercial facades to attract the dense passenger flow brought by the metro, enhancing the walking experience. AGA (Average Gross Area) increases from old to new towns, while GSI (Gross Space Index) decreases. This trend is attributed to changes in urban cell unit forms. Both cities’ old towns feature high-density low-rise residential areas, such as Shanghai’s Shikumen lanes and garden villas, and Sweden’s enclosed blocks and multi-storey row houses. New town residential areas in Shanghai include multi-storey worker villages and high-rise modern residential districts, while Stockholm predominantly features multi-storey apartment buildings (see base maps and photos). Additionally, the centre of Shanghai’s new town, SH-LJ, has extremely low building density due to the development of motorways, skyscrapers, and large urban parks. The wide, high-

level motorways, setbacks created by skyscrapers, and multiple urban parks contribute to a dispersed and fragmented urban texture. Comparing the AGA and GSI metrics for station core areas and overall areas, both Shanghai and Stockholm show an increasing trend in these indicators in metro core areas. This is particularly notable in central-type districts (old town centers, new town centers, and suburban shopping centers), where the increase in AGA is significant due to the high density of metro passenger traffic, necessitating large-scale buildings to meet commercial and office needs. Additionally, the proximity of the new town residential area SH-CA to the new town center SH-LJ results in a high metro passenger density, leading to a notable increase in AGA.

DISCUSSION

This study compares the urban morphological characteristics of metro station areas in typical districts of Shanghai and Stockholm from a walkability and TOD perspective. The cross-cultural comparative study reveals how metro stations interact with urban morphology under different social contexts. Analysis shows that in both Shanghai and Stockholm's new urban area, metro station core areas generally exhibit increased plaza density, higher building density, and larger building scales compared to peripheral areas. This indicates a common practice of high-density development around metro stations to efficiently manage passenger flow through plaza spaces, enhance urban vitality, and increase surrounding commercial value. In contrast, in the old towns, due to constraints such as land ownership and historical preservation, the overall morphological changes in metro station core areas are less pronounced. However, some Shanghai cases demonstrate that selecting metro sites in areas with higher road network density and better connectivity, combined with urban renewal and redevelopment, can improve the capacity and functional mix of metro core areas.

Urban development models significantly influence walkability around metro stations. Over the past 30 years, Shanghai's rapid urbanization has been driven by motor vehicles and road construction. This development model has impacted metro line planning and station layout, leading to metro stations often being situated alongside major roads with large land plots and lower road network density, which results in significant interference with pedestrian movement due to high-speed traffic. Conversely, Stockholm's new district development model, influenced by the neighbourhood unit concept, features a sparser road network and larger land plots. This increases the detour distance for pedestrians reaching metro stations, but the use of cul-de-sacs and loop roads within large plots helps separate pedestrian and vehicle traffic, enhancing walkability and safety.

The difference in population density between the two cities leads to distinct commercial development models near metro stations, which in turn affects the pedestrian environment around these stations. Although large-scale commercial complexes can meet the high-density passenger flow needs and their accompanying large plazas can handle metro passenger dispersal, this often results in larger land plots and reduced road network density in the core areas, further decreasing functional diversity and increasing walking distances. This reduces the opportunities for accessing diverse services on foot and can lead to increased car traffic, which encroaches on pedestrian spaces and raises the risk of traffic accidents. In Stockholm, the lower population density results in smaller commercial facilities near metro stations and a more mixed-use core area, facilitating the creation of urban micro-centers that attract residents to visit on foot.

In the end, the generic typology of six neighborhood types serves as good proxy for comparison, but it does not reflect the urban development trends (neighborhhod type 18 in Figure 3) and favourite car-oriented typologies (neighborhhod type 16 and 17 in Figure 3) that dominate in Swedish suburbs but are seldom developed in China. The typical gated community as a Chinese predominant type (exempliefied as Vällingby in Sweden) experienced several variations from the 1970s and still dominates as preferred type in Shanghai. Figure 7 on the left shows a luxurious gated community in the suburbs of Shanghai (Hongqiao) with an access to a metro station and western supermarkets. Figure 7 on the right illustrated experiments with neotraditional neighborhoods (so called waterfront cities) in Stockholm with a mix of buildings and traditional main street with a light railway (Hammarby Sjöstad) supported by car pools, automated supermarkets and indoor farms. These new experimental sustainable neighborhoods in Stockholm are rooted in Swedish traditions and do not exist in China. They are excluded from the comparison, but they are testbeds for sharing vehicles and mobility hubs. the generic typologies do not grasp the detail typo-morphological development that is typically captured by typomorphological studies. In Sweden, there are detailed typologies (Paulson, 1950; Rådberg, 1988; Engström et al., 1988; Rådberg and Friberg, 1996; SSBK, 1997; 2000; 2022; Björk et al., 2003 [1983]; 2009; 2018 [2000]; Stojanovski, 2019b; Stojanovski et al, 2022; 2023), whereas in China typologies are typically used for analyzing historical areas (Whitehand & Gu, 2007; Whitehand at al., 2014; 2016).

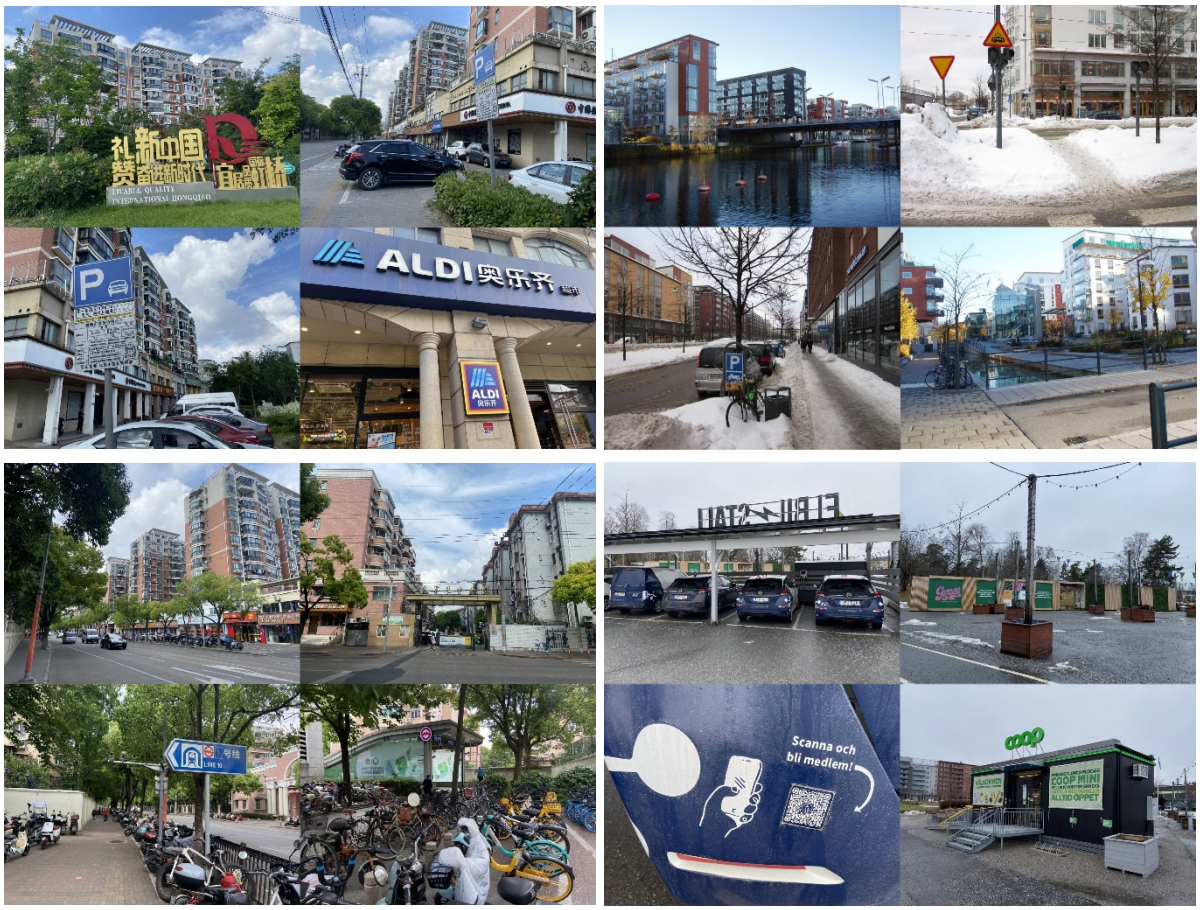

Figure 13: A typical gated community in Shanghai (Hongqiao) on the left and a typical new waterfront development in Stockholm (Hammarby Sjöstad as a prototype on the up right and Täby park on the bottom right where experiments with mobility hubs and shared electric cars are at place).

CONCLUSIONS

The discussion about application of typo-morphology and typologies and spatial analyses with morphological indicators is perpetual in morphological research. This paper presents generic typologies in Sweden and China and compares variables. However, the generic typologies do not grasp the detail typo-morphological development that is typically captured by typomorphological studies. A combination of refined Chinese typologies and morphometric analyses can offer a more detailed perspective, not only in the indicators for walkability and TOD, but also in preferences and (typological and morphological) evolution of Chinese and European cities. In the end, there are limitations in using typo-morphology in urban design practice that requires critical understanding and application of typologies. Typologies are usually historical facts, whereas the future is here to be invented. If a historical pattern of a neighbourhood is replicated today, the neighbourhood type will be different in the historical context. This might only has meaning if the typologies are based on historic information without considering the present conditions.

ABSTRACT

The presented work was awarded at a competition for the requalification of the surroundings of São Paulo's municipal market, a representative figure of the city's socioeconomic role as a strategic hub between the state's productive hinterland and the port of Santos. Currently, the territory is characterized by a convergence of flows, creating idiosyncratic spatial conditions. While the region has a strategic role in the state's trade and supply chains, the logistics behind the retail operation has precluded the occupation of the area for leisure (green areas) and created infrastructure issues which are manifested through acute pollution, heat islands and flooding episodes. Given this scenario, the competition required transversal planning strategies, capable of outlining interventions in a contained perimeter while fostering vectors of urban requalification in a long-term scenario. Given the complexity and challenges of the context, we needed to better understand the intricate dynamics at play in the region to enable a mora targeted and effective intervention. We conducted a series of exercises to anaçyse the impact of the city's form on its economic and productive dynamics, assessing whether urban morphology acts as a driver for the transition from a linear to a circular economy. The study is based on a morphological analysis that connects the built environment with the virtual space, where flows of extraction, production, consumption, and disposal operate. These flows were examined across two distinct periods, within the same productive land framework, in a territory yearning for transformation. The results of this analysis allowd us an in-depth exploration of the complexities within the central region, highlighting spatial weaknesses and potentialities while enhancing synergies between the socioeconomic agents and flows of the consolidated territory of São Paulo.

In this way, we were able to outline strategies and create design proposals that will enhance existing value chains and prompt a transition to a circular economy. The research presents a valuable opportunity to reflect on process of urban regeneration which begin from morphological concerns, and which can be materialized through concrete and spatial interventions

Keywords: urban regeneration; urban metabolism; green infrastructure; spatial clusterings; consolidated territories

INTRODUCTION

This paper discusses the metabolic analysis methodology developed to investigate the surrounding of the Municipal Market area, located in the central region of São Paulo. This site was the subject of a national competition organised by the Instituto de Arquitetos do Brasil and Associação Escola da Cidade in December 2023. The investigation was essential for a deep understanding of the territory, enabling the development of evidence-based regenerative strategies, as it turned to be highly praised by the technical jury, resulting in the highest awarded prize in the competition.

The action perimeter defined by the competition brief has been subject of public debate for decades. While the Market itself has a significant presence – shaping, transforming, and conditioning the territory, the brief invited proposals to investigate the area, agents, and dynamics around it, designing possibilities to overcome the programmatic and spatial super specialization that hinders an effective transformation of the area. Furthermore, the perimeter of the region holds a critical role in affordable housing production, flood mitigation, and green and road infrastructure, leading factors in our argument for the necessity of regeneration.

Context

Strategically located north of São Paulo's historical core and bounded by the Tamanduateí River and its historic floodplain, the immediate context of the São Paulo Municipal Market turned into a commercial hub for food products. While it emerged as a critical commercial nexus, connecting productive inland regions to the coastal areas (Prado Jr., 1998) through railways and roads, now represents as a gastronomic centre, offering specialty goods and raw products, establishing itself as a important tourist and cultural establishment.

Since the Market's inauguration in 1933, the area around it has consistently reinforced its commercial identity, catalysing urban development. This progress has been further spurred by industrialization and immigration, especially with the efforts of the Varzea do Carmo's floodplain reclamation, straightening Tamanduateí River, while attempting to mitigate flooding and facilitate urban expansion along the riverbanks, while it was not served anymore as a logistic modal of transport.

During this period, immediate neighbourhoods develop around the railway infrastructure and close to the Municipal Market. With the downturn of the global economy and the subsequent decline in coffee exports created a favourable condition for industrialisation to thrive as a domestic supplier of São Paulo's market. This process was accelerated by the settlement of European immigrants, who brought valuable expertise in industrial activities. The manufacturing industry and specially the textile industry were important remarks back in the area, which the last one, remains significant to this day.

The São Paulo Municipal Market accommodates more than 1,500 employees who collectively manage approximately 350 tons of food daily, and it attracts around 50,000 visitors per week. The competition's redevelopment proposal encompasses an area of approximately 53 hectares. This preset is a promising opportunity to enhance the tourism-cultural circuit beyond a diversity of economic cluster. However, despite its vibrant daytime activity – more than 2 million people move through its area- it exhibits a sparse residential density, making its atmosphere empty and unsecured for passersby at the end of business time.

Historically, public investments in this area have prioritized mobility and logistics infrastructure, overshadowing other important dimensions of the urban life, leaving little to no space for other uses that are considered relevant, and which are central to the competition's brief. In our understanding, the lack of success of previous projects and proposals for the area, were caused by the lack of depth in studies not considering certain topics for the area's maintenance.

The numerous interventions and transformations projects that took place at this territory, which many ended in failure, prompting us to question what factors these proposals considered and why, despite its well-documented challenges, the region continues to stand out as the largest and most important open-air market in the country. These idiosyncrasies spurred us to conduct a thorough investigation of the area, allowing us to envision desirable future scenarios for its development.

System Thinking

Currently, the industrial framework located in São Paulo's central region configures a decentralized production network, whereas resources and labour do not depend on proximity with the consuming public (Leite, 2012). The lack of industrial policy led incentives led industries to install outside the urban environment. The growth of flexible productive sectors and outsourcing of the means of production created the need for a vast network of suppliers and distributors. São Paulo faces a challenge in decentralizing its production while recentralizing its consumption (Figure 01).

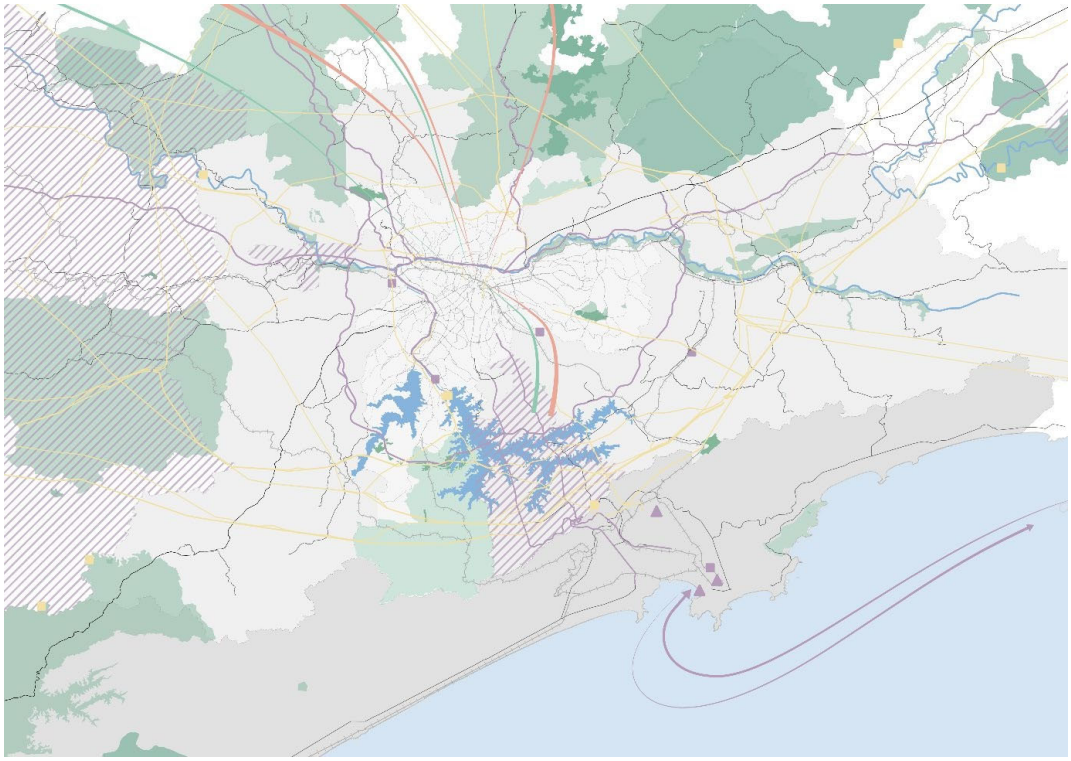

Figure 1. São Paulo's metropolitan area in 2023, showing economic activities that start, end or cross its urban area. In purple: logistics and transportation of goods; In yellow: energy supply; In blue: water basins; In green: food production; in Pink: Residues, Water Treatment and Solid disposals. Image made by author

The presence of various active economic clusters within the defined area, within the encompassed area, which were notably thriving, as evidenced by the inauguration of new commercial infrastructure hubs of retail, tech manufactures, food and other goods, were the first potential identified for the proposal.

The initial question raised by the project was to understand the flows and dynamics occurring within this territory, which did not begin or end within its boundaries, the concept of extended urbanization (Brenner N. and Katsikis, N, 2020) that points how city and non-city landscapes are dialectically co-produced under modern capitalism, systematically connected, though tangible and intangible layers. To this end, we introduced the concept of urban metabolism as a framework to conduct an in-depth analysis and comprehend the physical and non-physical dynamics at play in the area.

The region's historical context served as a reference point for a productive city that grew and developed based on its economic potential. Neighbourhoods that emerged during the industrialisation period retained their building structures and have continued to prosper, maintaining their commercial but no longer productive vocation. Thus, the second question that arose was to understand which spatial transformations may have contributed to this shift in vocation and whether it is still possible to regenerated it.

The concept of system thinking illustrates how productive and economic activities can serve as leverage for regeneration. We defended that it is crucial to first structure and enhance other activities to increase liveability, social safety, and connectivity to make the territory more attractive for its residents. The idea of urban metabolism, argue that it is possible to do so by increasing and redirecting value captured with the existing economic activity, which is at the core of this region's character. In this sense, the current economic clusters, can begin to engage with other stages of manufacturing process, such as research, design and prototyping, amongst others. A similar process was observed in the Brussels Canal Zone, as demonstrated by the project Cities of Making (CoM, 2018).

In this sense, the questions brought up in this exercise expected to create a base ground or foundation of a system thinking approach that could properly design in such a complex territory configuration, enhancing existing value chains, preserving local value and mitigating impact and externalities, such as mismanaged economical logistics and flooding risk.

Spatial Investigation

The exercise involved a comparative morphological analysis of the same territory, focusing on the area defined by the competition, across two distinct periods: 1930, at the Coffee Metropolis era, and 2023, the Consumer Metropolis. The aim was to identify small or large alterations in the urban fabric, with a particular focus on water and green infrastructures and transportation networks, that have undergone transformations in their configuration.

Following this comparative analysis, an economic study of the material and product flow from both periods was proposed to understand the strengths and weakness of the dynamics within the competition's defined perimeter. The next phase of the study sought to identify the spatial potential of the current territory using the Space Syntax methodology. This approach would provide region demarcation of high degree integration and connectivity within the area, ensuring that the groups proposal could be focused on zones with the greatest potential for impact and effectiveness.

The final stage of the exercise involved synthesising and cross-referencing all collected data to identify similarities or discrepancies that could provide a deeper understanding of the territory's transformation. This comprehensive approach aimed to develop a new methodology for proposing

urban interventions in complex urban areas, that would consider both the spatial transformations and the economic dynamics emerging from the use of those spaces, to provide better interventions for a desired city of tomorrow.

METHOD

To understand the territory through its morphology, the study aimed to analyse the region defined by the competition, comparing it across different temporal scenarios. The selection of time periods for analysis was based initially on the availability of data and cartographic records, and subsequently on the economic context of each era. As such, the study focused on the periods of 1930 and 2020, within a framework of territories seeking transformation, following moments of industrialisation and urban development. The first period represents a scenario poised for significant alteration in the coming years, while the second reflects the present-day context, allowing for the projection of a desired scenario rooted in the potential reindustrialisation of the area's functional activities, coupled with the (re)development of its territory.

The methodology is composed of four stages:

1. Morphological Urban Analysis: involving morphological analyses of the urban fabric within the defined areas across the two selected periods.

2. Metabolic Flow Mapping: focusing on mapping the metabolic flows and key products associated with the Municipal Market and its surroundings, using a qualitative approach.

3. Spatial Analysis, examining the region through Space Syntax methodology, using the Depthmap.exe software.

4. Cross-Referencing Spatial and Metabolic Data, the final stage of the study, where spatial data from cartographies and diagrams developed in the previous stages are cross-referenced.

Morphological Urban Analysis

The development of the morphological analysis consisted of comparing the two scenarios: The Coffee Metropolis in 1930 and the Post-Industrial Metropolis in 2020. In the first case, we analysed the city of São Paulo, which was still characterized by its coffee export economy and already displaying a significantly developed urban spatial configuration. It was also the stage for industrial development, which ultimately transformed and consolidated the urban fabric in the city centre. In the second case, we analysed the city in its current stage, using cartographies and data from 2020, where São Paulo is characterized as a commercial metropolis, with trade and services as key elements of its economic configuration, alongside the exodus of industrial activities to peri-urban contexts. In both temporal frameworks, we identified the region as being in a status prior to an imminent transformation, which in this case refers to a potential return to its industrial and productive vocation.

Using geospatial cartographic data from 2020, acquitted through public domain portals and presented in computer-aided design (CAD) software, along GIS software, a working file was created to organise and display relevant information for the study (figure 2). This included elements such as the road network, urban blocks, building structures, green and open spaces, hydrographic features, railway infrastructure, public urban equipment (metro and bus terminals), and bridges and crossings.

Elements such as land plots were excluded to this exercise, due to the lack of this information in historical cartography in some places within the region perimeter.

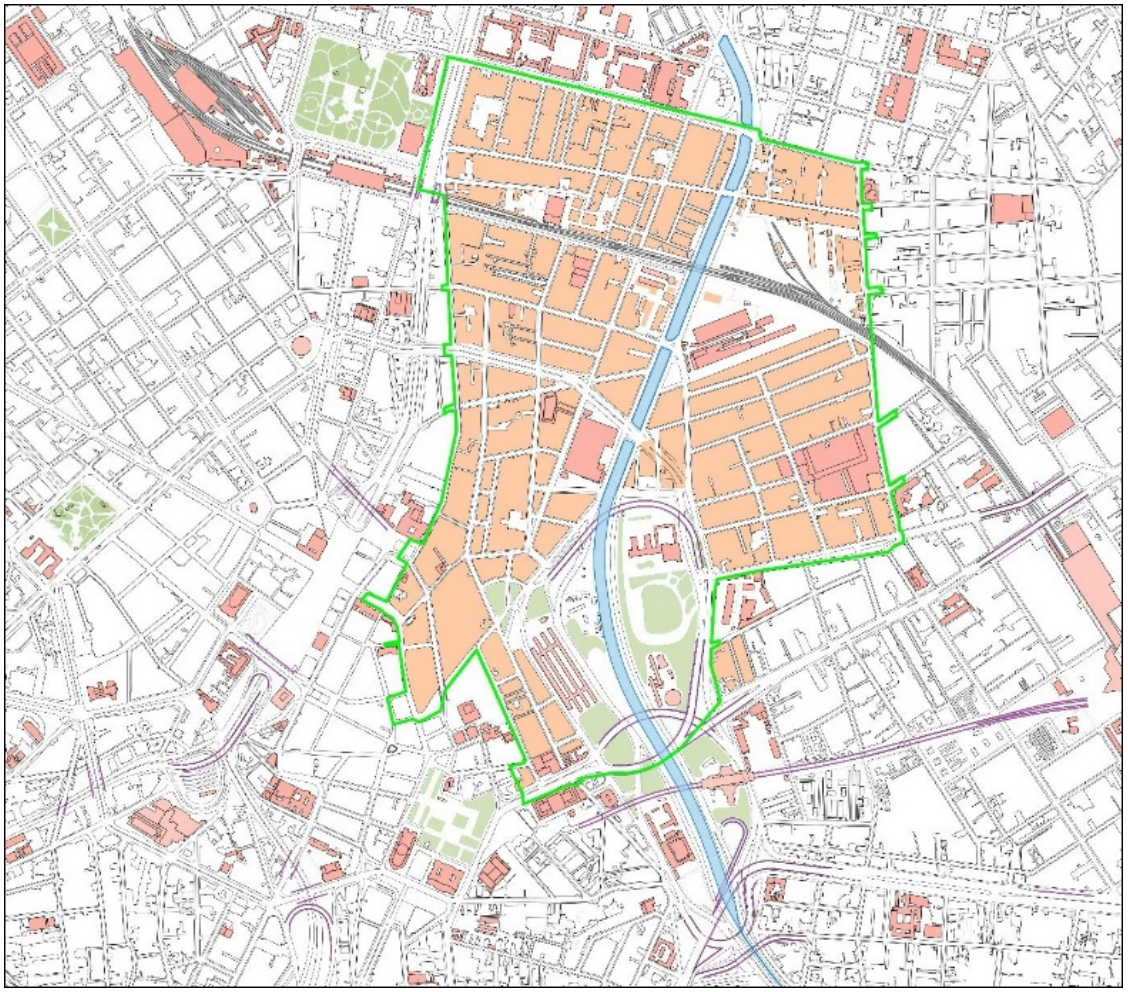

Figure 2. São Paulo's central urban context in 2020, in green the outlined perimeter of the competition. Image made by author

The 1930 cartography, named SARA Brasil 1930, was georeferenced using GIS software to ensure greater compatibility with modern territorial representations (figure 3). This allowed for the elaborations of roads, blocks and buildings present at the time. However, the representation of the built-up area could not be fully translated within the available timeframe. Therefore, only significant alterations in blocks and urban fabric were considered. Information on mass transit systems, specifically the tram network, was not represented in this cartography for clarity and visibility purposes but was considered in subsequent analyses.

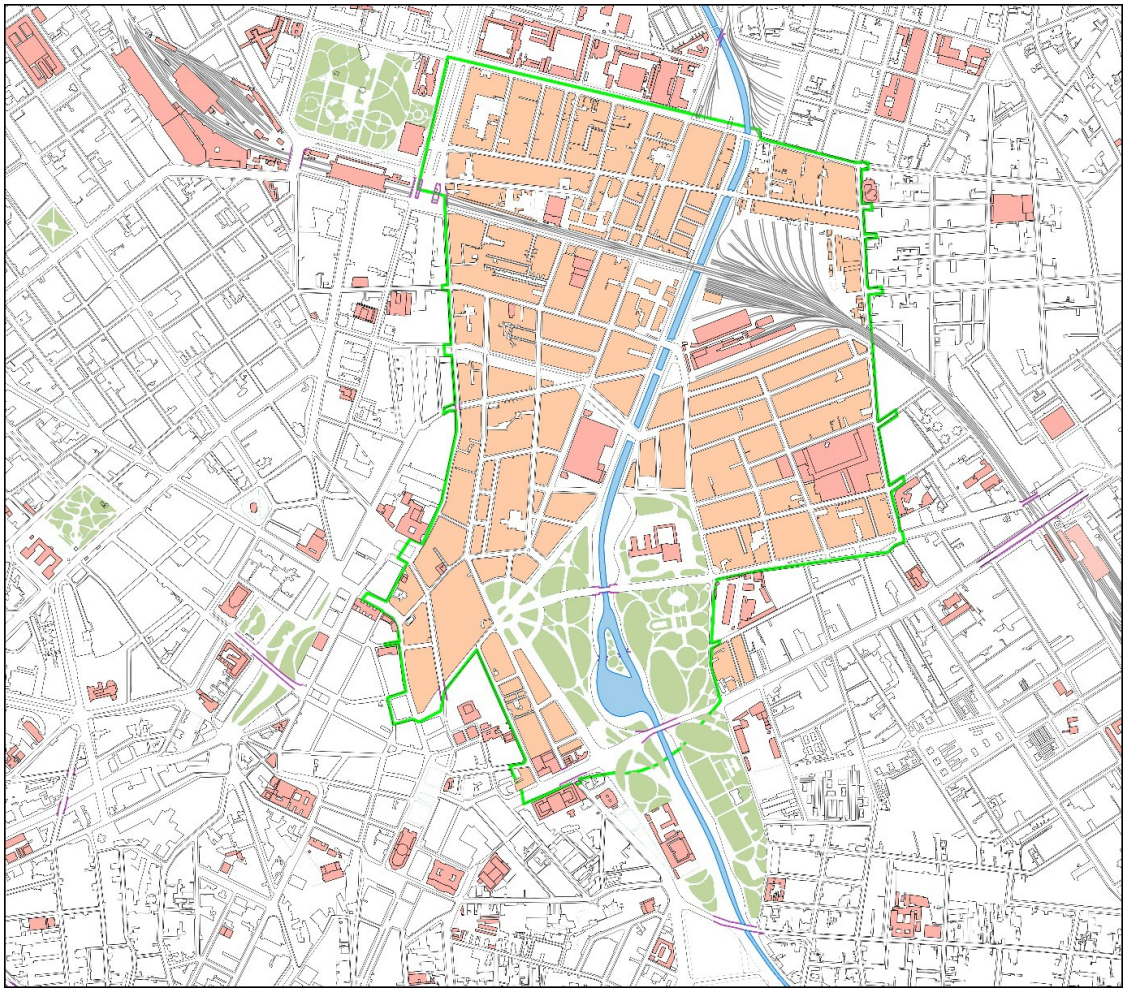

Figure 3. São Paulo's central urban context in 1930, in green the outlined perimeter of the competition. Image made by author

Metabolic Flow Mapping

The second step of the methodology was the metabolic analysis. We looked at the Urban Metabolism publication by the IABR – Project Atelier Rotterdam (Fabrications, n.d.) as a reference. Their understanding of the urbanized territory in sync with natural cycles as part of other widespread systems provided a practical framework to define our starting point for this exercise.

To conduct the "Metabolic Flowchart", we incorporated the concept of extended urbanization, discussed by Neil Brenner and Nikos Katsikis (2020), that pointed out how city and non-city landscapes are dialectically co-produced under modern capitalism, thus, the field of urban studies should treat them as a systematically connected.

> From this point of view, cities are supported by diverse metabolic inputs (labor, materials, fuel, water, and food) and engender a range of metabolic byproducts (waste, pollution, carbon), the vast majority of which are produced within, and eventually, absorbed back into non-city zones. (Brenner and Katsikis, 2020, p. 25)

In this exercise we tracked flows, from origin to its destination, most of the flows initiated in contexts out the urban limits and ended in the urban context. The flow analysis considered topics such as air, waste, energy, biota, housing, transportation logistics of raw materials, food, and manufactured goods, along with their result byproducts, including waste and economic implications. This metabolic

analysis seeks to deeply understand the intrinsic relationships and synergies between these inputs and how they interact with the built urban fabric.

In the case of the current situation of São Paulo, we faced with the dispersion and absence of certain data for the defined perimeter, a limitation which researches of the Global South often contend. While we couldn't assure quantitative precision, it was also an interesting exercise to work with these flows through their qualitative properties, resulting in a diagrammatic scheme (figure 4) that was suitable to present the concept.

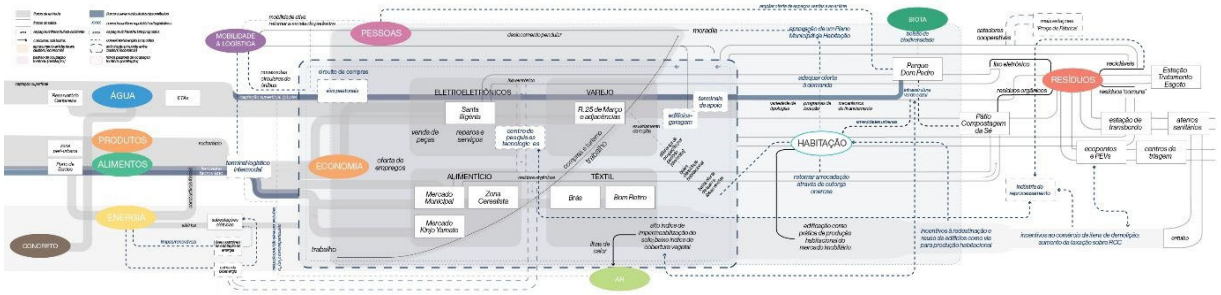

Figure 4. Metabolic Flow Map of São Paulo's economic activities in current and desired situation. Image made by author

The diagrammatic scheme of this concept presents information on flows and assets, illustrating the current situation while indicating a desired scenario of improved efficiency in these flows and their potential outcomes.

Thus, we were able to conduct a study of the qualitative properties of the system in another historical period, this allowed us the creation of a comparative case in which both periods could be analysed on the same level. The information collected to support the Metabolic Flowchart for the year of 1930 (figure 5), came from archives of public domain and historical records, authenticated by reliable institutions with certified dates.

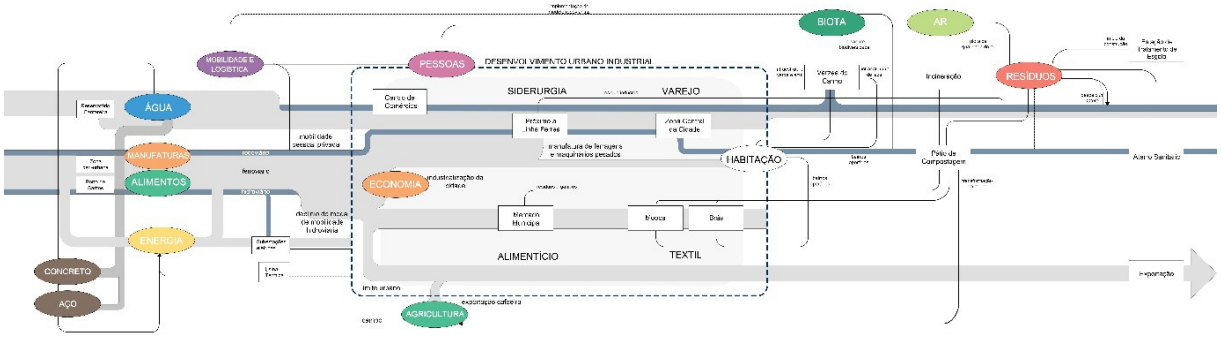

Figure 5. Metabolic Flow Map of São Paulo's economic activities in 1930. Image made by author

In this configuration, we were able to gather a significant amount of data, as a substantial amount of literature produced during São Paulo's urbanization process following the establishment of the infrastructure and energy provider, *The São Paulo Tramway, Light and Power Company Limited*. During the same period, the railway system managed by *The São Paulo Railway Company Limited*.

Was already well-established as the main route for exporting coffee production that was developing in the hinterland of the state, to its destination to the coastal area at the *Port of Santos*. Additionally, the concentration of new infrastructure projects for water supply and sewage in São Paulo's city centre were crucial factors that enabled prosperous and enduring industrial urban development.

Spatial Analysis

In the third stage of our work, we conducted a study of walkable pathways using Space Syntax analysis. The purpose of this analysis was to understand the hierarchical structures that compose the system within the limits defined by the competition, enabling us to identify spaces and urban fabrics that should concentrate interventions and design practices, supported by spatial validation that could enhance our project proposal.

To produce this analysis, we developed a cartography in the style of the Noli Map of Rome, depicting the current situation of the central region, which is the focus of the competition. In this cartography, we redrew the boundaries of the public realm, also considering walkable spaces such as galleries, passages, and squares that have defined opening and closing hours, in addition to areas like streets and avenues that do no present clear physical barriers but are not optimally utilized for public purposes. This cartography allowed for a more detailed execution of Space Syntax and understanding of different spatial manifestations occurring in the area, within a new layer of the perceived space.

After developing this cartography, we created axial maps using the depthMapX application of Space Syntax, allowing us to extract new cartographies and results for interpretation. The results for Connectivity (figure 6), Integration (figure 7), and Choice (figure 8) were used to interpretate the territory from a qualitative perspective.

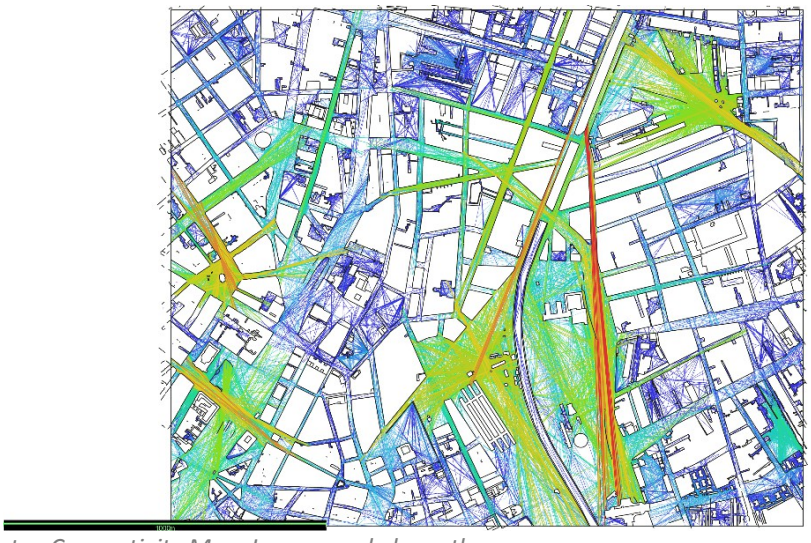

Figure 6. Space Syntax Connectivity Map. Image made by author

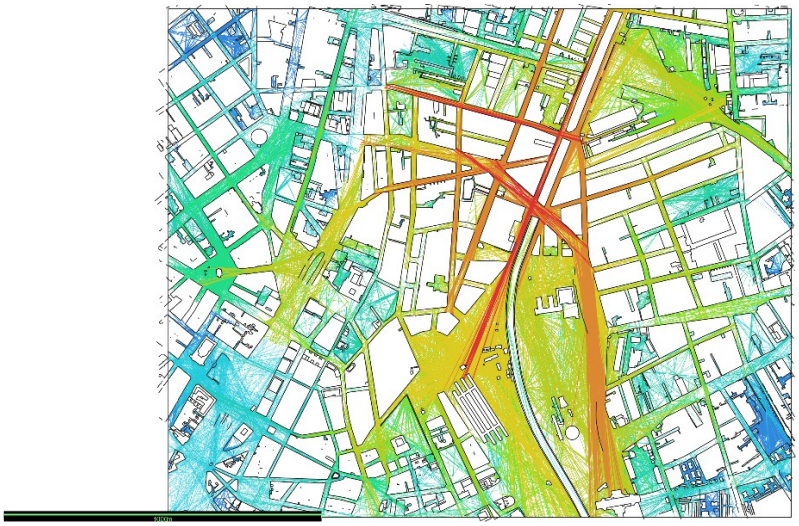

Figure 7. Space Syntax Integration Map. Image made by author

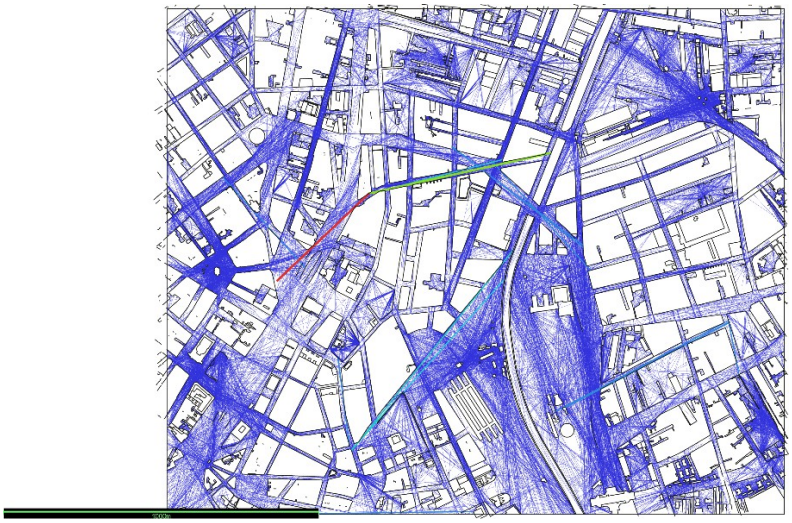

Figure 8. Space Syntax Choice Map. Image made by author

A high degree of integration and connectivity values were identified in the areas that are currently occupied by the road infrastructure, Avenida do Estado, that borders the Tamanduateí river. The spatial potential identified in this region, served as a foundation of a series of strategic design guidelines presented in the final proposal, with the most relevant in this scope, to propose a division of the roadway on both sides of the river bank, into two distinct routes: a local road with reduced speed limits happening above ground, and the structural avenue with reduced number of lanes, running underground along the same path as before, enabling the appropriation of the spaces above ground near the river, for public and collective use.

However, it was still necessary to ensure that these interventions, beyond improving spatial quality for the public, would not overburden the traffic network of São Paulo's central region. To this end, a new analysis was conducted using Space Syntax methodology, but now, based on an axial map of the city's road system, with a 2km analysis radius centred on the Municipal Market. The cartography compared two situations, one as a current state, and the other a desired scenario, considering potential impact on the redirection of the Avenida do Estado on the system.

The test conducted at this macro scale provided data on Connectivity (figure 9), Integration (figure 10), and Choice (figure 11), obtained through the application of the Space Syntax method using the Depthmap. exe software.

Figure 9. Space Syntax Macro Connectivity Map. Image made by author

Figure 10. Space Syntax Macro Integration Map. Image made by author

Figure 11. Space Syntax Macro Choice Map. Image made by author

The results did not indicate significant negative impacts, as it didn't display any degradations in the system's territory, regarding connection, integration, and choice themes. By that, it allowed us to assertively work upon the Avenida do Estado Road structure, thus supporting the interventions strategies in the proposal.

Cross-Referencing Spatial and Metabolic Data

The final stage of this study involved cross-referencing the data and information obtained though the previously mentioned methods. The findings were grouped according to their respective time periods. This allowed us to elucidate the morphological conditions present in each era, as well as their economic and market dynamics, with the aim of addressing the two hypotheses posed at the beginning of the study.

RESULTS AND DISCUSSIONS

Starting with the analysis of the 1930s, we were able to understand the economic and spatial conditions that propelled the area's industrial and productive activities. These conditions were not only defined by the physical aspects of the urban morphology but also by the logistical flows of the elements highlighted in the Metabolic Flow Map, which provided a basis for testing the initial hypotheses of the experiment.

Two main factors emerged from this analysis: the river and the railway line served as crucial foundations for the region's industrial development, supporting both logistics and supply chains. Although no definitive evidence of industrial waste disposal into the river during this period was found, it remained a point of consideration in our dissertation. Another key aspect was the Green and Blue Infrastructure of Parque do Carmo, or the later Varzea do Carmo floodplain, which played an

important spatial role in the growth of central neighbourhoods. In addition to providing recreational spaces for the population, it was the only mechanism for flood control available at that time.

The methodology allowed to highlight key issues, which were organized into the following spheres: logistics and mobility, sustainability, and economics.

In terms of logistics and mobility, the analysis revealed a prioritization of road transport in urban transformations, which remains the most utilized mode for the movement of goods and people. The proximity of a underutilized railway infrastructure near the Municipal Market presents a potential opportunity to improve goods transportation in this specific area.

In the realm of sustainability, there is a noticeable reduction in public green spaces near the Tamanduatei River.

To enhance biodiversity in the region and potentially restore the Varzea do Carmo floodplain area for recreational use and a infrastructure of flooding mitigation, the results of the Space Syntax analysis demonstrated the integrative potential this region offers to the system, should it be made accessible to the public.

From an economic perspective, waste treatment and transportation continue to be a weakness in the system. Economically, it would be valuable to consider the spatial conditions of the region to repurpose waste and reintegrate it into the production chain, with the Municipal Market itself serving as a focal point.

CONCLUSIONS

The study for the competition allowed an in-depth exploration of the complexities in São Paulo's central region. The team developed tools, outlined spatial strategies, and showed how reallocating resources could promote regeneration, in environmental, mobility, heritage, infrastructural, and economic aspects through a circular economy perspective.

The economic flow perspective, as an additional layer of analysis was introduced to the territory. This layer allowed the identification of spatiotemporal changes that either hindered or contributed to the degradation of the urban landscape, such as the underutilization of railway infrastructure and its decline due to road network investments. This shift led to the deterioration of green areas and the river, particularly where avenues were constructed in floodplain areas, restricting the river's natural course.

By identifying the spatial weaknesses and economic impacts, and analuzing them through the Space Syntax method, the study highlighted the potential for uban and landscape recovery in areas dominated by the avenue. These analyses (Figure 8, 9 and 10) enabled the anticipation and evaluation of the impacts that a potential reconfiguration of road network would have, both locally and at a metropolitan scale.

The methodology applied proved effective in identitying hidden potentials and elucidating the region's complexity graphically, presenting a proposal that connects public and collective spaces with existing economic infrastructures. This approach promotes new dynamics and perspectives for interconnected urban interventions that foster urban regeneration.

ABSTRACT

The world we live in is manifold, full of surprises, and constantly changing. Fortunately, it also offers a range of recurring and typical situations, thereby enabling us not to get lost, to experience the novel through the lens of the familiar and hence to develop a sense of feeling at home in the world. The study of typical situations in the built space has been a central contribution of Italian architects and urban researchers in the second half of the twentieth century. More than a century ago, the Austrian philosopher and founder of phenomenology Edmund Husserl applied the notion of type to denote a fundamental structuring element of human experience. Meanwhile, such related questions as the role of typification in human cognition and orientation have been underdeveloped within architecture and urban studies in general, and urban morphology in particular. The ability to recognise what kind of things are involved in any situation and to hold something new as an instance of a certain type is a fundamental human achievement that deserves to be focused on in urban morphology. As a newly formed team with a common interest in the interdisciplinary exchange between phenomenology and urban morphology, we aim to sharpen the understanding of the underlying notion of type as a fundamental structural property of the human lifeworld from two complementary viewpoints: architecture, urban morphology and heritage studies on the one hand, philosophy, phenomenology and research on experience and artefacts on the other. The paper presents the results of a workshop held at Husserl Archives Cologne in April 2024, which included a number of activities that enhanced the discussion on the role of typification in human experience and the studies of urban form. This question touches on fundamental, philosophical issues regarding the relationship between subject and object, and taking it seriously imposes a broader approach, including research on orientation, affordances, and memory.

Keywords: phenomenology, urban morphology, human experience, typification

INTRODUCTION

As a newly-formed team with a common interest in phenomenology, urban morphology and well-being, at our first workshop in Spring 2024 we sought to refine our understanding of the underlying

notion of type as a fundamental structural property of the human lifeworld from complementary perspectives: urban morphology, architecture and heritage studies on the one hand; philosophy, phenomenology, and research on experience and artefacts on the other. This complementary perspective on type and typical situations and the associated terms, concepts and topics was at the heart of this workshop. This paper begins with an examination of the core tenets of two foundational methods employed in this research: phenomenology and urban morphology. It delineates the formative inaugural event, presents the work process and discusses intermediate results. After that, it highlights the potential benefits of synergizing the two approaches and demonstrates how, starting from the exploration of type, we can go further. The paper concludes with a presentation of the main research areas that will be explored further, along with suggestions for future plans and perspectives.

METHOD

The tradition of urban form studies, or urban morphology, links architecture, urban history, planning and design through form, uniting a vast and growing community of researchers originally coming from such diverse disciplines as architecture, urban design, geography, history, anthropology, heritage studies and so on. The field encompasses several complementary approaches that are collaborating within the framework of the International Seminar on Urban Form (ISUF). One of them is rooted in the method of process-based typology founded by the Italian architect Saverio Muratori and has been further developed, among others, by Gianfranco Caniggia. It stands apart from other typological approaches in its emphasis on process and the history of the development of local urban palimpsests, which is particularly attuned to historical and cultural context. Another approach striving to link urban morphology to the phenomenology of human spatial perception is space syntax. This configurational approach to the study of urban form has been developed in the 1970s by Bill Hillier, Julienne Hanson and colleagues at the Bartlett, University College London. It examines the relationship between human behaviour and spatial configurations, comparing patterns of activity with patterns of space.

On the other side, phenomenology provides an understanding of the human experience of the world that is methodologically rigorous (Gallagher and Zahavi, 2012). In contrast to empirically-oriented disciplines, such as ethnology or psychology, it focuses on the structures of lived experience and shows (and reflects on) the ways in which things appear. The phenomenology of architecture (Seamon, 2023) offers comprehensive and in-depth investigations of the most fundamental concepts, terms and ideas in architecture – such as space and place (Casey, 2009; Malpas, 2018; Figal, 2020), dwelling, building and atmospheres (Bollnow, 2011; Böhme et al., 2014; Dodd, 2017), embodiment, environment and lifeworld (Harries, 1988; Seamon, 2018) as well as actions, perception and affordances (Rietveld and Brouwers, 2016). The experience of the lifeworld, or more precisely, of our home-world, is shaped by intentional attitudes including perception, movement, perspectivity, orientation, familiarity, historicity, and so forth (Dzwiza-Ohlsen, 2022). The concepts of typicality and habituality are profoundly relevant to urban morphology as they have a strong influence on how we perceive, interact with and inhabit our built environments.

The two-day event ‘Typical Situations’, held in Cologne, was an inter- and transdisciplinary workshop to foster the dialogue between urban morphology and philosophy. It took place at the Husserl Archives Cologne, and was collaboratively organised by Daria Belova, Thiemo Breyer, Sylvain Malfroy, Erik Norman Dzwiza-Ohlsen and Urs Primas. The workshop brought together participants from different research cultures and disciplines related to philosophy and architecture, such as

phenomenology, anthropology, enactivism, landscape architecture, urban planning and design, architectural history, and literature. The interests of the participants covered a wide range of topics and areas, including – but not limited to – phenomenology and philosophical anthropology; applied phenomenology with a focus on orientation, embodiment and ageing; phenomenology of architecture; architectural history; philosophy with a focus on metaphysics and ontology; affordances and landscape architecture; European avant-garde and architectural typology; terminology in morphology; phenomenological psychology; cognitive sciences; typological-processual as well as configurational approaches to urban morphology.

Table 1. The program of presentations of the workshop.

Day one: 12.04.2024 (11.00–19.00 CET)
11.00–11.45 Introduction of the speakers and the idea (Thiemo Breyer, Erik N. Dzwiza-Ohlsen, Sylvain Malfroy, Urs Primas and Daria Belova)
11.45–12.30 Sylvain Malfroy (Neuchâtel): "Situations: What They Do with Us and What We Do with Them. About Agency and Structural Tendencies"
12.30–13.15 Federico Vercellone (Torino): "Glossary of Morphology"
14.30–15.15 Erik N. Dzwiza-Ohlsen & Daria Belova (Cologne): "Bridging Phenomenology and Urban Morphology: The Case of Situational Typification"
15.15–16.00 Tina Röck (Dundee): "Types of Ideas and Essences – From Being to Becoming"
16.00–16.45 Irene Breuer (Wuppertal): "The Sublime Experience of Architectural Space Morphology"
16.45–17.30 Joint discussion with coffee on the way to Kolumba Museum
17.45–19.00 Guided architectural tour at Kolumba Museum
Day two: 13.04.2024 (10.00–18.00 CET)
10.00–10.30 Short introduction of the day
10.30–11.15 Julian Kiverstein & David Habets (Amsterdam): "Trusted Urban Places"
11.15–12.00 Penny Lewis (Dundee): "Arendt, the World and Architecture"
12.00–12.45 Urs Primas (Zurich): "On Typical Streets"
14.00–14.45 Luca Lanini (Pisa): "The Permanence of Type. Mies van der Rohe's Patio Houses"
14.45–15.30 Fabio Tommy Pellizzer (Venice): "The Interplay of Familiar and Unfamiliar"
15.30–16.15 Gabriella Cianciolo Cosentino (Cologne): "A-typical Situations"
16.30–19.00 Concluding discussion

Figure 1. The workshop team at "Kolumba". The Kolumba Museum in Cologne is an urban palimpsest that has been in perpetual renewal for some 2,000 years. It was converted into a space for contemplation after the Second World War by Gottfried Böhm and then in 2007 by Peter Zumthor. The varied atmospheres it provides for aesthetic experience interact with the artefacts on display in temporary exhibitions. Kolumba is a veritable laboratory for the phenomenological study of the experience of space. Photo credit: Associate of the Kolumba Museum.

RESULTS AND DISCUSSIONS

Overview

Thiemo Breyer, professor of philosophy and anthropology at the University of Cologne and director of the Husserl Archives Cologne, opened the workshop with an overview of the concepts of type and habit in Husserlian phenomenology: Our engagement with the world is not limited to isolated acts of consciousness. Rather, it is characterized by a continuous flow of habitual actions and practices structuring everyday experience. These habits are acquired through repeated engagement with the world and then become sedimented in our embodied being.

Federico Vercellone (University of Turin), co-editor with Salvatore Tedesco of a valuable Glossary of Morphology (2020), then looked at the roots of morphology. Johann Wolfgang von Goethe's process-based approach reads the evolution of form poetically, as an open-ended, non-deterministic process. His underlying idea of structural homologies between mind and nature might provide a way into an investigation of the relationships between human experience and urban form.

After these conceptual preliminaries, Sylvain Malfroy (retired at ZHAW Winterthur) addressed the typification of emerging situations. By way of example, he dissected the historical process that gave shape to the Tournay estate on the outskirts of Geneva currently undergoing a trend towards the fragmentation of land ownership and the disarticulation of its original functional structure. To characterise a part that cannot exist outside a relevant whole, Husserl had introduced the notion of 'moment', as opposed to 'piece'. Drawing on this distinction, Malfroy advocated an approach to changes of use and indices of constructability of land that is more attentive to the 'moments' that characterise each situation. In short, obsolete urban ensembles challenge us to make explicit the 'moments' and interdependent relationships that persist between different levels of scale: The politically crucial question is whether types of situations possess their own evidence, or whether they remain ultimately arbitrary.

Therefore, and according to the following presentation by Daria Belova, architect, and Erik Dzwiza-Ohlsen, philosopher (both researchers at the Husserl Archives Cologne), situational typification lies at a crucial intersection of materiality with human action, perception and affection. Both urban morphology and Husserlian phenomenology understand types in a dynamic way, involving processes of foundation, sedimentation and reactivation. Urban morphology does address the socio-cultural dimension of typical situations, albeit indirectly, through an investigation of invariant structures and typical processes underlying urban form. To this, the investigation of invariant structures of lived experience offered by phenomenology constitutes a fitting and necessary counterpart, especially when it comes to the persistent challenge of linking the individual-centred perspective of the micro-scale to the societal and institutional perspective of the macro-scale.

Then, the time had come to shake things up by exposing the audience to the backside of what we had been looking at so far. This vital role of philosophy was taken on by Tina Röck (University of Dundee, UK) by means of a summary of Martin Heidegger's critique of the Husserlian concepts of type and familiarity. Heidegger had been concerned by the ways in which immediate typification might prevent us from seeing what is actually present. Remaining within the comfort zone of the familiar, we all too easily limit ourselves to seeing how things surrounding us might serve our aims and needs. The related, crucial question of how to address the necessarily uncomfortable shift from a paradigm of

understanding to a paradigm of action and change kept occupying the participants during the remainder of the symposium.

The notion of the unfamiliar was also at the heart of the following contribution. Irene Breuer (Bergische Universität Wuppertal) introduced the aesthetic concept of the sublime: A bodily-felt emotion aroused by an excess of the sensual over the conceptual. While body and space are affectively intertwined, this co-belonging is characterized by conflicts, tensions and the suspension of meaning. Breuer exposed how contemporary architecture stages disruptive experiences by unsettling bodily habits and suspending institutionalized ways of reading space. In a fitting way, her contribution was followed up by a visit to the Kolumba complex, an urban palimpsest of some 2000 years of stratified urban artefacts, fascinating both from an architectural and morphological point of view, and as a phenomenological experience of atmospheres emerging from architectural interventions by Gottfried Böhm, in the 1940s and 1950s, and Peter Zumthor, in the 2000s.

The next day started with the introduction of a concept that might turn out crucial to our understanding of the interplay between typical urban situations and human habits: basic trust. Referring to the notion of affective scaffolds in psychology, Julian Kiverstein (University of Amsterdam) and David Habets (Amsterdam Medical Center) showed how people habitually draw upon environmental resources to sustain, amplify or dampen affective states. In this way, habits may be understood as nested in places. The city turns into a constellation of “trusted places” that are visited because of the effects they have on our bodies. It becomes clear that these places are not “outside” of us: Rather, our very existence is rooted in them.

Drawing on the work of Hannah Arendt, Penny Lewis (University of Dundee) singled out yet another perspective to the unfolding debate. Arendt’s work revolves around a central aspect of the human condition: we exist alongside each other, in plural. Therefore, the question of how we appear to each other takes centre stage. Arendt introduced a strong distinction between the twilight of the private realm – where one is concerned with one’s own life and well-being and that of friends and family – and the bright light of the public stage in which people take action concerning the affairs of the world. Obviously, this distinction is intimately related to formal properties of urban and architectural space facilitating mutual presence and visibility, but also withdrawal and seclusion.

Interestingly, there is one strand of urban morphology that explicitly addresses urban space in terms of relationships of visibility and movement. Urs Primas (ZHAW Winterthur) introduced the configurational approach of space syntax to investigate situational types of a central stage of public life: the urban street. Such a differentiation of street types according to their situation within a network can then be linked to the evolutionary typification of streets according to the processes of their formation that had been introduced in urban morphology by Gianfranco Caniggia and Gian-Luigi Maffei.

Turning the page from mutual visibility to seclusion, Luca Lanini (Università di Pisa) then focused on a crucial episode of modern architectural history by exploring the permanence of type in Mies van der Rohe’s patio house projects. While referring to the ubiquitous tradition of enclosing a place embodied by the Graeco-Roman patio house, Mies seems to attempt a cancelling of traditional domestic ideas as well as of any contextual middle-ground relating the house to its urban environment and to nature,

apparently liberating the destiny of the house and its owner from the rest of the world and from any constraints of social life.

Fabio Tommy Pellizzer (University of Cologne, Husserl Archives) then succeeded in the unlikely task of providing a preliminary synthesis of many topics that had been touched on before. Focusing on the interplay of the familiar and the unfamiliar, he started out with a discussion of the entanglement of generality and salience to move on to highlight the temporal constitution of typicality and sedimented meaning along the notions of perceiving, remembering, and expecting. Crucially, according to him, patterns of familiarity are embodied in artefacts – we never start from scratch. This leads to another important concept that needs to be added to the toolbox linking phenomenology and urban morphology: affordances. Affordances are understood as refractions of possibilities: what things have been for me, for others, and what they might or will afford.

Finally, Gabriella Cianciolo Cosentino (University of Cologne) closed the rich panoply of viewpoints with a surprising and unsettling take on the subject. She presented the results of a four-year research project investigating the transformation of prison spaces from different eras through graffiti. The marking of prison spaces with personal, devotional or political inscriptions is an age-old and recurring habit, possibly contributing to some sort of familiarity and feeling at home in a hostile environment designed to control both body and mind.

Perspectives

The workshop identified a range of bridging terminologies as well as several areas of common interest between participants that may facilitate synergies between disciplines. These areas should be further developed. On the one hand, the clarification of typomorphological concepts such as type, process, spontaneous consciousness or territory along insights from Husserlian philosophy may extend the pertinence of morphological concepts and methods beyond the study of physical urban form and lead the way towards a more comprehensive understanding of physical urban form as interlocking with social or cultural form. On the other hand, phenomenological approaches that are recently gaining traction in various areas of social or medical sciences are likely to benefit from the body of knowledge on the spatial structure and the temporal evolution of urban environments that has been accumulated within urban morphology.

A cross-examination of the notion of type both in phenomenology and in urban morphology promises to open new perspectives to both fields. In Husserlian phenomenology, the concept of “typification” refers to anticipations arising when we recognize beings, things or even situations. We tend to expect them to be alike to a certain type of beings, things or situations we are already familiar with. As these anticipations are strengthened or weakened depending on the way they are confirmed or disconfirmed by experience, typification is strongly related to habituality. Urban morphology, on the other hand, generally understands types as invariants underlying the spatial organization of artefacts such as buildings, urban fabrics or territorial structures.

But how do types emerge, and how do they change in time? And how can we build environments that connect different people by means of types? Regarding these questions, Husserl proposes the notion of generativity, referring both to the process of “generation” and to a process that occurs over the “generations” (Steinbock, 1995, 55). Some approaches to urban morphology have already attempted to go beyond the mere empirical observation and classification of types by postulating mental, social

or cultural “templates” (Deetz, 1967, 45) underlying their generation. For instance, Muratori conjectured that each development phase in the emergence of territorial structures goes along with a unique way of translating topographical features into “image concepts”. In his view, these invisible “mental labels” can be reconstructed through an analysis of regularities in landscapes reshaped by human activity (Muratori, 1967, 216). When it comes to the spatial-structural configuration of buildings, such regularities have been termed “a posteriori types” by Muratori and his followers, implying the presence of “a priori types” underlying their formation (Caniggia and Maffei, 1979, 49).

In an entirely different context, questioning the emergence of stable, socio-spatial patterns, space syntax pioneers Julienne Hanson and Bill Hillier have interpreted observable, “social-functional phenotypes”, such as typical floor plans or urban street network configurations, as indicators of underlying ordering principles, which they refer to as “social-functional genotypes” (Hillier and Hanson, 1984, 38). Regarding the further investigation and development of such conjectures, the phenomenological concept of generativity might prove crucial.

As far as the study of part-whole relationships is concerned, which is required to deepen our understanding of the city both as an “urban fabric” and as a “large-scale composition”, the conceptual pair moment/piece theorised by Husserlian philosophy is very enlightening (Smith et al., 1982; Malfroy, 2014). Muratori had already drawn our attention to this when he proposed a method for measuring the ‘degrees of organicity’ that qualifies an assembly of parts. In Husserl’s Logical Investigations, the “moment” is a property of a whole that cannot be detached (except by a process of abstraction). For example, in the case of a landscape garden, the typological character of “being landscaped” (rather than “being a kitchen garden”) cannot be isolated from the garden, but can only be verified as a “moment” concretised in the choice of planting, in the determination of the garden’s extent, in the layout of paths, in the treatment of boundaries and transition zones, and so on.

The possible and desirable convergence between the morphology of built forms, the management of historical heritage and phenomenology becomes immediately apparent when we ask ourselves whether a “composite object” can survive the loss of a “moment” as well as the loss of a “piece”. This question is generally treated under the heading of the “conditions of persistence” of artefacts (Haslanger, 2006). If we halve the area that embodies the ‘landscape moment’ of a garden, we destroy it more surely than if we remove a fountain, a bench or an arbour that are “pieces” of it. In other words, the existence of things of a certain type is entirely based on certain “moments”, whereas the detachable parts, i.e., the material parts of it, can be largely interchangeable. But a symmetrical issue to that of the conditions of persistence concerns the ‘conditions of emergence of artefacts of a new type’ (De Monticelli, 2008). Indeed, it may be that when an object of a certain type (for example, an aristocratic country manor) is deprived of its constituent moments (for example, its pleasure grounds) and thus ceases to exist as such, objects of another type take its place (for example, a hospital or a tourist hotel). The question then arises as to whether there is a rationally elucidable genetic chain linking the initial type of manor house to the successive types of hospital or tourist hotel. In other words, was it more probable that one transformation would occur than another? Husserlian phenomenology is driven by a realist aim, and it endeavours to show that the substratum of our actions is not an inert, passive reality, but a structured reality with which we can collaborate more or less intelligently.

Affordances provide another crucial notion to be included in the toolbox linking phenomenology to urban morphology. James J. Gibson (1904 - 1979), a pioneer of ecological psychology, coined the noun "affordance" from the verb "to afford" to capture how the environment provides opportunities for action (Gibson, 1977, 1979). According to him, affordances describe a relationship between the abilities of an organism and the environmental features of a situation (Marcus et al., 2016). Gibson argued that when we perceive a situation, we observe its affordances rather than its particular qualities. This viewpoint is of central importance to morphological analysis: While it is possible to objectively describe the physical properties of urban form, such a description would be of little use if it would not consider the activities, behaviours and uses that these physical features afford. Therefore, we may understand affordances as refractions of possibilities, thereby going beyond the physical layer of form.

For instance, the discussion on prisons as highly typified architectural environments paradoxically generating extremely unfamiliar situations prompted a consideration of the role of boundaries and limits as affordances. An important role of graffiti in prisons is to transcend the boundaries, to expand the physical and mental boundaries of the enclosed space. Furthermore, graffiti serves the function of an immaterial wall – a protection from demons and a sign of belonging to the group. Therefore, it has a dual function of transcending existing boundaries and creating new ones. Thus, affordances can manifest in different dimensions and belong to different layers of existence, ranging from the physical to the mental or spiritual. This leads to the question of material and immaterial forms and their interrelation. How can immaterial form transcend or alter the limits of physical form?

The phenomenological understanding of architectural and urban experiences involves the typicality of the senses (Merleau Ponty, 1945) as a fundamental aspect. There is a "typological" character of multimodal perception based on the stability of intersensory relations. The body is a coherent sensory organ, organizing smell, taste, vision, and touch around a "milieu" of action; it establishes types of intersensory relations and equivalences that give depth and richness to what we perceive. Typicality, therefore, may be conceived as an "echo" of one sense into another, an echo that resonates in different sensory fields and reverberates in different segments of experience. This typicality of senses, along with the concept of synaesthesia – a condition in which stimulation of one sensory field correspond to the experiences in the other sensory field, should be considered in the projects of enhancement of built environments, especially when aiming at well-being for different generations.

The phenomenological concept of embodiment provides a complementary to studies of physical form and can be another one of the bridges connecting phenomenology and urban morphology. Embodied habits are of particular interest for the question of how to shape familiar living environments. Embodied habits are discussed as an important resource of personal identity, particularly in the context of dementia, and the potential of dementia-sensitive living space design, especially in urban areas, is by no means exhausted (Dzwiza-Ohlsen, 2022). Additionally, the method of space syntax implies typification and categorisation (Hillier et al. 1984) and relates patterns of activities to the patterns of space. Patterns of space generate potentials for vision and movement, thereby facilitating the allocation of density, shops or transport stops – the patterns of activities. Therefore, the principles of orientation and movement highlighted in phenomenology and the notion of embodied cognition can further enrich the methodological insights of space syntax.

Patterns of familiarity are embodied in urban artefacts – we never start from scratch. The bodily-conferred principle of gradual, consistent and continuous space formation, based on traditional bodily habits, advocates a natural integrity of architectural forms and can be related to the typological process. From a joined phenomenological and architectural perspective, the historical, continuously formed city can be seen as a constellation of trusted urban places, which affect our bodies in a certain way, fostering basic trust. Such places deserve careful morphological study, they organise our affective experiences and give form to feelings: This is where congruent social, emotional and urban forms emerge. The concepts of nesting and sedimentation are of particular interest here: One might think of habits in terms of nesting. When habits become embedded in the body, sedimented or incorporated, we begin to experience the world through that habit. Typical places and situations are therefore incorporated, we orient ourselves by habits. It would be interesting to link the concepts of trusted urban place and basic trust with Caniggian process-based typology, particularly with gradual typification processes. This may allow to define environments that have formed through the spontaneous adding of innovations to traditional types and instances as potentially familiar and trusted.

Finally, as Thiemo Breyer has put it, through the lens of phenomenology we aim to discern the underlying structure of perception and cognition that gives rise to our understanding of the typicality of diverse urban landscapes. Combining phenomenology and urban morphology allows us to go further. The innovative potential of the framing of this workshop lay in the investigation of the complex interplay between human experience, urban environment and the nature of typical situations, focusing on how they shape our lived experience and define well-being in urban environments. Types allow for the emergence of legible and coherent urban environments, contributing to the formation of recognisable urban identities and fostering a sense of place and belonging. Habitual patterns of use and behaviour also play a crucial role in sharpening the usability of architectural spaces. Buildings contain elements that facilitate and support habitual activities, such as intuitive wayfinding systems and efficient circulation patterns. The concept of habit extends to the wider urban context, where the layout and configuration of streets and neighbourhoods influence daily routines and the relationship between rationality and experience. By aligning architectural design with habitual behaviour and routine, architects and urban designers may enhance the user's experience of the built environment.

CONCLUSIONS

The workshop identified a range of terminologies that require clarification and several areas of common interest among the participants that can facilitate the integration of disciplines and methodologies. Generally, a productive connectivity of (Husserlian) phenomenology, enactivism and anthropology with morphological methods such as the typological-processual or space syntax approaches can be established through the concepts of embodiment, familiarity, horizon, habit, and lifeworld.

We aim to develop research with the overarching objective of fostering inter- and transdisciplinary dialogue. Our goal is to identify methodologies for shaping urban environments in a manner conducive to enhancing the quality of life, well-being and to multi- and transgenerational transfers of meaning. We will facilitate the dialogue on the transformation of the meaning of place in time, with a view to

forming intergenerational environments for the present and future that are respectful of well-being. ‘Typical situations’ is an accepted umbrella term for our future collaborations.

The future plans of the team include, but are not limited to, several components aimed at exploring and refining key concepts and methodologies, such as a journal special issue and a glossary. To further promote dialogue and expand the group a wide variety of potential academic events is intended, such as workshops, conferences, open lecture series, art schools, design studios, and summer schools, for example on the topic of ‘intergenerational environments and meaning transfer’.

ABSTRACT

The disruptions in urban spaces and the population's quality of life caused by climate change phenomena urge a holistic interpretation. The funded research project CLIMATE ADAPTATION FOR OLDER PEOPLE LIVING IN VULNERABLE URBAN AREAS (CAOP, PTDC/GES-URB/2038/2021) aims to provide a Handbook for a Climate-Responsive and Community-Based Urban Planning/Design to deal with the effects of heat stress on health/quality of life through the development of a climate-sensitive and community-based urban planning and design methodology. Within the scope of a broader multidisciplinary team consisting of climate-change, health, and urban planning experts, the Faculty of Architecture (FAUP) researchers investigated the morphological and socio-urban conditions of two vulnerable urban areas located in the eastern part of Porto City, Portugal – the São Roque housing neighbourhood (1930s) and the social neighbourhood (1960s construction) and São Roque da Lameira Street (an ancient street). Consequently, an evaluation methodology was developed by this team to explore the spatial dimension of the vulnerability concept, recognising the role of public space in promoting inclusive, resilient, and sustainable communities with direct benefits for the well-being of older people. This paper primarily discusses the application of a methodology based on the “proxy attributes” of urban form and an understanding of older populations' practices and perspectives. Using morphological, ethnographic, and co-creation methodologies, it explicitly analyses the urban form's configurational and geometrical properties of the public spaces that promote healthier cities, and the public space uses and preferences of older residents. The findings suggest that some public space attributes can be considered for urban retrofitting measures by testing a tool to evaluate the relationship between urban spaces' spatial configuration with different thermal conditions and older populations' perceptions. These adaptive attributes are believed to safeguard the inhabitants during extreme heat events. Finally, the evidence presented in this paper shows that by exploring the potential of particular public space attributes design decisions can be better informed. Additionally, CAOP's multidisciplinary approach highlights the pressing importance of a comprehensive framework to support sustainable urban strategy development based on the multidimensional analysis of socio-morphological, microclimatic, and health issues.

Keywords: heat stress, older people, public spaces, urban form, healthy cities

INTRODUCTION

Nowadays, the climate adaptation issue is a cross-cutting challenge that presupposes developing an adjustment process to respond to actual and expected climate change and its effects (IPCC, 2014), particularly those of global warming. According to the IPCC (2023), warming will cause predictable increases in multiple climate hazards and present a variety of risks to ecosystems and human beings. The risks and dangers will be felt unevenly across different urban environments, according to their frequency and intensity. Against this background, adaptation measures are expected to protect the health and well-being of communities and the social fabric of public spaces (streets, squares, green and open spaces) (Foshag et al., 2020). Urban areas are more exposed and susceptible to the effects of climate change related to heat waves and extreme heat events, among others. Recognising the importance of this issue, the research project "CLIMATE ADAPTATION FOR OLDER PEOPLE LIVING IN VULNERABLE URBAN AREAS (CAOP). Designing a climate-responsive and community-based methodology" [PTDC/GES-URB/2038/2021] brings together a multidisciplinary group of researchers from the University of Porto and the University of Coimbra, supported by an international team of experts, in the pursuit of a plan that will contribute to mitigating and adapting to extreme temperatures.

The research project analyses two vulnerable urban areas – the São Roque da Lameira neighbourhood and the street of the same name in Porto, Portugal, considering that these study areas are at high risk of extreme temperatures in summer. A significant trend has been noted towards an increase in the number of days with very high temperatures (≥35°C) and tropical nights with high minimum temperatures of over 20°C, as well as in the annual rate of heat waves. Additionally, cold days and nights and the number of cold waves have decreased (CMP, 2018). In view of these changes, the CAOP focuses on investigating the impacts of extreme heat temperatures as, according to projections, their frequency is likely to increase. The CAOP research project seeks to ascertain the socio and spatial conditions that influence the adaptation capacity of the urban system to extreme heat and thus contribute to the thermal comfort and well-being of the people, particularly the elderly population. More specifically, it proposes (1) to analyse the morphological and socio-urban conditions of the selected areas, (2) to understand the practices, perspectives, and representations of older populations regarding these urban spaces, and (3) to create and evaluate a collaborative and integrative urban planning/design methodology.

The CAOP's multidisciplinary and holistic framework rests on a qualitative and quantitative approach to public spaces, along with studies, co-creation, and the participation of older people, with the ultimate goal of creating a Climate-Responsive and Community-Based Urban Planning/Design Manual. It is foreseen that this manual will assist the actions of local stakeholders with powers and functions in urban planning (municipalities, parish councils, companies, organisations, associations, and universities). Thus, the main goal of this paper is to present a proposal methodology consisting of a spatial-morphological analysis, thereby contributing to promoting age-friendly public spaces and the health and well-being of older people in the context of climate change. Facing the heat stress phenomenon, the analysis of the "proxy" attributes (an indirect measure of the desired outcomes, e.g. diversity, connectivity) (Feliciotti, Romice and Porta, 2016) of the public spaces, the observations of the physical characteristics and activities in the latter, and the co-creation process integrated into CAOP's methodology have enabled a more comprehensive understanding of the extreme heat

impacts. In turn, the socio-morphological perspective assesses how urban environments' social and physical structures interact to influence vulnerability to heat stress, i.e., exposure, sensitivity, and adaptability. Socio-economic factors with spatial and morphological characteristics are integrated into this approach to identify at-risk areas and populations and develop holistic mitigation and adaptation strategies.

More specifically, in CAOP's multidisciplinary framework, this line of approach, led by the Faculty of Architecture of the University of Porto (FAUP), proposes to address how urban form can minimise the impact of climate stress and to develop methods to assess the adaptability of form to climate impacts. To this end, selected configurational and geometrical properties will be operationalised using quantitative indicators and defined public space attributes will be qualitatively analysed using local observations, participatory sessions with older residents, and interview forms. This paper presents a holistic method of socio-spatial analysis that incorporates qualitative and quantitative approaches and focuses on evaluating the attributes of the urban form of two selected vulnerable areas, as well as the observations of the functional use and structure of their green/open spaces. The first section delves into framing the concept of vulnerability, users' vulnerability, and exposure in public spaces, which supports the theoretical approach to the spatial-morphological framework of public space adaptation to heat stress described in the second section (methodology). Section three (results) presents the application of the methodology with the operationalisation of the urban form attributes and the observation of their public space's characteristics and users' interactions in public spaces. Lastly, section four (conclusions) suggests possible guidelines to promote a more age-friendly public space by reducing exposure to high levels of heat.

Users' vulnerability, exposure in public spaces and adaptation strategies to heat stress

In this study, the analysis of the impact of high temperatures on public spaces focuses on users' vulnerability. The concept of vulnerability has been interpreted differently over time, however the CAOP project has adopted the idea proposed by the Intergovernmental Panel on Climate Change (IPCC) in its Third Assessment Report (TAR/AR3) (IPCC, 2001: 388). This interpretation understands vulnerability as the degree to which a system is susceptible to and unable to cope with the effects of climate change, including climate variability and extremes, which depends on the character, magnitude, and rate of climate change, the variation to which a system is exposed, and its sensitivity and adaptive capacity. Exposure refers to the contact between individuals and indoor or outdoor environments where environmental conditions, including air temperature, radiation load, atmospheric humidity and air speed represent a risk of increasing core body temperature or causing discomfort (IPCC, 2001: 373). Sensitivity, a property that determines the degree to which a system is affected (beneficially or adversely) by a given climate exposure is based on individuals' physiological state or behavioural response to changes in environmental temperatures. Adaptability is, therefore, a property that reflects the capacity or ability of a system, in this case, an urban system, to prepare for and respond to climate change, considering the continuous increase in greenhouse gas emissions.

Hence, when assessing the impacts of climatic phenomena, decreasing the vulnerability of older people to urban heat stress and promoting user-friendly urban public spaces involves considering parameters linked to exposure, sensitivity and the adaptive capacity of systems, i.e. (1) indicators related to climate variability; (2) indicators relating to the demographic, socio-economic profile that inform about the impact of extreme temperatures on human health and economic activities

(percentage of population exposed to several days of extreme heat) and (3) indicators related to the physical environment's capacity for adaptive change. In CAOP's research, the sociodemographic health profile indicators are related to particularly vulnerable groups, such as older people. According to the World Health Organization (WHO), older people are particularly vulnerable groups because of their physical and economic condition, and they are also susceptible to the outside temperatures in extreme heat (WHO, 2021). Works such as IPCC (2021) and Figueiredo, Midão et al. (2024) explain the direct correlation between high temperatures and the health problems experienced by this fringe of the population.

Creating attractive urban green and open spaces can help with this control. Public health needs to provide green spaces that encourage older people to be active while equally allowing for social interaction. For example, Owen et al. (2010) have shown that physical activity improves cardiovascular health, mental health, neurocognitive development, and well-being. Along with the quality of the green/open spaces, the quality of facilities and the outdoor thermal environment have an essential influence on the frequency and activities of residents in open spaces. Moreover, regarding the different outdoor thermal perceptions of older people, various authors (Yung et al., 2019) argue that they depend not only on physiological elements, but also on physical and individual factors (age, biological sex, education, economic level, and chronic illness). In this regard, studies such as that of Ma et al. (2021) highlight the importance of exploring the relationship between a number of influencing factors (age and chronic disease) and the thermal perceptions of older people.

Following this line of reasoning, CAOP's methodology incorporates the development of a socio-morphological approach, targeting identified areas within the urban environment that are more susceptible to high temperatures and the effects of heat waves. This approach is based on site-specific observations, questionnaire surveys and activity logs to investigate older people's spatial-temporal distributions and thermal perceptions (i.e., thermal sensation, thermal comfort, and thermal acceptability). At the same time, the configurational properties of public spaces are quantified to establish a correlation between the qualitative and quantitative analyses. The sensitivity of public spaces to extreme heat conditions depends on their physical, environmental, and sociocultural characteristics, and their adaptability and coping depend on their accessibility and inclusiveness. These characteristics affect thermal comfort within these spaces and the people using them (Quesada-Ganuza et al., 2023). Thus, in CAOP's research context, the socio-morphological approach is based on the analysis of "proxy" attributes directly related to promoting older adults' health and well-being through age-friendly public spaces in vulnerable areas: proximity, porosity, diversity, accessibility, centrality, and redundancy. For example, the analysis focuses on whether older people have access to age-appropriate health and recreational facilities close to their homes. The following section proposes a holistic methodology supported by different analysis tools for the varying scales of the case studies. This analysis aims to be used as a critical and comprehensive framing of the concept of users' vulnerability, exposure in public spaces, and adaptation strategies to heat stress.

METHOD

The proposed method aims to evaluate socio and morphological vulnerability, to select small typo-morphological units of the São Roque da Lameira study area located in the Campanhã parish of Porto and, according to this assessment, analyse their public spaces in detail, combining spatial analysis with the observations recorded by the FAUP research team and with the community of users, namely the

older residents. The parish of Campanhã, on the eastern side of the municipality of Porto, combines a higher concentration of older adults and municipal housing neighbourhoods, having recently been defined as an Urban Rehabilitation Area (ARU) to strategically promote its improvement (CMP, 2018). Additionally, this area is the hottest part of Porto: on days with this synoptic situation, the axis between Praça das Flores and São Roque is identified as a "thermal peak" (Monteiro, 1993). Within this broader heat concentration zone, although the urbanised areas such as São Roque da Lameira are in locations with slightly lower sun exposure, they present specific sociodemographic characteristics that increase their social vulnerability: In 2011, São Roque da Lameira ranked higher on the Ageing Index than other surrounding areas and also displayed the second highest Ageing Rate figure (257,3 %). As for the Dependency Ratio, calculated as the ratio between the dependent population (residents in the 0-14 and ≥ 65 age groups) and the active population (residents of working age), the São Roque area stands out negatively, with around 70 dependent people for every 100 working-age people. In population terms, São Roque emerges as the oldest area within the ARU, with 29.6% of its residents aged 65 years or over. At the same time, the rate of children (up to and including the age of 14) of its total resident population is also lower (11.5%) (CMP, 2018). This socio-dynamic continued until 2013, when such social neighbourhoods contributed to the high figures of the Ageing Rate and Dependency Ratio of the São Roque Area, approximately 304,4 % and 44,31%, respectively. Therefore, combining these climate and sociodemographic characteristics, two study areas were selected: São Roque da Lameira Street (an important and busy axis in this part of the city) and the São Roque da Lameira neighbourhood (a residential area with public housing blocks and private semi-detached houses) (Figure 1).

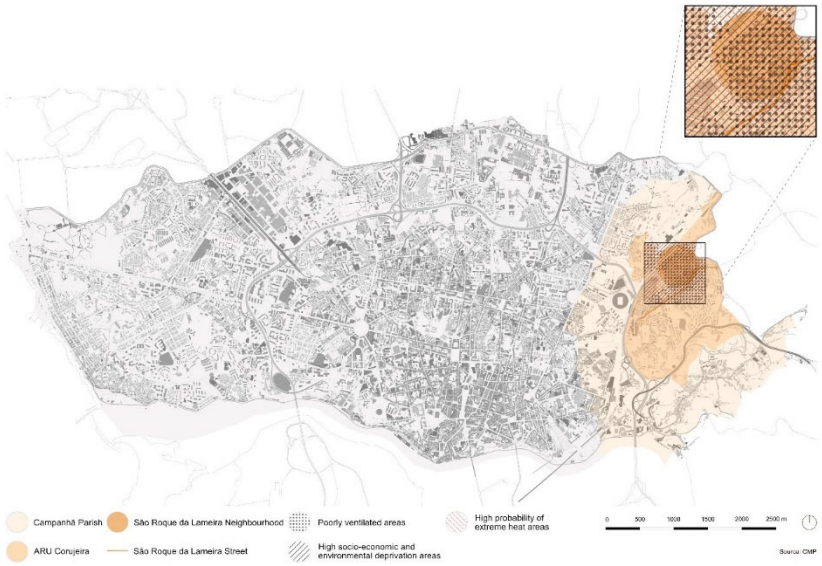

Figure 1. The study area: São Roque da Lameira climatic condition and the location of the study areas (street and neighbourhood). Porto: authors 2024, using municipal cartography.

The public spaces of the neighbourhood and street of São Roque da Lameira are heterogeneous as far as public space attributes are concerned. Both are indicative of the morphological and spatial diversity of the area (Figure 2). The neighbourhood presents a homogeneity of uses, pedestrianisation of the street network, and no maintenance of the public spaces, while the street displays a diversity of uses and disabled pedestrian paths. Acknowledging these neighbourhood characteristics, the study adopts

a multidimensional method comprised of several tools and tasks that seek to assess various aspects of the public space on different scales and from complementary perspectives. Therefore, the methodology includes a broader quantitative dimension and a local qualitative analysis.

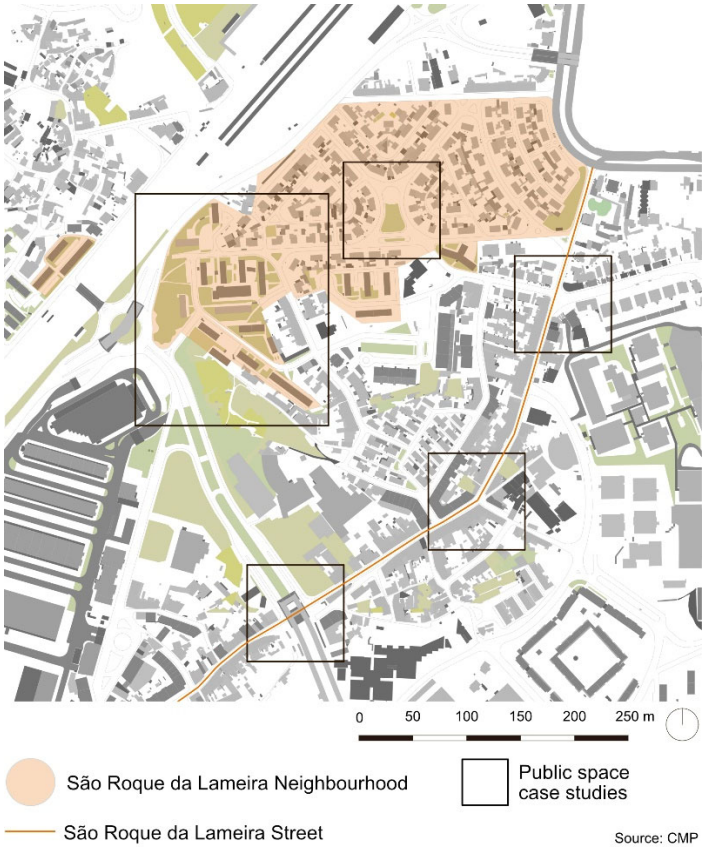

Figure 2. São Roque da Lameira case studies – public spaces of São Roque da Lameira neighbourhood and street. Porto: authors 2024, using municipal cartography.

As regards the quantitative dimension, the methodology is based on the analysis undertaken and tested by Monteiro and Pinho (2020), focusing on morphological units in the same geographical context (Porto). The adaptation of this method by the FAUP team to the CAOP project is explained in detail in a previous paper (Lameira, Fernandes, Ramos and Martins, 2024). It consists of the initial procedure of delimiting and characterising the morphological units and identifying the typological process for each. After defining the typo-morphological units, the physical and functional vulnerability analysis is conducted, evaluating the correlations between the urban form's configurational and structural characteristics of the different typo-morphologies and the classification of the typo-morphological units. It explores the physical and functional dimensions of vulnerability, which implies an intrinsic relationship with the social dimension. Firstly, physical vulnerability is evaluated based on the street system in order to gauge the degree of accessibility, centrality, and spatial redundancy of the units under study. Public spaces/green infrastructure (streets, squares, green spaces) are also subject to analysis, associated with proximity, porosity, and diversity. Secondly, functional vulnerability focused on the activities carried out in each typology is evaluated according to public service facilities, among other criteria - indicators such as the availability of primary and secondary activities.

In the qualitative approach of the next step, it is essential to coordinate the evaluation of the "proxy" attributes of the public spaces with the attributes ascertainable through observation of the materials, use of green spaces, presence of trees, and perceptions of the residents, mainly the older dwellers. This complementary study uses a qualitative, multiple-case approach to make the diagnosis. Empirical data, consisting of a participatory workshop, observations, a survey form, and informal conversations, were undertaken by the FAUP group of researchers and are currently being analysed. Walk-along interviews with users will also be undertaken in the near future as part of the ongoing process.

On the one hand, the participatory workshop brought together inhabitants, researchers, and representatives from local associations and the municipality in a working session to collectively map routines in the public spaces in this area and obstacles to a more comfortable usage. At this point, the aim was to gather data on dimensions associated with use and users, accessibility, amenities, urban furniture and artificial elements, comfort, safety, the image of the space, the environment, and social interaction, as well as to identify potential and co-create proposals for improvements. On the other hand, the observations were conducted systematically, mapping the public life and dynamics of the spaces in the neighbourhood and street, moving within the space to gather more information and different perspectives. These observations were undertaken in the case studies' major public areas (five squares in the neighbourhood and three crossings/squares in the street) on several summer days in August 2024. Late mornings and evenings of weekdays and weekends were the chosen periods. Each observation had a duration of 30 minutes, noting the people spending time in spaces (their activities and characteristics) and the passers-by (their trajectories and profiles), as well as the attributes of the space and their use (bus stops, benches, shade, trees, among other features).

A survey form was also used to collect georeferenced information on the location and conservation of urban furniture and green spaces, among other parameters. The development of this step is intended to generate a diagnostic report of the public spaces in the neighbourhood and street of São Roque, assessing not only the degree of friendliness but also the strengths and weaknesses of each area according to the older people's perceptions, as well as proposing actions for improvement. These actions can be applied in cases with similar vulnerabilities identified in the study area. This prospective diagnosis will be accomplished with informal conversations, where some older users may identify their choices, sense of belonging and well-being, sense of comfort and safety, their perception of the state of repair of the public space, well-being in hot and windy weather, accessibility, amenities, furniture, and urban equipment, in addition to their ideas and suggestions.

This collected and evaluated information will enable proposals to be drawn up with different levels of implementation which, together with the proposed methodology for the socio-morphological analysis, constitute the starting point for the preparation of the Measures and guidelines of the Climate-Responsive and Community-Based Urban Planning/Design Manual, the final output of the CAOP research project. Therefore, these qualitative and quantitative analyses are intended to classify types of urban form, relating the characteristics of form that support the resilience of the environmental, social, and health dimensions with the same stress.

RESULTS AND DISCUSSIONS

This section presents the preliminary results of the methodology and its different tasks. As previously stated, the analysis focuses on the operationalisation of the vulnerability concept in an urban system

- São Roque da Lameira area, relating to social, health and physical conditions, and systemic interaction, exploring the spatial dimension of vulnerability. With a previous morphological analysis, it was possible to identify different morphological units that emphasise the diversity of the São Roque urban area: continuous frontage (UM1), discontinuous frontage (UM2), fragmentation (UM3), exceptional (UM4) and rural nuclei (UM5) –, as can be seen in Figure 3. The preliminary results will then be presented, expressed in maps on factors related to urban form measures with a potential impact on the social interaction and health of the older people in this area. The study focused on the UM1, corresponding to São Roque da Lameira Street and the UM2-UM3, to the neighbourhood, since they are both predominantly residential areas within a compact tissue. However, the analysis will be conducted locally, given the nature of the spatial analysis parameters.

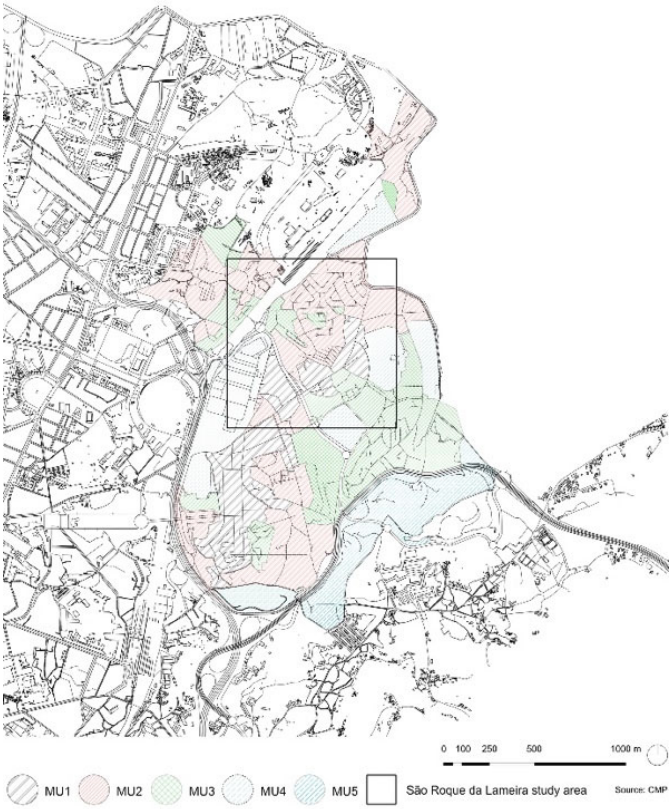

Figure 3. Preliminary identification of morphological units. Porto: authors 2024, using municipal cartography.

The factors mentioned above are related to (1) the measurement of the distance from different parts of the neighbourhood to key nodes along São Roque da Lameira Street, such as transportation hubs, commercial centres, and other activity points; (2) the measurement of the proximity of the neighbourhood to the nearest bus stations, an essential factor for public transit accessibility; (3) the assessment of the accessibility of essential indoor services, such as pharmacies and community centres for residents, (4) the evaluation of the amount of green space within the neighbourhood that is accessible to residents, especially considering factors such as proximity, slope, and pathways; and finally; (5) the evaluation of the slope gradient within the neighbourhood to assess accessibility challenges, especially for older adults or people with mobility impairments.

To measure these indicators, a walkable area was defined, i.e. starting from the central point of the São Roque neighbourhood (Origin Point, Figure 4), we established a 5, 10, or 15-minute walking, referring to accessibility to essential services, amenities, or infrastructure. Figure 4 illustrates the

covered area by the resident population over 65, considering a pre-determinate walking speed (V=0.8 m/s, CML, 2013; Alves et al., 2020), using the data obtained by Qqis Network Analysis. Within the walkable area of the São Roque da Lameira neighbourhood, access varies to green spaces, bus stops, facilities and the São Roque da Lameira street nodes (Figure 4).

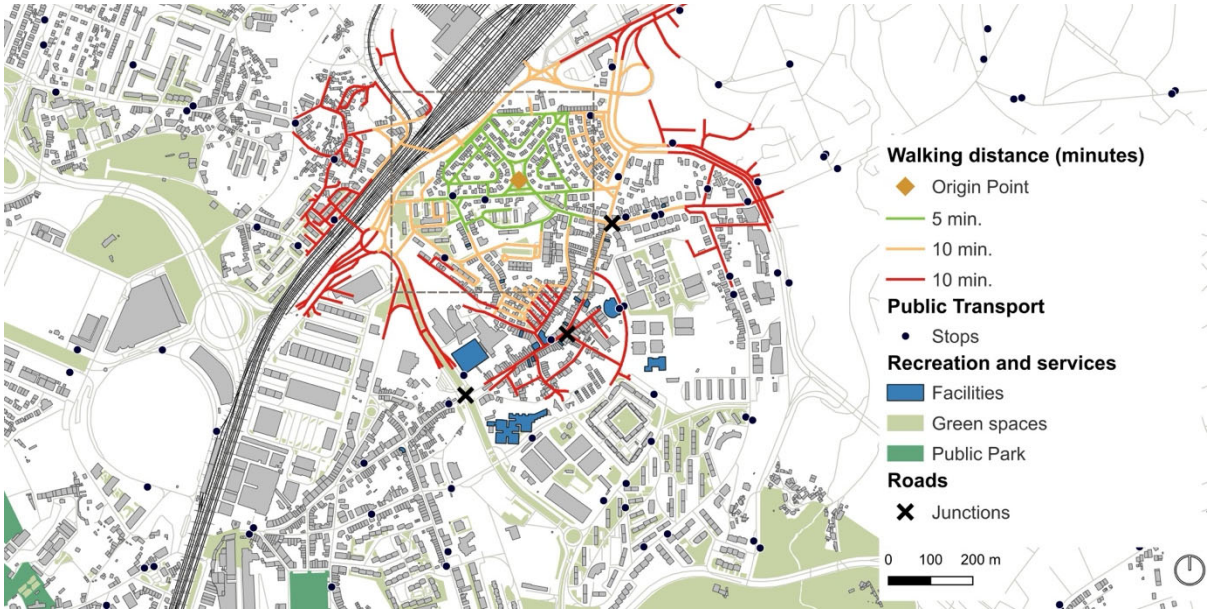

Figure 4. Walkable paths in the São Roque da Lameira neighbourhood. The characteristics of the pedestrian network and the characteristics of individuals influence the speed at which individuals travel and, consequently, the time taken to access a given point. As the characteristics of individuals influence speed, the circulation speed for adults with restricted mobility, such as the older population, was considered V=0.8 m/s (CML, 2013; Alves et al., 2020); São Roque da Lameira neighbourhood accessibility to a) São Roque da Lameira street nodes: central points of activity, transportation, or commercial hubs; b) public transport: bus stops; c) social facilities: pharmacy, social centre, healthcare centres, grocery store, bakery, butcher, supermarket, coffee shop, church. Porto: authors 2024, using municipal cartography and data obtained by Qqis Network Analysis.

The following observations were garnered on the afore mentioned parameters**.** Firstly**,** the distance between the São Roque da Lameira neighbourhood and the main São Roque da Lameira street nodes, central points of activity, transportation, and commercial hubs is a critical factor in urban planning, influencing both the quality of life for residents and the vibrancy of the area. Within a 10-minute walking distance, the older residents of the São Roque neighbourhood have access to one central node, with an additional 5 minutes needed to reach another junction. Upon analysing the access coverage and the distance from the São Roque da Lameira neighbourhood to nearby bus stops, we concluded that within a 5-minute walk, the older residents can only reach two bus stops, and within 10 minutes, they can reach four additional stops. While there is a relatively dense and comprehensive public transport network, physical barriers and the poor condition of pavements observed on-site reduce adequate accessibility. Furthermore, when evaluating the distance between the São Roque da Lameira neighbourhood and the facilities, essential services, and social infrastructures (shown in blue in Figure 4), it is evident that older adults must walk at least 15 minutes to access these resources. Lastly, regarding access to public green spaces, strategies are needed to improve overall urban liveability, ensuring that all residents, regardless of their mobility, can easily reach and enjoy these green spaces, as they are more than 15 minutes away on foot.

As illustrated by Figure 5, the slope is a critical factor influencing walking activity in the São Roque da Lameira area. In the study area, (1) most of the area consists of gentle to moderate slopes, shown in green in Figure 5, which can enhance physical fitness and introduce variety to walking routines, especially benefiting older people; (2) some areas are characterised by excessively steep slopes, depicted in red in Figure 5, which may discourage frequent walking due to the increased physical effort required and potential discomfort, leading older people to avoid these areas; (3) While the neighbourhood itself is relatively flat, the surrounding areas feature increasingly steep slopes and physical barriers such as traffic lanes, as seen on the left side of the neighbourhood. In the São Roque study area, there are specifically (1) gentle slopes (0 to 9%): from 0 to 5%, they are almost flat and comfortable for most pedestrians, including people with limited mobility, and from 5% to 9% slightly more noticeable but still manageable for walking, common in the residential streets and pavements; (2) moderate slopes (10 to 18%): from 10% to 12%, the range begins to feel more challenging for pedestrians, particularly those with mobility issues. Walking uphill becomes more effortful, and from 13 to 18%, slopes are noticeable and demanding, especially over longer distances.

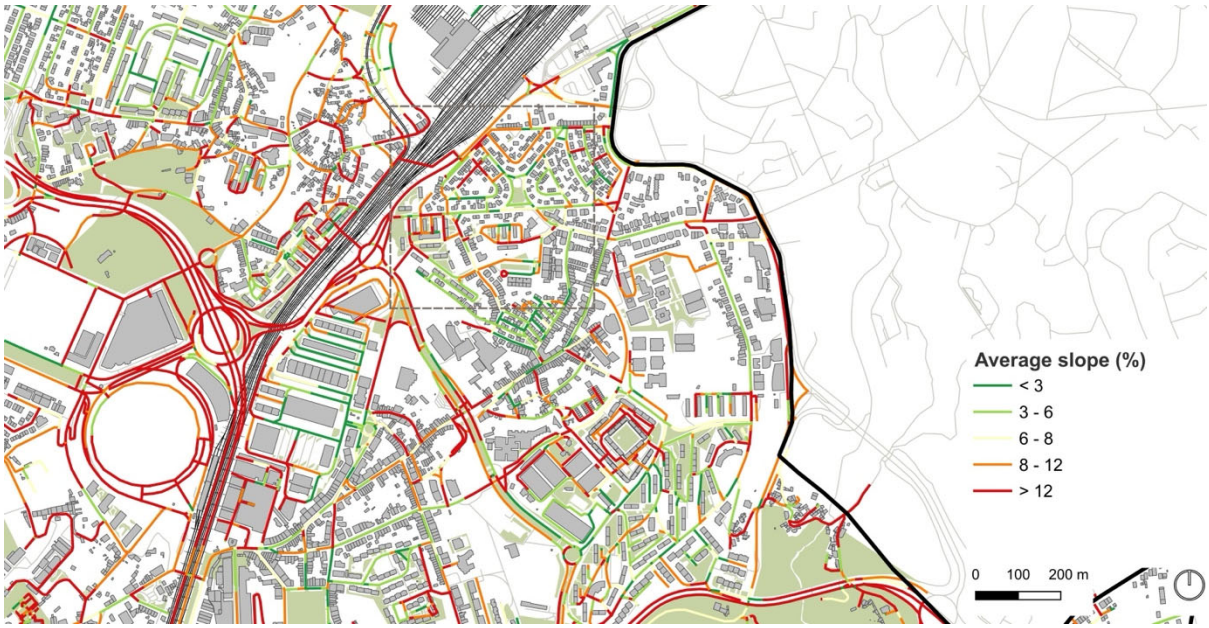

Figure 5. Slopes in the São Roque da Lameira neighbourhood, obtained from the digital terrain model made according to the available municipality data. Porto: authors 2024, using municipal cartography.

The use of public spaces depends significantly on the factors discussed above. However, it also depends on factors such as ease of walking, safety, and the specific needs of older individuals. Therefore, participatory sessions, informal conversations, and on-site observations served to establish a critical evaluation of the quality of São Roque's public space. Thus, the following observations are worthy of note. The participatory session and the informal conversations provided the opportunity to collect the perceptions of several residents and local users (Figure 6). Some of the aspects mentioned were, in particular, (1) public spaces with obstacles and uneven terrain that cause a sense of unsafety and discourage their use; (2) interventions to renovate public spaces that do not consider the needs of residents, particularly older adults (“it's got even worse”); (3) inadequate physical maintenance of spaces, which are deteriorating due to the breakdown or unsuitability of materials; (4) accumulation of solid waste, whether due to the actions of some users or to the lack of regular public cleaning; and (5) insufficient social facilities (such as nursing homes and daycare centres) and closed-down premises

(such as a daycare centre for people with special needs). The participant residents suggested increased vegetation, shade and rest furniture, and the improvement of pavements, lighting, and social facilities.

Figure 6. Photographs of the participatory session and one of the maps produced by the participants. Auditorium of Campanhã parish (Porto), photo credit: authors, 2024.

The observations in the neighbourhood (Figure 7) point to the use of public spaces by recurrent people, possibly related to their daily routines and personalities. Besides groups of children playing, teenagers and young adults, the older users were mainly couples, a lady strolling with her grandson (who, due to a lack of nursery placements, needs this support while his parents are working), individual older people walking their dogs, and a group of older women gathering for evening chats. The neighbourhood is also used by residents and non-residents, the latter relying on shortcuts, both through the existing public spaces and by creating informal paths on the green areas.

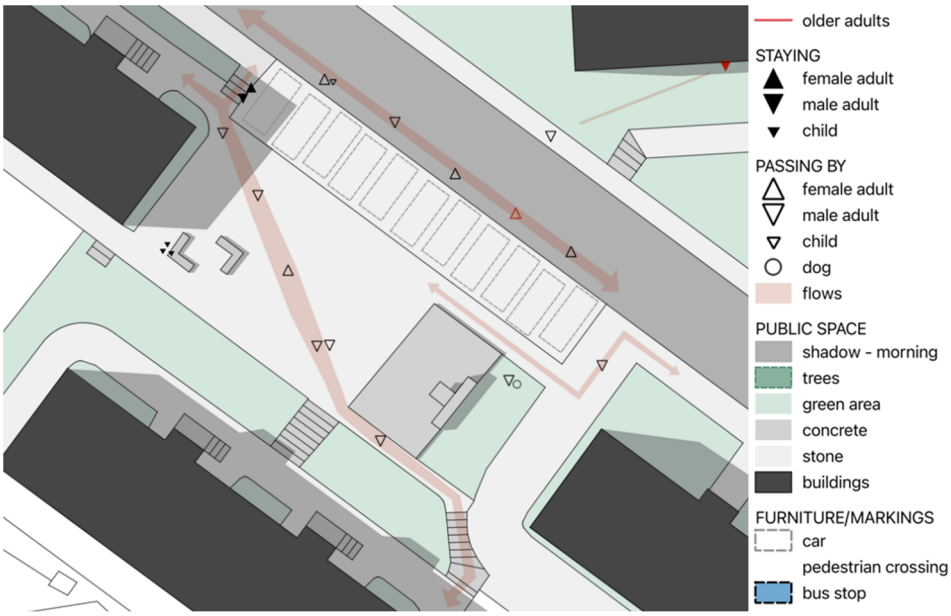

Figure 7. Diagram of one of the public spaces in the São Roque da Lameira neighbourhood, showing the characteristics of the space, user activities and routes. Porto: authors 2024, on municipal cartography.

The observations in São Roque da Lameira Street (Figure 8) revealed that most pedestrian movements occur within the scope of proximity routines and needs (such as buying hot bread, grocery shopping). Some older adults take short round trip routes and proximity circuits (taking a particular street in one direction and a different one to return), showing how daily chores are integrated in a broader stroll.

The bus stops, always crowded in this area and rapidly refilled after the departure of each bus, suggest insufficient or non-existent seating space and shading. Another frequently observed situation was that of older adults frequently having to stop to catch their breath along the routes, with no rest points or furniture available, requiring them to hold onto existing signposts or sit on low walls.

These observations show that, in line with the studies of other authors (Foshag et al., 2020), one of the most pressing issues regarding older people is their safety and accessibility needs. It is essential to understand the most valuable and frequent route that older people take in their daily lives in the neighbourhood and its level of safety and accessibility, analysing it from the perspective of older adults and their specific needs. For instance, bus stops in this area may appear to be easily accessible for many older adults (through the numeric distance indicators and area coverage), the routes to reach them remain challenging, making it essential to consider a finer network of rest points and better-equipped stops. However, this spatial-morphological study demonstrates that in addition to safety and accessibility needs, urban design must respond to increased overall comfort in terms of use (shading, furniture and equipment). In this regard, areas of sunlight and shade must be taken into consideration, based on the various users and respective uses, according to which different scales of design adjustments are proposed: climate-controlled seating and meeting areas, shared activities and pedestrian spaces, rest zones with gentle slopes, suitably positioned signage and lighting equipment , and cooling resources such as bodies of water or shaded areas, trees and vegetation, as well as the use of materials with high solar reflectance, and cooling façade and floor systems.

CONCLUSIONS

From a socio-spatial perspective, in the context of urban public spaces vulnerable to high heat levels, promoting policies and processes for social inclusion and spatial rehabilitation in the study area is a challenge for the municipality. In the CAOP project, as in the Un-Habitat Policy (Martinuzzi and Lahoud, 2020), it is believed that inclusive design, well-managed and adequately maintained public spaces can significantly impact the communities' social and economic conditions, as well as the health

and well-being of the population, mainly the elderly. Also, urban form is believed to significantly affect heat stress, especially in the context of rising global temperatures and urbanisation (Emmanuel and Perera, 2017). To address the issue of urban climate mitigation and adaptation, this paper proposes a holistic approach, combining socio and spatial dimension analyses. Although this is a work in progress, it may be concluded that by integrating quantitative and qualitative tools into urban planning and design processes, cities can develop environments that protect vulnerable populations from heat stress and promote the health, well-being, and social engagement of older people. These tools help analyse and design urban environments, focusing on urban systems' spatial configurations and physical forms that involve urban form characteristics that are conducive to accessibility, safety, comfort, social interaction, and inclusion. From this perspective, the preliminary findings point to factors that affect how well public places work for older people. The width of pavements, the materials with which public spaces are made, how they are shaded, and creating connected and “cool islands” are factors that call for further consideration. In the next evaluation phase, the recommendations will be cross-checked with the information collected from the residents' interviews, which will be completed with information on users' public space observations. This analysis will contribute to the design of guidelines or “urban codes” that incorporate urban form measures to deal with climate change. In summary, the holistic approach designed by the FAUP team within the CAOP framework seeks to promote functional, inviting, and unique public spaces that support older people's health and well-being, identifying low-cost and low-scale intervention potential. Moreover, the socio-spatial vulnerability framework assessment proposed in this multidimensional study is intended to be replicable in urban areas or contexts with similar challenges.

ABSTRACT

This article aimed to analyze changes in the urban landscape over a defined time frame, utilizing remote sensing to examine urban expansion in a medium-sized city, using Arapiraca, Brazil, as a case study. To assess the Land Use and Land Cover changes (LULCC) in the city, this study employed data from the Landsat 8 satellite, which comprises two instruments: the Operational Land Imager (OLI) and the Thermal Infrared Sensor (TIRS); as well as the Landsat 5 satellite, which features the Thematic Mapper (TM) instrument. Both sensors were integrated into the Surface Energy Balance Algorithms for Land (SEBAL) to estimate surface temperature and energy balance components. Additionally, multi-spectral classifications and geostatistical analyses were applied to the MOD11A1.061 Terra Land Surface Temperature and Emissivity Daily Global 1km and MOD13Q1.061 Terra Vegetation Indices 16-Day Global 250m products. The Normalized Difference Vegetation Index (NDVI) was used to assess vegetation conditions, while Land Surface Temperature (LST) was considered for detecting local climate patterns. The analyses revealed substantial changes over the analyzed period, with a significant reduction in agricultural areas and a considerable increase in urban areas between 1987 and 2022.

Keywords: urban planning, Landsat, NDVI, LST, SEBAL

INTRODUCTION

The growth of global urbanization in recent decades has been particularly evident in developing countries. According to the United Nations report "World Urbanization Prospects: The 2018 Revision," the global urban population has increased significantly, especially in regions of Asia, Africa, and Latin America (United Nations, 2019). Since the 1970s, there has been a notable urban growth in these regions, especially when compared to developed countries (Nagendra et al., 2018), exacerbated by the disordered and chaotic manner of urbanization that creates a mismatch with the principles of sustainable development (Cabral and Cândido, 2019).

As a way to mitigate the impacts of changes caused by disordered urbanization, the proposal to implement public policies seems indisputable, with easy access to information emerging as an expression linked to governmental actions. In developed countries, academic communities,

researchers, and scientific associations participate in decision-making, regardless of the prevailing political position. However, in Brazil, the scenario still shows few advancements and many setbacks (Spink and Burgos, 2019).

In developing countries, disorganized growth results in changes in land cover use, capable of increasing thermal sensation, leading to changes in the microclimate that often result in a loss of environmental quality for the population (Li et al., 2018).

In this context, urban climate is an environmental derivative that can be understood as a sensitive phenomenon, thus exposed to various changes in climatic dynamics and their frequencies (Mendonça and Simões, 2012). It is important to highlight that urban climate is not only related to environmental issues but also to urban concerns, such as how cities are built and the elements inserted into urban spaces (Correia Filho et al., 2022). Therefore, it is observed that physical structures and dynamics in the city also influence the formation of urban heat islands (UHI).

In tropical countries, this phenomenon compromises the quality of life for residents (Silva and Ferreira, 2023). UHIs can be interpreted as the increase in air temperature at a given point, driven by factors such as obstacles to natural ventilation caused by excessive building density, lack of greenery, and changes in surface materials (Mendonça, 2015).

In Brazil, a significant aggravating factor for climate change is construction patterns. Urban planning rarely considers climatic factors as effectively determining aspects. Basic principles such as the thermodynamic characteristics of soil surface materials or building facades, wind permeability, and the maintenance of vegetation in urban spaces are not explored (Masiero and Souza, 2013).

Given this scenario, it is speculated that Brazil will undergo intense and rapid changes in climate patterns. The agricultural sector is expected to be the most affected, as well as poorer regions, such as the Northeast, whose extensive semi-arid area could become arid, forcing the resident population to migrate to other cities due to water scarcity and health issues (BIRD, 2023).

In this context lies the city of Arapiraca, located in the Agreste region of Alagoas State, situated in Northeast Brazil (NEB). The city's formation is directly linked to agriculture, fairs, and commerce, maintaining relationships with its surroundings, sometimes as a dependent and sometimes as a service provider (Santos, 2019). Between 1950-1980, the city cultivated 50,000 hectares of tobacco, the largest area cultivated in Brazil, exporting to other states and countries. Despite its rapid growth, the process of verticalization in the city is slow. The urban area is predominantly horizontal, with buildings occupying almost the entire lot (Silva, 2019).

The successive expansions of the city's perimeter, especially in the last 40 years, have resulted in the emergence of large urban voids, which, without proper planning, have driven real estate speculation and the occupation of peripheral neighborhoods due to lower land prices. Additionally, the increase in closed horizontal residential developments has fueled urban segregation, as this logic disregards the zoning established by the master plan, creating its own regulations (Neves, 2022). It is also worth mentioning the significant impact of housing programs like Minha Casa Minha Vida (PMCMV) on urban growth. In Arapiraca, a population increase of approximately 28.69% was observed from 1991 to 2010 (Correia Filho et al., 2022).

It can be asserted that Arapiraca exemplifies how medium-sized cities are important for the country's development, as they encourage a reduction in migration to capitals and metropolitan regions (Correia Filho et al., 2022). The municipality encompasses different functions, becoming central to the provision of commerce, administrative services, and industrial development. These types of cities polarize a region and reduce the need for displacement to other metropolises and states, playing an intermediary role between small and large cities (Santos, 2019).

Based on the above, this article aimed to discuss changes in the urban landscape from a temporal perspective, using remote sensing in the area of urban expansion in a medium-sized city, taking Arapiraca, Alagoas, Brazil, as a case study.

METHOD

Study area

The city of Arapiraca is located in the Agreste Alagoano mesoregion, in the central part of the state of Alagoas, Brazil, between latitude 9°75'25'' South and longitude 36°60'11'' West. It covers a territorial area of 345.65 km², with a population of 234,696 inhabitants and a population density of 678.99 inhabitants/km² (IBGE, 2022). The urbanized area corresponds to 52.07 km² and has only 12.2% of urban households on public roads with adequate urbanization (presence of drainage, sidewalks, paving, and curbs) (IBGE, 2019).

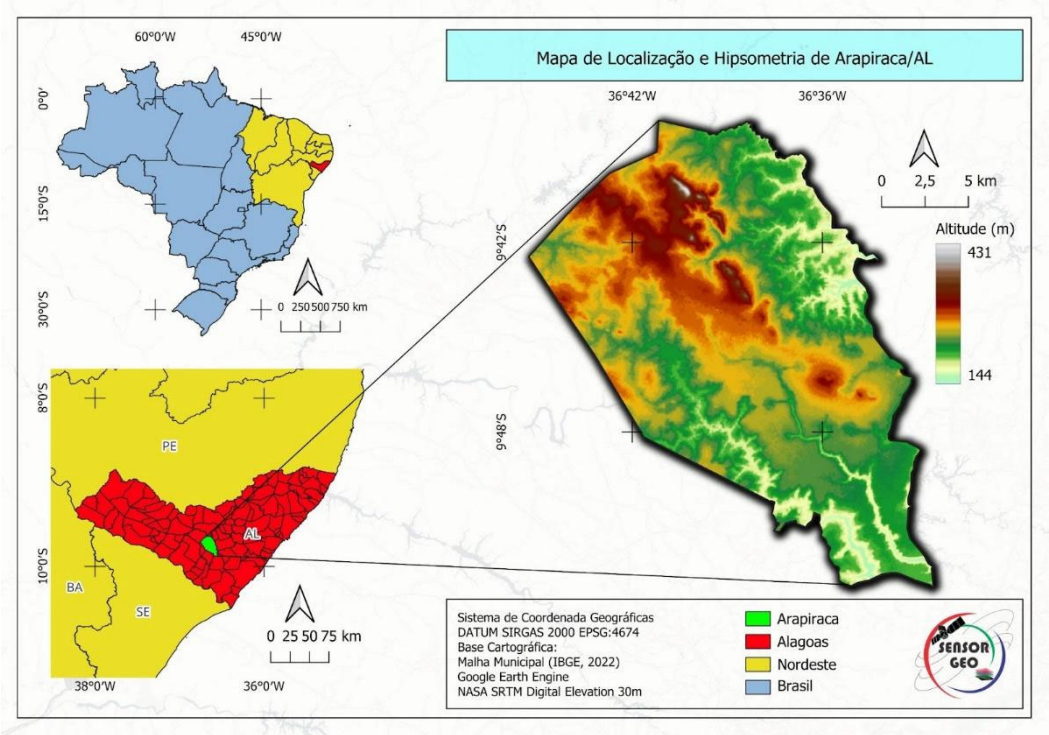

Figure 1. Location of the city of Arapiraca, located in the Agreste Alagoano, mesoregion of the State of Alagoas, Northeast Brazil. In the image, the urban perimeter was not separated from its rural area.

The city has a predominantly semi-arid climate (SILVA, 2019). The months from April to September have the lowest temperatures, with August being the coldest month, having an average minimum of 18.6 °C. From October to March, the highest temperatures reach 33.2 °C in December. In this sense,

its humidity shows values inversely proportional to temperature throughout the year, exceeding 80% during high-temperature periods and falling below 50% during cooler periods. There are two well-defined seasons: dry (warm and dry conditions during spring/summer) and rainy (autumn/winter) (Barros et al., 2012).

The sectors that employ the most in the city are agriculture, commerce, and industry (SANTOS, 2019). In 2021, the city's Gross Domestic Product (GDP) was R$ 25,248.44, and its Human Development Index (HDI) in 2010 was 0.649 (IBGE, 2024).

Methodological Procedures

To evaluate Land Use and Land Cover Changes (LULCC) in the city, this article used the Landsat 8 satellite, which consists of two instruments: Operational Land Imager (OLI) and Thermal Infrared Sensor (TIRS); and the Landsat 5 satellite, which has the Landsat Thematic Mapper (TM) as its instrument. Both sensors were implemented in the Surface Energy Balance Algorithms for Land (SEBAL) algorithm, estimating temperature and energy balance components of surface cover, along with multi-spectral classifications and geo-statistical analyses applied to the MOD11A1.061 Terra Land Surface Temperature and Emissivity Daily Global 1km and MOD13Q1.061 Terra Vegetation Indices 16-Day Global 250m products. The Normalized Difference Vegetation Index (NDVI) will also be used to analyze vegetation conditions. Additionally, Land Surface Temperature (LST) will be considered for detecting local climate.

Database

The images were acquired through Google Earth Engine (GEE)[79], based on scripts developed in JavaScript[80]. These scripts were designed to utilize time series and filtering functions, allowing for the quantification of images with a lower percentage of cloud cover. The geocentric projection system adopted was UTM DATUM SIRGAS 2000, with reference EPSG:4674. The time span of the images covered the entire period of the Landsat 8 and Landsat 5 satellites, with a temporal range of 37 years and a highlight on two images.

Surface Energy Balance Algorithm

The Surface Energy Balance Algorithm for Land (SEBAL) is a remote sensing processing model used in hydrological and agricultural studies to estimate evapotranspiration (ET). Using satellite images, such as those from Landsat, SEBAL provides a reliable approach to monitoring interactions between the Earth's surface and the atmosphere, contributing to a better understanding of hydrological cycles and sustainable management of water and agricultural resources (Allen et al., 2002).

---

[79] Google Earth Engine is a free platform that can be used for scientific, academic, business and government purposes, and can be accessed through the website: https://earthengine.google.com/

[80] In this study, the scripts were run on Google Earth Engine, which is freely available on the GitHub website (https://github.com/JoaoAccioly/Arapiraca-Research.git).

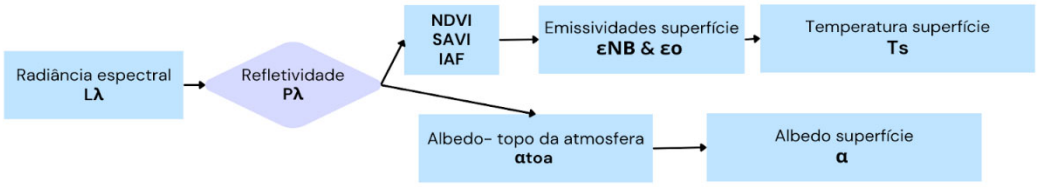

Figure 2. SEBAL flowchart used in matrix calculations (adapted from Allen et al., 2002)

Spectral radiance (Lλ)

According to Allen et al. (2002), the calculation of the spectral radiance of each band (Lλ) is performed using Equation 1, representing the radiation energy emitted by the observed band at the top of the atmosphere by the satellite. This radiance is determined using the following equation established for the Landsat 5 satellite, as follows:

$$L_\lambda = (\frac{LMAX-LMIN}{255}) \times DN + LMIN \quad (1)$$

where DN is the digital number, LMAX and LMIN are the calibration constants. The LMIN and LMIN values are calibration constants. The values of LMIN and LMAX are shown in table 2.

Table 2. Radiometric calibration values for Landsat 5 - TM (Allen et al., 2002).

After 15, Jan, 1984 (w*m-2*ster-1*ʜm-1)							
Bands	1	2	3	4	5	6	7
LMIN	-1.500	-2.800	-1.200	-1.500	-0.370	1.238	-0.150
LMAX	152.100	296.800	204.300	206.200	27.190	15.600	14.380

For Landsat 8, the equation for calculating spectral radiance is simplified, given by equation 2, according to Kamran (2005) and Allen et al. (2002).

$$L_\lambda = Gain * DN + Bias \quad (2)$$

where “gain” is the multiplicative factor and “bias” the additional factor for each band. The values are tabulated and found in the image metadata, for Landsat 8, for the scaled bands (2 to 7) Gain: 0.0000275 and Bias: -0.2; the thermal band (10) Gain: 0.00341802 and Bias: 149.

Reflectance (Pλ)

In this calculation, the fluxes represent the reflectance at the top of the atmosphere, at the sensor level, obtained through specific information from each pixel of the image. Thus, it was possible to calculate the reflectance’s corresponding to band 2 for Landsat 8 and bands 1 to 7 (excluding the thermal band) for Landsat 5, following the approach established by Chander, Markham, and Helder (2009). We quantified this by applying the following specific equation for Landsat images, allowing us to assess the proportion of reflected radiation in relation to the amount of radiation incident on the surface, as proposed in the equation below by Allen et al. (2002):

$$P_\lambda = (\frac{\pi - L_\lambda}{ESUN_\lambda * cos\theta * d_r}) \quad (3)$$

where dr is the Earth-Sun distance extracted from the metadata of the Surface Reflectance (SR) images from Google Earth Engine; Lλ is the radiance of each band calculated using equations 1 and 2 for Landsat 5 and Landsat 8, respectively; cosθ is the solar incidence angle, calculated by extracting the solar elevation angle (b) available in the image metadata and relating it as θ = (90° - b); the ESUN values correspond to the irradiance of each band, which varies for each sensor system, as described in tables 3 and 4 below.

Table 3. Irradiance values (ESUN) for Landsat 5 - TM (Allen et al., 2002)

	Band 1	**Band 2**	**Band 3**	**Band 4**	**Band 5**	**Band 7**
Landsat 5	1957	1829	1557	1047	219.3	74.52

Table 4. Irradiance values (ESUN) for Landsat 8 - OLI/TIRS (Ruhoff et al., 2015)

	Band 2	**Band 3**	**Band 4**	**Band 5**	**Band 6**	**Band 7**
Landsat 8	1982	1827	1540	932	234	79

Surface temperature (Ts)

After correcting the radiance for the thermal bands of the sensors, we calculated the surface temperature (Ts) using the following modified Plank equation as described by the SEBAL model:

$$T_S = \frac{K2}{ln(\frac{\varepsilon_{NB} * K1}{R_C} + 1)} \quad (4)$$

where NB is the emissivity; RC is the corrected radiance of the thermal band from the sensors; K1 and K2 are constants specific to Landsat images. For Landsat 5 (Band 6), K1 and K2 are 607.76 and 1260.56, respectively (adapted from Allen et al., 2002), and for Landsat 8 (Band 10), K1 and K2 are 774.89 and 121.08, respectively (Coelho and Corrêa, 2013).

Image Classification

The acquisition of land cover data was carried out through the MapBiomas platform, which provides annual data on land use and cover throughout Brazil for free (Available at: https://brasil.mapbiomas.org/). To cover the analyzed temporal space, two versions of MapBiomas were used: version 5 for the classification of 1987 and version 8 for the classification of 2022. The processing, clipping, and analysis of the classes included in the study area were performed using Quantum GIS software version 3.30.1.

The temperature classification process in the matrix data followed an analysis of anomalous temperature values within the urban mesh, discarding areas of exposed soil and considering only

inhabited areas. In GEE, the classification and data analysis steps are as shown in Figure 4, describing a geostatistical processing after the temperature calculation performed by the SEBAL algorithm has been completed, with a classification based on surface temperature fragmented into average temperature variations.

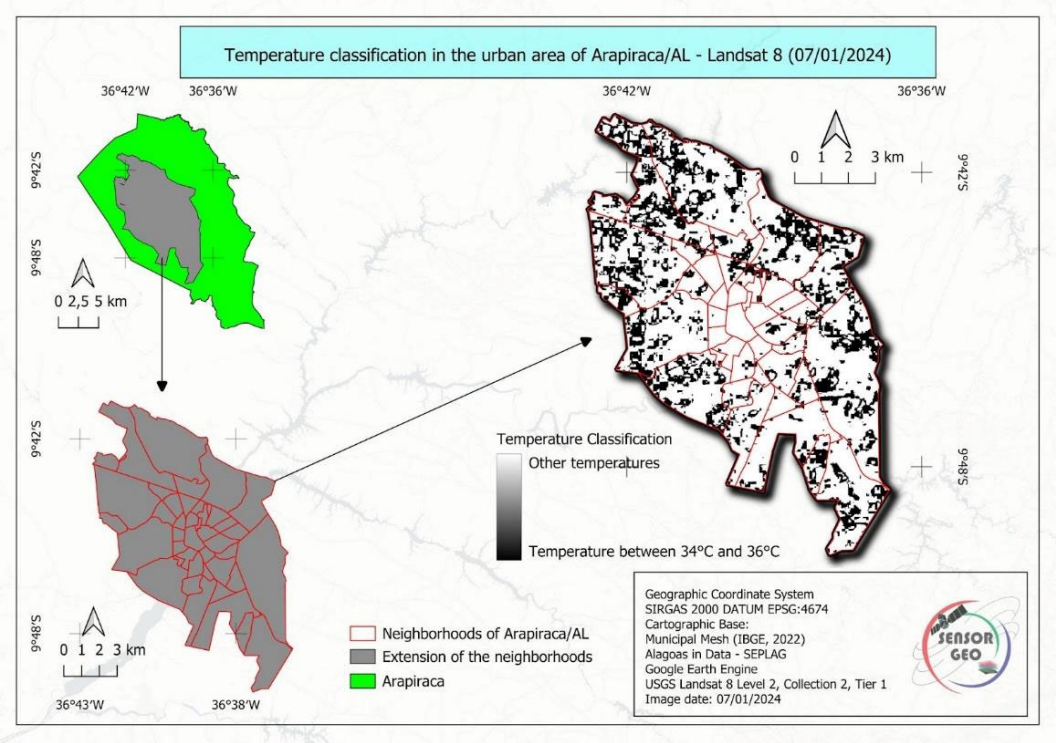

Figure 3. Temperature Classification for Landsat 8 Image.

RESULTS AND DISCUSSIONS

LULCC and its impacts

The evaluation of LULCC in the city of Arapiraca between the years 1987 and 2022 (Fig. 5) has changed substantially in just a few decades. There is a notable transformation in the city's landscape, with urbanized areas growing irregularly, creating large voids on the fringes of urban occupations. Furthermore, Neves (2022) points out that consolidated areas with urban infrastructure are not adequately occupied. The mode of occupation also results in segregation at three levels: spontaneous, with the creation of favelas and tenements; planned, when the population is displaced to the peripheries of the city without adequate facilities to meet their needs; and voluntary, with the establishment of high-end gated residential communities that end up functioning as islands surrounded by underprivileged populations.

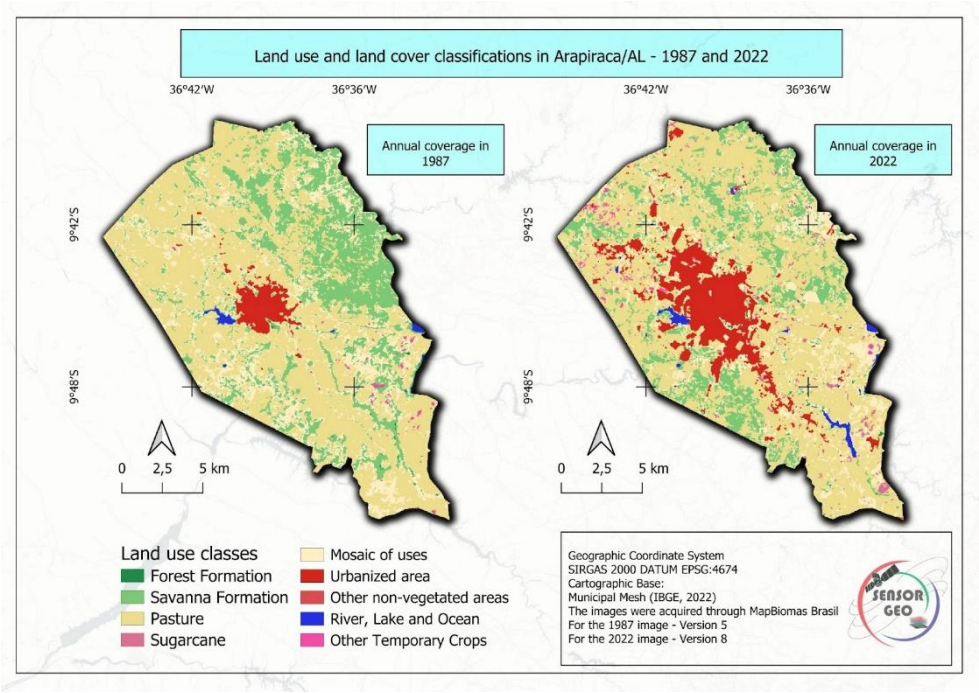

Figure 4. Environmental, geographic, and socioeconomic behavior for the City of Arapiraca. The environmental indicators for 1987 and 2022 (MapBiomas, 2024).

The non-vegetated area class showed the greatest change among the analyzed classes, with an increase of 313.2% between 1987 and 2022. The body of water in the city of Arapiraca and the forest also underwent notable changes, with percentage variations from 0.5% and 10.41% in 1987 to 0.86% and 14.21% in 2022, respectively. The area designated for agri-livestock experienced a reduction of 15.50% (Table 5).

Table 5. Area of classified variables

Classes	1987 area in km^2	2022 area in km^2	Difference (2022-1987) area in km^2
Non- vegetated areas	10.130	41.860	31.730
Body of water	1.860	2.980	1.120
Forest	36.010	49.150	13.140
Agri-livestock	297.660	251.410	-46.250

NDVI x LST

The data on surface temperature variation and NDVI extracted with the average clipped values for the municipality of Arapiraca and converted into a single product denote the seasonal behavior of temperature versus NDVI in an alternating manner, where the maximums of one variable coincide with the minimums of the subsequent variable. Both analyzed elements demonstrate similar patterns. The change in vegetation health throughout the year shows susceptibility to changes in the precipitation regime, considering that the characteristics of the caatinga biome present in the study region directly influence the NDVI values.

The analysis obtained through satellite data supports the investigation conducted by Torres (2017), who affirms the high soil impermeability in the city of Arapiraca due to the use of asphalt and the

limited green urban spaces. According to the author, among the few green areas found in the city, impermeabilization can be identified in their surroundings. The lack of green areas negatively impacts local climatic conditions. Although there is a correlation between the variables, this correlation does not directly determine a causal link between the analyzed factors.

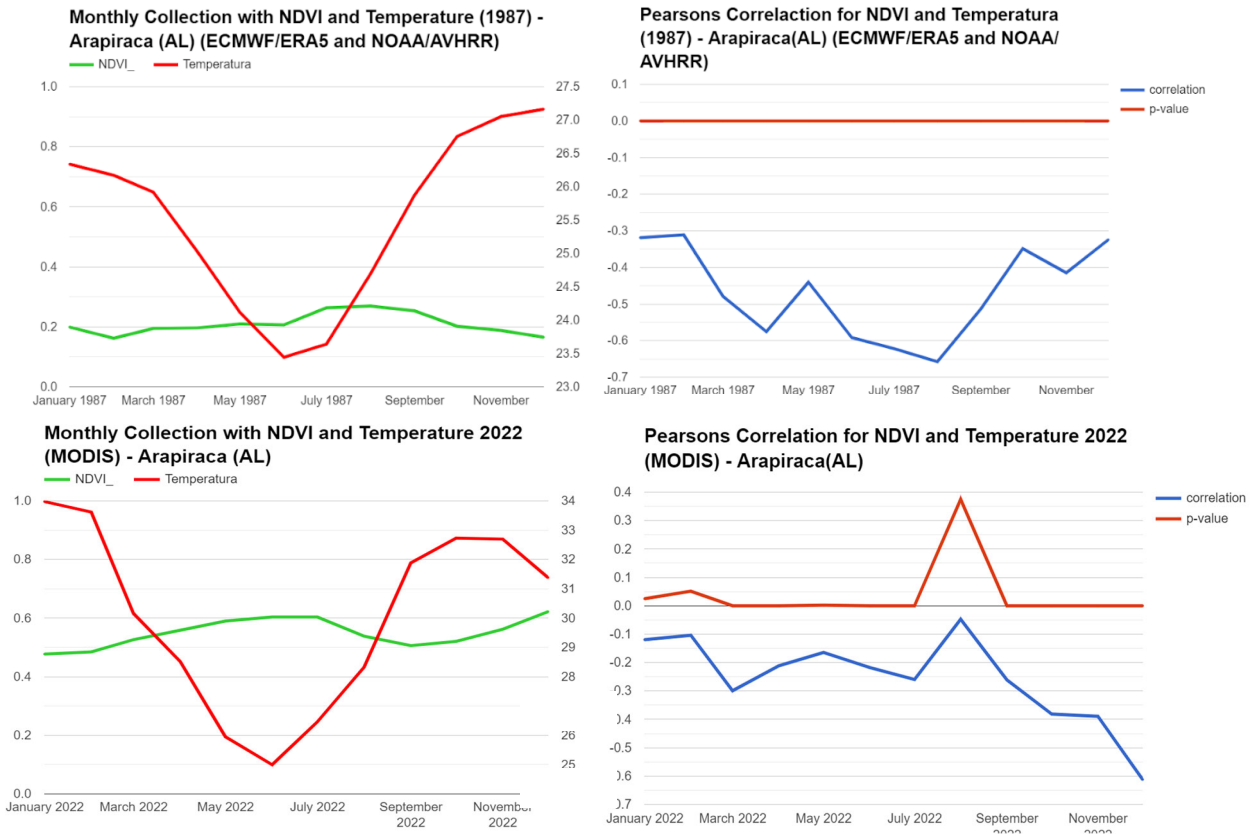

Figure 5. Time series and Pearson's correlation of temperature vs NDVI.

Relationships between Urban Temperature and Local Sustainable Actions

Based on the results obtained from the map (Fig. 5), there has been an increase in surface temperature throughout the city's territory. The reduction of native vegetation, in favor of agricultural interests, has impacted the thermal comfort of the population (Correia Filho et al., 2021).

In addition to the urban expansions already mentioned, with housing access programs such as PMCMV, gated residential communities undermine the sustainability dimensions established within municipal laws (Neves, 2022). The author also points out that some gated residential communities today are being built within environmental preservation areas.

The municipality of Arapiraca has an inadequate structure for local climatic conditions, significantly contributing to the thermal discomfort of its inhabitants. There is a notable need for new land use standards through effective planning that aims to address different guidelines than those currently being implemented (Torres, 2017).

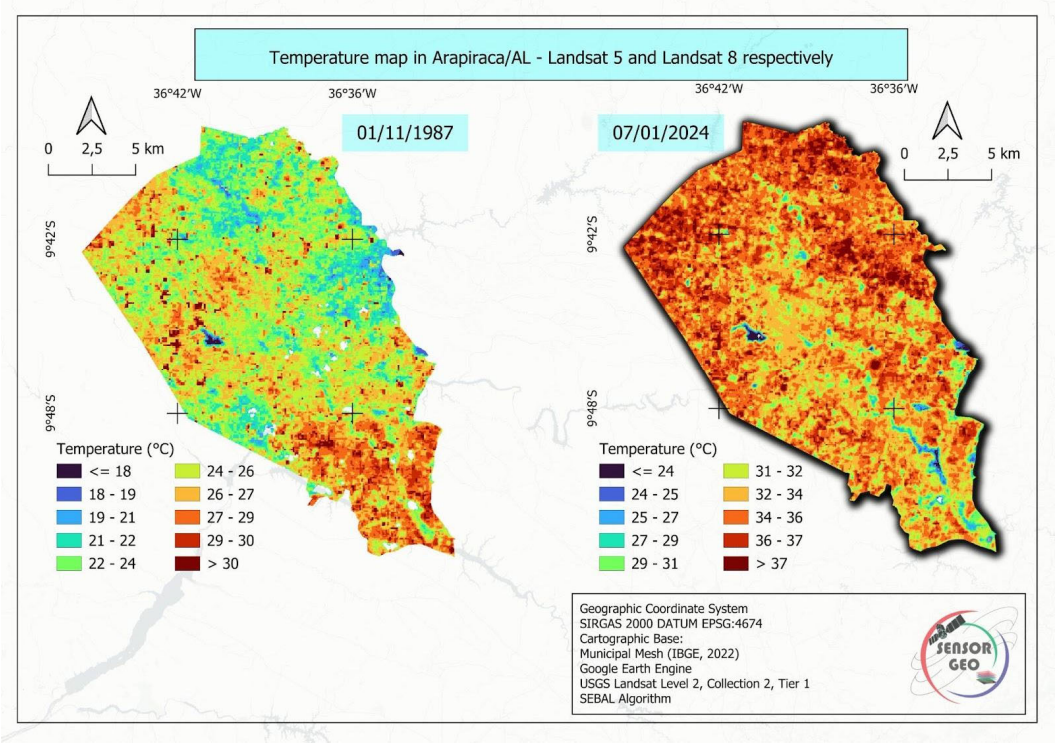

Figure 5. Temperature classification for Landsat 5 and 8 images.

Due to the unavailability of images with low cloud cover in the study region in 2022, the 1987 image was analyzed compared to an image from 2024, both available in the Landsat data line. The behavior of surface temperature in the images calculated with SEBAL demonstrated the variations in surface temperature at each time point along with their respective spatial distributions. To evaluate the accuracy of the calculations performed in the Google Earth Engine environment, in situ data available from the weather station of the National Institute of Meteorology (INMET) network were extracted, located in the study area (Station code: A353, lat: -9.8044, lon: -36.6191). Table 6 shows the variability of surface temperature on the approximate day and time of the Landsat 8 scene acquisition.

Table 6. Comparison between estimated and measured data

	Empirical data		**Estimated data**
Date/Hour	Air Temperature (Dry Bulb)	Temperature	Scene Time
2024/01/07 - 11:00	27.6°C		
2024/01/07 - 12:00	29.7°C	31.42	12:36:08
2024/01/07 - 13:00	32°C		

Analyzing the surface temperatures at 12:00 PM and 1:00 PM (empirical data) results in an average of 30.85 °C. To approximate the time of scene acquisition (12:36:08), the percentage error between the average value of the approximated empirical data and the estimated data is 1.84%. This demonstrates the effectiveness and accuracy of the calculations based on the SEBAL model and the surface data.

Indications of Urban Heat Island

During the analysis of the surface temperature classification for the urban area of the municipality of Arapiraca, it was possible to highlight two points within the urban space that have temperature variations above the average for the urban area and are not areas of exposed soil. The coordinates of

the highlighted points are provided in Table 7, projected in decimal format in the WGS84 system; however, the coordinates on the map (Figure 6) are projected in degrees, using the SIRGAS 2000 system.

Table 7. Locations with temperature variations

	Pont 1	Ponto 2
Latitude	-36.65864572554982	-36.648946857751966
Longitude	-9.767666340431381	-9.7504102536360140

The neighborhoods Primavera and Brasília indicated some points with surface temperature variations that may constitute urban heat islands on a micro-scale in these areas, considering that the composition of materials used for land cover is predominantly concrete, ceramic roofing, and asphalt. Additionally, there is a noticeable absence of vegetation in these areas, as the physical properties of the constituent materials directly contribute to the heating of these spaces. The albedo is relatively low in non-vegetated areas, resulting in less reflection and greater absorption of solar radiation. However, it is important to highlight that, even considering the accuracy of the algorithm used to estimate surface temperature and classify anomalous variations from the average surface temperature, a thorough investigation is necessary, using measured data from these neighborhoods to validate the findings obtained via the sensor system.

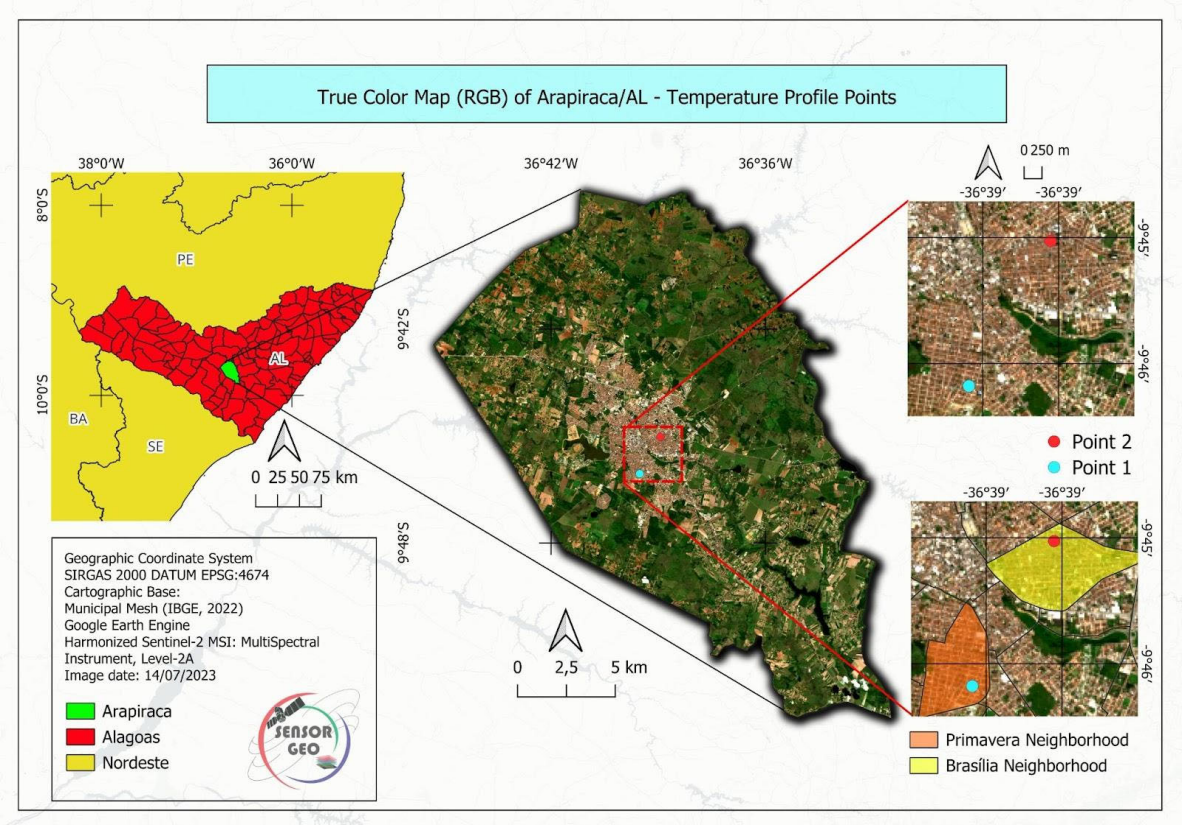

Figure 6. Points in the urban area

The heat retention at these points was compared with the surrounding areas and plotted horizontally in Figure 7. The surface temperature variations between point 1 and the neighboring regions show a

variation of ±2°C relative to the average surface temperature in the latitudinal profile. Ignoring the larger-scale intensity effects of this surface temperature variation, and limiting the profile to the urban grid, it is possible to observe a balanced temperature profile between points 1 and 2 in the line profile. Even with the temperature contrast with the adjacent water body, the microclimate at these specific points demonstrates characteristics that require further detailed analysis, especially concerning the thermal dynamics involving construction materials and urban vegetation in these neighborhoods.

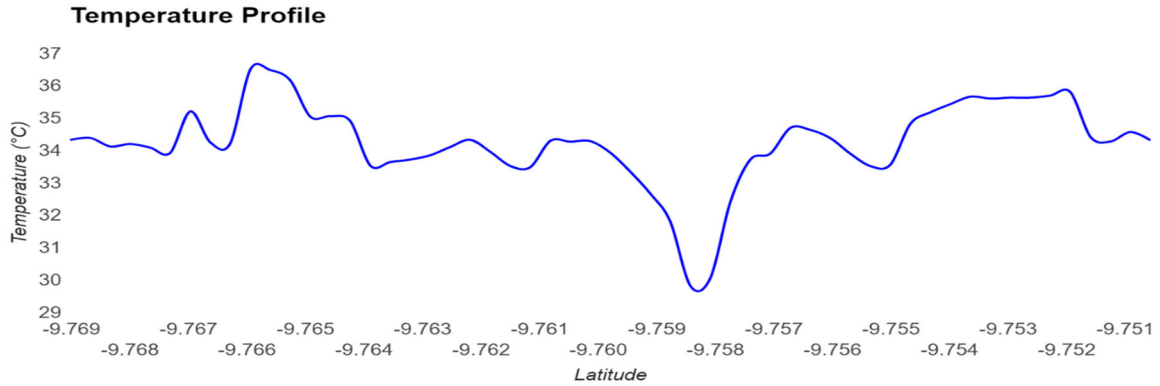

Figure 7. Temperature profile between points.

CONCLUSIONS

The analyses show a substantial change between the periods studied, with a significant reduction in the area allocated to agriculture and a considerable increase in urban area between 1987 and 2022. Relating the city to the state, it is noted that Arapiraca exerts more influence on its neighboring cities, as the residents of these municipalities commute daily in search of public and private services of medium and high complexity. However, the analysis of the city's urban expansion indicates a lack of planning, as the territorial and demographic growth in the city has not been accompanied by strategies to mitigate the evident climate changes, such as the incorporation of urban greenery. The intense transformation in land use and cover, reflected in disordered urban growth, contributes to the emergence of particularities in the urban environment, with conditions that directly affect the thermal comfort of its inhabitants. The analysis of the factors examined highlights the need for effective urban planning that includes sustainability guidelines, with political measures that promote balanced urban space expansion.
